Engineering and Other Services for the Marine Export of Solid Waste

Study of the Friends of the Hudson River Park Pier 76 Concept

Prepared for the
New York City Department of Sanitation

July 2007

GREELEY AND HANSEN

Executive Summary

The New York City Department of Sanitation (DSNY) requested that Greeley and Hansen review and evaluate a proposal for the development of a consolidated solid waste and recyclables transfer facility with a rooftop park on Pier 76 on the Hudson River at 36th Street (the "Pier 76 proposal"). The proposal was developed by a team of engineering and design consultants retained by Friends of Hudson River Park and the Coalition to Protect Our Parks as a replacement for two Manhattan-based facilities in the City's Solid Waste Management Plan: a proposed marine transfer station (MTS) for recyclables on the Gansevoort peninsula and an MTS for commercial waste at West 59th Street and the Hudson River.

The Pier 76 proposal envisions using the 6-acre pier as a site for a new solid waste containerization facility, a new recyclables transfer facility, a modified New York City Police Department (NYPD) Tow Pound, stables for an NYPD Mounted Unit, other facilities and a rooftop park. The proposal appears to be based on a number of assumptions, including that the existing pile-supported foundation infrastructure of Pier 76 could support the proposed facility. Greeley and Hansen conducted a technical evaluation of Pier 76 based on the original 1961 plans for the Pier, inspection reports prepared in November 2006 and December 2001 and an analysis of the MTS design requirements. We have concluded that the existing substructure and concrete deck structure of Pier 76 cannot carry the expected loads from a DSNY containerization facility and a rooftop park. The basis for this conclusion is fully explained in Section 2 below. In summary:

- Neither pier 76 itself or the pile clusters have sufficient load bearing capacity to support a DSNY containerization facility.

- The existing piles cannot accommodate the additional lateral forces a containerization facility would impose.

- The column grid needed for a containerization facility is significantly different from the beam and pile spacing of Pier 76.

- The Pier 76 pier deck cannot support the loads that would be imposed by full containers stacked two high.

- The weight of the proposed rooftop park will considerably reduce the load bearing capacity of the existing Pier 76 pier deck.

- The existing pier deck cannot accommodate the shuttle car system needed to move empty and full containers into and out of the building or the gantry cranes that would move containers on to and off of barges.

In addition, the Pier 76 proposal raises a number of operational and technical issues (discussed in Section 3 below) that could greatly restrict or prohibit certain operations on the pier including:

- The proposed facility appears to provide only one single-lane exit ramp. This is an unacceptable feature as it would prevent access and halt operations in the event of a breakdown.

- The access ramps to the proposed facility are too steep to safely operate DSNY equipment. To meet DSNY design criteria, the ramp would need to be approximately 413 feet, not the 130 feet shown in the Pier 76 proposal. It is not clear how or if the pier can accommodate such an access ramp.

- It is unlikely that the lane widths and turning radii of the access ramps in the proposed facility could accommodate an industry-standard 32-cubic-yard collection vehicle.

- The proposed facility does not include a means to access the loading floor or pier deck by operating equipment, service vehicles and emergency vehicles. Such access is critical to the safe operation of a DSNY facility of this kind.

- The 30-foot distance shown from the solid waste tipping floor to the top of the proposed rooftop is insufficient space to provide structural support to operate collection vehicles and to incorporate building systems, including fire protection, dust suppression, HVAC and lighting. To properly address these issues, the elevation of the rooftop park would likely exceed 70 feet.

- The proposed design does not appear to provide any space for HVAC equipment above the floors. To address this, the roofs will have to be raised higher than the Pier 76 proposal indicates or this equipment would need to be housed below the tipping floors. Given the size of the existing pier and the amount of HVAC equipment required for the proposed facility, it is not clear how the design could be modified to address this issue.

To address some of these issues, it is likely that the rooftop park would be a series of small flat areas connected by steep ramps and/or stairs, rather than the large gently-sloping open space depicted in the Pier 76 proposal. Assuming that all of the operational, technical and design issues noted above could be resolved, we estimate that the Pier 76 proposal will cost $436 million to build—approximately $311 million more than the Gansevoort and West 59th Street MTSs in the City's SWMP. In light of this analysis, we have concluded that the Pier 76 proposal is not a viable alternative for the proposed recyclables transfer facility at the Gansevoort peninsula and for making the West 59th Street MTS available for the transfer of commercial waste.

Section 1 Introduction

The New York City Department of Sanitation (DSNY) has requested that Greeley and Hansen review and evaluate a proposal for the development of a consolidated solid waste and recyclables transfer facility with a park on the roof on Pier 76 which is on the Hudson River waterfront at 36th Street. The proposal was developed by a team of engineering and design consultants retained by Friends of Hudson River Park and the Coalition to Protect Our Parks and is being promoted by these groups as a replacement for a proposed recyclables transfer facility to be located at the Gansevoort Peninsula and the West 59th Street Marine Transfer Station (MTS), which is currently proposed to be made available for the transfer of commercial waste.

The Pier 76 proposal is documented in a seven (7) page report (see Attachment 1) dated May 2007 that includes conceptual illustrations of the proposed consolidated facility. The Executive Summary of the proposal describes the proposed concept and states:

> *"The substructure of Pier 76 is already in place and appears to be in excellent condition, with capacity to carry the expected loads of this program."*

It is inferred from this statement that the consolidated solid waste transfer station concept proposed is based upon reuse of the existing pier structure and its foundation elements, either in whole or in part, to support the new consolidated facilities.

This report presents a technical evaluation of the Pier 76 proposal including review of two inspection reports and assessments of the ability of the existing Pier 76 structures to carry the expected loads and of how the proposed consolidated facility design addresses operational and technical requirements. Additionally, this report includes a review of the rooftop park concept that is part of the consolidated facility proposed for Pier 76. Finally, an estimate of the probable cost of constructing the proposed consolidated facility is presented and compared to the costs of facilities it is proposed to replace.

Description of the Existing Pier 76 Structures

Pier 76 is located on the Hudson River along the west side of Manhattan, opposite the Jacob K. Javits Convention Center and currently supports and houses the New York City Police Department (NYPD) Tow Pound and stables for an NYPD Mounted Unit. Original construction documents for Pier 76 obtained from the New York City Department of Design and Construction are dated 1961 and indicate that the pier was constructed for United States Lines, Co. under the auspices of the City of New York Department of Marine and Aviation.

The pier is approximately 615 feet wide at the inshore headhouse structure, 300 feet wide at the outshore end and extends approximately 726 feet into the Hudson River from the physical bulkhead line. An additional pile-supported structure is located inland of the original bulkhead line. Inshore of this structure, a concrete cribbing system retains fill as a cut-off wall below the platform.

The pier supports a steel framed shed on a 9-inch thick reinforced concrete deck slab supported by 3-foot wide by 2-foot deep concrete cap beams spaced at 10-foot intervals along the north-south width of the pier. The cap beams are supported by timber piles with concrete extensions that extend from the piles at approximately mean low water (MLW) elevation to the bottoms of the cap beams. The concrete extensions consist of a reinforced concrete pipe section placed over the top of the timber pile approximately 24 inches and filled with grout or concrete. The timber piles are braced at the low water level with 3-inch by 8-inch timber staylathing installed on both sides of the piles, immediately below the concrete extensions. Column loads imposed by the shed structure above are carried by clustered pile groupings of various configurations depending on the column loads.

The original construction drawings indicate that the timber friction piles were to be driven to an elevation -81 feet to achieve an allowable bearing capacity of 20 tons.

Review of Inspection Reports

In December 2001 the firm of Goodkind & O'Dea, Inc. submitted to the New York State Department of Transportation a document titled "In-Depth Inspection Report Pier & Bulkhead Inspection for New York City West Side Piers Pier 76". The report describes the areas of Pier 76 that were inspected and the methodologies employed to inspect and evaluate the condition of the timber piles, concrete extensions, underside of the reinforced concrete deck slab and the timber staylathing.

It is noteworthy that the top of the concrete pier deck was not inspected as the Goodkind & O'Dea representatives were not given access by the pier's tenant, the NYPD, to the areas within the shed structure. Additionally, there were no records published of the field inspections of the timber piles, staylathing or concrete structures beneath the 615-foot wide headhouse portion of the pier.

The report's Conclusion, Recommendations and Cost Estimate Section stated that, "Pier 76 is generally in good condition with a live load rating of 602 PSF", but noted there were several instances where cracks, spalls and exposed reinforcing steel were observed. Additionally, the report noted moderate evidence of teredo (marine borer) infestation observed in approximately 1 percent of the timber piles with greater infestation and section losses up to 40 percent observed in the timber staylathing.

A structural "red flag" was issued for a portion of the pier due to breakage of the concrete pile extensions at the northeast corner of the pier. The report recommended repairs to the damaged concrete and timber members that it estimated would cost $145,000.

In November 2006 the firm of HPA Engineers, P.C. submitted to the Hudson River Park Trust a document titled "Inspection of Permanently Remaining Piers and Bulkhead Structures Pier 76". This report describes the areas inspected and the methodologies employed in inspecting and evaluating the condition of the timber piles, concrete extensions, pile caps, underside of the reinforced concrete deck slab and the timber staylathing. The purpose of the report was to identify

structural and non-structural deficiencies and to determine whether the structural condition of the pier had deteriorated since the previous Goodkind & O'Dea inspection. The top of the concrete pier deck within the shed structure was again not inspected.

This report describes continued deterioration of the staylathing due to teredo infestation and indicates that at 45 years old, the original timber pile treatment is nearing the end of its predicted life and will start to lose its effectiveness as time progresses.

The report further notes that the repairs previously recommended by Goodkind & O'Dea in its December 2001 inspection report were apparently never implemented and stated that "none of the timber piles showed evidence of prior repair." HPA further states: "The overall uniform live load rating for Pier 76 remains at 602 PSF" except at areas with damaged pile extensions. The report recommends that repairs be made to several of the concrete pile extensions, but offers no estimate of costs.

Description of the Pier 76 Proposal

The proposal for Pier 76 envisions the pier serving as a site for a new solid waste containerization facility, a new recyclables transfer facility, a modified NYPD Tow Pound, stables for an NYPD Mounted Unit, other facilities and a rooftop park. It is inferred from our reading of the report documenting the proposal (see Attachment 1) that the existing pile supported foundation infrastructure of Pier 76 would be utilized to support these facilities since the engineering/design team states:

> *"The substructure of Pier 76 is already in place and appears to be in excellent condition, with capacity to carry the expected loads of this program."*

The proposed solid waste containerization facility would be situated at the western end of the pier and would be similar in arrangement and operation to the containerization facilities designed for the DSNY that are to be developed pursuant to the City's Solid Waste Management Plan. The proposed recyclables transfer facility would be located inboard of the containerization

facility and would be similar in arrangement and operation to one of DSNY's existing marine transfer stations, such as the West 135th Street MTS.

Truck access to and egress from the proposed consolidated transfer station facility and the tow pound would be through an entrance gateway located at the northeast corner of Pier 76. The proposal envisions the entranceway being beneath a raised section of the Hudson River Park. This feature would allow pedestrians and bicyclists to rise above and pass over the grade level entrance and exit for sanitation and other vehicles. It would also allow pedestrians and cyclists to gain access to the proposed rooftop park.

The proposed rooftop park would be constructed above the consolidated transfer stations and tow pound. It would begin at an elevation 20 feet above grade and is shown sloping up to a level 60 feet above ground level.

Section 2 Structural and Geotechnical Considerations

Typical Design Requirements of a DSNY Containerization Facility

The design of the containerization facility proposed for Pier 76 will need to accommodate the physical and operational requirements of a heavy industrial facility in a harsh marine environment. In response to these requirements, DSNY containerization facility designs include the following:

- High-strength structural steel is used to accommodate the heavy floor loads and long, column-free spans required in the waste dumping, processing and container handling areas.
- Long-span steel roof trusses are employed to enclose the tipping and loading levels in order to maximize open space for improved accessibility and operational flexibility. The adopted building column grid supporting the roof structures above the tipping and load-

ing levels has been configured to optimize collection vehicle turning maneuvers on the tipping floor.

- Clearance heights have been set to provide a minimum of 26'-0" vertical clearance above the truck dumping and waste processing areas to accommodate the front-end wheel loaders and excavator at the loading level and the Department's inventory of large, dump-truck-style collection vehicles at the tipping floor level. These features are illustrated in the cross section of a typical DSNY containerization facility in Figure 2-1.

- The tipping floors (Figure 2-2) are designed to accommodate the heaviest collection vehicles in the Department's inventory and other vehicles anticipated to travel on the tipping floor areas subject to moving equipment loads. The tipping floor bays adjacent to the backing logs are designed to resist the gravity and impact loads imposed by a pair of the Department's critical Heil 23A collection vehicles dumping their contents onto the loading level from two adjacent bays. The Heil 23A is also the governing DSNY collection vehicle in a moving position. This vehicle was determined to impose more critical wheel loads on the tipping floor when evaluated against AASHTO HS-25 design loads and the critical wheel loads imposed by the front-end wheel loaders designated for use at the loading level.

- The loading level (Figure 2-3) floor framing is sized to support the most critical load resulting from a 15-foot maximum depth of MSW piled on the floor or wheel loads imposed by the specified front-end wheel loaders or excavator equipment positioned anywhere on the floor to facilitate the through-the-floor container loading. The loading level has a series of rectangular loading slots, one above each container location and sized to be slightly smaller than the interior dimensions of the container.

Figure 2-1
Cross Section of a DSNY Containerization Facility

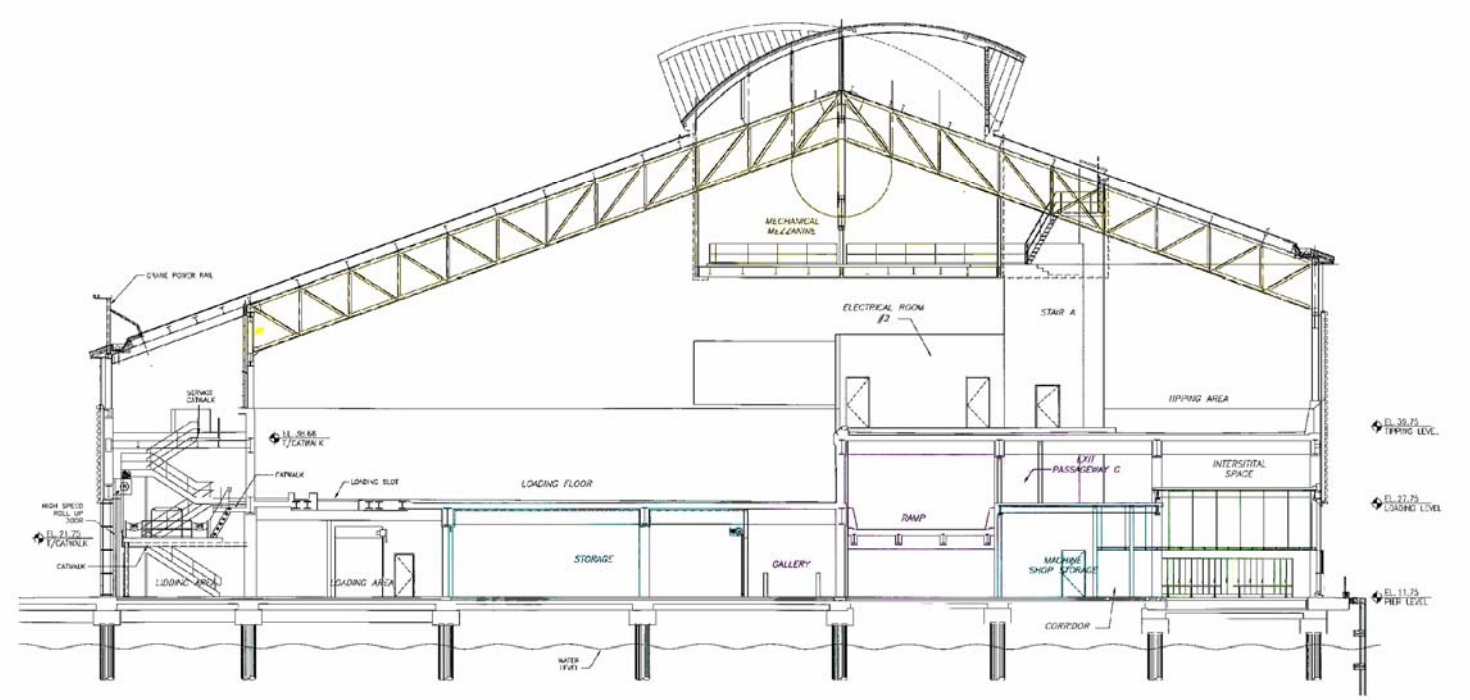

Figure 2-2
DSNY Containerization Facility Tipping Floor Level

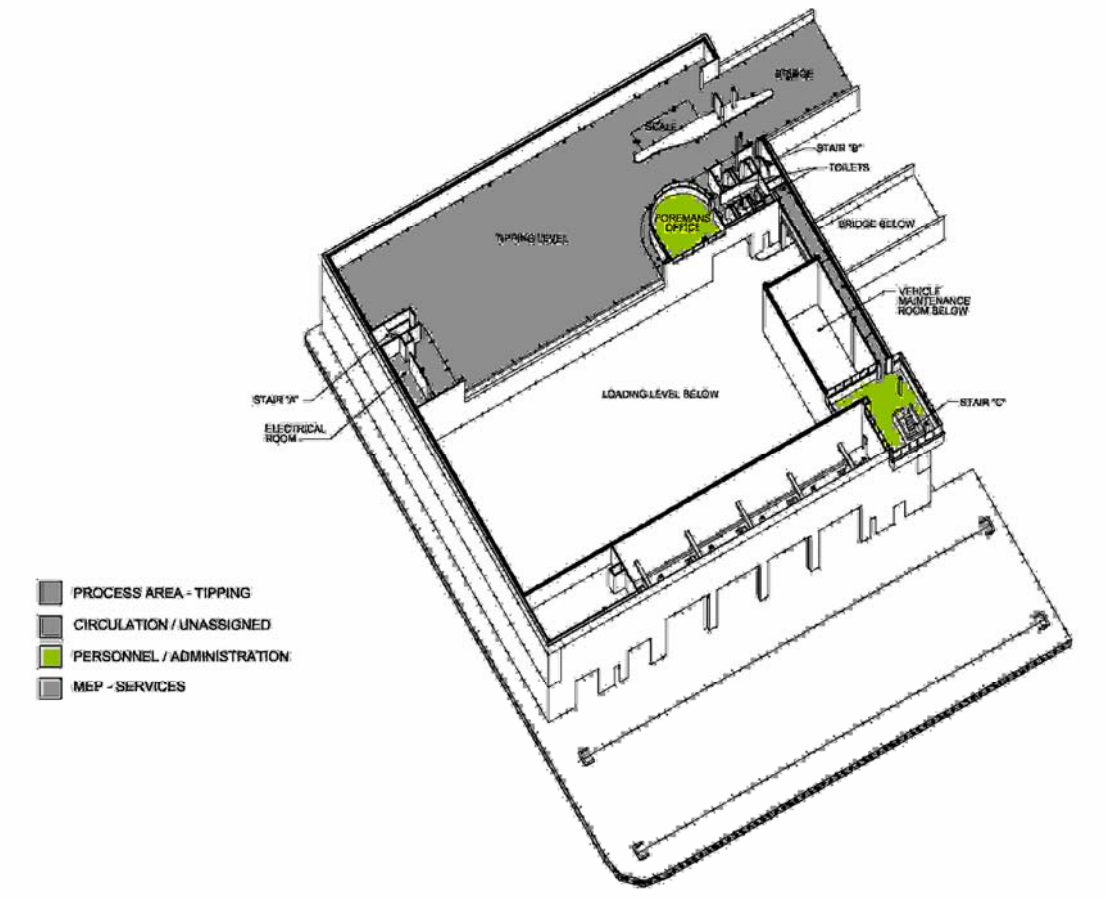

Figure 2-3
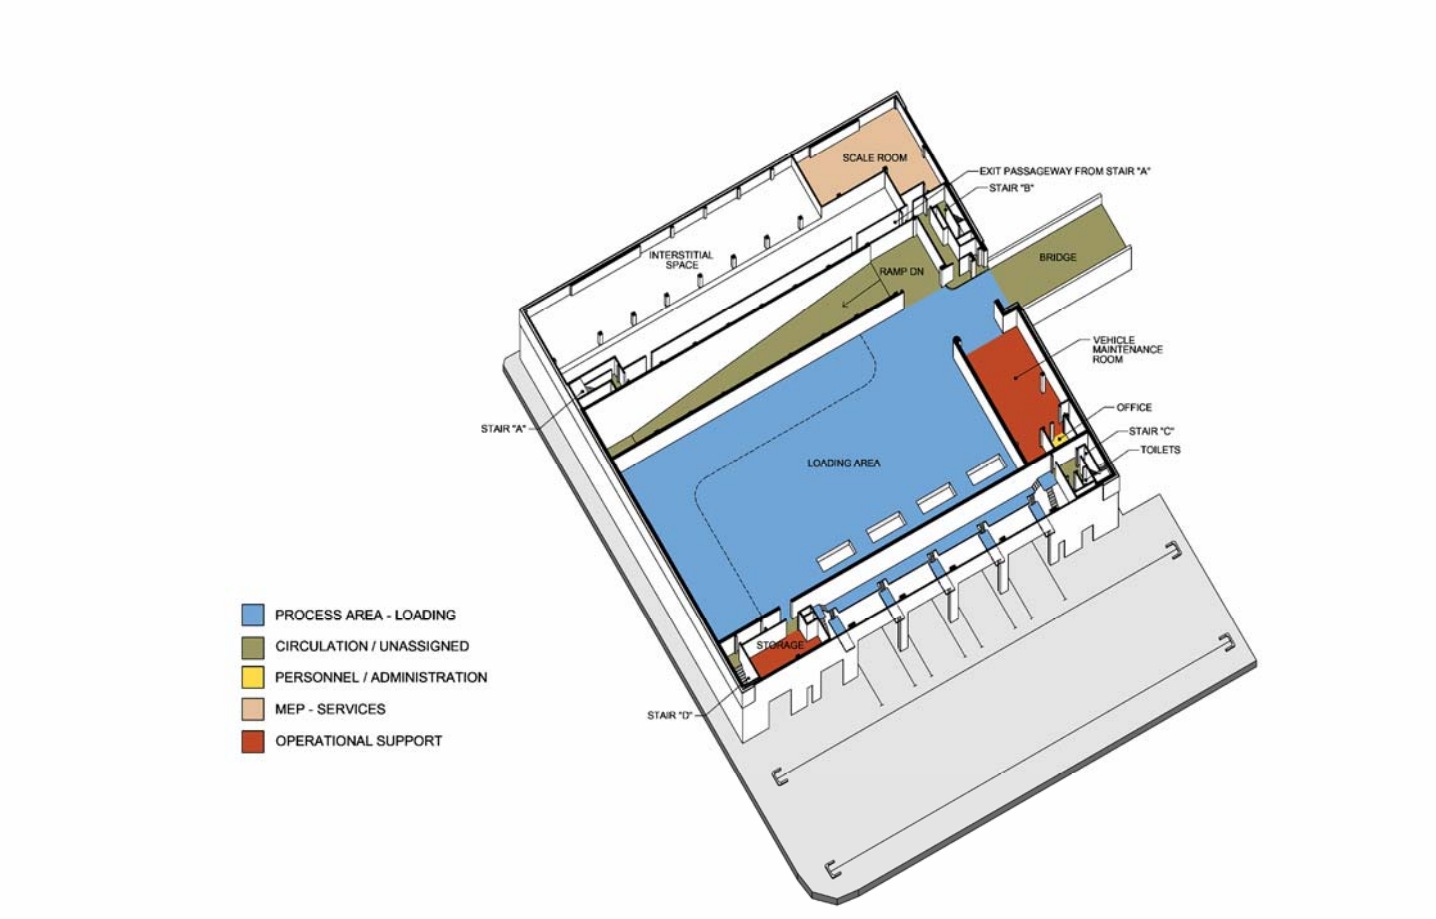
DSNY Containerization Loading Floor Level



- An internal ramp is provided to facilitate light vehicular access between the loading level and the pier deck level. The ramp is designed to accommodate the wheel loads of a DSNY rack-type truck or an AASHTO HS-15 vehicle. The ramp is framed in concrete-encased structural steel with a cast-in-place concrete deck.

- The entire pier deck floor area serviced by the gantry cranes is designed to resist the weight of filled containers stacked two high. The pier deck (Figure 2-4) framing will be constructed of continuous reinforced concrete pile bents supporting a precast, prestressed concrete plank floor deck with a composite cast-in-place reinforced concrete topping, and a wearing surface consisting of precast concrete pavers installed on a one-inch thick sand bedding. Due to the high concentrated loads of the gantry cranes (Figure 2-5), a continuous pile-supported, reinforced concrete girder, fortified to transfer horizontal operating loads into the concrete deck slab, is required directly beneath each rail of the gantry crane.

- The floor deck of the enclosed lidding area is designed to support the weight of a filled container on a shuttle carriage moving along each of four sets of rails into and out of the lidding area. The floor area behind the lidding area and beneath the loader slots will be designed to accommodate a filled container on a shuttle carriage plus substantial tamping loads imposed by the excavator working at the loading level above.

Finally, to accommodate expected physical and operational requirements the North Shore and other DSNY containerization facility designs call for the main building structure, exterior pier deck and access ramps to be supported on high-capacity foundation piles driven to a dense subsurface soil stratum or rock. Geotechnical analysis indicates that larger diameter steel pipe piles, with their top sections filled with concrete to below mean low water level, offer better

Figure 2-4
DSNY Containerization Facility Pier Level

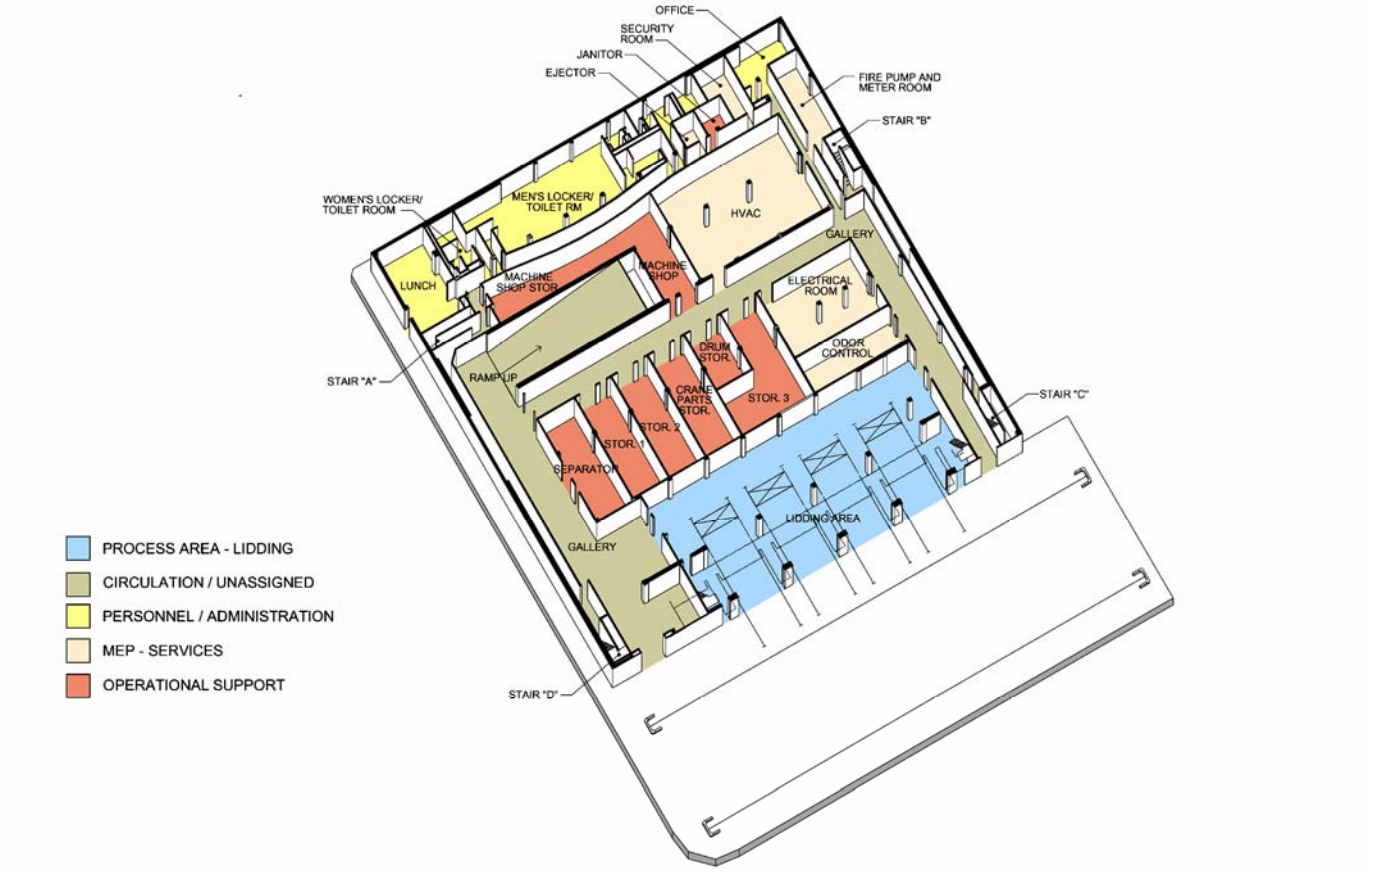


Figure 2-5
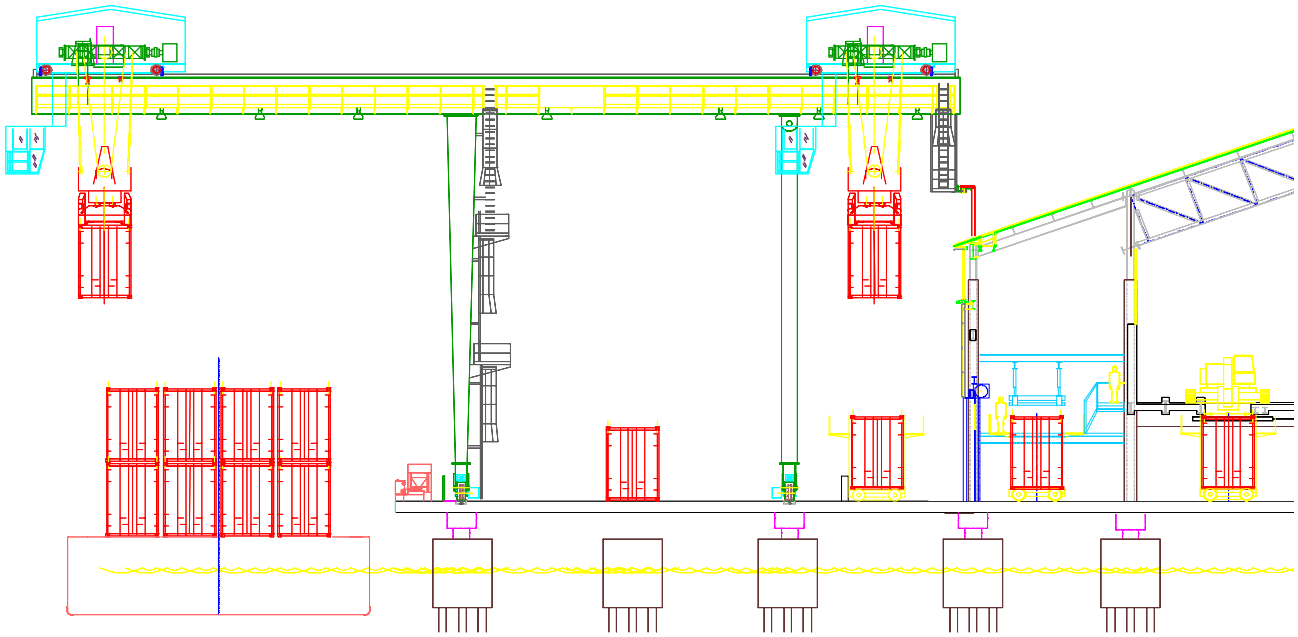
DSNY Containerization Facility
Container Handling Gantry Crane



downward load capacity and lateral resistance against seismic loads than concrete piles, and better corrosion resistance than steel H-piles in the tidal zone.

Structural Feasibility of Pier 76 Reuse

The substructure and concrete deck structure of Pier 76, as they currently exist, are not capable of carrying the expected loads from a DSNY containerization facility for the following reasons:

- **Pier 76 does not have sufficient load bearing capacity to support a DSNY containerization facility.** A DSNY containerization facility design incorporates approximately 300 piles, each with an allowable capacity of 275 tons, to support the building and pier. Based on these numbers, the total load capacity needed to support the building is roughly 80,000 tons. The portion of Pier 76 that underlies the proposed containerization facility has approximately 1600 piles, each with an allowable capacity of 20 tons which yields a. total load capacity of 32,000 tons. The required pile capacity is roughly 250% greater than the available capacity; therefore, the existing pier does not have sufficient capacity to support the new structure.

- **The column grid needed for a containerization facility is significantly different from the beam and pile spacing of Pier 76.** In order to accommodate the heavy loads from the vehicles, equipment and piles of waste, the column grid of a DSNY containerization facility is closely spaced with dimensions varying from 18 feet to 25 feet in the east-west direction and varying from 27 feet to 33 feet in the north-south direction. The average spacing is roughly 20 feet by 30 feet. The spacing of the existing pile clusters at Pier 76 is roughly 85 feet by 30 feet which is too far apart to accommodate the required column grid for a containerization facility.

- **The existing Pier 76 pile clusters do not have sufficient load bearing capacity to support a DSNY containerization facility.** The typical interior column loads for a DSNY containerization facility range from 400 to 800 tons. At the columns that support the

long-span transfer truss above the tipping area, the column loads increase to as high as 1,100 tons. The existing 9-inch concrete pier deck at Pier 76 is only load-rated to support a 20.5 ton truck and is not capable of supporting concentrated column loads between timber pile clusters. The largest pile clusters at Pier 76 have only 15 piles which can safety support a maximum of 300 tons which is less than that required to support the column loads of a DSNY containerization facility. Additional pile clusters would also be required to support the required concentrated column loads and spacing for the proposed facility.

- **The existing Pier 76 pier deck cannot support the loads that would be imposed by full containers stacked two high.** The existing pier deck is 9 inches thick and can support a 20.5 ton vehicle. Such a vehicle would impose a load on the deck of roughly 16 tons on its rear axle and 4 tons on its front axle. The design weight of a full container is 30 tons. The containers are supported on four ISO blocks and during normal operations will need to be stacked two high, anywhere on the pier deck. The double-stacked arrangement imposes a load of 15 tons per ISO block on the pier deck. In addition, the containers can be placed as close as 12 inches apart. Thus, four adjacent containers, stacked two high, will impose a load of 60 tons in an area slightly more concentrated than the rear axle of a truck. This is 370% higher than the rated capacity of the pier deck. In order to stack containers in the deck area, the entire deck would need to be replaced.

- **The weight of the proposed rooftop park will considerably reduce the load bearing capacity of the existing Pier 76 pier deck.** The service live load capacity of the existing pier was calculated as 602 PSF. If the park area is constructed using approximately 18 inches of soil, the service live load capacity would be reduced to an estimated 375 PSF and would reduce the rated allowable truck load accordingly.

- **The existing pier deck cannot accommodate the shuttle car system that would be used to move empty and full containers into and out of the building.** For safety con-

siderations and to facilitate equipment maneuvering on the pier deck, the typical design adopted for the shuttle car system calls for its pair of rails to be embedded in the concrete deck. In addition each rail needs to be supported by a continuous and pile supported concrete beam to accommodate the heavy shuttle car wheel loads. The existing Pier 76 pier deck slab is not thick enough to allow the shuttle cars rails to be embedded and the configuration of the existing piles do not provide adequate load capacity to support the shuttle car system.

- **The existing pier deck cannot support the gantry cranes that would move containers on to and off of barges.** Each gantry crane weighs 375 tons and is supported on four legs. When operating, each leg of the crane exerts a force of up to 149 tons on the pier deck. This is over 900% more than the rated truck axle load of 16 tons the existing pier deck can accommodate. The two crane rails are supported on continuous pile supported reinforced concrete girders. The piles under Pier 76 are 20-ton capacity piles spaced at 8 feet on center in the direction of the crane travel. Even a pair of these piles would be overstressed more than 600% under the weight of the operating crane.

- **The existing piles cannot accommodate the additional lateral forces a containerization facility would impose.** Due to the heavy weight of a DSNY containerization facility and the weight of the equipment and waste piles it houses, the lateral forces calculated for the design seismic event are very high, generally ranging from 15 to 30 tons at each column. There are approximately 1600 piles under the area that the containerization facility would occupy If the allowable lateral load on each timber pile is 0.5 tons, the capacity of the group to resist lateral forces is on the order of 800 tons. The lateral force from the structure alone under a seismic event is on the order of 1,600 tons. The lateral force from the self weight of the existing pier will add an additional 400 to 800 tons of lateral load under a seismic event. Consequently, the timber piles do not have sufficient lateral capacity to support both the existing pier deck and a DSNY containerization facility under the design seismic event.

The principal observation and conclusions cited above would also apply to the recyclables transfer facility. Specifically, the overall load bearing capacity of Pier 76, the load bearing capacity of the pile clusters and the arrangement of the piles are not adequate to accommodate a recyclables transfer facility similar in arrangement and operation to one of DSNY's existing marine transfer stations, such as the West 135th Street MTS. Additionally, the considerable number of piles that would have to be removed to create the barge slips needed could diminish the viability and require the reconstruction of a considerable portion of the existing pier structures. Finally, the docking and maneuvering of barges will exacerbate the lateral force issue described above.

Section 3 Review of Operational Components of the Pier 76 Concept

Access and Circulation of Vehicles

According to the Pier 76 proposal, trucks bound for the consolidated facility would enter at grade level and then travel up a ramp that appears to be approximately 130 feet in length to reach the weigh station at an elevation 20 feet above grade. After passing through the weigh station, trucks carrying recyclables would make a 90 degree left turn to the recycling tipping area, maneuver and then dump their loads into open hopper barges. Trucks carrying solid waste, once through the weigh station, would travel up an additional ramp to reach the waste tipping floor which is at an elevation 30 feet above grade. To exit, all trucks would use a single lane ramp that is approximately 100 feet long and turns 90 degrees as the trucks exit. The proposed consolidated facility design does not appear to include any ramps for accessing the loading level of the proposed containerization facility or the pier level where the container handling equipment operate.

The access ramps in the proposed consolidated facility appear to have slopes of 15% or greater. In deference to the capabilities of its equipment and for safety, DSNY design criteria call for truck ramps to have slopes of 6-8%, to include transition areas (i.e., vertical curves) at the start of a ramp to prevent trucks from bottoming out and to have flat zones before and after

a scale. Based on this design criteria, the access ramp of the proposed consolidated facility would have a total length of 413 feet rather than the 130 feet shown. Given the size of the existing pier and the facility layout proposed, it is not clear how or if such a ramp could be accommodated.

In addition to the slopes, the ramps in the proposed consolidated facility appear to have lane widths and turning radii that would be problematic. Specifically, the lane widths and turning radii should be able to accommodate the dimensions of a 32 cubic yard collection vehicle, which is a vehicle commonly employed by commercial haulers. Hence, the lane widths should be at least 17 feet and the turning radius for inside lanes should be a minimum of 32 feet. The lane widths and turning radii shown in the proposal do not appear to meet these standards.

The proposed consolidated facility design appears to be based upon use of only inbound scales and tare keys for determining and keeping track of the amounts of solid waste and recyclables delivered. Such systems, while workable, involve transactions at the weigh station that take considerably longer and are more likely to cause queues than the transactions associated with the separate inbound/outbound scale arrangements that are the current state of the art and will be employed at all DSNY containerization facilities. Additionally, the inbound/outbound arrangements are generally much more accurate. They do, however, require slightly more space and it does not appear that the proposed consolidated facility design could be modified to accommodate a sufficient number of outbound scales to allow for the implementation of such a system.

The proposed consolidated facility appears to provide only one single lane ramp for exiting from the transfer facilities. If a truck were to break down on this ramp, truck access to and all operations at the transfer facilities would have to be halted until it was removed. This is an unacceptable feature. To prevent such a problem, the exit lanes from a DSNY containerization facility run adjacent to the access lane, which allows the access lane to be temporarily used for bypass in the event an exiting truck breaks down. Additionally, this arrangement allows for easy and quick access to the disabled vehicle, which is something the single lane arrangement in the proposed

concept would not allow. Given the size of the existing pier, the previously noted deficiency in the length of its access ramps and the circulation pattern defined, it is not clear how or if the proposed consolidated facility design could be modified to address this issue.

The proposed consolidated facility does not appear to include a means for operating equipment, service vehicles and emergency vehicles to gain access to the loading floor of the containerization facility or the pier deck. Without such an access route, the proposed transfer facilities could not be operated efficiently or safely. DSNY containerization facility designs address this issue by providing a ramp off the main vehicle access ramp that connects directly to the loading floor and through the provision of an internal ramp that can carry service and emergency vehicles to the pier deck. Given the size of the existing pier and the arrangement of facilities, it is not clear how or if the proposed consolidated facility could be modified to address this issue.

Spatial and Layout Considerations

As shown, the distance from the solid waste tipping floor to the top of the rooftop park is 30 feet. This is insufficient clearance to allow for the collection vehicles to raise their tailgates, provide for structural long-span support of the roof and park structures above and incorporate building systems such as fire protection, dust suppression, HVAC ducts and lighting. It is therefore probable the elevation of the rooftop park could exceed +70 feet.

Depending on the framing configuration, the overall depth of the floor slab and framing at the proposed recyclables tipping area would need to be on the order of 4 to 5 feet deep due to the heavy loads on the truck rear axles when tipping and the long clear spans needed. The structure thickness shown in the Pier 76 proposal appears to be much less. Hence, the proposed recycling tipping floor height of 20 feet above the pier level may not be sufficient to accommodate full and empty barges during expected tidal conditions. As a result, the proposed elevation of the recyclables tipping floor as well as the elevation of the roof above it may need to be increased.

Increases to the height of the rooftop park to address the concerns noted above will cause the slope of the park to be steeper or necessitate the use of stairs. In either case, the rooftop park would become more difficult to maintain as a green space and more difficult for the public to access and enjoy.

HVAC Considerations

The proposed consolidated facility design does not appear to provide any space for installing HVAC equipment above the floors. Consequently, the roofs will have to be raised higher than the Pier 76 proposal indicates or this equipment would need to be housed below the tipping floors, down on the pier deck, or elsewhere in the consolidated facility. The first option would make the rooftop park slopes even steeper and the second option would make providing vehicular access to the pier level even more critical. Additionally, the second option would likely require the installation of larger equipment and considerably more duct work to address and compensate for the distances between the location where the equipment is installed and the spaces to be ventilated, heated and cooled. This arrangement, combined with the fact the volume of the proposed consolidated facility is four times greater than that of a typical DSNY containerization facility, it is likely that the equipment room needed will be at least four times larger than the 10,000 square foot equipment mezzanine a DSNY containerization facility includes. Given the size of the existing pier, the facility arrangement proposed and previously noted absence of access to the pier deck, it is not clear how the proposed consolidated facility design could be modified to address this issue

Section 4 Review of Pier 76 Rooftop Park Proposal

Length and Grade of Overpass and Entrance to Rooftop Park

The proposed concept calls for sections of the Hudson River Park walkway and bike path to the northeast and southeast of Pier 76 to be gently sloped up so as to allow pedestrians and cyclists to pass above trucks and other vehicles entering and exiting the proposed consolidated

facility. The gently sloped bike path and walkway will also serve to allow pedestrians and cyclists to enter the rooftop park that would be above the consolidated facilities.

The proposal does not define an exact slope for the walkway and bike path; however, it is not unreasonable to assume that a 5% slope (i.e., 1 foot of rise for each 20 feet of length) would be the maximum grade that would be comfortable for pedestrians, the handicapped and cyclists to negotiate. At that slope a distance of 400 feet would be needed to rise the necessary 20 feet from existing grade. Essentially, this means for nearly 400 feet to the north and south of Pier 76 the eastern and western edge of the Hudson River Park walkway and bike path would be walls. There appears to be sufficient space available for this concept to the south of Pier 76. To the north, however, it appears the implementation of this concept would block access to an excursion boat dock and impinge upon a tourist bus staging area. Consequently, it is clear that while this concept would eliminate a safety concern, it cannot be implemented without imposing at least considerable visual and other impacts and complicating traffic and pedestrian movements to the north of Pier 76.

Rooftop Park Grade and Area

The proposal shows the rooftop park starting at an elevation of 20 feet above grade and sloping up to a large flat area above the containerization facility that is at an elevation of 60 feet. As noted above, because of clearance and structural issues it is more likely that the elevation of the portion of the rooftop park above the containerization facility to be positioned at the western end of the pier would need to be at least 70 feet. To rise to this elevation at a 5% slope would require a distance of 1,000 feet, which is approximately 275 feet greater than the length of the pier. Consequently, the rooftop park is more likely to be several small flat areas at different elevations connected by ramps with slopes greater than 5% or stairs instead of the single, large gently sloping open space the proposed concept suggests.

Section 5 Comparison of Probable Costs

Probable Construction Cost of Pier 76 Proposal

An estimate of the probable construction cost of the Pier 76 proposal is shown in Table 5-1 below. Costs shown are estimated to the midpoint of construction which is projected to be October of 2013.

Table 5-1
Estimated Cost of Pier 76 Proposal

Pier 76 Demolition	**Cost**	
Environmental assessment & remediation	$2,100,000	
Demolition	$10,600,000	
	Total	$12,700,000
Ramps and Circulation	**Cost**	
Foundations	$9,600,000	
Structure	$10,600,000	
	Total	$20,200,000
Containerization Facility	**Cost**	
Foundations	$21,900,000	
Structure	$59,400,000	
Equipment	$32,600,000	
HVAC	$ 8,100,000	
Plumbing	$ 4,100,000	
Electrical	$22,000,000	
	Total	$148,100,000
Recyclables Transfer Facility	**Cost**	
Foundations	$18,900,000	
Structure	$51,900,000	
Equipment	$17,200,000	
HVAC	$ 6,300,000	
Plumbing	$3,200,000	
Electrical	$17,000,000	
	Total	$114,500,000

Table 5-1
Estimated Cost of Pier 76 Proposal
(continued)

Tow Pound and Stables	**Cost**	
Foundations	$17,100,000	
Structure	$46,900,000	
Equipment	$1,200,000	
HVAC	$ 4,600,000	
Plumbing	$2,300,000	
Electrical	$12,600,000	
	Total	$84,700,000
Rooftop Park and Transitions	**Cost**	
Structure	$45,400,000	
Plumbing	$1,600,000	
Electrical	$ 8,800,000	
	Total	$55,800,000
Total Estimated Cost of Pier 76 Proposal		**$436,000,000**

This estimate is based on the extensively detailed construction cost estimate prepared in January of 2005 for the DSNY's North Shore, Queens containerization facility (see Attachment 2). Of the four containerization facilities to be developed by the DSNY pursuant to the City's Solid Waste Management Plan, North Shore was chosen as a basis for estimating Pier 76 costs because, like the consolidated facility proposed for Pier 76, it will be entirely over water. In addition to the North Shore estimate, the preliminary estimates for the Pier 76 proposal reflect consideration of the following:

- The impact of inflation. Since January of 2005, the costs of construction materials have risen by an average of 6% per year and the cost of labor has increased by approximately 3% per year.

- The determination that the substructure of Pier 76 does not have the capacity to carry the loads the proposed consolidated facility would impose and would have to be replaced.

- The more extensive and difficult demolition effort the Pier 76 proposal would require.

- The greater amounts of steel each component of the Pier 76 proposal would have to include in order to handle the loads the rooftop park would generate.

- The modifications to the Hudson River Park walkway and bike path and the construction of the rooftop park.

Finally, the construction cost estimate for Pier 76 reflects consideration of a recent trend in the bidding of public contracts in New York City which has seen an overall reduction in the number of bidders willing or able to compete for large projects and is resulting in unexpectedly high bid prices for such projects.

Probable Construction Cost of a Recycling Transfer Facility at the Gansevoort Peninsula

It is assumed that the construction cost of a recyclables transfer facility at the Gansevoort Peninsula would be slightly lower than the cost shown in Table 5-1 for the recyclables transfer facility at Pier 76. In part, this is because differences in the structures to be removed would result in lower demolition costs for a recyclables transfer facility at Gansevoort. It also reflects the fact that the facility at Gansevoort would require lower quantities of steel because it would not have a rooftop park incorporated into its design structural loads. Finally, building heating, ventilation and air conditioning costs would also be less because the volume of the recyclables transfer facility at Gansevoort would be lower and easier to service than the volume of the recyclables transfer facility at Pier 76.

Probable Construction Cost of Refurbishing the West 59th Street MTS

The West 59th Street Marine Transfer Station was originally constructed in the late nineteenth century as a passenger ship pier and was modified in the mid-twentieth century to serve as a

marine transfer station by the Department of Sanitation (DSNY). The facility was rehabilitated in the 1980's to its existing configuration, which consists of an entrance ramp, tipping floor and pier level with a separate operations building that houses personnel facilities.

The City's Solid Waste Management Plan calls for the West 59th Street MTS to be refurbished and made available to serve as a commercial waster transfer facility. The refurbishment of the West 59th Street MTS would principally consist of stabilization of the foundation systems to achieve a 20-year service life and replacement of building systems as necessary and, based on line item estimates prepared for the containerization facilities, is expected to cost between $40 and $45 million.

Comparison of Costs

Assuming the operational and technical issues discussed in Section 3 could be addressed, a comparison of the estimated cost to implement the Pier 76 proposal to the cost of implementing the Gansevoort and West 59th Street MTS proposals is shown in Table 5-2 below:

Table 5-2
Comparison of Costs

Total Estimated Cost of Pier 76 Proposal		$436,000,000
	Cost	
Gansevoort Recyclables Transfer Facility	$ 82,500,000	
West 59th Street MTS	$ 42,500,000	
	Total	$125,000,000
Total Difference		**$311,000,000**

Section 6 Conclusion

In summary, the principal findings of the technical evaluation of the Pier 76 proposal described in this report are as follows:

- The substructure of Pier 76 does not have the capacity to carry the loads the proposed consolidated facility would impose, thus implementing the Pier 76 proposal would require the demolition and replacement of the existing pier and substructure.

- The proposed consolidated facility has many operational and technical problems and deficiencies that it may not be possible to correct or address without diminishing or eliminating important features of the proposal, including the rooftop park.

- Clearance and structural requirements are likely to cause the rooftop park to be a series of smaller flat areas connected by steep ramps and/or stairs instead of the large gently sloping open space shown.

- The Pier 76 proposal would cost $311 million dollars more to implement than it would cost to build both a recycling transfer facility at the Gansevoort peninsula and the current proposal for the West 59th Street MTS.

In light of these findings, the Pier 76 proposal cannot be considered a viable alternative for the proposed recyclables transfer facility to be located at the Gansevoort peninsula and for making the West 59th Street MTS available for the transfer of commercial waste.

Michael Singer Studios

Halcrow

Friends of Hudson River Park and the Coalition to Protect Our Parks retained an engineering/design team, led by Halcrow and including Weisz + Yoes Architecture and Michael Singer Studio, to investigate the feasibility of using Pier 76 on the Hudson River waterfront (at 36th Street) as a consolidated solid waste transfer station, replacing the proposed Gansevoort recycling facility and Pier 99 transfer station, both planned on Manhattan's West Side, within Hudson River Park.

The engineering/design team has undertaken a preliminary evaluation of a **Pier 76 combined transfer station** and the results are encouraging. The following is a summary description of the planned facility.

Expediting the Solid Waste Management Plan Manhattan's West Side

Under the Hudson River Park Act, Pier 76 is obligated to remove from its current use the Manhattan tow pound. This plan seeks to replace this function with a solid waste marine transfer station with the capacity both to (1) accept and transfer into barges all of Manhattan's recyclables and (2) process, containerize and load into barges most of Manhattan's commercial waste. The goal is to locate a West Side transfer facility in Manhattan south of 96th Street in a way that would most effectively meet the needs of the NYC Department of Sanitation and private haulers and best meet community concerns, all within the context of the Mayor's Solid Waste Management Plan (SWMP).

The substructure of Pier 76 is already in place and appears to be in excellent condition, with capacity to carry the expected loads of this program.

Waste Transfer +

Pier 76 (244,600 sq/ft) is more than twice the square footage of the proposed Gansevoort (35,000 sq/ft) and Pier 99 (57,100 sq/ft) footprints combined. This will add flexibility to the waste transfer operations planned for the West Side. There is capacity to handle two recycling barges at a time within an enclosed facility on the south side of the Pier; one for metal, glass and plastic and another for paper. Unlike Pier 99, the footprint of which is limited by the Hudson River Park Act, Pier 76 also has ample space for on-site compaction and containerization of commercial waste.

This consolidation will eliminate the need for a new transfer station in Hudson River Park at Gansevoort and Pier 99 will be freed up for park use at the north end of the Park. Prelimarily it appears that **NYPD tow pound and stable functions can be retained at the Pier.**

On the roof of the Pier we envision a spacious new Park as a major public space connecting to the new development and parks in the Hudson Yards. – a waterfront "porch" for a renovated Jacob Javits Convention Center and Far West Side.

Access

Currently, one of the worst grade crossings for Hudson River Park is at the Ferry Terminal exit just north of Pier 76, due to the narrow width of the Park at this point, the exiting buses and other vehicles, and the entrance to the tow pound. Indeed, one fatality and many accidents have occurred at this location.

The Plan calls for a raised section of the Hudson River Park on the east side of Pier 76, allowing pedestrians and bicyclists to rise above grade, while sanitation trucks and all other vehicles (including the buses out of the Ferry Terminal) will cross below at grade.

Below the **elevated walkway and bikeway**, traffic remains at grade. The sanitation trucks rise inside the Pier to the tipping floor on the second level. All queuing for peak activities is accommodated indoors and off the street – another major advantage over Pier 99.

The gentle slope lifting the bike path and walkway will also bring people halfway up to a rooftop park to be built above the consolidated transfer station. Crossing into the rooftop, pedestrians would then continue up a gently sloped roof to the main expanse of park. Views will be focused to the north on the Palisades and the boat traffic at the Passenger Ship Terminal. There could be a terrace connection to the Javits Center and the park will serve as a destination on the Hudson for the High Line and Hudson Yards, connecting Midtown to the West Side Ferry Terminal.

Plans and Diagrams

Preliminary Evaluation Plans and Diagrams reflecting the layout being developed for Pier 76 are attached.

Future Work

Over the next two months, the engineering/design team will refine the preliminary evaluation and test the assumptions on which it is based. The goal is to come up with a more detailed concept plan that will further demonstrate the feasibility of using Pier 76 as a consolidated marine transfer station. Preliminary cost estimates will also be developed. It is estimated that **construction on this facility could begin immediately** setting a precedent for siting and operating working waterfront facilities city wide.

Detailed Construction Cost Estimate DSNY North Shore Containerization Facility – January 2005

North Shore Marine Transfer Station Conversion
Draft Final Cost Estimate
January 2005

Description	North Shore
Demolition	$2,225,000
Environmental Cleanup	$153,000
Sitework and Utilities	$1,922,000
Dredging	$1,898,000
Service Water	$156,000
Bilge Water	$51,000
Ramps w/ Foundations	$6,611,000
Structural Steel	$8,096,000
Pile Foundations	$3,379,000
Precast Structural Concrete	$1,442,000
Cast-in-Place Concrete	$6,914,000
Reinforced Concrete Walls	$668,000
Reinforced Concrete Elevated Slab	$2,425,000
Concrete Encase. for Bms & Cols	$1,713,000
Concrete for Composite Deck	$224,000
Fendering System	$1,313,000
Marine Hardware	$578,000
Architectural Work	$6,700,000
Dust and Odor Control Systems	$238,000
Lidding/Unlidding Process	$374,000
Maintenance Bay Equipment	$66,000
Safety Equipment	$25,000
Interior Paint Marking and Signage	$36,000
Heat Tracing	$680,000
I&A Equipment	$374,000
Heating and Ventilitation	$2,648,000
Plumbing	$1,048,000
Fire Protection	$624,000
Gantry Cranes (Labor)	$400,000
Interior and Exterior Electrical Work	$7,691,000
CONTROL COMPONENTS AND DEVI	$12,000
DISCONNECT SWITCHES	$107,000
