

2018

**LEGIONNAIRES' DISEASE ANNUAL
SURVEILLANCE REPORT**

Summary and Frequently Asked Questions

What is Legionnaires' disease?

- Legionnaires' disease is a form of pneumonia caused by *Legionella* bacteria.
- People can contract Legionnaires' disease by *inhaling* droplets of water (mist) contaminated with *Legionella* bacteria into their lungs.
- People cannot contract Legionnaires' disease by *drinking* water contaminated with *Legionella* bacteria.
- People generally develop symptoms of Legionnaires' disease between 2 and 10 days after they inhale *Legionella* bacteria. The time between inhaling *Legionella* bacteria and the development of symptoms is called the disease incubation period.
- *Legionella* bacteria are very common in the natural environment. Most people who are exposed to the bacteria do not develop Legionnaires' disease.

How common is Legionnaires' disease in NYC?

- Legionnaires' disease is not a common disease. Among the 8.5 million people living in New York City (NYC), between 200 and 700 cases of Legionnaires' disease are reported each year. Legionnaires' disease patients who are hospitalized therefore account for a small proportion of the approximately 35,000 hospitalizations for pneumonia that occur in New York City each year.¹ In 2018, there were 656 reported cases of Legionnaires' disease. By comparison, about 52,000 cases of laboratory confirmed influenza² were reported that same year.

Is the rate of Legionnaires' disease increasing in New York City and across the United States?

- While it remains a relatively rare infection, the rate of Legionnaires' disease is increasing significantly in NYC. This increase in the disease rate might be driven by: (1) more people who have *Legionella* pneumonia getting diagnosed and reported to the Health Department due to increased use of diagnostic testing by health care providers; (2) more people contracting *Legionella* pneumonia; or (3) some combination of these factors. Factors that might increase the number of people contracting *Legionella* pneumonia include an aging population, aging plumbing infrastructure or changing weather patterns.
 - From 2007-2018, there was an 11.9% average increase in the rate of Legionnaires' disease cases citywide each year.
 - The rate of Legionnaires' disease increased significantly in all boroughs and demographic groups over this period.
- Data from the Centers for Disease Control and Prevention (CDC) show that rates of Legionnaires' disease increased across the country from 2010-2018. During that period, 15 jurisdictions had an average annual percent increase in cases that was larger than the increase in NYC. See Appendix A.

Who gets Legionnaires' disease?

- Most healthy people do not develop Legionnaires' disease even if they are exposed to *Legionella* bacteria. People at higher risk for Legionnaires' disease include those who are aged 50 years or older, people with chronic lung disease or other chronic conditions, or people taking immunosuppressive medications.
- The majority (71%) of people diagnosed with Legionnaires' disease in 2018 were adults aged 55 years or older. Almost all those diagnosed (99%) reported at least one chronic health condition, most commonly diabetes (34%) or lung disease (21%).
- Over half (59%) of people diagnosed with Legionnaires' disease in 2018 reported a history of smoking.
- Men were nearly twice as likely as women to be diagnosed with Legionnaires' disease (9.5 and 5.9 per 100,000 people, respectively). Among all racial groups, non-Hispanic Black New Yorkers had the highest rate of disease (14.5 per 100,000 people).
- In 2018, most Legionnaires' disease cases (29%) occurred in Manhattan; however, the Bronx had the highest rate (12.3 cases per 100,000 people).

When does the Health Department investigate Legionnaires' disease cases?

The Health Department follows up on every Legionnaires' disease case diagnosed in residents of New York City to confirm their clinical history and understand more about how they may have been exposed to *Legionella* bacteria. The Health Department also continuously monitors for clusters of cases that might be related to a common environmental source of *Legionella* bacteria exposure.

- Community cluster investigations: The Health Department investigates cases of Legionnaires' disease that cluster closely in time and geography among people who live in different buildings. This pattern of disease indicates a possible community source of exposure, such as a cooling tower. The Health Department performs evaluations of nearby cooling towers when surveillance finds a cluster of Legionnaires' disease cases.
 - The Health Department investigated two community clusters in 2018, both occurring in the Washington Heights neighborhood of Manhattan. A total of 59 cases and two death were linked to these clusters.
 - The Health Department collected a total of 58 samples from 26 cooling tower systems as a part of these investigations. One cooling tower was identified as the source of both outbreaks.
 - All cooling towers in NYC are required to be registered in an online system, sampled by owners at least every 90 days of operation and are inspected by the Health Department for compliance with NYC cooling tower regulations¹.
- Building water system evaluations: The Health Department evaluates the water system in a building when two or more residents of the building are diagnosed with Legionnaires' disease within 12 months of each other. The Health Department also evaluates a building water system when a single case occurs in a person who spent the entirety of the disease incubation period in a higher-risk setting (e.g., shelter or assisted living facility).
 - The Health Department conducted evaluations of ten NYC building water systems in 2018. Legionella was found in 9 of these buildings; the Health Department worked with the building owners to remediate the building water system.

I. Legionnaires' Disease in NYC Over Time

Figure 1.1 Number and Rate of Reported Legionnaires' Disease Cases*, NYC, 2000-2018†

*Numbers represent all confirmed cases of legionellosis, which includes Legionnaires' disease and a flu-like illness called Pontiac fever. Pontiac fever makes up fewer than 2% of reported legionellosis cases each year.

†2015 South Bronx Legionnaires' Disease Outbreak: An outbreak linked to a cooling tower in the South Bronx involved 133 NYC residents with illness onset July 2 to August 3, 2015.³ In response, the Health Department added rules to the New York City Administrative Code that placed new requirements on building owners concerning the registration, inspection and maintenance of cooling towers.

‡For national trends, see Appendix A.

The rate of Legionnaires' disease has increased significantly in NYC. Between 2007 and 2018, disease rates increased in all NYC boroughs and demographic groups. This increase may reflect a more vulnerable population (older adults or persons living in poverty), aging plumbing infrastructure or changing weather patterns. Increased use of diagnostic testing may also influence the rate of disease. Similar increasing rates of Legionnaires' disease have been seen across the United States. Data from the CDC show that rates of Legionnaires' disease have increased in 96% of reporting jurisdictions during 2010-2018. During that period, 15 jurisdictions had an average annual percent increase in cases that was larger than the increase in NYC (Appendix A).

II. Geographic Distribution of Legionnaires' Disease

Figure 2.1 Legionnaires' Disease Rate by Neighborhood

Tabulation Area (NTA), 2018*

Annual rate per 100,000 people

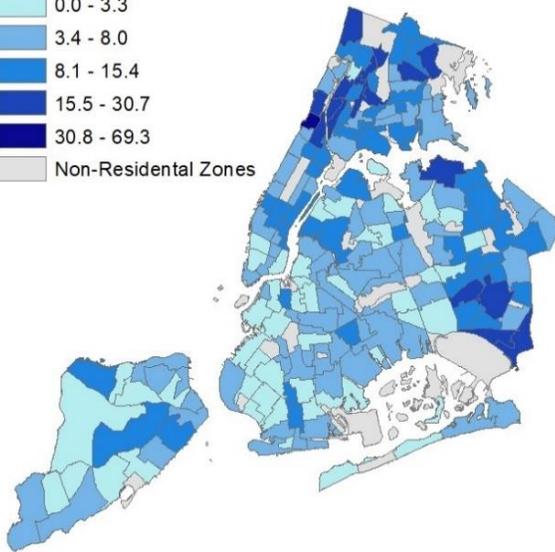

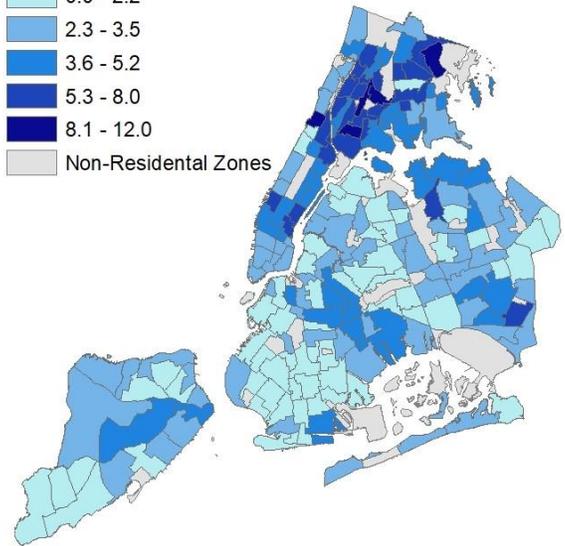

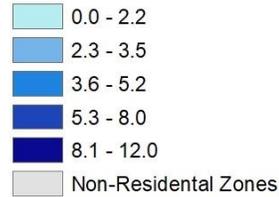

Figure 2.2 Average Legionnaires' Disease Rate by NTA, 2007-

2017†

Annual rate per 100,000 people

Legionnaires' disease rates vary substantially across NYC's neighborhoods. Because there are relatively few cases of Legionnaires' disease diagnosed each year (when compared to the total population), neighborhoods with highest rates of disease may vary from year to year (Figure 2.1). Longer-term rates are more stable (Figure 2.2). Geographic difference in disease rates may reflect different environmental exposures, variations in health system practices, and, variations in health conditions that increase the risk of Legionnaires' disease like smoking, chronic lung disease, diabetes and other chronic conditions that suppress the immune system. Multiple factors likely contribute to the occurrence and detection of Legionnaires' disease in neighborhoods with the highest rates of disease. Many neighborhoods with the highest rates of disease also have older populations and the highest rates of poverty (Figures 2.2, 2.3, and 2.4). Environmental sources of *Legionella* bacteria may vary by neighborhood, based on the type and maintenance of infrastructure in the area, including cooling tower systems. In addition, the rate of testing for Legionnaires' disease may not be uniform across the city due to variations in health system practices.

III. Demographic and Clinical Characteristics

Table 3.1: Legionnaires' Disease Case Reporting Summary, NYC, 2018

	N	%
Confirmed Cases	656	100%
Method of Diagnosis		
Urine antigen test (UAT) only	614	94%
Bacterial culture only	8	1%
Bacterial culture and UAT	26	4%
Missing/unknown	8	1%
Case Classification		
Community-associated	610	93%
Possible health care-associated*	16	2%
Definite health care-associated**	30	5%

* Person spent some (1-9) nights during their disease incubation period in an Article 28 health care facility

** Person spent ≥10 nights during their disease incubation period in an Article 28 health care facility
(See: health.ny.gov/facilities/hospital/regulations).

The majority of Legionnaires' disease cases are diagnosed by urine antigen test (UAT). The UAT provides rapid results allowing for prompt treatment of patients. Clinical bacterial cultures are necessary for cases to be linked to potential environmental sources. However, bacterial cultures are infrequently available because appropriate specimens are difficult to obtain. Clinical bacterial cultures were available for only 5% of cases in 2018, thus limiting the opportunity for environmental source matching to clinical cases.

People who spend time in hospitals or nursing homes are at higher risk for Legionnaires' disease. This higher disease risk exists because people in health care settings are more likely to have health conditions or receive treatments that suppress their immune systems. The Health Department refers cases that occur in people who spent one or more nights during their disease incubation period (the 10 days before feeling sick) in a hospital or nursing home to New York State for further follow-up and possible environmental testing of the health care facility.

A small percent of Legionnaires' disease cases (7%) in 2018 occurred among individuals who spent one or more nights in a health care facility during their 10-day disease incubation period.

In 2018, Legionnaires' disease did not occur at the same rate across all demographic groups. Rates of Legionnaires' disease were higher among men than women, higher among older people, and higher among people living in poverty.

Gym shower	18	3%
Whirlpool spa, hot tub	10	2%
Steam room	2	0%
Swimming pool	1	0%

* The incubation period is the 10 days prior to the date of symptom onset.

† DOHMH collects exposure information for non-routine water-related exposures or water service disruptions that have previously been associated with the occurrence of Legionnaires' disease in the United States and worldwide.

Figure 3.1 Clinical and Behavioral Characteristics of People Diagnosed with Legionnaires' Disease, Overall and by Age, NYC, 2018

Most healthy people do not develop Legionnaires' disease even if they are exposed to *Legionella* bacteria. People who smoke or have chronic health conditions are at greater risk for Legionnaires' disease. Among people with Legionnaires' disease in 2018, 99% had at least one chronic medical condition and 59% were previous or current smokers. The most commonly reported medical condition was diabetes (34%), followed by lung disease (21%). People with who were under 50 at the time they were diagnosed with Legionnaires' disease are more likely to report being current smokers or have been diagnosed with HIV.

Legionella bacteria are found naturally in the environment, meaning that exposure can occur from a variety of sources. As part of the surveillance process, DOHMH interviews each diagnosed person about their water use to identify common sources of exposure. However, it is rare that patient interviews identify possible common sources of exposure for different people. In 2018, the majority of people with Legionnaires' disease (58%) reported exposure to aerosols outside their home, water service disruption in their homes, or exposure to aerosols in their homes beyond routine water use. For this reason, the Health Department routinely initiates an evaluation of a building's water system if two or more cases occur within 12 months in residents of the building, as this may indicate a common source of exposure (see 'Building Water System Evaluations' on page 8).

IV. Cluster Detection Methods and Investigation Summary

The Health Department routinely analyzes Legionnaires' disease surveillance data to identify possible clusters of cases. Depending on the location and timing of cases, as well as the presence of possible common exposures, the Health Department might initiate one of the following responses:

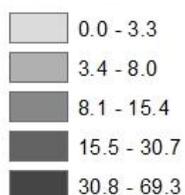

- **Community cluster investigation:** The Health Department investigates cases of Legionnaires' disease that cluster closely in time and geography among people who live in different buildings. This pattern of disease indicates a possible community source of exposure, such as a cooling tower. The Health Department performs evaluations of nearby cooling towers when surveillance finds a cluster of Legionnaires' disease cases
- **Building water system evaluation:** The Health Department evaluates the water system in a building when two or more residents of the building are diagnosed with Legionnaires' disease within 12 months of each other. The Health Department also evaluates a building water system when a single case occurs in a person who spent the entirety of the disease incubation period in a higher-risk setting (e.g., shelter or assisted living facility).

Table 4.1: Health Department Response Summary, 2018

10	10 Building Water System Evaluations were initiated. 9 out of 10 buildings required remediations.	2	2 Community Clusters were identified, both in the Lower Washington Heights Community. 58 environmental samples were collected from 26 cooling tower systems. 2 clinical and environmental <i>Legionella</i> isolates matched via whole genome sequencing
