****A negative sign indicates a greater likelihood of fatality and a positive sign indicates a lower likelihood of a fatal crash**

Table B-35. Binary Logit Model For Severity of Pedestrian Crashes

¹ Here, Pfatal = 1 – Psevere and accordingly a positive sign on the models represents a lower likelihood of a fatality, and a negative sign will represent a greater likelihood of a fatality

Appendix C: Datasets and Data Dictionaries

C.1 Data Compilation

A crash database was built to support descriptive statistics, spatial analysis, and crash cause modeling procedures. The compilation of the datasets used in this study represents a significant cooperative effort by various agencies within New York City and New York State. In addition to the New York City Department of Transportation, these included the New York City Department of Health & Mental Hygiene, the New York State Department of Transportation, the New York State Department of Health, and the New York State Department of Motor Vehicles.

Geodatabases were used to store and analyze data from these sources. This structure provides an efficient and manageable way to collect, organize, and maintain the complex data related to pedestrian crashes which includes points (pedestrian crashes), lines (roadways), polygons (municipal boundaries etc.) and raster data (orthoimages of locations).

Information joined to the crash data includes socioeconomic information available from the decennial census of the U.S. Bureau of Census; vital statistics of NYCDOHMH; land use information from primary land use tax output (PLUTO) of the New York City Department of City Planning; transportation network and performance related GIS layers from NYCDOT; and ZIP code and census tract layers from StreetMap US of Environmental Systems Research Institute (ESRI).

The first step of data compilation is to geocode the NYSDOT crash data using GIS software (we used ArcGIS 9.3). Each crash record of the NYSDOT data was geocoded with the attributes of either Census Tracts or 5-digit Zip Codes. In order to have the most feature-rich attribute datasets available, pseudo zip code boundaries were used; that is, all census tracts that had their geographic centroids inside of a zip code were aggregated to that zip code. This allowed us to aggregate and use much of the demographic data that is only available for census designated areas. This layer is again overlaid with other GIS layers that include such information as detailed roadway characteristics, intersection characteristics, vehicle speed, and signal locations, among many others. All information that could not be directly linked to the single location of an accident, such as a roadway volume that may have been recorded a block away, were spatially joined to the dataset

and given a confidence interval in feet, which can be used to determine the appropriateness of the collocated measure. For the purposes of this study, it is recommended that only features located within 50 feet, the same distance that was found to be appropriate in the buffering method discussed in the next chapter, be considered as sources of measurements.

Using the above mentioned steps, three geodatabases were created. This appendix defines the variables included in each of the 3 separate databases produced for this project. These are (A) a disaggregate pedestrian severe injury & fatality crash database and aggregated databases of (B) pedestrian severe injury & fatality crashes by tract and (C) pedestrian severe injury & fatality crashes by zip code. In addition, all coding is defined and the source of each variable is given. Data compilation and its place in the study process, is described in figure C-1
