RE: Issuance of Final Environmental Impact Statement and Notice of Completion in support of the New Comprehensive Solid Waste Management Plan and Department of Sanitation ULURP Applications C050175PSK, C050176PSK, C050174PSQ and C050173PCM

Dear Involved Agency/Interested Party:

The New York City (City) Department of Sanitation (DSNY) issued a Draft New York City Comprehensive Solid Waste Management Plan for the next twenty-year planning period (New SWMP) in October 2004. DSNY, as lead agency for the environmental review, encloses a Final Environmental Impact Statement (FEIS) for the New SWMP and the accompanying Notice of Completion for the FEIS pursuant to the City Environmental Quality Review Procedures and the State Environmental Quality Review Act in October 2004. The FEIS also supports the above-referenced DSNY Uniform Land Use Review Procedure (ULURP) applications for the four proposed Converted Marine Transfer Stations. In preparation for the FEIS, DSNY issued a Draft Scoping Document in May 2004 and a Final Scoping Document and Draft EIS (DEIS) in October 2004 after conducting an enhanced public participation process that included ten public scoping meetings and a public comment period which ran from May 17 to July 11, 2004. The enhanced public participation process continued with eight DEIS public hearings in December 2004 and a DEIS public comment period which ran from October 22, 2004 to January 24, 2005. Additional outreach was conducted in connection with ULURP public hearings held in January 2005.

The FEIS will also be available at twenty-two public repositories and on the DSNY website (www.nyc.gov/sanitation), and will be available by contacting DSNY, all as set forth in the enclosed Notice. The FEIS Statement of Findings will also appear on the DSNY website. A second distribution of the Notice will be mailed to an expanded distribution list shortly.

As set forth in the enclosed FEIS and Notice, the New SWMP is a plan for the management of all of the solid waste generated in the City. In particular, the New SWMP proposes to award a 20-year contract for the processing and marketing of recyclables and the development of a recyclables processing facility in the City, the development of four Converted Marine Transfer Stations (MTSs) (rather than eight as previously contemplated), the award of up to five contracts with private transfer station operators for barge or rail export of DSNY-managed waste, and an intergovernmental agreement to dispose of a portion of Manhattan's DSNY-managed waste at the Essex County Resource Recovery Facility in New Jersey. In addition, the New SWMP makes available the West 59th Street MTS in Manhattan for putrescible commercial waste export from the City.

Sincerely,

Harry Szarpanski

Harry Szarpanski

State Environmental Quality Review Act/City Environmental Quality Review
NOTICE OF COMPLETION OF FINAL ENVIRONMENTAL IMPACT STATEMENT

April 1, 2005

Name of Action: New Comprehensive Solid Waste Management Plan

CEQR #: 03DOS004Y

SEQRA Classification: Type I

Lead Agency: New York City Department of Sanitation, 125 Worth Street, NY, NY 10013

Location: City-wide

This notice is issued pursuant to Article 8 (State Environmental Quality Review Act - SEQRA) of the Environmental Conservation Law; 6 NYCRR Part 617, the regulations implementing SEQRA; and the City Environmental Quality Review procedures set forth in Executive Order 91 of 1977 as amended (43 RCNY Chapter 6) and Chapter 5, Title 62 of the Rules of the City of New York (CEQR). The Department of Sanitation for the City of New York (DSNY), being the agency having principal responsibility for carrying out the Action, is the lead agency for conducting the environmental review of the Action. DSNY has caused a Final Environmental Impact Statement (FEIS) to be completed for the New York City Comprehensive Solid Waste Management Plan for at least the next 20 years (2005-2025) (New SWMP), together with related solid waste management and Recyclables processing facility development and procurement (collectively, the Proposed Action). The FEIS is available for public inspection at the offices of the Department through the Contact Person listed below and on the Department's website http://nyc.gov/sanitation.

For further information or to obtain a compact disc (CD) of the FEIS, please contact:

Harry Szarpanski, Assistant Commissioner
New York City Department of Sanitation
Bureau of Long Term Export
44 Beaver Street, 12th Floor
New York, NY 10004
Phone: (917) 237-5520 Fax: (212) 269-0788

In addition to the New SWMP approval, the Proposed Action in the Draft New SWMP encompasses, among other things the following:

- Siting of four new marine transfer stations (Converted MTSs) to containerize waste for Long Term Export,

- Contracting with several private waste transfer stations for barge and/or rail export of DSNY-managed Waste, which may involve facility modifications at certain of these transfer stations; and

- Contracting for development of a Recyclables processing facility at the South Brooklyn Marine Terminal in Brooklyn, and developing a City-owned a Recyclables acceptance facility in Manhattan.

These actions require various discretionary approvals as further described below.

The draft scope of work for the Environmental Impact Statement (EIS) was presented at public scoping meetings held between June 15 and July 1, 2004. The period to receive public comments on the proposed EIS scope of work remained open until July 11, 2004. A Draft EIS (DEIS) was issued on October 22, 2004, together with the Final Scope, and, thereafter, eight public hearings on the DEIS were held during the period December 1 to December 20, 2004. Copies of the DEIS were circulated and made available on the DSNY website and at 22 public repositories throughout the City. Public comments on the DEIS were accepted by DSNY throughout an extended public comment from October 22, 2004 through January 24, 2005. The questions and concerns received on the DEIS have been addressed in the April 1, 2005 Final Environmental Impact Statement (FEIS). A Findings Statement, to be issued in accordance with CEQR/SEQRA, will appear on the Department's website. Comments on the FEIS are requested and will be received by DSNY for at least 10 days after the filing of this Notice. All comments should be sent to the Contact Person listed above.

Background

DSNY has developed a new comprehensive long-term plan for the City's solid waste that builds on the continuation of the City's successful recycling, composting and waste prevention programs already in place. The proposed New SWMP and the status of the City's programs designed to reduce the quantity of waste exported are described in the Draft New SWMP document, which is separate from the FEIS. The New SWMP would provide for the management of all solid waste generated in New York City for the 20-year planning period, as required under the Environmental Conservation Law for the permitting of new solid waste management facilities. The New SWMP incorporates certain elements of the existing SWMP, which was approved in 1992 and subsequently amended, and proposes changes to the City's Long Term Export Program for DSNY-managed Waste, to the City's Recycling Program, and to management of commercial waste in the City. The Planning Unit is the City of New York.

Approximately 50,000 tons per day (tpd) of waste is generated in New York City. Waste that DSNY collects from residents, not-for-profit institutions and other City, state and federal agencies, as well as waste from special DSNY operations such as street and lot-cleaning operations consists of refuse (mostly collected from curbside) and source-separated recyclables (collectively, DSNY-managed waste). In FY 2002, this DSNY-managed waste averaged approximately 11,123 tpd of refuse and 2,555 tpd of separately collected recyclables: newspaper

and mixed paper; metal, glass and certain plastics (MGP) and yard wastes. DSNY-managed refuse is exported from the City under short-term contracts entered into for the phased closure of the City's Fresh Kills landfill, which closed completely in March 2001 pursuant to state law. DSNY delivers about 38% of this refuse in collection vehicles directly to disposal facilities or private transfer stations outside of New York City, about 14% to a private transfer station in the Bronx where it is loaded onto rail for further transport, and approximately 48% of this refuse to other private transfer stations in the City, which load it onto truck trailers for further transport out of the City for disposal. The current export contracts result in approximately 6000 tpd of DSNY-managed waste being transported through the private truck-to-truck transfer stations in the City. Under a 20-year contract DSNY delivers much of the recyclable paper to the West 59th Street MTS for transport by barge to a private paper mill on Staten Island, while DSNY delivers the remaining paper and the MGP to other private recyclables handling and processing facilities in Queens, Brooklyn, the Bronx and New Jersey. DSNY also collects leaves and yard waste seasonally for composting. Other DSNY and City managed wastes that are recycled (derelict vehicles, auto tires, lot cleaning, asphalt and asphalt millings from road resurfacing, interagency road material reuse, etc.) totaled approximately 2,840 tpd in FY2002. Commercial carters collect waste generated by the private sector, such as commercial construction and demolition debris (C&D debris), soil and rock from excavations (clean fill), and refuse and source-separated recyclables from business establishments (collectively, Commercial Waste). In 2003, commercial waste quantities generated in the City averaged approximately 7,248 tpd of putrescible waste (having organic matter that causes odors), 2,641 tpd of designated recyclable waste (mainly paper and metal); 8,626 tpd of non-putrescible C&D debris (excluding clean fill), and 19,069 tpd of clean fill material. Much C&D debris, and virtually all clean fill material, is recycled. Other waste generated in the City but not managed by DSNY includes medical waste, dredge spoils, and biosolids from water pollution control plants.

Description and Location of Proposed Action

The Proposed Action for Long Term Export has the following specific elements.

- For the entire Bronx wasteshed, enter into a long-term contract with one or two private waste companies for truck-to-rail disposal of DSNY-managed Waste from existing transfer stations in the Bronx.

- For the Brooklyn wasteshed formerly served by the Greenpoint MTS (Brooklyn CDs 1, 3, 4 and 5), enter into a long-term contract with one or two private waste companies for truck-to-rail or truck-to-barge disposal of the DSNY-managed Waste from existing transfer stations in Brooklyn.

- For the Brooklyn wasteshed formerly served by the Hamilton Avenue MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18, as well as limited quantities of Commercial Waste, will be received and containerized.

- For the Brooklyn wasteshed formerly served by the Southwest Brooklyn MTS, develop a City-owned Converted MTS on the adjacent site of the former Southwest Brooklyn Incinerator, where DSNY-managed Waste from Brooklyn CDs 11, 12, 13 and 15, as well as limited quantities of Commercial Waste, will be received and containerized.

- For the Manhattan wasteshed, Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12, enter into a long-term service agreement with the Port Authority of New York and New Jersey for the use of the Essex County Resource Recovery Facility in Newark, New Jersey to receive and process DSNY-managed Waste delivered in City collection vehicles.

- For the Manhattan wasteshed formerly served by the East 91st Street MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Manhattan CDs 5, 6, 8 and 11, as well as limited quantities of Commercial Waste, will be received and containerized.

- For the Queens wasteshed formerly served by the Greenpoint MTS, enter into a long-term contract with a private transfer station for truck-to-rail or truck-to-barge disposal of the DSNY-managed Waste from Queens CDs 1 through 6.

- For the Queens wasteshed formerly served by the North Shore MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Queens CDs 7 through 14, as well as limited quantities of Commercial Waste, will be received and containerized.

- For the four wastesheds served by Converted MTSs, enter into 20-year service agreements with one or more waste management companies, for transport of containerized waste by barge directly from an MTS to disposal facilities or to intermodal facilities for transloading to railcars or a larger barge, and for disposal at an appropriately permitted out-of-City facility.

Section 40.3.1.1 of the FEIS describes the capacity that DSNY proposes to permit at each of the four Converted MTSs. This proposal is subject to approval by NYSDEC as part of its review of Part 360 Solid Waste Facility permit applications for the Converted MTSs. Table 1 provides additional information on the location of proposed Long Term Export facilities.

Rail export from certain of the private transfer stations in the Proposed Action would require use of off-site, in-City, existing intermodal facilities that do not require discretionary approvals, identified in Table 2.

Table 1
Proposed Draft New SWMP Long Term Export Facilities and Potential Contractors

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Converted MTS[1]	DSNY, Hamilton Avenue Converted MTS, Hamilton Avenue at Gowanus Canal, Brooklyn	Brooklyn 7	Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18
Converted MTS[1]	DSNY, Southwest Brooklyn Converted MTS, Shore Pkwy at Bay 41st Street, Brooklyn	Brooklyn 11	Brooklyn CDs 11, 12, 13 and 15
Converted MTS[1]	DSNY, East 91st Street Converted MTS, East 91st Street and York Avenue, Manhattan	Manhattan 8	Manhattan CDs 5, 6, 8 and 11
Converted MTS[1]	DSNY, North Shore Converted MTS, 31st Avenue and 122nd Street, Queens	Queens 7	Queens CDs 7 through 14
Truck-to-Rail TS	Waste Management, Harlem River Yard, 98 Lincoln Avenue, Bronx	Bronx 1	Bronx CDs 1 through 12
Truck-to-Rail TS[2]	Allied Waste Services, East 132nd Street Transfer Station, Bronx and Oak Point Rail Yard, Oak Point Avenue and Barry Street, Bronx	Bronx 1	Bronx CDs 1 through 12
Truck-to-Barge TS	Waste Management, 485 Scott Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1,3, 4 and 5
Truck-to-Rail TS	Allied, 72 Scott Avenue-598 Scholes Street, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5
Truck-to-Rail/Barge TS[3]	Waste Management, 30-58 Review Avenue, Queens and the LIRR Maspeth Rail Yard, Maspeth Avenue and Rust Street Queens	Queens 2	Queens CDs 1 through 6
Waste-to-Energy Facility[4]	Port Authority of New York and New Jersey, Essex County RRF, Newark, New Jersey,	NA	Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12

Notes:

(1) From among the selected proposers responding to DSNY's MTS RFP, DSNY will award one or more contracts for the acceptance, transport and disposal of containerized waste from the Converted MTSs.

(2) This facility would include use of an off-site intermodal rail yard, as noted in the Table, where containers would be loaded onto railcars.

(3) Pending the outcome of negotiations between DSNY and Waste Management, the Review Avenue Transfer Station would be modified to operate as either a truck-to-barge or a truck-to-truck-to-rail facility. If operated in a truck-to-rail mode, an off-site intermodal rail yard, as noted in the Table, would be required, where containers would be loaded onto railcars.

(4) The Essex County RRF is a permitted and operating WTE facility in Newark, New Jersey. DSNY-managed Waste would be delivered in collection vehicles to this facility or via hopper barges from the existing MTSs, if an enclosed barge unloading facility (EBUF) were to be developed in the vicinity of the Essex County RRF some time in the future.

LIRR = Long Island Railroad

Table 2
Proposed Draft New SWMP Long Term Export – Potential Support Facilities

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Support Facilities			
Intermodal Truck-to-Truck-to-Rail Yard [(1)]	Oak Point Rail Yard, Oak Point Avenue and Barry Street, Bronx	Bronx 2	Bronx CDs 1 through 12
Intermodal Yard Truck-to-Truck-to-Rail [(1)]	LIRR, Maspeth Rail Yard, Maspeth Avenue and Rust Street, Queens	Queens 2	Queens CDs 1 through 6

Note:
(1) Both the East 132nd Street Truck-to-Truck-to-Rail Transfer Station in the Bronx and the Review Avenue Truck-to-Truck-to-Rail Transfer Station in Queens would dray containers between their respective transfer stations and intermodal rail yards that are in the respective project service areas but not at the same sites as the transfer stations. These intermodal yards are existing facilities that would receive non-discretionary permits from DSNY for handling solid waste and, as such, are not subject to environmental review. However, the movement of containers on tractor chassis between the transfer stations and the intermodal yard is subject to an environmental review that is reported in the FEIS section reporting the environmental review of the respective transfer station.
LIRR = Long Island Railroad

The Proposed Converted MTSs would be subject to zoning performance standards, solid waste management facility permit standards under 6 NYCRR part 360, and local Air and Noise Code standards. The facilities would have state-of-the-art odor controls that neutralize odor rather than mask it with a scent, and would be equipped with sufficient ventilation to maintain negative air pressure to prevent the escape of untreated air from building openings. Sufficient on-site queuing areas and tipping bays would be provided at all proposed Converted MTS facilities to prevent the queuing of DSNY trucks on public streets. The barges serving the converted MTSs could carry up to 48 intermodal containers and would be towed by tugboat to intermodal facilities, where the containers would be transloaded to trains or ocean-going vessels for transport to out-of-City disposal facilities. The primary objective of this element of the Proposed Action is the containerization of waste and the long-distance export of that waste in containers by barge or rail.

The Proposed Action for Recycling has the following specific elements.

- Develop a materials processing facility at the 30th Street Pier (in Brooklyn Community District 7) through a public-private partnership involving a 20-year service agreement with a private Recyclables processor; and

- Develop a Recyclables acceptance facility at the former DSNY MTS facility on Pier 52 at Gansevoort Street in the Hudson River Park.

Table 3 provides additional information on the location of these facilities.

Table 3
Proposed Action Recycling Facilities

Facility Type	Operator/Owner, Facility Name, and Address	Community District
Recyclables Processing/Acceptance[1]	Hugo Neu Corporation, 30th Street Pier at the South Brooklyn Marine Terminal, Brooklyn	Brooklyn 7
Recyclables Acceptance[2]	DSNY, Former site of Gansevoort MTS, Pier 52, Manhattan	Manhattan 2

Notes:

(1) This 30th Street Pier at SBMT is a complex of facilities that would be designed to receive and process DSNY Curbside Recyclables. Curbside Recyclables collected in Brooklyn would be delivered by truck to this facility. Curbside Recyclables from other boroughs would be delivered by barge. Recyclables would be transferred from this facility by barge. As a recycling facility, it is expected to qualify for a solid waste management facility registration rather than a permit. However, the waterfront construction requires USACE Section 10/404 permits and the NYSDEC Article 15/25 permits that are subject to environmental review.

(2) The timetable for designing, permitting and constructing this facility, which would receive truck deliveries of DSNY MGP Curbside Recyclables collected in Manhattan for barge transfer to the 30th Street Pier at SBMT for processing, is approximately seven years. Accordingly, the environmental review of this facility is deferred until more detailed design information is available. However, an analysis of the potential for off-site traffic, air quality and noise impacts from directing DSNY's Manhattan Recyclables collection vehicles to this destination was conducted.

A proposed change to DSNY's recycling program would be a 20-year contract for the receipt, processing and marketing of source-separated recyclable MGP and a portion of the City's paper. DSNY would procure services from a new private recyclables recovery and processing facility to be built by Hugo Neu Corporation (HNC) at the 30th Street Pier in the South Brooklyn Marine Terminal (SBMT). Approximately 85% of the recyclables would be delivered by barge to this facility, and 75% will leave post-processing via barge. DSNY trucks collecting curbside recyclables in the Bronx would tip this material at the existing HNC facility in the Bronx from which it would be transported by barge to the SBMT facility. DSNY trucks collecting curbside recyclables in northern Brooklyn and Queens would tip this material at HNC's facility in Long Island City, from which it would be transported by barge to the SBMT facility. Only Brooklyn Community Districts 9, 14, and 15 will deliver recyclables via collection trucks to the SBMT facility.

In addition, DSNY proposes to construct and operate a recyclables acceptance facility (recyclables handling and recovery facility under 6 NYCRR §360-12) at the former DSNY MTS facility on Pier 52 at Gansevoort Street in the Hudson River Park or at another location on the Manhattan waterfront, at which MGP and certain paper would be transferred to barge for transport to the HNC facility at the SBMT in Brooklyn for processing. This recyclables acceptance facility would require amendment of the Hudson River Park Act and would be the subject of a supplemental environmental review, as appropriate, once a facility design is

developed. DSNY would no longer deliver recyclable paper to the West 59th Street MTS in Manhattan, but would take it instead to the new recyclables acceptance facility for further transport by barge.

The elements of the Proposed Action for Commercial Waste are intended to achieve a more balanced distribution and reduce effects from Commercial Waste transfer operations in those CDs that currently have the greatest number of transfer stations. These actions are:

- Make the existing Manhattan West 59th Street MTS site available to private waste management companies to use for the transfer of Commercial Waste collected by private carters in Manhattan. The facility could be: (i) refurbished and used in conjunction with an EBUF; or (ii) redeveloped as a containerization facility.

- Design measures to encourage private carters to deliver Commercial Waste during the 8:00 p.m. to 8:00 a.m. time period to the four proposed Converted MTSs that are elements of the Proposed Action for Long Term Export (Hamilton Avenue and Southwest Brooklyn, Brooklyn; East 91st Street; Manhattan; and North Shore, Queens).

- Negotiate arrangements with the owners/operators of the selected private transfer stations in the Bronx, Brooklyn and Queens that submitted proposals in response to the Brooklyn, Queens and Bronx RFPs and Brooklyn request for a Best And Final Offer that are potential elements of the Proposed Action to require Commercial Waste (in addition to DSNY-managed Waste) processed at these facilities to be containerized and exported from the project service area by barge and/or rail.

Other Elements of the Draft New SWMP

In the context of refining and improving Existing Programs, the Draft New SWMP also discusses new initiatives in waste reduction, reuse and recycling. These include, among other things, conducting a comprehensive waste characterization study, undertaking an electronics recycling effort, adding a website for the NYC Stuff Exchange, expanding the NY Wa$teMatch industrial materials exchange program, and enhancing education and outreach efforts. As authorized under the Existing SWMP DSNY will use the Staten Island Transfer Station now under construction at 310 West Service Road for the long term export by rail of DSNY-managed Waste, when the facility and rail connection are complete.

Required Approvals

The New SWMP requires approval by the New York City Council and the New York State Department of Environmental Conservation (NYSDEC). In addition, the New SWMP elements related to the siting of the four proposed Converted MTSs require discretionary approval for a Site Selection Action from the New York City Planning Commission pursuant to Uniform Land Use Review Procedure (ULURP). The Department of Sanitation must approve the proposed long term contracts for transport and disposal of DSNY-managed waste, the proposed long-term contract for receipt and marketing of metal, glass and plastic recyclables and paper, and proposed construction of a pier at the Hugo Neu MGP Recyclables Acceptance facility. Certain other

approvals are required: *U.S. Army Corps of Engineers*: Section 10 (River and Harbors Act) for structures and work in navigable waters of the United States; Section 103 of the Marine Protection Research and Sanctuaries Act; Section 404 (Clean Water Act) for discharging of dredged or fill material in waters of the United States; and Section 401 (Clean Water Act) Water Quality Certification. From the *New York State Department of Environmental Conservation*, the following approvals have been identified as required: Article 27, Title 7 of the Environmental Conservation Law (ECL) Permit to construct and operate a solid waste management facility; Article 15, Title 5 (Protection of Waters) Permit for excavation in or fill of navigable waters; Article 15, Title 5 ECL (Protection of Waters) Section 401 Water Quality Certification; Article 25 ECL (Tidal Wetlands); Article 36 ECL (Flood Plain Management) approval for construction in a floodplain; Article 17 ECL (State Pollutant Discharge Elimination System (SPDES) General Permit (Section 402 of Clean Water Act) for stormwater discharges from construction activity; Coastal Zone Consistency Certification (19 NYCRR §600). From the *New York State Department of State*, approval may be needed under Article 42 of the State Executive Law (Waterfront Revitalization of Coastal Areas and Inland Waterways); Consistency with the Federal Coastal Zone Management Act (15 CFR Part 930); review by the New York State Office of Parks, Recreation and Historic Preservation; and review under Section 106 (National Historic Preservation Act) and New York State Historic Preservation Act Section 14.09. The *New York State Office of General Services* must approve the transfer to the City of a small amount of underwater land to accommodate the proposed footprint of the East 91st Street MTS. Certain other approvals may also be required, as summarized in Sections 1.7 and 2.5 of the FEIS.

Environmental Review

The FEIS provides an environmental review of the above noted sites/facilities that are elements of the Proposed Action for the New SWMP. (Final site selection for certain elements of the Proposed Action is dependent upon the outcome of current procurement actions by DSNY.) The FEIS also considers a range of Alternatives to the Proposed Action elements, including the No Action Alternative. Sections 1.3.3 and 1.4.4 of the FEIS provide additional information on the scope of Alternatives considered to the Proposed Actions for Long Term Export and Recycling, respectively. Environmental reviews were also conducted for a number of these Alternative sites/facilities considered during development of the Draft New SWMP.

In compliance with CEQR/SEQRA, the FEIS addressed: Land Use, Zoning, and Public Policy; Socioeconomic Conditions; Community Facilities and Services; Open Space; Cultural Resources; Urban Design, Visual Resources, and Shadows; Neighborhood Character; Natural Resources; Hazardous Materials; Water Quality; Waterfront Revitalization Program; Infrastructure, Solid Waste and Sanitation Services, and Energy; Traffic, Parking, Transit, and Pedestrians; Air Quality; Odor; Noise; Public Health; and Construction Impacts. Several of these facilities are existing permitted facilities that require no modifications or permit approvals for exporting DSNY-managed Waste by barge or rail, while others require only minor modifications not requiring environmental review, and still others would require discretionary permits or major modifications requiring environmental review. As such, the level of environmental review conducted for these facilities varied. The analysis for the proposed Converted MTSs conservatively used current conditions (with no waste activities at these currently permitted facilities) as the baseline against which to compare future conditions, rather than comparing future build conditions with past activity at these MTS sites. Use of the Staten

Island Transfer Station was the subject of an Environmental Impact Statement as part of the 2000 SWMP Modification. This facility is fully permitted and is under construction. The Essex County Resource Recovery Facility is a permitted and operating waste-to-energy facility and therefore did not require analysis.

Mitigation

The only potential impacts that were estimated to be significant without mitigation were with respect to traffic and noise, and all such impacts could be mitigated and are proposed to be mitigated. For the Proposed Action, the following measures were identified to mitigate estimated significant adverse impacts related to traffic and noise, respectively:

- Traffic signal timing adjustments would mitigate estimated traffic impacts identified at: (1) three intersections near the Southwest Brooklyn Converted MTS, and at two intersections near the Southwest Brooklyn Converted MTS using the Alternative route analyzed in the FEIS in response to comments received during public meetings on the ULURP application for this facility; (2) two intersections near the Hamilton Avenue Converted MTS; (3) two intersections near the East 91st Street Converted MTS; (4) two intersections near the North Shore Converted MTS; and (5) one intersection near the Scott Avenue/Scholes Street Truck to Rail TS.
- A reduction in the number of DSNY and other City agency vehicles making deliveries to the facility during the facility peak hour would be required to mitigate estimated traffic impacts identified at one intersection near the East 132nd Street TS and Oak Point Rail Yard.
- A restriction on the number of Commercial Waste vehicles delivering waste to the Southwest Brooklyn, Hamilton Avenue, East 91st Street and North Shore Converted MTSs during certain hours will mitigate estimated off-site noise impacts at receptors along the routes to these facilities between 8:00 p.m. and 8:00 a.m.
- DSNY Collection vehicles from Queens CD 9 en route to the North Shore Converted MTS will be routed further on the Van Wyck Expressway to Exit 14, Linden Place to mitigate estimated off-site noise impacts at receptors along College Point Boulevard.
- A restriction on the number of relayed DSNY collection vehicles delivering waste between the hours of 1:00 a.m. and 5:00 a.m., and construction of a louvered fence on both sides of the facility ramp, will mitigate estimated on-site noise impacts at property boundary points of the North Shore Converted MTS; and
- A restriction on the number of relayed DSNY collection vehicles delivering waste to the: (1) Hamilton Avenue and East 91st Street Converted MTSs during certain hours will mitigate estimated off-site noise impacts at receptors along routes to these facilities between 2:00 a.m. and 5:00 a.m.; and (2) Southwest Brooklyn Converted MTS will mitigate estimated on-site noise impacts at two off-site noise sensitive receptors between 2:00 a.m. and 3:00 a.m.

Alternatives

Alternatives to the Long Term Export elements of the Proposed Action that were considered included the No Action Alternative as well as conversions of four other existing DSNY MTS sites to Converted MTSs to containerize waste: West 135th Street MTS in Manhattan; the West 59th Street MTS in Manhattan; the Greenpoint MTS in Brooklyn; and the South Bronx MTS in the Bronx. In addition, an Alternative was considered that would involve the development of a new truck to rail facility in Brooklyn Community District 1 to serve the Brooklyn portion of the former Greenpoint MTS wasteshed. The FEIS also analyzed the alternative of refurbishing and reactivating the existing MTSs to supply DSNY-managed waste in open hopper barges to an enclosed barge unloading facility (EBUF) in the New York/New Jersey harbor region where it would be containerized for transport to disposal sites, although no location for such an EBUF has been identified. The FEIS incorporates the results of the investigation conducted for the 2004 Comprehensive Commercial Waste Management Study concerning four potential sites for truck-to-rail/barge transfer stations in Manhattan. DSNY in 2000 had previously evaluated the technical feasibility and environmental impacts associated with developing each of 24 export facility options on 15 different sites, pursuant to the 2000 SWMP Modification Final Environmental Impact Statement. DSNY's consideration of alternatives also evaluated the information obtained through a Request for Expressions of Interest to Provide Waste Disposal Capacity on February 17, 2004, that sought expressions of interest to (1) sell or otherwise provide to DSNY, for its exclusive use, permitted waste disposal capacity in New York State; (2) sell or otherwise provide to DSNY, for its exclusive use, land in New York State that is suitable to serve as a site for a waste disposal facility; and/or (3) serve as a host community for a disposal facility located in New York State that would receive waste managed by DSNY.

The repositories for the FEIS are located as follows:

Repository Location	Repository Address	Days and Hours of Operation	Phone Number
Manhattan Community Board 8 Office	505 Park Avenue	call for days and hours	(212) 758-4340
NYCDEP Office of Environmental Coordination	100 Gold Street, Manhattan	M-F, 9-5	(212) 788-9956
96th Street Regional Public Library	112 East 96th Street	M/Th 12-8;Tu/F 1-6; W 10-4; Sa 10-5; closed Sun	(212) 289-0908
Manhattan Community Board 9 office	565 West 125th Street	call for days and hours	(212) 864-6200
George Bruce Public Library	518 West 125th Street	M 10-6; W 12-8; Th 11-6; F 1-6; Sa 10-5; closed Tu/Sun	(212) 662-9727
Manhattan Community Board 4 Office	330 West 42nd Street, 26th Floor	call for days and hours	(212) 736-4536
Riverside Public Library (Community Bd 7)	127 Amsterdam Avenue at West 65th Street	M 10-6; W 12-8; Th 1-8; F 1-6; Sa 10-5; Closed Tu/Sun	(212) 870-1810
Brooklyn Community Board 7 office	4201 4th Avenue	call for days and hours	(718) 854-0003

Repository Location	Repository Address	Days and Hours of Operation	Phone Number
Sunset Park Public Library	5108 4th Avenue at 51st	M 1-8; T, Th/F 1-6; W 10-6; Sa 10-5; closed Sun	(718) 567-2806
Brooklyn Community Board 11 Office	2214 Bath Avenue	call for days and hours	(718) 266-8800

EXECUTIVE SUMMARY ES-1

CHAPTER 1 PROPOSED ACTION 1-1

1.1 INTRODUCTION 1-1
1.2 PURPOSE AND NEED 1-2
1.3 PROPOSED ACTION - LONG TERM EXPORT 1-3
1.3.1 Existing Conditions/No Action 1-3
1.3.2 Long Term Export - Proposed Action 1-6
1.3.3 Alternatives to the Proposed Action 1-14
1.4 PROPOSED ACTION - RECYCLING FACILITIES 1-18
1.4.1 Existing Conditions/No Action 1-21
1.4.2 Recycling Proposed Action 1-21
1.4.3 Advantages of the Proposed Action - Recycling Facilities 1-25
1.4.4 Alternatives to the Proposed Action 1-26
1.5 PROPOSED ACTION - COMMERCIAL WASTE MANAGEMENT 1-27
1.5.1 Existing Conditions 1-27
1.5.2 Proposed Action - Commercial Waste Management 1-29
1.5.3 Advantages of the Proposed Action 1-30
1.5.4 Other Commercial Waste Initiatives 1-31
1.6 PUBLIC REVIEW PROCESS - CEQR AND SEQRA 1-34
1.6.1 Long Term Export 1-35
1.6.2 Preparation of the DEIS 1-35
1.7 REQUIRED ACTIONS, PERMITS AND APPROVALS 1-38
1.7.1 Federal 1-38
1.7.2 New York State 1-38
1.7.3 New York City 1-39
1.8 PUBLIC OUTREACH PROCESS/ENVIRONMENTAL JUSTICE 1-39
1.8.1 Introduction 1-39
1.8.2 The EJ Program 1-40

CHAPTER 2 DESCRIPTION OF FACILITY SITES 2-1

2.1 INTRODUCTION 2-1
2.1.1 Overview 2-1
2.1.2 General Information, Plan Policies and Key Assumptions – Proposed Plan Long Term Export Facilities 2-7
2.2 SITE DESCRIPTIONS – PROPOSED PLAN FACILITIES LONG TERM EXPORT 2-17
2.2.1 Hamilton Avenue Converted MTS, Brooklyn 2-17
2.2.2 Southwest Brooklyn Converted MTS, Brooklyn 2-28
2.2.3 East 91st Street Converted MTS, Manhattan 2-41
2.2.4 North Shore Converted MTS, Queens 2-55
2.2.5 52nd Street Barge Staging Area, Brooklyn 2-68
2.2.6 Harlem River Yard Barge to Rail Intermodal Yard 2-72
2.2.7 65th Street Intermodal Yard, Brooklyn 2-76
2.2.8 Harlem River Yard Truck to Rail TS 2-84
2.2.9 East 132nd Street TS 2-92
2.2.10 Scott Avenue Truck To Barge TS, Brooklyn 2-100
2.2.11 Scott Avenue/Scholes Street Truck To Rail TS 2-109
2.2.12 Review Avenue Truck To Rail/Barge TS 2-116
2.2.13 Collection Vehicle Transport To Essex County WTE Facility 2-129

Table of Contents

2.3 PROPOSED PLAN RECYCLING FACILITIES 2-132
2.3.1 30th Street Pier At The South Brooklyn Marine Terminal 2-132
2.3.2 Gansevoort Recyclables Acceptance Facility 2-136
2.4 ALTERNATIVES CONSIDERED – LONG TERM EXPORT FACILITIES 2-139
2.4.1 South Bronx Converted MTS, Bronx 2-139
2.4.2 Greenpoint Converted MTS, Brooklyn 2-146
2.4.3 West 135th Street Converted MTS, Manhattan 2-154
2.4.4 West 59th Street Converted MTS, Manhattan 2-162
2.4.5 Existing South Bronx MTS, Bronx 2-171
2.4.6 Existing Southwest Brooklyn MTS, Brooklyn 2-173
2.4.7 Existing Greenpoint MTS, Brooklyn 2-175
2.4.8 Existing Hamilton Avenue MTS, Brooklyn 2-176
2.4.9 Existing West 135th Street MTS, Manhattan 2-178
2.4.10 Existing West 59th Street MTS, Manhattan 2-181
2.4.11 Existing East 91st Street MTS, Manhattan 2-183
2.4.12 Existing North Shore MTS, Queens 2-185
2.4.14 215 Varick Avenue Transfer Station 2-194
2.4.15 Steel Style Shipyard 2-203
2.5 SUMMARY OF POTENTIALLY APPLICABLE PERMITS FOR SITES CONSIDERED 2-208

CHAPTER 3 OVERVIEW OF STUDY METHODOLOGIES FOR SITE-SPECIFIC ANALYSES 3-1

3.1 INTRODUCTION 3-1
3.2 ANALYSIS YEARS AND FUTURE NO-BUILD CONDITIONS 3-2
3.3 DEFINITION OF SITES AND STUDY AREAS 3-3
3.3.1 Site Definition 3-3
3.3.2 Study Area Delineation 3-3
3.3.3 Maps and Figures 3-5
3.4 LAND USE, ZONING, AND PUBLIC POLICY 3-6
3.5 SOCIOECONOMIC CONDITIONS 3-11
3.6 COMMUNITY FACILITIES AND SERVICES 3-12
3.7 OPEN SPACE 3-13
3.8 CULTURAL RESOURCES 3-15
3.9 URBAN DESIGN, VISUAL RESOURCES, AND SHADOWS 3-16
3.10 NEIGHBORHOOD CHARACTER 3-18
3.11 NATURAL RESOURCES 3-19
3.11.1 Introduction 3-19
3.11.2 Previous Studies and Literature - Types and Sources of Information Collected 3-20
3.11.3 Current Ecological Field Studies - Types and Sources of Information Collected 3-21
3.11.4 Screening Methodology 3-22
3.11.5 Impact Analysis Methodology 3-22
3.11.6 Typical Mitigation Measures 3-23
3.12 HAZARDOUS MATERIALS 3-24
3.12.1 Introduction 3-24
3.12.2 Definition of Study Area 3-24
3.12.3 Types and Sources of Information Collected 3-25
3.12.4 Screening Methodology 3-25
3.12.5 Historical Land Use Review 3-25
3.12.6 Regulatory Agency List Review 3-26
3.12.7 Site and Surrounding Area Reconnaissance 3-27
3.12.8 Impact Analysis Methodology 3-27
3.12.9 Typical Mitigation Measures 3-30
3.13 WATER QUALITY 3-31
3.13.1 Introduction 3-31
3.13.2 Review of Existing Water Quality Data 3-31
3.13.3 Pollutant Loadings 3-31

Table of Contents

3.13.4 Modeling Evaluation of Stormwater Impacts 3-34
3.14 WATERFRONT REVITALIZATION PROGRAM 3-35
3.14.1 Introduction 3-35
3.14.2 Governing Policy 3-35
3.15 INFRASTRUCTURE, SOLID WASTE AND SANITATION SERVICES, AND ENERGY 3-41
3.15.1 Introduction 3-41
3.15.2 Water Supply 3-41
3.15.3 Sanitary Sewage and Stormwater 3-42
3.15.4 Solid Waste 3-42
3.15.5 Energy 3-43
3.16 TRAFFIC, PARKING, TRANSIT, AND PEDESTRIANS 3-44
3.16.1 Introduction 3-44
3.16.2 Background 3-44
3.16.3 Operational Assumptions 3-45
3.16.4 Trip Generation 3-47
3.16.5 Screening Methodology 3-59
3.16.6 Data Collection 3-59
3.16.7 Data Compilation 3-61
3.16.8 Analysis 3-61
3.16.9 Impact Analysis Methodology 3-64
3.16.10 Typical Mitigation Measures 3-66
3.16.11 Transit and Pedestrians 3-67
3.17 AIR QUALITY 3-69
3.17.1 Introduction 3-69
3.17.2 Air Quality Standards and Impact Significance Criteria 3-70
3.17.3 Regulatory Setting 3-79
3.17.4 Methodology Used to Estimate Potential On-site Impacts 3-80
3.17.5 Methodology Used to Estimate Potential Off-Site Impacts 3-88
3.17.6 Combined Impact Analysis 3-97
3.17.7 Mitigation Measures 3-98
3.18 ODOR 3-99
3.18.1 Introduction 3-99
3.18.2 Overview 3-99
3.18.3 Odor Impact Criteria 3-102
3.18.4 Odor Analysis 3-105
3.18.5 Sampling Program 3-106
3.18.6 Odor Modeling Methodology 3-112
3.18.7 Mitigation Measures 3-122
3.19 NOISE 3-123
3.19.1 Introduction 3-123
3.19.2 Background 3-123
3.19.3 Criteria 3-126
3.19.4 Noise Sources 3-130
3.19.5 Screening Methodology 3-130
3.19.6 Noise Monitoring 3-133
3.19.7 Impact Analysis 3-135
3.19.8 Combined Impact Analysis 3-141
3.19.9 Typical Mitigation Measures 3-142

CHAPTER 4 ENVIRONMENTAL REVIEW: HAMILTON AVENUE CONVERTED MTS 4-1
4.1 INTRODUCTION 4-1
4.2 LAND USE, ZONING, AND PUBLIC POLICY 4-2
4.2.1 Existing Conditions 4-2
4.2.2 Future No-Build Conditions 4-8
4.2.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-10
4.3 SOCIOECONOMIC CONDITIONS 4-11

Table of Contents

4.3.1 Existing Conditions 4-11
4.3.2 Future No-Build Conditions 4-18
4.3.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-19
4.4 COMMUNITY FACILITIES AND SERVICES 4-20
4.4.1 Existing Conditions 4-20
4.4.2 Future No-Build Conditions 4-20
4.4.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-20
4.5 OPEN SPACE 4-24
4.5.1 Existing Conditions 4-24
4.5.2 Future No-Build Conditions 4-26
4.5.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-26
4.6 CULTURAL RESOURCES 4-27
4.6.1 Existing Conditions 4-27
4.6.2 Future No-Build Conditions 4-28
4.6.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-28
4.7 URBAN DESIGN, VISUAL RESOURCES, AND SHADOWS 4-30
4.7.1 Existing Conditions 4-30
4.7.2 Future No-Build Conditions 4-37
4.7.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-37
4.8 NEIGHBORHOOD CHARACTER 4-39
4.8.1 Existing Conditions 4-39
4.8.2 Future No-Build Conditions 4-41
4.8.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-41
4.9 NATURAL RESOURCES 4-42
4.9.1 Existing Conditions 4-42
4.9.2 Future No-Build Conditions 4-47
4.9.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-47
4.10 HAZARDOUS MATERIALS 4-51
4.10.1 Existing Conditions 4-51
4.10.2 Future No-Build Conditions 4-54
4.10.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-54
4.11 WATER QUALITY 4-55
4.11.1 Existing Conditions 4-55
4.11.2 Future No-Build Conditions 4-58
4.11.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-61
4.12 WATERFRONT REVITALIZATION PROGRAM 4-63
4.12.1 Introduction 4-63
4.12.2 Consistency Assessment 4-65
4.13 INFRASTRUCTURE, SOLID WASTE AND SANITATION SERVICES, AND ENERGY 4-78
4.13.1 Existing Conditions 4-78
4.13.2 Future No-Build Conditions 4-82
4.13.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-82
4.14 TRAFFIC, PARKING, TRANSIT, AND PEDESTRIANS 4-84
4.14.1 Introduction 4-84
4.14.2 Existing Conditions 4-84
4.14.3 Future No-Build Conditions 4-94
4.14.4 Potential Impacts with the Hamilton Avenue Converted MTS 4-99
4.15 AIR QUALITY 4-113
4.15.1 Definition of the Study Areas 4-113
4.15.2 Existing Conditions 4-113
4.15.3 Future No-Build Conditions 4-114
4.15.4 Potential Impacts with the Hamilton Avenue Converted MTS 4-114
4.16 ODOR 4-125
4.16.1 Existing Conditions 4-125
4.16.2 Future No-Build Conditions 4-125
4.16.3 Potential Impacts with the South Bronx Converted MTS 4-125

Table of Contents

4.17 NOISE 4-128
4.17.1 Existing Conditions 4-128
4.17.2 Future No-Build Conditions 4-131
4.17.3 Potential Impacts with the Hamilton Avenue Converted MTS 4-132
4.18 COMMERCIAL WASTE TO THE HAMILTON AVENUE CONVERTED MTS 4-144
4.18.1 Existing Conditions 4-144
4.18.2 Future No-Build Conditions 4-144
4.18.3 Potential Impacts of Sending Commercial Waste to the Hamilton Avenue Converted MTS ... 4-144

CHAPTER 5 ENVIRONMENTAL REVIEW: SOUTHWEST BROOKLYN CONVERTED MTS 5-1

5.1 INTRODUCTION 5-1
5.2 LAND USE, ZONING, AND PUBLIC POLICY 5-2
5.2.1 Existing Conditions 5-2
5.2.2 Future No-Build Conditions 5-8
5.2.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-8
5.3 SOCIOECONOMIC CONDITIONS 5-10
5.3.1 Existing Conditions 5-10
5.3.2 Future No-Build Conditions 5-12
5.3.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-12
5.4 COMMUNITY FACILITIES AND SERVICES 5-14
5.4.1 Existing Conditions 5-14
5.4.2 Future No-Build Conditions 5-14
5.4.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-14
5.5 OPEN SPACE 5-17
5.5.1 Existing Conditions 5-17
5.5.2 Future No-Build Conditions 5-19
5.5.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-19
5.6 CULTURAL RESOURCES 5-20
5.6.1 Existing Conditions 5-20
5.6.2 Future No-Build Conditions 5-21
5.6.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-21
5.7 URBAN DESIGN, VISUAL RESOURCES, AND SHADOWS 5-22
5.7.1 Existing Conditions 5-22
5.7.2 Future No-Build Conditions 5-31
5.7.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-31
5.8 NEIGHBORHOOD CHARACTER 5-32
5.8.1 Existing Conditions 5-32
5.8.2 Future No-Build Conditions 5-34
5.8.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-34
5.9 NATURAL RESOURCES 5-35
5.9.1 Existing Conditions 5-35
5.9.2 Future No-Build Conditions 5-40
5.9.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-40
5.10 HAZARDOUS MATERIALS 5-43
5.10.1 Existing Conditions 5-43
5.10.2 Future No-Build Conditions 5-46
5.10.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-47
5.11 WATER QUALITY 5-48
5.11.1 Existing Conditions 5-48
5.11.2 Future No-Build Conditions 5-52
5.11.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-54
5.12 WATERFRONT REVITALIZATION PROGRAM 5-56
5.12.1 Introduction 5-56
5.12.2 Consistency Assessment 5-58
5.13 INFRASTRUCTURE, SOLID WASTE AND SANITATION SERVICES, AND ENERGY 5-73

Table of Contents

5.13.1 Existing Conditions 5-73
5.13.2 Future No-Build Conditions 5-76
5.13.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-76
5.14 TRAFFIC, PARKING, TRANSIT, AND PEDESTRIANS 5-78
5.14.1 Introduction 5-78
5.14.2 Existing Conditions 5-78
5.14.3 Future No-Build Conditions 5-88
5.14.4 Potential Impacts with the Southwest Brooklyn Converted MTS 5-89
5.14A TRAFFIC, PARKING, TRANSIT, AND PEDESTRIANS – ALTERNATE ROUTE 5-107
5.14a.1 Introduction 5-107
5.14a.2 Existing Conditions 5-107
5.14a.3 Future No-Build Conditions 5-122
5.14a.4 Potential Impacts with the Southwest Brooklyn Converted MTS 5-131
5.15 AIR QUALITY 5-151
5.15.1 Definition of Study Areas 5-151
5.15.2 Existing Conditions 5-151
5.15.3 Future No-Build Conditions 5-152
5.15.4 Potential Impacts with the Southwest Brooklyn Converted MTS 5-152
5.15A AIR QUALITY- ALTERNATE ROUTE 5-163
5.15a.1 Definition of Study Areas 5-163
5.15a.2 Existing Conditions 5-163
5.15a.3 Future No-Build Conditions 5-164
5.15a.4 Potential Impacts with the Southwest Brooklyn Converted MTS 5-164
5.16 ODOR 5-170
5.16.1 Existing Conditions 5-170
5.16.2 Future No-Build Conditions 5-170
5.16.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-170
5.17 NOISE 5-174
5.17.1 Existing Conditions 5-174
5.17.2 Future No-Build Conditions 5-177
5.17.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-178
5.17A NOISE – ALTERNATE ROUTE 5-194
5.17a.1 Existing Conditions 5-194
5.17a.2 Future No-Build Conditions 5-194
5.17a.3 Potential Impacts with the Southwest Brooklyn Converted MTS 5-196
5.18 COMMERCIAL WASTE TO THE SOUTHWEST BROOKLYN CONVERTED MTS 5-202
5.18.1 Existing Conditions 5-202
5.18.2 Future No-Build Conditions 5-202
5.18.3 Potential Impacts of Sending Commercial Waste to the Southwest Brooklyn Converted MTS 5-202

CHAPTER 6 ENVIRONMENTAL REVIEW: EAST 91ST STREET CONVERTED MTS 6-1

6.1 INTRODUCTION 6-1
6.2 LAND USE, ZONING, AND PUBLIC POLICY 6-2
6.2.1 Existing Conditions 6-2
6.2.2 Future No-Build Conditions 6-8
6.2.3 Potential Impacts with the East 91st Street Converted MTS 6-10
6.3 SOCIOECONOMIC CONDITIONS 6-11
6.3.1 Existing Conditions 6-11
6.3.2 Future No-Build Conditions 6-17
6.3.3 Potential Impacts with the East 91st Street Converted MTS 6-18
6.4 COMMUNITY FACILITIES AND SERVICES 6-20
6.4.1 Existing Conditions 6-20
6.4.2 Future No-Build Conditions 6-20
6.4.3 Potential Impacts with the East 91st Street Converted MTS 6-20
6.5 OPEN SPACE 6-24

Table of Contents

6.5.1 Existing Conditions 6-24
6.5.2 Future No-Build Conditions 6-28
6.5.3 Potential Impacts with the East 91st Street Converted MTS 6-28
6.6 CULTURAL RESOURCES 6-29
6.6.1 Existing Conditions 6-29
6.6.2 Future No-Build Conditions 6-33
6.6.3 Potential Impacts with the East 91st Street Converted MTS 6-33
6.7 URBAN DESIGN, VISUAL RESOURCES, AND SHADOWS 6-34
6.7.1 Existing Conditions 6-34
6.7.2 Future No-Build Conditions 6-39
6.7.3 Potential Impacts with the East 91st Street Converted MTS 6-39
6.8 NEIGHBORHOOD CHARACTER 6-47
6.8.1 Existing Conditions 6-47
6.8.2 Future No-Build Conditions 6-49
6.8.3 Potential Impacts with the East 91st Street Converted MTS 6-49
6.9 NATURAL RESOURCES 6-51
6.9.1 Existing Conditions 6-51
6.9.2 Future No-Build Conditions 6-55
6.9.3 Potential Impacts with the East 91st Street Converted MTS 6-56
6.10 HAZARDOUS MATERIALS 6-59
6.10.1 Existing Conditions 6-59
6.10.2 Future No-Build Conditions 6-60
6.10.3 Potential Impacts with the East 91st Street Converted MTS 6-60
6.11 WATER QUALITY 6-62
6.11.1 Existing Conditions 6-62
6.11.2 Future No-Build Conditions 6-67
6.11.3 Potential Impacts with the East 91st Street Converted MTS 6-68
6.12 WATERFRONT REVITALIZATION PROGRAM 6-70
6.12.1 Introduction 6-70
6.12.2 Consistency Assessment 6-70
6.13 INFRASTRUCTURE, SOLID WASTE AND SANITATION SERVICES, AND ENERGY 6-86
6.13.1 Existing Conditions 6-86
6.13.2 Future No-Build Conditions 6-89
6.13.3 Potential Impacts with the East 91st Street Converted MTS 6-89
6.14 TRAFFIC, PARKING, TRANSIT, AND PEDESTRIANS 6-92

CHAPTER 31 MESEROLE STREET TRUCK TO RAIL TS 31-1

31.1 INTRODUCTION 31-1
31.2 LAND USE, ZONING, AND PUBLIC POLICY 31-2
31.2.1 Existing Conditions 31-2
31.2.2 Future No-Build Conditions 31-9
31.2.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-9
31.2.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-9
31.3 SOCIOECONOMIC CONDITIONS 31-10
31.3.1 Existing Conditions 31-10
31.3.2 Future No-Build Conditions 31-12
31.3.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-12
31.3.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-13
31.4 COMMUNITY FACILITIES AND SERVICES 31-14
31.4.1 Existing Conditions 31-14
31.4.2 Future No-Build Conditions 31-16
31.4.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-16
31.4.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-16
31.5 OPEN SPACE 31-17
31.5.1 Existing Conditions 31-17
31.5.2 Future No-Build Conditions 31-18
31.5.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-18
31.5.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-18
31.6 CULTURAL RESOURCES 31-20
31.6.1 Existing Conditions 31-20
31.6.2 Future No-Build Conditions 31-23
31.6.3 Potential Impact with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-24
31.6.4 Potential Impact with the IESI NY Corporation Truck to Rail TS 31-24
31.7 URBAN DESIGN, VISUAL RESOURCES, AND SHADOWS 31-25
31.7.1 Existing Conditions 31-25
31.7.2 Future No-Build Conditions 31-26
31.7.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-26
31.7.4 Potential Impact with the IESI NY Corporation Truck to Rail TS 31-26
31.8 NEIGHBORHOOD CHARACTER 31-31
31.8.1 Existing Conditions 31-31
31.8.2 Future No-Build Conditions 31-31
31.8.3 Potential Impacts with the TransRiver Marketing Company, L.P Truck to Rail TS 31-33
31.8.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-33
31.9 NATURAL RESOURCES 31-34
31.9.1 Existing Conditions 31-34
31.9.2 Future No-Build Conditions 31-38
31.9.3 Potential Impacts with TransRiver Marketing Company, L.P. TS 31-38
31.9.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-39
31.10 HAZARDOUS MATERIALS 31-40
31.10.1 Existing Conditions 31-40
31.10.2 Future No-Build Conditions 31-43
31.10.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-43
31.10.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-43
31.11 WATER QUALITY 31-44
31.12 WATERFRONT REVITALIZATION PROGRAM 31-45
31.12.1 Introduction 31-45
31.12.2 Consistency Assessment for TransRiver Marketing Company, L.P. TS 31-47
31.12.3 Consistency Assessment for IESI NY Corporation TS 31-56
31.13 INFRASTRUCTURE, SOLID WASTE AND SANITATION SERVICES, AND ENERGY 31-57
31.13.1 Existing Conditions 31-57
31.13.2 Future No-Build Conditions 31-60

31.13.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-60
31.13.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-62
31.14 TRAFFIC, PARKING, TRANSIT, AND PEDESTRIANS 31-64
31.14.1 Existing Conditions 31-64
31.14.2 Future No-Build Conditions 31-74
31.14.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS 31-79
31.14.4 Potential Impacts with IESI NY Corporation TS 31-91
31.15 AIR QUALITY 31-92
31.15.1 Definition of Study Areas 31-92
31.15.2 Existing Conditions 31-92
31.15.3 Future No-Build Conditions 31-93
31.15.4 Potential Impacts with the TransRiver Marketing Company, L.P. TS 31-93
31.15.5 Potential Impacts with IESI NY Corporation TS 31-101
31.16 ODOR 31-103
31.16.1 Existing Conditions 31-103
31.16.2 Future No-Build Conditions 31-103
31.16.3 Potential Impacts with the TransRiver Marketing Company, L.P. TS 31-103
31.17 NOISE 31-106
31.17.1 Existing Conditions 31-106
31.17.2 Future No-Build Conditions 31-109
31.17.3 Potential Impacts with the Trans River Marketing Company L.P Truck to Rail TS 31-110
31.17.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS 31-114

CHAPTER 32 CONSTRUCTION IMPACTS 32-1

32.1 INTRODUCTION 32-1
32.2 CONSTRUCTION SCHEDULE 32-1
32.3 CONSTRUCTION ACTIVITIES AND EQUIPMENT 32-2
32.3.1 Construction Activities 32-2
32.3.2 Construction Equipment 32-3
32.4 POTENTIAL CONSTRUCTION IMPACTS 32-4
32.5 CONSTRUCTION IMPACTS TO THE MARINE ENVIRONMENT 32-8
32.5.1 Benthic Communities 32-8
32.5.2 Epibenthic Communities 32-16
32.5.3 Adult Finfish 32-20
32.5.4 Ichthyoplankton 32-22
32.6 OPERATIONAL IMPACTS 32-34
32.6.1 Benthic Communities 32-35
32.6.2 Epibenthic Communities 32-36
32.6.3 Adult Finfish 32-36
32.6.4 Ichthyoplankton 32-37
32.7 OVERVIEW OF MARINE ENVIRONMENTAL IMPACTS 32-38

CHAPTER 33 PUBLIC HEALTH EVALUATION 33-1

33.1 INTRODUCTION 33-1
33.2 AIR POLLUTION 33-2
33.2.1 Air Pollutants of Concern 33-2
33.2.2 Health Effects of Air Pollutants of Concern 33-2
33.2.3 Public Health Assessment of Air Pollutants of Concern 33-13
33.3 PUBLIC HEALTH EVALUATION OF NOISE 33-18
33.4 PUBLIC HEALTH EVALUATION OF ODORS 33-20
33.5 VERMIN CONTROL MEASURES 33-21
33.6 PUBLIC HEALTH CONCERNS OF HOST COMMUNITIES 33-22
33.6.1 Introduction 33-22
33.6.2 Traffic and Respiratory Health 33-22

Table of Contents

33.6.3 Asthma Causes and Triggers 33-27
33.6.4 Asthma Morbidity and Mortality in Host Communities 33-32
33.7 CONCLUSIONS 33-35

CHAPTER 34 EVALUATION OF THE PROPOSED ACTION 34-1

34.1 POTENTIAL IMPACTS OF THE PROPOSED PLAN 34-1

CHAPTER 35 UNAVOIDABLE ADVERSE IMPACTS 35-1

CHAPTER 36 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES 36-1

CHAPTER 37 GROWTH-INDUCING ASPECTS OF THE SWMP 37-1

CHAPTER 38 REFERENCES/BIBLIOGRAPHY 38-1

CHAPTER 39 LIST OF PREPARERS 39-1

39.1 INTRODUCTION 39-1
39.2 PRIME AND SUBCONSULTANT RESPONSIBILITIES 39-1
39.3 PREPARERS 39-2
39.3.1 HDR 39-2
39.3.2 PB 39-4
39.3.3 HydroQual 39-6
39.3.4 EEA 39-7
39.3.5 Urbitran 39-8
39.3.6 Cambridge Environmental 39-9

CHAPTER 40 – RESPONSIVENESS SUMMARY 40-1

40.1 INTRODUCTION 40-1
40.2 COMMENT INDEX 40-3
40.3 COMMENTS AND RESPONSES 40-76
40.3.1 GENERAL COMMENTS 40-76
40.3.2 COMMENTS AND RESPONSES 40-148
40.3.3 INVOLVED AGENCY COMMENTS 40-277
40.3.4 COMMENTS ON COMMERCIAL WASTE STUDY 40-322
40.3.5 TRANSFER, TRANSPORT AND DISPOSAL PLAN 40-400
40.3.6 ENHANCED ENVIRONMENTAL JUSTICE PUBLIC PARTICIPATION PLAN AND INTERIM IMPLEMENTATION REPORT 40-432

Table of Contents

VOLUME III: APPENDICES (ON CD-ROM IN BACK OF VOLUME II)

Appendix A – Agency and Utility Correspondence
Appendix B – Demographic and Socioeconomic Data
Appendix C – Essential Fish Habitat Assessment for DSNY Eight MTSs
Appendix D – Commercial Waste to the MTS Summary Report
Appendix E – Off-site Noise Analysis TNM Results
Appendix F – Phase II Site Investigation Reports
Appendix G – Compendium of Comments
Appendix H – Selected Outreach Material for Enhanced Public Participation
Appendix I – Commercial Waste Management Study
Appendix J – Collection Vehicle Odor Sampling Report
Appendix K – Truck Simulation Summary Report
Appendix L – Equipment-induced Vibrations Memo
Appendix M – Tonnages Memo
Appendix N – Construction Schedules

EXECUTIVE SUMMARY

TABLE ES-1 PROPOSED DRAFT NEW SWMP FACILITIES AND POTENTIAL CONTRACTORS ES-11
TABLE ES-1 (CONTINUED) ES-12
PROPOSED DRAFT NEW SWMP FACILITIES AND POTENTIAL CONTRACTORS ES-12
TABLE ES-2 DRAFT NEW SWMP ALTERNATIVES ES-18
TABLE ES-3 SUMMARY OF AIR QUALITY, TRAFFIC, ODOR AND NOISE ANALYSES FOR PROPOSED ACTION FACILITIES AND CONTRACTS ES-21
TABLE ES-4 SUMMARY OF IMPACT ANALYSES PROPOSED ACTION FACILITIES AND CONTRACTS ES-22

CHAPTER 1

1.3-1 FACILITIES UTILIZED FOR INTERIM EXPORT 1-5
1.3-2 NEW SWMP LONG TERM EXPORT FACILITIES AND POTENTIAL CONTRACTORS 1-10
1.3-3 NEW SWMP LONG TERM EXPORT – POTENTIAL SUPPORT FACILITIES 1-13
1.3-4 NEW SWMP LONG TERM EXPORT – ALTERNATIVE CONSIDERED 1-16
1.3-5 ALTERNATIVES CONSIDERED IN THE 2000 SWMP FEIS 1-20
1.4-1 RECYCLING FACILITIES 1-24
1.6-1 LIST OF PUBLIC REPOSITORIES 1-37

CHAPTER 2

2.1-1 PROPOSED PLAN FACILITIES AND ALTERNATIVES 2-3
2.1-2 EXPECTED CONVERTED MTS AVERAGE THROUGHPUTS 2-11
2.1-3 PRIVATE TRANSFER STATION CAPACITIES 2-13
2.5-1 FEDERAL, CITY AND STATE PERMIT ACTION DETERMINATION 2-209
2.5-2 FEDERAL, CITY AND STATE PERMIT ACTION DETERMINATION 2-211

CHAPTER 3

3.13-1 STORMWATER RUNOFF QUALITY FOR VARIOUS STUDIES 3-33
3.14-1 LOCAL WATERFRONT REVITALIZATION POLICIES AND SUBPOLICIES & THEIR APPLICABILITY 3-37
3.16-1 AVERAGE PEAK DAY FACILITY LOAD ALLOCATION 3-48
3.16-2 PEAK HOUR TRIPS 3-51
3.16-3 ANNUAL GROWTH RATES FOR STUDIED AREAS 3-62
3.16-4 LOS CRITERIA FOR SIGNALIZED AND UNSIGNALIZED INTERSECTIONS 3-64
3.16-5 SIGNIFICANT IMPACTS FOR SIGNALIZED AND UNSIGNALIZED INTERSECTIONS 3-65
3.17-1 NATIONAL AND STATE AMBIENT AIR QUALITY STANDARDS (G/M^3) 3-72
3.17-2 ANNUAL AND SHORT-TERM GUIDELINE CONCENTRATIONS 3-76
3.17-3 BACKGROUND CONCENTRATIONS 3-78
3.17-4 CO BACKGROUND LEVELS 3-79
3.17-5 TUGBOAT EMISSION FACTORS 3-86
3.17-6 CEQR CO SCREENING THRESHOLDS 3-89
3.17-7 THERMAL STATE CONDITIONS FOR LIGHT DUTY GASOLINE TRUCKS 3-95
3.17-8 REASONABLE WORST-CASE METEOROLOGICAL CONDITIONS 3-96
3.17-9 EIGHT-HOUR PERSISTENCE FACTORS 3-97
3.18-1 ODOR CLASSES AND EXAMPLES 3-101
3.18-2 ODOR LIMITS OF STATE AND LOCAL AGENCY JURISDICTIONS 3-103
3.18-3 BACKGROUND SAMPLING RESULTS 3-104
3.18-3 SUMMARY OF ODOR PANEL EVALUATION RESULTS FALL 1998 AND SUMMER 1999 SAMPLING EVENT FROM FAN EXHAUST 3-109
3.18-4 SUMMARY OF ODOR PANEL EVALUATION RESULTS SUMMER 2004 SAMPLING EVENT FROM COLLECTION VEHICLES GARAGE 3-109
3.18-5 SUMMARY OF ODOR PANEL EVALUATION RESULTS FALL 1998 AND SUMMER 1999 SAMPLING EVENT FROM FULL AND EMPTY BARGES 3-110
3.18-6 H_2S SAMPLING RESULTS 3-111
3.18-7 SUMMARY OF EMISSION RATES 3-114

3.18-8 MODELED ODOR EMISSION RATES/FACTORS NEW YORK CITY ZONING REGULATION MAXIMUM PERMITTED SOUND PRESSURE LEVEL (IN DECIBELS) 3-118
3.19-1 NEW YORK CITY ZONING REGULATION MAXIMUM PERMITTEDSOUND PRESSURE LEVEL (IN DECIBELS) 3-129
3.19-2 NEW YORK CITY ZONING REGULATION MAXIMUM PERMITTEDSOUND PRESSURE LEVEL ..... (CURRENT OCTAVE BAND) (IN DECIBELS) 3-129

CHAPTER 4

4.3-1 1990-2000 POPULATION 4-13
4.4-1 COMMUNITY FACILITIES AND SERVICES 4-21
4.5-1 PUBLIC PARKS AND OPEN SPACES 4-24
4.11-1 EXISTING WATER QUALITY CONDITIONS AND STANDARDS 4-57
4.11-2 EXISTING PERMITTED DISCHARGES 4-60
4.11-3 ESTIMATED EXISTING POLLUTANT LOADS AND RUNOFF FLOWS 4-60
4.11-4 IMPERVIOUS AREA AND ESTIMATED POLLUTANT LOADS 4-61
4.13-1 AVERAGE MONTHLY DRY WEATHER AND AVERAGE FLOWS OWLS HEAD WATER POLLUTION CONTROL PLANS FISCAL YEAR 2003 4-80
4.14-1 HCM ANALYSIS - EXISTING CONDITIONS 4-93
4.14-2 HCM ANALYSIS - FUTURE NO-BUILD CONDITIONS 4-98
4.14-3 WEEKDAY AND WEEKEND TRAFFIC 4-108
4.14-4 HCM ANALYSI - 2006 FUTURE BUILD CONDITIONS 4-109
4.14-5 HCM ANALYSIS - 2006 FUTURE BUILD CONDITIONS WITH MITIGATION 4-110
4.15-1 REPRESENTATIVE AMBIENT AIR QUALITY DATA 4-113
4.15-2 EMISSION SOURCES CONSIDERED FOR ON-SITE AIR QUALITY ANALYSIS 4-115
4.15-3 HIGHEST ESTIMATED CONCENTRATIONS OF THE CRITERIA POLLUTANTS FROM ON-SITE EMISSIONS HAMILTON AVENUE CONVERTED MTS 4-117
4.15-4 HIGHEST ESTIMATED NON-CANCER HAZARD INDEX AND CANCER RISK OF TOXIC AIR POLLUTANTS FROM ON-SITE EMISSIONS 4-119
4.15-5 ESTIMATED POLLUTANT CONCENTRATION NEAR SELECTED ROADWAY INTERSECTIONS 4-123
4.16-1 ODOR SOURCES INCLUDED IN ODOR ANALYSIS 4-125
4.16-2 HIGHEST PREDICTED ODOR CONCENTRATION(S) FROM ON-SITE SOURCES 4-127
4.17-1 EXISTING HOURLY (MONITORED) NOISE LEVELS ON SITE 4-130
4.17-2 EXISTING NOISE LEVELS (L_{EQ}) AT THE NEAREST NOISE-SENSITIVE RECEPTOR 4-131
4.17-3 OFF-SITE NOISE TRAFFIC VOLUME 4-132
4.17-4 EQUIPMENT MODELED IN THE NOISE ANALYSIS AND REFERENCE NOISE LEVELS (LEQ) 4-134
4.17-5 EQUIPMENT MODELED IN THE NOISE ANALYSIS AND SPECTRAL NOISE LEVELS (L_{MAX}) 4-135
4.17-6 ZONING CODE ANALYSIS PREDICTED SPECTRAL NOISE LEVELS (L_{MAX}) AT THE PROPERTY BOUNDARY 4-136
4.17-7 CURRENT NOISE CODE ANALYSIS 4-138
4.17-8 OFF-SITE NOISE SCREENING RESULTS 4-139
4.17-9 OFF-SITE NOISE ANALYSIS TRUCK SIMULATION 20TH STREET WEST OF 4TH AVENUE 4-142
4.17-10 OFF-SITE NOISE ANALYSIS USING TRUCK SIMULATION DATA AND ADJUSTED COLLECTION VEHICLES 20TH STREET WEST OF 4TH AVENUE 4-143

CHAPTER 5

5.4-1 COMMUNITY FACILITIES AND SERVICES 5-15
5.5-1 PUBLIC PARKS AND OPEN SPACES 5-17
5.11-1 EXISTING WATER QUALITY CONDITIONS AND STANDARDS 5-50
5.11-2 EXISTING PERMITTED DISCHARGES 5-52
5.11-3 ESTIMATED EXISTING POLLUTANT LOADS AND RUNOFF FLOWS 5-54
5.11-4 IMPERVIOUS AREA AND ESTIMATED POLLUTANT LOADS 5-55
5.13-1 AVERAGE MONTHLY DRY WEATHER AND AVERAGE FLOW OWLS HEAD WATER POLLUTION CONTROL PLANT FISCAL YEAR 2003 5-75

List of Tables

5.14-1 HCM Analysis- Existing Conditions 5-86
5.14-2 HCM Analysis - Future No-Build Conditions 5-93
5.14-3 Weekday and Weekend Traffic 5-102
5.14-4 HCM Analysis- 2006 Future Build Conditions 5-103
5.14-5 HCM Analysis - 2006 Future Build Conditions with Mitigation 5-104
5.14A-1 HCM Analysis- Existing Conditions 5-119
5.14A-2 HCM Analysis - Future No-Build Conditions 5-129
5.14A-3 Weekday and Weekend Traffic 5-145
5.14A-4 HCM Analysis- 2006 Future Build Conditions 5-146
5.14A-5 HCM Analysis - 2006 Future Build Conditions with Mitigation 5-148

5.15-1 Representative Ambient Air Quality Data 5-151
5.15-2 Emission Sources Considered for On-Site Air Quality Analysis 5-153
5.15-3 Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions 5-155
5.15-4 Highest Estimated Non-Cancer Hazard Index and Cancer Risk of Toxic Air Pollutants from On-Site Emissions 5-157
5.15-5 Maximum Estimated Pollutant Concentrations Near Selected Roadway 5-161
5.16-1 Odor Sources Included in Odor Analysis 5-171
5.16-2 Highest Predicted Odor Concentration(s) from On-Site Sources 5-173
5.17-1 Existing Hourly (Monitored) Noise Levels On Site 5-176
5.17-2 Existing Noise Levels (L_{EQ}) at the Nearest Noise-Sensitive Receptor 5-177
5.17-3 Off-Site Noise Traffic Volume 5-178
5.17-4 Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{EQ}) 5-179
5.17-5 Equipment Modeled in the Noise Analysis and Spectral Noise Levels (L_{MAX}) 5-182
5.17-6 CEQR Analysis Existing and Predicted Noise Levels (L_{EQ}) at the Nearest Noise-Sensitive Receptor 5-186
5.17-7 Zoning Code Analysis Predicted Spectral Noise Levels (L_{MAX}) at the Property Boundary 5-188
5.17-8 Current Noise Code Analysis 5-189
5.17-9 Off-Site Noise Screening Results 5-191
5.17-10 Off-Site Noise Analysis TNM Results 5-193
5.17A-1 EXISTING HOURLY (MONITORED) NOISE LEVELS ON SITE(1) SOUTHWEST BROOKLYN CONVERTED MTS 5-195
5.17A-2 OFF-SITE NOISE TRAFFIC VOLUME 5-196
5.17A-3 OFF-SITE NOISE SCREENING RESULTS 5-197
5.17A-4 OFF-SITE NOISE ANALYSIS TNM RESULTS 5-197
5.17A-5 COMBINED ONJ-SITE AND OFF-SITE NOISE ANALYSIS 5-199

CHAPTER 6

6.3-1 1990-2000 Population 6-13
6.4-1 Community Facilities and Services 6-21
6.5-1 Public Parks and Open Spaces 6-27
6.6-1 Cultural Resources in the Study Area 6-32
6.11-1 Existing Water Quality Conditions and Standards 6-64
6.11-2 Existing Permitted Discharges 6-65
6.11-3 Estimated Existing Pollutant Loads and Runoff Flows 6-67
6.11-4 Impervious Area and Estimated Pollutant Loads 6-68
6.13-1 Average Monthly Dry Weather and Average Flows Wards Island Water Pollution Control Plant Fiscal Year 2003 6-88
6.14-1 HCM Analysis- Existing Conditions 6-100
6.14-2 HCM Analysis - No-Build Conditions 6-106
6.14-3 Weekday and Weekend Traffic 6-116
6.14-4 HCM Analysis - 2006 Future Build Conditions 6-117
6.14-5 HCM Analysis - 2006 Future Build Conditions with Mitigation 6-118

List of Tables

6.15-1 Representative Ambient Air Quality Data 6-120
6.15-2 Emission Sources Considered for On-Site Air Quality Analysis 6-122
6.15-3 Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions 6-124
6.15-4 Highest Estimated Non-Cancer Hazard Index and Cancer Risk of Toxic Air . Pollutants from On-Site Emissions 6-126
6.15-5 Maximum Estimated Pollutant Concentrations Near Selected Roadway Intersections 6-130
6.16-1 Odor Sources Included in Odor Analysis 6-133
6.16-2 Highest Predicted Odor Concentration(s) from On-Site Sources 6-136
6.17-1 Existing Hourly (Monitored) Noise Levels On Site 6-140
6.17-2 Existing Noise Levels (Leq) at the Nearest Noise-Sensitive Receptor 6-141
6.17-3 Off-Site Noise Traffic Volume 6-142
6.17-4 Equipment Modeled in the Noise Analysis and Reference Noise Levels (Leq) 6-143
6.17-5 Equipment Modeled in the Noise Analysis and Spectral Noise Levels (Lmax) 6-144
6.17-6 CEQR Analysis Existing and Predicted Noise Levels (Leq) at the Nearest Noise-Sensitive Receptors 6-147
6.17-7 Zoning Code Analysis Predicted Spectral Noise Levels (L_{MAX}) at the Property Boundary 6-149
6.17-8 Current Noise Code analsysis with Refined On-Site Queuing Collection Vehicle Utilization Factors 6-151
6.17-9 Off-Site Noise Screening Results 6-152
6.17-10 Off-Site Noise Analysis Truck Simulation 6-155
6.17-11 Off-Site Noise Analysis using Truck Simulation Data and Adjusted Collection Vehicles - York Avenue between East 90TH Street and East 91ST Street 6-156
6.17-12 combined On-Site and Off-Site Noise Analysis Existing and Predicted Noise Levels (L_{EQ}) at the Nearest Noise-Sensitive Receptor with East 91ST Street Converted MTS 6-158
6.17-13 Off-Site Noise Analysis using Truck Simulation Data and Adjusted Collection Vehicles York Avenue between East 90th Street and East 91st Street 6-158

CHAPTER 7

7.3-1 1990-2000 Population 7-12
7.4-1 Community Facilities and Services 7-19
7.5-1 Public Parks and Open Spaces 7-21
7.11-1 Existing Water Quality Conditions And Standards 7-52
7.11-2 Existing Permitted Discharges 7-53
7.11-3 Estimated Existing Pollutant Loads And Runoff Flows 7-55
7.11-4 Impervious Area And Estimated Pollutant Loads 7-56
7.13-1 Average Monthly Dry Weather and Average Flows Tallman Island WPCP Fiscal Year 2003. 7-74
7.14-1 HCM Analysis- Existing Conditions 7-88
7.14-2 HCM Analysis- Future No-Build Conditions 7-94
7.14-3 Weekday and Weekend Traffic 7-105

31.15-4 HIGHEST ESTIMATED NON-CANCER HAZARD INDEX AND CANCER RISK OF TOXIC AIR POLLUTANTS FROM ON-SITE EMISSIONS TRANSRIVER MARKETING COMPANY, L.P. TS 31-98
31.15-5 ESTIMATED POLLUTANT CONCENTRATIONS NEAR SELECTED ROADWAY INTERSECTIONS TRANSRIVER MARKETING COMPANY, L.P. TS 31-102
31.16-1 ODOR SOURCES INCLUDED IN ODOR ANALYSIS 31-103
31.16-2 HIGHEST PREDICTED ODOR CONCENTRATION(S) FROM ON-SITE SOURCES 31-105
31.17-1 EXISTING HOURLY (MONITORED) NOISE LEVELS ON SITE 31-108
31.17-2 OFF-SITE NOISE TRAFFIC VOLUME 31-110
31.17-3 EQUIPMENT MODELED IN THE NOISE ANALYSIS AND REFERENCE NOISE LEVEL (L_{EQ}) TRANSRIVER MARKETING COMPANY L.P. TRUCK TO RAIL TS 31-111
31.17-4 OFF-SITE NOISE SCREENING RESULTS TRANSRIVER MARKETING COMPANY L.P. TRUCK TO RAIL TS 31-113

CHAPTER 32

32.5-1 POTENTIAL IMPACTS TO MARINE COMMUNITIES AT CONVERTED MTSS 32-9
32.5-2 ORGANISMS COLLECTED IN BENTHIC GRABS AT THE PROPOSED CONVERTED MTSS IN THE PROPOSED ACTION 32-10
32.5-3 SHANNON-WEAVER INDEX AND RANK OF BENTHIC IMPACT AT CONVERTED MTSS 32-14
32.5-4 CONSTRUCTION ACTIVITY AND POTENTIAL IMPACTS 32-15

List of Tables

32.5-5 DEGREE OF EXPECTED BENTHIC IMPACTS 32-15
32.5-6 EPIBENTHIC ORGANISMS COLLECTED AT EACH CONVERTED MTS APRIL 2003 – FEBRUARY 2004 32-17
32.5-7 ADULT FINFISH SENSITIVITY TO SUSPENDED PARTICLES AND NOISE ASSOCIATED WITH MARINE CONSTRUCTION 32-21
32.5-8 NUMBER OF ADULT FINFISH COLLECTED AT EACH CONVERTED MTS JANUARY – DECEMBER 2003 32-23
32.5-9 LIFE HISTORY CHARACTERISTICS OF FINFISH FOUND IN THE CENTRAL PART OF THE MID-ATLANTIC BIGHT 32-25
32.5-10 FINFISH LARVAE COLLECTED AT PROPOSED CONVERTED MTS 33-30
32.6-1 EXISTING AND PROPOSED PLATFORM COVERAGE AT PROPOSED CONVERTED MTS 33-34

CHAPTER 33

33.2-1 NYSDEC TOXICITY BENCHMARKS FOR HAPS 33-16
33.6-1 ASTHMA PREVALENCE AMONG CHILDREN 4 TO 5 YEARS OLD 33-33
33.6-2 ASTHMA PREVALENCE AMONG ADULTS 33-33
33.6-3 HOSPITALIZATION RATES FOR SELECTED ZIP CODES 33-34

CHAPTER 34

34.1-1 TONNAGE ALLOCATION FOR LONG-TERM EXPORT OPTIONS 34-2
34.1-2 PROPOSED ACTION LONG-TERM EXPORT ESTIMATED ANNUAL COSTS FOR WASTE TRANSFER, TRANSPORTATION AND DISPOSAL BY SCENARI 34-4
34.3-1 TONNAGE ALLOCATION FOR LONG-TERM EXPORT OPTIONS A THROUGH D 34-10
34.4-1 PROPOSED ACTION LONG-TERM EXPORT ESTIMATED ANNUAL COSTS FOR WASTE TRANSFER, TRANSPORTATION AND DISPOSAL BY OPTION 34-13

CHAPTER 40

40.3-1 CONVERTED MTSS DSNY AND COMMERCIAL WASTE ANTICIPATED CAPACITY REQUIREMENTS AND CAPACITIES EVALUATED IN THE NEW SWMP DEIS 40-78
40.3-2 CONVERTED MTSS DSNY-PROPOSED WEEKLY AND DAILY PERMIT LIMITS 40-79
40.3-3 CONVERTED MTS DSNY-PROPOSED EMERGENCY PERMIT LIMITS 40-80
40.3-4 PRIVATE VENDOR ROUND TRIP TRANSFER STATIONS TRACTOR TRAILER MILEAGE TO PORTAL OF EGRESS 40-299
40.3-5 CONVERTED MTS AVERAGE THROUGHPUTS(1) 40-402
40.3-6 PHASING OF COMMERCIAL WASTE INTO CONVERTED MTS SYSTEM WASTE STREAMAVERAGE DAILY TONNAGE 40-403
40.3-7 PHASING OF COMMERCIAL WASTE INTO THE CONVERTED MTS SYSTEM DAILY CONTAINERS REQUIREMENTS 40-403
40.3-8 IN-CITY HARBOR BARGE REQUIREMENTS PHASE 1 40-405
40.3-9 IN-CITY HARBOR BARGE REQUIREMENTS PHASE 2 40-405
40.3-10 IN-CITY HARBOR BARGE REQUIREMENTS PHASE 3 40-406
40.3-11 IN-CITY HARBOR BARGE REQUIREMENTS PHASE 4 40-406
40.3-12 MAXIMUM AMOUNT OF RAILCARS AND CONTAINERS REQUIRED FOR SYSTEM 40-407
40.3-13 MAXIMUM AMOUNT OF OCEAN-GOING BARGES AND CONTAINERS REQUIRED FOR SYSTEM 40-409
40.3-16 PUBLIC SCOPING MEETING LOCATIONS 40-438
40.3-17 DEIS HEARING LOCATIONS 40-441
40.3-18 INFORMATIONAL MEETING/ULURP HEARING LOCATIONS 40-443

Bronx RFP	DSNY's Request for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from the Bronx, issued December 22, 2003
Brooklyn BAFO	Best and Final Offer to Receive, Transfer, Transport and Dispose of Department of Sanitation Managed Waste from Brooklyn Formerly Delivered to the Greenpoint Marine Transfer Station.

Definitions	
Brooklyn RFP	DSNY's Request for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from Brooklyn Formerly Delivered to the Greenpoint Marine Transfer Station
City	New York City
City Council	The legislative body of the City of New York
Commercial Waste	The wastes, including recycled material, generated in the City by business establishments and construction activity and collected by private carters that are respectively defined in the DSNY Rules as Putrescible Waste and Non-Putrescible Waste
Converted MTS	One of DSNY's eight marine transfer stations, modified to containerize waste for out-of-City export by barge or rail
Curbside Recyclables	Paper and MGP collected through the Curbside Program
Curbside Recycling Program or Curbside Program	The collection of source-separated materials designated by DSNY as recyclables from residences, City agencies and non-profit institutions housed in tax-exempt property
Draft New SWMP	Draft Comprehensive Solid Waste Management Plan, September 2004
DSNY-managed Waste	Solid waste that DSNY collects from all residential households in the City and the institutional waste of City, state and federal agencies that DSNY collects and/or for which DSNY arranges disposal
DSNY TS Rules	DSNY Transfer Station Operational Requirement Rules
EJ Community	Census block groups with populations that meet the EJ Policy criteria
EJ Policy	NYSDEC's policy guidance on Environmental Justice (EJ) and Permitting issued in March 2003
EJ Program	DSNY's enhanced public participation and outreach program
Existing Programs	Ongoing programs approved in the 1992 SWMP, as amended, that will continue under the New SWMP
Existing SWMP	1992 comprehensive Solid Waste Management Plan, as amended

Definitions	
Fill Material	Waste as defined in DSNY Rules that is typically comprised of clean material consisting of earth, ashes, dirt, concrete, rock, gravel, asphalt millings, stone or sand
IESI	IESI Corporation
Interim Export	Short-term DSNY contracts with in- and out-of-City transfer stations and out-of-City disposal sites for export of DSNY-managed Waste
Long Term Export Program	Those facilities and services pertaining to the export of DSNY-managed Waste from the City that is a component of the Proposed Action
MGP	Metal, glass and plastic defined as Recyclables by DSNY
MTS RFP	DSNY's Request for Proposals to Transport and Dispose of Containerized Waste from One or More Marine Transfer Stations, issued December 22, 2003
New Initiatives	New activities described in the Draft New SWMP that are enhancements to Existing Programs
New SWMP	The new Comprehensive Solid Waste Management Plan for the period 2005 through 2024 prepared pursuant to 6 NYCRR Part 360-15
Non-Putrescible Waste	Waste as defined in DSNY Rules that is typically comprised of inert waste generated from commercial and residential demolition, new construction and renovation projects, and contains inorganic materials, some of which are recycled. The non-recycled fraction is processed by the City's non-putrescible transfer stations for shipment to disposal facilities. This waste is also referred to as construction and demolition (C&D) debris to distinguish it from fill material, which is a subset of non-putrescible waste comprised of materials such as excavated fill, stone rubble and road millings that are graded into materials such as sand and aggregate and stockpiled at fill material transfer stations in the City and reused in other building projects.
Onyx	Onyx Waste Services, Inc.

Definitions	
Paper	Material made of paper that DSNY defines as a Recyclable
Part 360 Noise Code	6 NYCRR Part 360-1.14(p)- operational requirements related to solid waste management facilities
Proposed Action	Actions in three major categories – Long Term Export, Recycling, and Commercial Waste – proposed to be implemented under the New SWMP that are subject to environmental review
Proposed Plan	The Draft New SWMP
Proposed Plan Facilities	Those facilities and contracts that would be implemented under the Proposed Action
Putrescible Waste	Waste as defined in DSNY Rules that is typically comprised of material generated by business establishments and collected by private carters in the City that may be delivered to putrescible transfer stations or recycled, which may contain organic matter
Queens RFP	DSNY's Request for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from Queens Formerly Delivered to the Greenpoint Marine Transfer Station
Recyclables	Materials defined by DSNY as recyclable such as Paper and MGP
Rules	Rules of the City of New York
Sampling Protocol	Sampling Protocol for the Department Barge Odor Study, finalized on October 2, 1998, and updated on June 18, 1999
Sludge Composting EIS	Final Generic Environmental Impact Statement for the New York City Sludge Management Plan, dated May 1992
Study	Commercial Waste Management Study
TransRiver, American Ref-Fuel	TransRiver Marketing Company, L.P., which may also be referred to as American Ref-Fuel Company LLC or ARC/TRM

THE NEW YORK CITY
COMPREHENSIVE SOLID WASTE MANAGEMENT PLAN

Prepared by:

NEW YORK CITY DEPARTMENT OF SANITATION

CEQR No: 03-DOS-004Y

April 1, 2005

EXECUTIVE SUMMARY

1.0 INTRODUCTION

The New York City (City) Department of Sanitation (DSNY) is proposing a draft New Comprehensive Solid Waste Management Plan (Draft New SWMP) for the next 20-year planning period. As lead agency principally responsible for undertaking the action, DSNY has caused this Final~~Draft~~ Environmental Impact Statement (F~~D~~EIS) to be prepared in accordance with the State Environmental Quality Review Act (SEQRA) and its implementing regulations (6 NYCRR Part 617) and City Environmental Quality Review procedures (CEQR) set forth in Executive Order 91 of 1977, as amended, and Rules of Procedure for CEQR found in Section 6, Title 62 of the Rules of the City of New York (RCNY). The F~~D~~EIS is intended to support the adoption of the New SWMP and its related approvals, which together constitute the Proposed Action. As further discussed below, the Draft New SWMP incorporates elements of the existing SWMP and includes major changes to the City's Long Term Export Program for DSNY-managed Waste,[1] to the City's Recycling Program, and to management of Commercial Waste[2] in the City.

A Draft New SWMP, published in October 2004, describes the Proposed Action that, in summary, is to:

- Improve DSNY's Curbside Recycling Program through the award of a 20-year processing contract and the development of a new in-City Recyclables processing facility as well as a Manhattan Recyclables acceptance facility.
- Implement the City's Long Term Export Program through: the development of four Converted Marine Transfer Stations (Converted MTSs); award up to five contracts with private transfer stations for barge or rail export of DSNY-managed Waste for disposal; and, enter into an intergovernmental agreement to dispose of a portion of Manhattan's DSNY-managed Waste at a waste-to-energy (WTE) facility in Newark, New Jersey.

---

[1] DSNY collects and disposes of Putrescible and Non-Putrescible Waste from all residences in the City, institutions, not-for-profit organizations, lot cleaning operations, and other City, state and federal agencies (DSNY-managed Waste).

[2] Commercial Waste is those wastes, including recycled material, generated in the City by business establishments and construction activity, and collected by private carters, that are respectively defined in DSNY's Rules as Putrescible Waste and Non-Putrescible Waste. Most, but not all, Commercial Waste generated is processed through the City's putrescible and non-putrescible transfer stations.

- Provide the capacity for barge export of Putrescible Commercial Waste from the City at one existing Manhattan MTS as well as at the four Converted MTSs.

For environmental review purposes, the ~~New SWMP~~DEIS evaluated a reasonable range of facilities and sites as Alternatives to the Proposed Action, including. ~~This FDEIS provides~~ a comprehensive environmental review of 17 sites/facilities, as applicable, that are the Proposed Action in the Draft New SWMP.[3] Subsequent to publication of the DEIS, three (3) of these 17 sites/facilities are no longer part of the Proposed Action, and are now considered Alternatives, resulting in 14 sites/facilities that are part of the Proposed Action[4]. Section 1.3 of this FEIS provides additional details on the Alternatives considered to the Proposed Action. ~~Comprehensive e~~This FEIS also contains environmental reviews ~~were also conducted~~, as applicable, for the ~~16~~17 other Alternative sites/facilities considered during development of the Draft New SWMP, including two additional potential Long Term Export facility site options, referenced in this FEIS that, if selected as part of the Proposed Action, would be the subject of supplemental environmental reviews.

[3] The number does not include the Essex County Resource Recovery Facility, proposed to receive waste from two of three Manhattan wastesheds, because this is an existing permitted facility in New Jersey that is not subject to environmental review under CEQR. Final site selection for certain elements of the Proposed Action is dependent upon the outcome of current procurement actions by DSNY.

[4] Referring to Table ES-2, this total includes the Review Avenue Truck to Rail and Truck to Barge options as two separate facilities, the Oak Point and Maspeth Railyards as separate facilities, and also includes the two recycling facilities that are elements of the Proposed Action.

2.0 PURPOSE AND NEED

In accordance with the requirements of New York State's Solid Waste Management Act (New York Environmental Conservation Law, Section 27-0707), and implementing regulations (6 NYCRR Subpart 360-15), the City's first Comprehensive Solid Waste Management Plan, approved in 1992 ~~(1992 SWMP)~~, as amended by the 1996 and 2000 SWMP Modifications (Existing SWMP), ~~established~~ provides the framework for its solid waste management and recycling programs ~~over a 10-year period~~through April 2005. Approved modifications to the 1992 SWMP (1996 SWMP Modification) focused on further expansion of recycling. In 2000, further approved amendments to the SWMP (2000 SWMP Modification) were made, which principally focused on the City's plan to address the closure of the Fresh Kills Landfill on Staten Island. ~~The 1992 SWMP, as amended (Existing SWMP), expires at the end of October 2004.~~ The City and the City Council have requested that the New York State Department of Environmental Conservation (NYSDEC) extend the Existing SWMP to cover the period between the submittal of the Draft New SWMP to the City Council and its adoption and the approval of the adopted Draft New SWMP by NYSDEC.

Each day, the City's 8.1 million residents, commuters, visitors, businesses and residential and commercial construction activity generate very large and diverse quantities of solid waste material. The Draft New SWMP sets forth a plan for the long-term management of the City's solid waste in a cost-effective and environmentally responsible manner and, in addition to the Proposed Action, incorporates by reference the Existing SWMP to support Existing Programs, including the New Initiatives described in the Draft New SWMP. These Existing Programs and New Initiatives, approved pursuant to the Existing SWMP, are, therefore, not part of the Proposed Action that is subject to environmental review in this F~~D~~EIS.

The City's existing solid waste management system:

- Recycles or disposes of approximately 14,000 tons per day (tpd) or 4,240,000 tons per year (tpy) of DSNY-managed Waste currently generated in the City;

- Recycles or disposes of approximately 10,000 tpd (3,000,000 tpy) of Putrescible Commercial Waste that is generated, and approximately 6 million to 8.3 million tpy of Non-Putrescible Commercial Waste that is currently generated; and

- Provides for the management of Biosolids, Medical Waste and Dredge Spoils and Fresh Kills closure construction and end use.

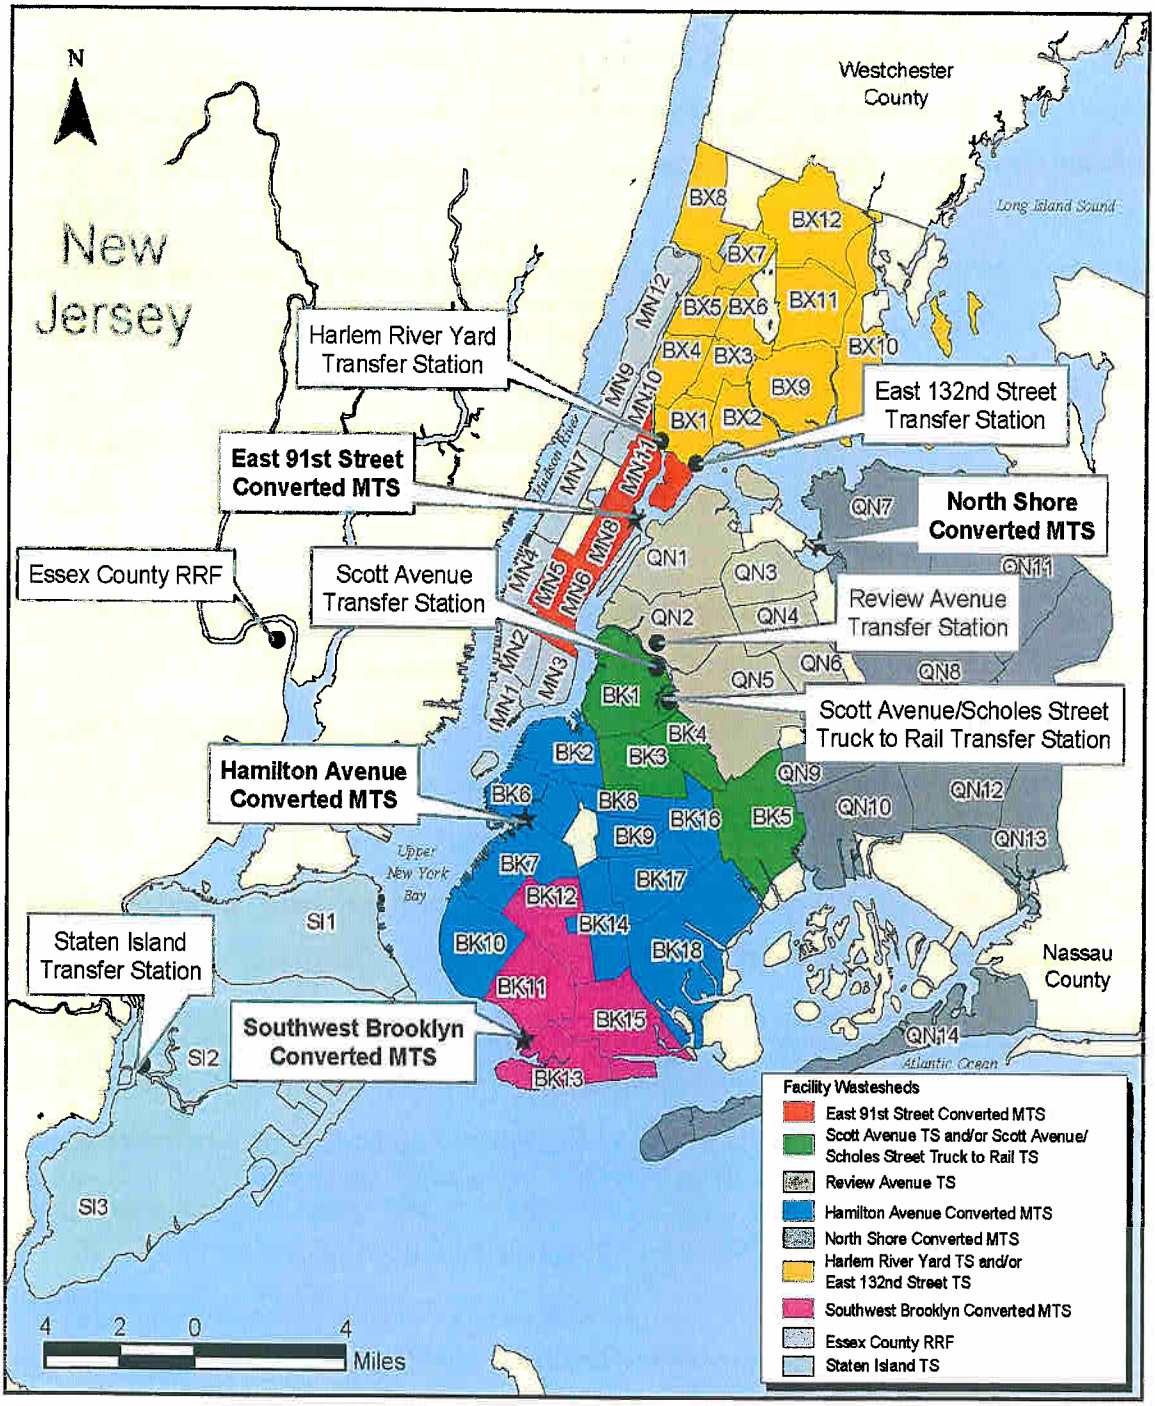
3.0 PROPOSED ACTION

The following section describes the Proposed Action for Long Term Export, Recycling and Commercial Waste Management. The FDEIS also evaluates the reasonable Alternatives that were considered.

Long Term Export

The City has long recognized the importance of moving quickly to develop a more permanent system of waste export, to address both the rising cost of nearby landfill disposal as well as the current over-reliance on a truck-dependent system. In July of 2002, Mayor Bloomberg announced a plan to establish a system that would take advantage of the City's waterways and existing infrastructure. The plan called for the physical conversion of the City's existing Marine Transfer Stations (MTSs) to enable waste to be containerized on ~~site, making the waste suitable for~~site for export out-of-City by barge and rail. ~~export.~~

The Proposed Action for Long Term Export builds on the Mayor's previously announced plan, but offers an expedited timeframe, a lower cost and reduced reliance on complex MTS conversions outlined initially. The Proposed Action adheres to the two main principles of the Mayor's earlier plan: the containerization of waste and the long-distance export of that waste in containers by barge or rail by primarily relying on a mix of Converted MTSs and private transfer stations with the addition of the existing Essex County Resource Recovery Facility (Essex County RRF) in Newark, New Jersey, where waste would be delivered in collection vehicles. The Proposed Action for Long Term Export is:



- For the entire Bronx wasteshed, enter into a long-term contract with one or two private transfer station waste companies for truck-to-rail disposal of DSNY-managed Waste from the Bronx.
- For the Brooklyn wasteshed formerly served by the Greenpoint MTS, enter into a long-term contract with one or two private transfer stations for truck-to-rail or truck-to-barge disposal of the DSNY-managed Waste from Brooklyn CDs 1, 3, 4 and 5.

- For the Brooklyn wasteshed formerly served by the Hamilton Avenue MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18 will be received and containerized.
- For the Brooklyn wasteshed formerly served by the Southwest Brooklyn MTS, develop a City-owned Converted MTS on the adjacent site of the former Southwest Brooklyn Incinerator, where DSNY-managed Waste from Brooklyn CDs 11, 12, 13 and 15 will be received and containerized.
- For the Manhattan wasteshed, Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12, enter into a long-term service agreement with the Essex County RRF in Newark, New Jersey to receive and process DSNY-managed Waste delivered in City collection vehicles.
- For the Manhattan wasteshed formerly served by the East 91st Street MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Manhattan CDs 5, 6, 8 and 11 will be received and containerized.
- For the Queens wasteshed formerly served by the Greenpoint MTS, enter into a long-term contract with a private transfer station for truck-to-rail or truck-to-barge disposal of the DSNY-managed Waste from Queens CDs 1 through 6.
- For the Queens wasteshed formerly served by the North Shore MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Queens CDs 7 through 14 will be received and containerized.
- For the four wastesheds served by Converted MTSs, enter into 20-year service agreements with one or more waste management companies, for transport of containerized waste by barge directly from an MTS to disposal facilities or to intermodal facilities for transloading to railcars or a larger barge, and for disposal at an appropriately permitted out-of-City facility.

Figure ES-1, Locations of Draft New SWMP Long Term Export Facilities and Wastesheds Served, identifies the boroughs and CDs that would be assigned to specific facilities.

In the Bronx and Brooklyn CDs 1, 3, 4 and 5, shown in Figure ES-1 and noted in Table ES-1, the decision as to whether DSNY contracts for export of DSNY-managed Waste generated in these wastesheds ~~with~~ through one or ~~two potential~~ more private transfer stations will be determined by ~~upcoming~~ DSNY negotiations with the ~~proposing~~ private waste management companies pursuant to the Long Term Export Program procurements now underway in the Bronx, Brooklyn and Queens. The procurement documents issued to implement the Proposed Action have specified that the facilities must be located within the wasteshed they will serve and that all waste received at those facilities (including Commercial Waste) be exported by barge or rail. All contracts entered into for the purpose of implementing the Proposed Action would define the amounts, types and origins of the waste a facility could receive.

Figure ES-1
Locations of Draft New SWMP Long Term Export Facilities and Wastesheds Served

Recycling

Through the first half of 2002, DSNY collected and recycled metal, glass and plastic (MGP) and Paper materials sufficient to divert 20% of the DSNY-managed Waste (curbside/containerized) waste stream from disposal. The program flourished in many respects, and compared favorably with the recycling programs of other major cities throughout the United States.

On July 1, 2002, the City's recycling program, having incurred budget cuts in the aftermath of the events of September 11, 2001 and the subsequent economic recession, temporarily suspended glass and plastic recycling. Diversion rates suffered; however, plastic and glass recycling programs were restored in Fiscal Year (FY) 2003 and FY 2004, respectively, and funding for composting and other services was restored in FY 2005.

Moving forward, cost-effective recycling programs are now an even greater priority. To address this priority, the Proposed Actions for recycling will commit the City to a 20-year contract for processing MGP. This long-term commitment will facilitate the development of state-of-the-art processing infrastructure in the City, which, in turn, will generate the consistent streams of materials necessary to foster reliable secondary materials markets. The 20-year contract also ushers in a new era of waterborne transportation of Recyclable materials, mirroring the transportation goals of the Draft New SWMP as a whole. Consistent with the commitment to emphasize waterborne transport as an element of the Draft New SWMP, the City will also develop a Recyclables acceptance facility in Manhattan that would transport Manhattan Recyclables by barge to the newly proposed Recyclables processing facility in Brooklyn.

Accordingly, the Proposed Action for recycling has the following new elements.

- Develop a materials processing facility at the 30th Street Pier (in Brooklyn Community District 7) through a public-private partnership involving a 20-year service agreement with a private recyclables processor; and
- Develop a Recyclables acceptance facility in Manhattan.

Commercial Waste

Commercial Waste management is as complex a system as the DSNY-managed Waste counterpart. The volume of Putrescible and Non-Putrescible Commercial Waste managed in the City is even larger, accounting for nearly 75% of the City's total waste stream. Commercial Waste is managed by the private sector through a system of private carters and private transfer stations. Both elements of the systems are subject to regulation – the private carters by the City's Business Integrity Commission (BIC), and the private transfer stations by DSNY and NYSDEC.

Except for that portion of Commercial Waste carted directly out of the City, waste export occurs through a network of land-based transfer stations, points at which waste from local collection trucks is transferred for long-haul export. These transfer stations are generally located in M3 districts (districts reserved for heavy industry) which are well buffered from residential communities. However, waste trucks traveling to and from these transfer stations often pass through residential communities on their way to the designated truck routes.

Two features of the current Commercial Waste management system have served as the focus of recent concern. The first is that Manhattan has no private transfer stations, despite the fact that over 40% of the City's Putrescible Commercial Waste is generated in Manhattan. As a result, although some waste is driven directly out of the City, most of Manhattan's Commercial Waste is driven to another borough before it is exported from the City. Further, because only one of the City's 19 private putrescible transfer stations exports waste by means other than transfer trailer, the export of waste—not just its collection—creates truck traffic.

To achieve a more balanced distribution and reduce effects from Commercial Waste transfer operations in those Community Districts (CDs) that currently have the greatest number of transfer stations, the following measures are proposed:

- Assess the feasibility of providing the site of the existing Manhattan West 59th Street MTS to private waste management companies to use for the transfer of Commercial Waste collected by private carters in Manhattan. The facility could be: (i) refurbished and used in conjunction with an enclosed barge unloading facility (EBUF); or (ii) redeveloped as a containerization facility.

- ~~Design~~ Develop measures to encourage private carters to deliver Commercial Waste during the 8:00 p.m. to 8:00 a.m. time period to the four Converted MTSs that are elements of the Proposed Action for Long Term Export (Hamilton Avenue and Southwest Brooklyn, Brooklyn; East 91st Street; Manhattan; and North Shore, Queens).

- Negotiate arrangements with the owners/operators of the selected private transfer stations in the Bronx, Brooklyn and Queens that submitted proposals in response to the BQB Requests for Proposals (RFPs) and Brooklyn Best and Final Offer (BAFO) and that are potential elements of the Proposed Action to require Commercial Waste (in addition to DSNY-managed Waste) processed at these facilities to be containerized and exported from the project service area by barge and/or rail.

Table ES-1 lists the 15 Proposed Action facilities and/or potential contractors evaluated, as applicable, in this FDEIS.

3.1 Major Advantages of the Draft New SWMP

Combined, the principal elements of the Draft New SWMP constitute a comprehensive and balanced approach to addressing the City's long-term waste export needs. The major advantages of the Draft New SWMP are described below.

Long Term Export

The following considerations guided formulation of the Long Term Export Program:

- Reducing the City's dependence on transport by transfer trailer to disposal sites is a priority. Approximately 93% of all truck-transferred DSNY-managed Waste is disposed in landfills, and most of the landfills under contract are within a radius of 200 miles of the City. A combination of factors is causing the depletion of this capacity and an increase in disposal price. The recent re-bidding of some Interim Export contracts that rely on truck transport to landfills has reflected an average increase of 19% over the initial contract prices.

Table ES-1
Proposed Draft New SWMP Facilities and Potential Contractors

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Long Term Export Facilities			
Converted MTS	DSNY, Hamilton Avenue Converted MTS, Hamilton Avenue at Gowanus Canal, Brooklyn	Brooklyn 7	Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18
Converted MTS	DSNY, Southwest Brooklyn Converted MTS, Shore Pkwy at Bay 41st Street, Brooklyn	Brooklyn 11	Brooklyn CDs 11, 12, 13 and 15
Converted MTS	DSNY, East 91st Street Converted MTS, East 91st Street and York Avenue, Manhattan	Manhattan 8	Manhattan CDs 5, 6, 8 and 11
Converted MTS	DSNY, North Shore Converted MTS, 31st Avenue and 122nd Street, Queens	Queens 7	Queens CDs 7 through 14
Truck-to-Rail TS	Waste Management, Harlem River Yard, 98 Lincoln Avenue, Bronx	Bronx 1	Bronx CDs 1 through 12
Truck-to-Rail TS(1)	Allied Waste Services, East 132nd Street Transfer Station, Bronx and Oak Point Rail Yard, Oak Point Avenue and Barry Street, Bronx	Bronx 1	Bronx CDs 1 through 12
Truck-to-Barge TS	Waste Management, 485 Scott Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5
Truck-to-Rail TS	Allied, 72 Scott Avenue-598 Scholes Street, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5
Truck-to-Rail/Barge TS (1)(2)	Waste Management, 30-58 Review Avenue, Queens and the LIRR Maspeth Rail Yard, Maspeth Avenue and Rust Street, Queens	Queens 2	Queens CDs 1 through 6
Waste-to-Energy Facility (3)	Port Authority of New York and New Jersey, Essex County RRF, Newark, New Jersey	NA	Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12
~~**Long Term Export Potential Support Facilities**~~			
~~**Barge Staging Area** (4)~~	~~DSNY, 52nd Street Barge Staging Area, 52nd Street and 1st Avenue, Brooklyn~~	~~Brooklyn 7~~	~~NA~~
~~**Intermodal Barge-to-Rail Yard** (5)~~	~~Harlem River Yard, East 132nd Street and St. Anns Avenue, Bronx~~	~~Bronx 1~~	~~NA~~

Table ES-1 (Continued)
Proposed Draft New SWMP Facilities and Potential Contractors

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
~~Intermodal Barge-to-Rail Yard (5)~~	~~NYCEDC, 65th Street Intermodal Yard, Brooklyn~~	~~Brooklyn 10~~	~~NA~~
Recycling Facilities			
Recyclables Processing Facility (64)	30th Street Pier at the South Brooklyn Marine Terminal (SBMT), Brooklyn	Brooklyn 7	City-wide
Truck to Barge Marine Transfer Station (75)	Former site of Gansevoort MTS, Pier 52, Manhattan	Manhattan 2	Manhattan CDs 1 through 12

Notes:

(1) Both the East 132nd Street Truck-to-Truck-to-Rail Transfer Station in the Bronx and the Review Avenue Truck-to-Truck-to-Rail Transfer Station in Queens would dray containers between their respective transfer stations and intermodal rail yards that are in the respective project service areas but not at the same sites as the transfer stations. These intermodal yards are existing facilities that would receive non-discretionary permits from DSNY for handling solid waste and, as such, are not subject to environmental review. However, the movement of containers on tractor chassis between the transfer stations and the intermodal yard is subject to an environmental review that is reported in the FDEIS section for each respective transfer station.

(2) Pending the outcome of negotiations between DSNY and Waste Management, the Review Avenue Transfer Station would be modified to operate as either a truck-to-barge or a truck-to-truck-to-rail facility.

(3) The Essex County RRF is a permitted and operating WTE facility in Newark, New Jersey. As such, the facility itself is not subject to environmental review in this FDEIS. DSNY-managed Waste would be delivered in collection vehicles to this facility or via hopper barges from the existing MTSs, if an EBUF were to be developed in the vicinity of the Essex County RRF some time in the future. The routing of DSNY collection vehicles to bridge and tunnel portals leaving the City is subject to environmental review and is reported in Chapter 16 of this FDEIS.

~~(4)The 52nd Street Barge Staging Area historically served the existing MTSs as a location where barge movements between individual MTSs and Fresh Kills could be staged. A replacement in kind of the pier structure is proposed. Its purpose in the Long Term Export Program will be more limited; principally, a supply storage facility and a location to temporarily moor barges that are scheduled for maintenance at other facilities.~~

~~(5)Two~~ An ~~intermodal barge to rail facilities at Harlem River Yard and the 65th Street Rail Yard, respectively, may be constructed as transload facilities to move containers between the Converted MTSs and railheads. DSNY has modified its Rules to allow a non discretionary permit by registration process for intermodal facilities handling containerized waste that is not subject to environmental review. However, the USACE Section 10/404 permits and the NYSDEC Article 15/25 permits pertaining to waterfront construction are subject to environmental review. Note that there are other existing intermodal facilities that may be used for intermodal transfer of containers from the Converted MTSs.~~

~~(6)~~(4) This 30th Street Pier at SBMT is a complex of facilities that would be designed to receive and process DSNY Curbside Recyclables. Curbside Recyclables collected in Brooklyn would be delivered by truck to this facility. ~~Curbside Recyclables from other boroughs would be delivered by barge.~~ Recyclables would be transferred from this facility by barge. ~~As a recycling~~This facility~~, it~~ is ~~not~~ subject to regulation under 6 NYCRR Part 360 Regulations through a registration process. ~~as a solid waste facility. However, the~~ The waterfront construction requires USACE Section 10/404 ~~permits~~ and ~~the~~ NYSDEC Article 15/25 permits, ~~that~~ and these are subject to environmental review.

Notes for Table ES-1 (continued):

~~(7)~~(5) The timetable for designing, permitting and constructing this facility, which would receive truck deliveries of DSNY MGP Curbside Recyclables collected in Manhattan for barge transfer to the 30th Street Pier at SBMT for processing, is approximately seven years. Accordingly, the environmental review of this facility is deferred until more detailed design information is available However, an analysis of the potential for off-site traffic, air quality and noise impacts from directing DSNY's Manhattan Recyclables collection vehicles to this destination was conducted.

LIRR = Long Island Rail Road
NYCEDC – New York City Economic Development Corporation
NA = Not Applicable

- Remote disposal capacity remains available, but truck-based transfer is not economically viable.
- Developing a barge/rail transport system capable of accessing this remote capacity could offset potential increases in disposal costs.
- Developing a long-term solution that is equitable to the greatest extent possible.
- An alternative to long-distance transport, the delivery of DSNY-managed Waste in collection trucks to a regional WTE facility, achieves an approximately 75% reduction in the volume of waste (ash residue and non-processible waste) disposed in landfills, and reduces the potential impact of landfill price inflation. A long-term disposal contract with a WTE facility can provide a buffer against inflationary price increases that are likely to affect regional landfill capacity.

The proposed Long Term Export Program is a comprehensive plan that balances the City's need to export waste over the long term with the environmental benefit of significantly reducing the transfer trailer traffic associated with Interim Export. Its major advantages include the following:

- DSNY-managed Waste delivered to private transfer facilities in the Bronx, Brooklyn and Queens will be exported by barge or rail and, depending on the outcome of negotiations, the Commercial Waste processed at these facilities may also be exported by barge or rail.
- The in-City facilities proposed would be developed on either existing MTS or private transfer station sites.
- The proposed combination of facilities provides the City with redundancy in the DSNY-managed Waste system that accommodates future increases in waste generated in the City as a function of population growth. Occasional conditions that may affect certain components of the system will not disrupt future waste export.

- Use of existing private transfer station and Essex County RRF capacity: (i) allows some components to be implemented on a faster timetable; and (ii) avoids City investment in new capital projects.

- The Converted MTSs will provide capacity that could be available to containerize Commercial Waste for barge/rail export.

- The projected economics of the Proposed Action are less costly to the City than four alternative scenarios that were evaluated and the Mayor's original plan.

Recycling

The major advantages of the Proposed Action to develop a Recyclables processing facility are that it:

- Commits the City to maintain its Curbside MGP Program over the next 20-years.

- Creates a relationship in which the processor has economic incentives to expand product markets, and thereby increase the net recovery rate for MGP. Historically, DSNY has had considerable difficulty in establishing stable and cost-effective relationships with the contractors that have processed its Curbside MGP, in part due to the practice of contracting for a five-year term with a short-notice cancellation clause. This created economic uncertainty for the contractor and discouraged investments in facility upgrades to improve recovery rates. The 20-year term of the service agreement removes these disincentives and will create a relationship in which the processor has economic incentives to expand product markets and increase the net recovery rate for MGP processed.

- Enhances the opportunity to produce and market new products by recovering materials that are now marginal. The City's Curbside MGP have high proportions by weight of glass, particularly mixed-color broken glass, a material that does not have economic markets. Better technology to be used in the materials processing facility, in addition to aggressive research and development – both afforded by a long-term contract – will address this situation.

- Secures competitive price terms for the City and stabilizes costs over the long term.

- Creates a waterborne transportation network that is consistent with the City's goal of reducing truck traffic. An estimated 85% of the Recyclable materials will be delivered to the new Recyclables processing facility via barge, and 75% will leave post-processing via barge. This is a shift that will help reduce truck traffic on City streets and improve the local environment.

- Creates significant local employment opportunities through creation of an estimated 160 construction jobs and 100 permanent jobs when facility operations commence.

The major advantages of the Proposed Action to develop a Recyclables acceptance facility in Manhattan are that it:

- Eliminates the need for Recyclables collection vehicles to travel from Manhattan to acceptance or processing facilities in other boroughs or New Jersey;
- Facilitates the relocation of the recycled Paper barge operation now based at the West 59th Street MTS to Gansevoort, which will enable the West 59th Street MTS site to be potentially developed for export of Commercial Waste; and
- Results in a more equitable distribution of transfer facilities among the City's boroughs.

Commercial Waste

These Proposed Actions, if fully implemented, would facilitate the City's transition from an almost wholly truck-based waste export system to a predominantly rail- and/or barge-based export system for the City's Putrescible Waste.

Developing the West 59th Street MTS site for transfer of a portion of Manhattan-generated Commercial Waste would:

- More equitably distribute the impacts of Commercial Waste transfer among the City's boroughs;
- Reduce the volume of transfer trailer truck traffic in the City;
- Provide the site most proximate to midtown, a major generator of Commercial Waste; and
- Shorten carters' current travel time from the end of their midtown collection route to their tipping locations in other boroughs, resulting in a decline in the overall duration of commercial collection operations and fewer vehicle miles traveled in the City.

The advantages of using the Converted MTSs to containerize Commercial Waste include that it:

- Capitalizes on unused capacity during the hours when private carter collection operations occur. As DSNY would tip during the day and private carters at night, there is minimal potential for conflict in terms of processing both waste streams at the Converted MTSs.
- Potentially removes approximately 178 transfer trailers from the City's streets that would otherwise be transporting waste for export. As containerization facilities, the four Converted MTSs have potentially available capacity for processing up to approximately 3,915 tpd of Commercial Waste.

The advantages of requiring private transfer station owners/operators who are containerizing and exporting DSNY-managed Waste by barge and/or rail to also containerize and export by barge or rail any Commercial Waste processed at their respective facilities are that it:

- Reduces outbound transfer trailer traffic from the private transfer stations, thus reducing truck traffic in these communities; and
- Accelerates the conversion of the City's private transfer network towards a barge- and/or rail-based system that will have long-term economic and environmental benefits for the City.

4.0 SELECTION AND ENVIRONMENTAL REVIEW OF THE PROPOSED ACTION AND CONSIDERATION OF ALTERNATIVES

4.1 Siting Criteria and Site Screening

The types of sites considered for the Proposed Action were: (i) existing MTS sites as locations for the Converted MTSs; (ii) existing truck-receiving privately owned solid waste transfer sites that are currently capable of exporting or can be modified to export by barge, rail or truck-to-rail; and (iii) new sites that could be developed as truck-receiving solid waste transfer sites that would be capable of exporting by barge, rail or truck-to-rail.

Table ES-2 identifies the ~~13~~ 17 Alternatives considered for detailed environmental review in this F~~D~~EIS. The existing MTSs in Manhattan also are considered as Alternatives to the Gansevoort acceptance facility Proposed Action. Section 1.3 of this FEIS provides additional discussion on the Alternatives considered.

4.2 Environmental Review of Proposed Action and Alternatives

As this F~~D~~EIS demonstrates, the Draft New SWMP Plan would enable export of DSNY-managed Waste and some of the City's Commercial Waste in an efficient and environmentally sound manner. Any impacts associated with the Proposed Action are capable of being mitigated. This summary conclusion is supported by the comprehensive environmental reviews, as applicable, of the Proposed Action and Alternatives in Chapters 4 through 31 of this F~~D~~EIS. In compliance with CEQR/SEQR, these environmental reviews addressed: Land Use, Zoning, and Public Policy; Socioeconomic Conditions; Community Facilities and Services; Open Space; Cultural Resources; Urban Design, Visual Resources, and Shadows; Neighborhood Character; Natural Resources; Hazardous Materials; Water Quality; Waterfront Revitalization Program; Infrastructure, Solid Waste and Sanitation Services, and Energy; Traffic, Parking, Transit, and Pedestrians; Air Quality; Odor; and Noise.

Table ES-2
Draft New SWMP Alternatives

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Barge Staging Area	DSNY, 52nd Street Barge Staging Area, 52nd Street and 1st Avenue, Brooklyn	Brooklyn 7	NA
Intermodal Barge-to-Rail Yard (1)	Harlem River Yard, East 132nd Street and St. Anns Avenue, Bronx	Bronx 1	NA
Intermodal Barge-to-Rail Yard	NYCEDC, 65th Street Intermodal Yard, Brooklyn	Brooklyn 10	NA
Converted MTS	DSNY, South Bronx Converted MTS, Farragut Street, Bronx	Bronx 2	Bronx CDs 1 through 12
Converted MTS	DSNY, Greenpoint Converted MTS, North Henry and Kingsland Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4, and 5; Queens CDs 1 through 6

Truck to Rail TS(2)	Varick Avenue Transfer Station, 215 Varick Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4, and 5
Intermodal Facility(2)	Steel Style, 401 South Water Street, New Windsor, New York	N/A	To Be Determined

Notes for Table ES-2:

N/A = Not Applicable.

(1) An intermodal barge-to-rail facility at Harlem River Yard was proposed as a transload facility to move containers between the Converted MTSs and railheads. DSNY has modified its Rules to allow a non-discretionary permit by registration process for intermodal facilities handling containerized waste that is not subject to environmental review. However, the USACE Section 10/404 permits and the NYSDEC Article 15/25 permits pertaining to waterfront construction are subject to environmental review. Note that there are other existing intermodal facilities that may be used for intermodal transfer of containers from the Converted MTSs.

(2) This FEIS includes site descriptions of the 215 Varick Avenue truck-to-rail transfer station in Brooklyn and the Steel Style intermodal site in New Windsor, New York. These facilities were not reviewed in the DEIS, but could potentially become elements of the Long Term Export program as an outcome of the procurement processes DSNY is currently conducting. In that case, these facilities would be subject to environmental review, as required.

Table ES-3 summarizes the results of technical evaluations of potential air (on-site and off-site), traffic, odor, and noise (on-site and off-site) impacts of the Proposed Action Facilities. Several of these facilities are existing permitted facilities that require either no modifications, minor modifications, or major modifications for exporting DSNY-managed Waste by barge or rail. As such, the level of environmental review conducted for these facilities varied. A description of the analyses undertaken for each element of the Proposed Action is described in more detail in this FDEIS.

For the Proposed Action, the following measures were identified to mitigate estimated adverse impacts:

- Traffic signal timing adjustments would mitigate estimated traffic impacts identified at : (1) three intersections near the Southwest Brooklyn Converted MTS, and at two intersections near the Southwest Brooklyn Converted MTS using the Alternative route analyzed in the FEIS in response to comments received during public meetings on the ULURP application for this facility; (2) two intersections near the Hamilton Avenue Converted MTS; (3) two intersections near the East 91st Street Converted MTS; (4) two intersections near the North Shore Converted MTS; and (5) one intersection near the Scott Avenue/Scholes Street Truck to Rail TS.
- A reduction in the number of DSNY and other City agency vehicles making deliveries to the facility during the facility peak hour would be required to mitigate estimated traffic impacts identified at one intersection near the East 132nd Street TS and Oak Point Rail Yard.~~; and~~
- A restriction on the number of Commercial Waste vehicles delivering waste to the Southwest Brooklyn, Hamilton Avenue, East 91st Street and North Shore Converted MTSs during certain hours will mitigate estimated off-site noise impacts at receptors along the routes to these facilities between 8:00 p.m. and 8:00 a.m.
- DSNY Collection vehicles from Queens CD 9 en route to the North Shore Converted MTS will be routed further on the Van Wyck Expressway to Exit 14, Linden Place to mitigate estimated off-site noise impacts at receptors along College Point Boulevard.
- A restriction on the number of relayed DSNY collection vehicles delivering waste between the hours of 1:00 a.m. and 5:00 a.m., and construction of a louvered fence on both sides of the facility ramp, will mitigate estimated on-site noise impacts at property boundary points of the North Shore Converted MTS; and
- A restriction on the number of relayed DSNY collection vehicles delivering waste to the: (1) Hamilton Avenue and East 91st Street Converted MTSs during certain hours will mitigate estimated off-site noise impacts at receptors along routes to these facilities between 2:00 a.m. and 5:00 a.m.; and (2) Southwest Brooklyn Converted MTS will mitigate estimated on-site noise impacts at two off-site noise sensitive receptors between 2:00 a.m. and 3:00 a.m.

Table ES-4 provides a summary of the impact assessments for the Proposed Action across all remaining environmental review categories.

Table ES-3

5.0 PUBLIC REVIEW PROCESS –CEQR AND SEQRA

Adoption and approval of the Draft New SWMP will provide the basis on which the facilities selected for development by the City could receive permits. The City's commitment of resources to develop and operate the facilities would be predicated upon the findings presented in the ~~Final Environmental Impact Statement (~~FEIS~~)~~ that, consistent with social, economic, and other essential considerations of City and state policy, from among the reasonable Alternatives, the Proposed Action is one that minimizes or avoids significant adverse environmental effects to the maximum extent practicable, and that adverse effects would be minimized or avoided by incorporating identified mitigative measures, as practicable (2001 CEQR Technical Manual: pages 1 through 11; Section 270, Agency Findings).

Pursuant to CEQR/SEQRA rules and procedures, the DSNY is designated as lead agency. Involved agencies with discretionary approval of the Draft New SWMP are the City Council and the New York State Department of Environmental Conservation (NYSDEC). Agencies interested in the Long Term Export Program elements of the Proposed Action and assessments of facilities and services related to that program that are included in this FD~~D~~EIS are listed below.

Federal Agencies

- United States Army Corps of Engineers (USACE)
- United States Environmental Protection Agency (USEPA), Region 2

New York State Agencies

- Department of State
- Office of Parks, Recreation and Historic Preservation (OPRHP)
- Office of General Services (OGS)

New York City Agencies

- City Office of Environmental Coordination (OEC)
- Department of Environmental Protection (NYCDEP)
- Department of Transportation (NYCDOT)

- City Planning Commission
- New York City Economic Development Corporation (NYCEDC)
- Landmarks Preservation Commission (LPC)
- Department of Health (NYCDOH)
- Department of Parks and Recreation (NYCDPR)

The purpose of this FDEIS is to provide decision-makers with an understanding of the potential environmental consequences of the Proposed Action so that they may make an informed decision about the actions they are asked to undertake. In addition, this FDEIS provides the basis to make reasoned comparisons of the Alternatives to the Proposed Action.

A series of Public Scoping Meetings were held between June 15 and July 1, 2004 to solicit comments and concerns from the public and regulatory agencies regarding the proposed approach to evaluation of the Proposed Action (see Chapter 1, Section 1.8, Public Outreach Process/Environmental Justice, for a description of the public participation and outreach program). In addition to comments received at the Scoping Meetings, written comments were accepted until July 11, 2004. The Final Scoping Document was revised ~~to address the public~~in consideration of the comments received. The DEIS was issued on October 22, 2004.

As part of the Environmental Impact Statement (EIS) process, ~~an~~ this FEIS ~~will be~~was prepared after: (1) a public comment process extending from October 22, 2004 to January 24, 2005 (a period of 94 days); and (2) eight public hearings on ~~this~~ the DEIS~~.~~, held in the communities potentially affected by the Proposed Action, to solicit comments and concerns from the public and regulatory agencies on the DEIS. Additionally, public hearings on ULURP applications for the four Converted MTSs were held by the Community Boards of the Community Districts potentially affected by these elements of the Proposed Action.

Following the close of the DEIS comment period, all comments received at the public hearing and in writing were reviewed and are addressed in Chapter 40 of this FEIS. This FEIS also includes necessary revisions, additions and clarifications to the document, as well as categorized responses to comments received. Issuance of this FEIS is required for: (1) City Council adoption and NYSDEC approval of the Final New SWMP; (2) City Planning Commission approval of the

pending ULURP applications; and (3) approval by the appropriate issuing authorities of other permits required to implement the Proposed Action.

~~A public hearing to provide an opportunity for the public to comment on the DEIS will be held no sooner than 30 days after the distribution of the DEIS.~~ The ~~DEIS~~ FEIS is available at DSNY's website: www.nyc.gov/sanitation. Copies of the ~~DEIS~~ FEIS can be viewed at the Public Repositories listed in Table 1.6-1 of Chapter 1. Compact disks of the ~~D~~FEIS can be obtained by sending a mail or fax request to Assistant Commissioner, Harry Szarpanski P.E., DSNY Bureau of Long Term Export, 44 Beaver Street, New York, New York 10004, fax number (212) 269-0788.

~~Following the close of the DEIS comment period, all comments received at the public hearing and in writing will be reviewed and addressed in the FEIS. The FEIS will include necessary revisions, additions and clarifications to the document, as well as categorized responses to comments received. Issuance of the FEIS is required for City Council adoption of the Final New SWMP.~~

The FEIS findings ~~will be~~are used to support all other public actions and approvals inclusive of anticipated potential permit actions. These potential actions are listed in Chapter 1, Section 1.7 of the DEIS. Additionally, Chapter 2, Section 2.5 provides a table listing the possible applicability of permit requirements to specific sites.

6.0 OVERVIEW OF ~~D~~FEIS CHAPTERS

Chapter 1, Proposed Action, describes the purpose and need, defines the Proposed Action, and identifies the Alternatives considered and the involved and interested public agencies.

Chapter 2, Description of Facility Sites, provides, in Sections 2.2 through 2.4, a description of the important characteristics of each of the 17 Proposed Action sites at which potential export facilities were considered, and describes the 14 Alternative sites for which detailed environmental reviews, as applicable, were conducted. Section 2.5 provides a summary of potentially applicable permits for these sites.

Chapter 3, Overview of Study Methodologies for Site-Specific Analyses, describes, in Sections 3.2 through 3.19, the analytical methods that were applied, consistent with CEQR/SEQRA requirements, to evaluate the potential environmental impacts of the Proposed Action and Alternatives. CEQR/SEQRA requirements were refined in a process of consultation with interested agencies and applied consistently to all site/facility options.

Chapter 3 describes the methodologies used to conduct environmental reviews in the categories:

- Definition of Study Areas
- Analysis Years and Baseline Conditions
- Land Use, Zoning, and Public Policy
- Socioeconomic Conditions
- Community Facilities and Services
- Open Space
- Cultural Resources
- Urban Design, Visual Resources, and Shadows
- Neighborhood Character
- Natural Resources
- Hazardous Materials
- Water Quality
- Waterfront Revitalization Program
- Infrastructure, Solid Waste and Sanitation Services, and Energy
- Traffic, Parking, Transit, and Pedestrians

- Air Quality
- Odor; and
- Noise

Chapters 4 through 31 report the results of the impact analyses in the above-listed categories for each Proposed Action and Alternative.

Chapters 32 through ~~39~~ 40 discuss the following:

- Chapter 32, Construction Impacts
- Chapter 33, Public Health Evaluation
- Chapter 34, Evaluation of the Proposed Action
- Chapter 35, Unavoidable and Adverse Impacts
- Chapter 36, Irreversible and Irretrievable Commitment of Resources
- Chapter 37, Growth-Inducing Aspects of the Proposed Action
- Chapter 38, References/Bibliography
- Chapter 39, List of Preparers
- Chapter 40. Responsiveness Summary

Appendices included in Volume III of this FD EIS include:

- Appendix A – Agency and Utility Correspondence
- Appendix B – Demographic and Socioeconomic Data
- Appendix C – Essential Fish Habitat Assessment of Eight MTS Sites
- Appendix D – Commercial Waste to the MTS Summary Report
- Appendix E – Off-Site Noise Analysis TNM Results
- Appendix F – Phase II Site Investigation Reports
- Appendix G –Compendium of Comments
- Appendix H – Selected Outreach Material for Enhanced Public Participation
- Appendix I – Commercial Waste Management Study
- Appendix J – Collection Vehicle Odor Sampling Report
- Appendix K – Truck Simulation Summary Report
- Appendix L – Equipment-Induced Vibration Memo
- Appendix M – Tonnages Memo
- Appendix N – Preliminary Construction Schedules

This page intentionally left blank.

CHAPTER 1 PROPOSED ACTION

1.1 Introduction

The New York City (City) Department of Sanitation (DSNY) is proposing a New Comprehensive Solid Waste Management Plan (Draft New SWMP) for the next 20-year planning period. As lead agency principally responsible for undertaking the action, DSNY has caused this Final~~Draft~~ Environmental Impact Statement (F~~D~~EIS) to be prepared in accordance with the State Environmental Quality Review Act (SEQRA) and its implementing regulations (6 NYCRR Part 617) and City Environmental Quality Review procedures (CEQR) set forth in Executive Order 91 of 1977, as amended, and Rules of Procedure for CEQR found in Section 6, Title 62 of the Rules of the City of New York (RCNY). The F~~D~~EIS is intended to support the adoption of the Draft New SWMP and its related approvals, which together constitute the Proposed Action. As further discussed below, the Draft New SWMP incorporates elements of the existing SWMP and includes major changes to the City's Long Term Export Program for DSNY-managed Waste,[1] to the City's Recycling Program, and to management of Commercial Waste[2] in the City.

A Draft New SWMP, published in October 2004, describes the Proposed Action that, in summary, is to:

- Improve DSNY's Curbside Recycling Program through the award of a 20-year processing contract and the development of a new in-City Recyclables processing facility as well as a Manhattan Recyclables acceptance facility.
- Implement the City's Long Term Export Program through: the development of four Converted Marine Transfer Stations (Converted MTSs); award up to five contracts with private transfer stations for barge or rail export of DSNY-managed Waste for disposal; and, enter into an intergovernmental agreement to dispose of a portion of Manhattan's DSNY-managed Waste at a waste-to-energy (WTE) facility in Newark, New Jersey.

---

[1] DSNY collects and disposes of Putrescible and Non-Putrescible Waste from all residences in the City, institutions, not-for-profit organizations, lot cleaning operations, and other City, state and federal agencies (DSNY-managed Waste).

[2] Commercial Waste is those wastes, including recycled material, generated in the City by business establishments and construction activity and collected by private carters that are respectively defined in DSNY's Rules as Putrescible Waste and Non-Putrescible Waste. Most, but not all, Commercial Waste generated is processed through the City's putrescible and non-putrescible transfer stations.

- Provide the capacity for barge export of Putrescible Commercial Waste from the City at one existing Manhattan MTS as well as the four Converted MTSs.

Sections 1.3, 1.4 and 1.5 describe the Proposed Action for Long Term Export, Recycling and Commercial Waste Management, respectively, as well as the reasonable Alternatives that were considered.

The SEQRA/CEQR environmental review process is intended to ensure that the protection and enhancement of the environment, and human and community resources be given appropriate weight with social and economic considerations in determining public policy, and that those factors be considered together in reaching decisions on the Proposed Action. The FDEIS provides a means for agency decision makers and the public to systematically consider significant adverse environmental impacts, alternatives and mitigation. The FDEIS facilitates the weighing of social, economic and environmental factors early in the planning and decision-making process.

1.2 Purpose and Need

In accordance with the requirements of New York State's Solid Waste Management Act (New York Environmental Conservation Law, Section 27-0707) and implementing regulations (6 NYCRR Subpart 360-15), the City's first Comprehensive Solid Waste Management Plan, approved in 1992 (1992 SWMP) established the framework for its solid waste management and recycling programs over a 10-year period. Approved modifications to the 1992 SWMP (1996 SWMP Update and Modification) focused on further expansion of recycling. In 2000, further approved amendments to the SWMP (2000 SWMP Modification) were made, which principally focused on the City's plan to address the closure of the Fresh Kills Landfill on Staten Island. The 1992 SWMP, as amended (Existing SWMP), expires at the end of October 2004. ~~The~~ At the request of the City and the City Council, ~~have requested that~~ the New York State Department of Environmental Conservation (NYSDEC) extended the 1992 SWMP, as amended, (Existing SWMP) ~~to cover the period between the submittal of the Draft New SWMP to the City Council and its adoption and the approval of the adopted Draft New SWMP by NYSDEC~~through April 2005.

Each day, the City's 8.1 million residents, commuters, visitors, businesses and residential and commercial construction activity generate very large and diverse quantities of solid waste material. The Draft New SWMP sets forth a plan for the long-term management of the City's solid waste in a cost-effective and environmentally responsible manner and, in addition to the Proposed Action, incorporates by reference the Existing SWMP to support Existing Programs, including the New Initiatives described in the Draft New SWMP. These Existing Programs and New Initiatives approved pursuant to the Existing SWMP are therefore not part of the Proposed Action that is subject to environmental review in this FDEIS.

The City's existing solid waste management system:

- Recycles or disposes of approximately 14,000 tons per day (tpd) or 4,240,000 tons per year (tpy) of DSNY-managed Waste currently generated in the City;
- Recycles or disposes of approximately 10,000 tpd (3,000,000 tpy) of Putrescible Commercial Waste that is generated, and approximately 20,000 tpd to approximately 27,700 tpd (6 million to 8.3 million tpy) of Non-Putrescible Commercial Waste that is currently generated; and
- Provides for the management of Biosolids, Medical Waste and Dredge Spoils and Fresh Kills closure construction and end use.

1.3 Proposed Action – Long Term Export

1.3.1 Existing Conditions/No Action

Since delivery of waste to the Fresh Kills Landfill ceased in 2001, the City has relied on interim export contracts for disposal (Interim Export). Under these existing Interim Export contracts, all DSNY-managed Waste is: (i) tipped at in-City, private transfer stations and transferred primarily by trailer (except for approximately 1,4800 tpd transferred by rail from the Harlem River Yard in the Bronx) to out-of-City disposal sites; or (ii) direct-hauled in collection vehicles to out-of-City transfer stations or disposal facilities. For purposes of environmental review, Interim Export constitutes Existing Conditions/No Action. If the Draft New SWMP were not adopted, DSNY would continue the export of DSNY-managed Waste from the City under Interim Export

Contracts, the No Action Alternative. Interim Export contracts are for three year period and can be extended in accordance with their terms for two one-year extensions. After expiration of the term these contracts would be re-bid, as necessary.

Under the Interim Export contracts as they currently exist, significant numbers of DSNY collection vehicles deliver to private transfer stations within the City, where the waste is transferred to private long-haul transfer trailers for transport to disposal facilities. Existing transfer stations are located in manufacturing zoned areas and their distribution is uneven throughout the City. The areas of the City where private transfer stations are relatively concentrated experience correspondingly more heavy truck traffic as a consequence of transfer trailer traffic. For example, the East Williamsburg Industrial Park in Brooklyn Community District #1 has three transfer stations currently utilized by Interim Export for approximately 2400 tpd of Brooklyn's DSNY-managed Waste. This volume represents about 20% of the City-wide DSNY-managed Waste exported. Based on recent figures, DSNY vehicles delivered an average of approximately 909 tons per day to the Waste Management transfer station at 485 Scott Avenue in approximately 83 collection vehicles per day, requiring 42 daily outbound transfer trailers trips[3]. DSNY delivered approximately 1394 tpd to the Waste Management transfer station at 123 Varick Avenue in approximately 127 collection vehicles per day, requiring about approximately 64 daily outbound transfer trailers trips. DSNY delivered 92 tpd to the Allied/BFI transfer station at 598 Scholes Street in approximately 9 collection vehicles per day, requiring approximately 5 outbound transfer trailers trips. On an annual basis, the Interim Export contracts result in approximately 6000 tpd of DSNY-managed putrescible waste being transported through the City's truck-to-truck transfer stations.

Table 1.3-1 lists both the in-City and out-of-City transfer stations or disposal sites that currently receive waste delivered by or on behalf of DSNY and the maximum capacity available at each facility under current Interim Export contracts.

[3] Truck figures are estimates based on tonnages reported for the period August through December, 2004, using 11 tons per DSNY collection vehicle and 22 tons per transfer trailer, as per the Preliminary Mayor's Management Report for FY 2005. Numbers have been rounded up.

Table 1.3-1
Facilities Utilized for Interim Export

Borough Served	Facility Name/Operator	Facility Address	Maximum Capacities Available for DSNY-managed Waste (tpd)
Bronx	**Waste Management/ Harlem River Yard**	98 Lincoln Street, Bronx, NY	1,800

Note:
(1) Denotes a WTE facility
tpd = tons per day

1.3.2 Long Term Export – Proposed Action

The City has long recognized the importance of moving quickly to develop a more permanent system of waste export, to address both the rising cost of nearby landfill disposal as well as the current over-reliance on a truck-dependent system. In July of 2002, Mayor Bloomberg announced a plan to establish a system that would take advantage of the City's waterways and existing infrastructure. The plan called for the physical conversion of the City's existing Marine Transfer Stations (MTSs) to enable waste to be containerized on site, making the waste suitable for out-of-City barge and rail export.

The Proposed Action for Long Term Export, described herein, builds on the Mayor's previously announced plan, but offers an expedited timeframe, a lower cost and reduced reliance on complex MTS conversions outlined initially. The Proposed Action adheres to the ~~two main~~ principles of the Mayor's earlier plan: the containerization of waste and the long-distance export of that waste in containers by barge or rail by primarily relying on a mix of Converted MTSs at existing MTS sites and existing private transfer stations with the addition of the use of ~~existing~~ the Essex County Resource Recovery Facility (Essex County RRF) in Newark, New Jersey, ~~where~~ to which waste would be delivered in collection vehicles.

The Proposed Action for Long Term Export has the following specific elements.

- For the entire Bronx wasteshed, enter into a long-term contract with one or two private ~~transfer station~~ waste companies for truck-to-rail disposal ~~for~~ of DSNY-managed Waste from existing transfer stations in the Bronx.
- For the Brooklyn wasteshed formerly served by the Greenpoint MTS (Brooklyn CDs #1, #3, #4 and #5), enter into a long-term contract with one or two private ~~transfer station~~ waste companies for truck-to-rail or truck-to-barge disposal of the DSNY-managed Waste from existing transfer stations in Brooklyn ~~CDs 1, 3, 4, and 5~~.
- For the Brooklyn wasteshed formerly served by the Hamilton Avenue MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18 will be received and containerized.

- For the Brooklyn wasteshed formerly served by the Southwest Brooklyn MTS, develop a City-owned Converted MTS on the adjacent site of the former Southwest Brooklyn Incinerator, where DSNY-managed Waste from Brooklyn CDs 11, 12, 13 and 15 will be received and containerized.

- For the Manhattan wasteshed, Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12, enter into a long-term service agreement with the Port Authority of New York and New Jersey for the use of the Essex County RRF in Newark, New Jersey to receive and process DSNY-managed Waste delivered in City collection vehicles.

- For the Manhattan wasteshed formerly served by the East 91st Street MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Manhattan CDs 5, 6, 8 and 11 will be received and containerized.

- For the Queens wasteshed formerly served by the Greenpoint MTS, enter into a long-term contract with a private transfer station for truck-to-rail or truck-to-barge disposal of the DSNY-managed Waste from Queens CDs 1 through 6.

- For the Queens wasteshed formerly served by the North Shore MTS, develop a City-owned Converted MTS on the same site, where DSNY-managed Waste from Queens CDs 7 through 14 will be received and containerized.

- For the four wastesheds served by Converted MTSs, enter into 20-year service agreements with one or more waste management companies, for transport of containerized waste by barge directly from an MTS to disposal facilities or to intermodal facilities for transloading to railcars or a larger barge, and for disposal at an appropriately permitted out-of-City facility.

Figure 1.3-1, Locations of Draft New SWMP Long Term Export Facilities and Wastesheds Served, identifies the boroughs and CDs that would be assigned to specific facilities.

Table 1.3-2 lists the potential Long Term Export facilities proposed in the Draft New SWMP. In the Bronx and Brooklyn CDs 1, 3, 4 and 5, noted in Table 1.3-2, the decision as to whether DSNY contracts for export of DSNY-managed Waste generated in these wastesheds with one or two potential transfer stations will be determined by upcoming negotiations with the proposing companies.

Table 1.3-2
Proposed Draft New SWMP Long Term Export Facilities and Potential Contractors

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Converted MTS[1]	DSNY, Hamilton Avenue Converted MTS, Hamilton Avenue at Gowanus Canal, Brooklyn	Brooklyn 7	Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18
Converted MTS[1]	DSNY, Southwest Brooklyn Converted MTS, Shore Pkwy at Bay 41st Street, Brooklyn	Brooklyn 11	Brooklyn CDs 11, 12, 13 and 15
Converted MTS[1]	DSNY, East 91st Street Converted MTS, East 91st Street and York Avenue, Manhattan	Manhattan 8	Manhattan CDs 5, 6, 8 and 11
Converted MTS[1]	DSNY, North Shore Converted MTS, 31st Avenue and 122nd Street, Queens	Queens 7	Queens CDs 7 through 14
Truck-to-Rail TS	Waste Management, Harlem River Yard, 98 Lincoln Avenue, Bronx	Bronx 1	Bronx CDs 1 through 12
Truck-to-Rail TS[2]	Allied Waste Services, East 132nd Street Transfer Station, Bronx and Oak Point Rail Yard, Oak Point Avenue and Barry Street, Bronx	Bronx 1	Bronx CDs 1 through 12
Truck-to-Barge TS	Waste Management, 485 Scott Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1,3, 4 and 5
Truck-to-Rail TS	Allied, 72 Scott Avenue-598 Scholes Street, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5
Truck-to-Rail/Barge TS[3]	Waste Management, 30-58 Review Avenue, Queens and the LIRR Maspeth Rail Yard, Maspeth Avenue and Rust Street Queens	Queens 2	Queens CDs 1 through 6
Waste-to-Energy Facility[4]	Port Authority of New York and New Jersey, Essex County RRF, Newark, New Jersey,	NA	Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12

Notes:

(1) From among the selected proposers responding to DSNY's MTS RFP, DSNY will award one or more contracts for the acceptance, transport and disposal of containerized waste from the Converted MTSs.

(2) This facility would include use of an off-site intermodal rail yard, as noted in the Table, where containers would be loaded onto railcars.

(3) Pending the outcome of negotiations between DSNY and Waste Management, the Review Avenue Transfer Station would be modified to operate as either a truck-to-barge or a truck-to-truck-to-rail facility. If operated in a truck-to-rail mode, an off-site intermodal rail yard, as noted in the Table, would be required, where containers would be loaded onto railcars.

(4) The Essex County RRF is a permitted and operating WTE facility in Newark, New Jersey. DSNY-managed Waste would be delivered in collection vehicles to this facility or via hopper barges from the existing MTSs, if an enclosed barge unloading facility (EBUF) were to be developed in the vicinity of the Essex County RRF some time in the future.

LIRR = Long Island Rail~~r~~Road

Development of the Converted MTSs will also require support facilities such as ~~a barge staging area and~~ intermodal facilities for transloading containerized waste to railcars or larger barges that are subject to review in this F~~D~~EIS. Rail export from certain of the private transfer stations in the Proposed Action would require use of off-site intermodal facilities.

Currently, Interim Export contracts provide for disposal of all DSNY-managed Waste. The principal features of Interim Export are:

- DSNY contracts with 21 private transfer stations (located both within and outside the City) or out-of-City disposal facilities, to provide sufficient capacity to dispose of approximately 12,500 tpd on an average daily basis.
- 48% of DSNY-managed Waste is moved to out-of-City disposal sites by transfer trailers.
- 14% of DSNY-managed Waste is moved to out-of-City disposal sites by rail.
- 38% of DSNY-managed Waste is moved to out-of-City disposal sites in DSNY collection vehicles.[4]

The following considerations guided the formulation of the Long Term Export Program:

- Reducing the City's dependence on transport by transfer trailer to disposal sites is a priority. Some 93% of all truck-transferred DSNY-managed Waste is disposed in landfills and most of the landfills under contract are within a radius of 200 miles of the City. A combination of factors is causing the depletion of this capacity and an increase in disposal price. The recent re-bidding of some Interim Export contracts that rely on truck transport to landfills has reflected an average increase of 19% over the initial contract prices.
- Remote disposal capacity remains available, but truck-based transfer is not economically viable.
- Developing a barge/rail transport system capable of accessing this remote capacity could offset potential increases in disposal costs.
- Developing a long-term solution that is equitable to the greatest extent possible.
- An alternative to long-distance transport, the delivery of DSNY-managed Waste in collection trucks to regional WTE facilities, achieves an approximately 75% reduction in the volume of waste (ash residue and non-processible waste) disposed in landfills, and reduces the potential impact of landfill price inflation. A long-term disposal contract with a WTE facility can provide a buffer against inflationary price increases that are likely to affect regional landfill capacity.

[4] Includes Interim Export from Manhattan and Staten Island.

The proposed Long Term Export Program is a comprehensive plan that balances the City's need to export waste over the long term with the environmental benefit of significantly reducing the transfer trailer traffic associated with Interim Export. Its major advantages include the following:

- DSNY-managed Waste delivered to private transfer facilities in the Bronx, Brooklyn and Queens will be exported by barge or rail and, depending on the outcome of negotiations, the Commercial Waste processed at these facilities may also be exported by barge or rail.
- The in-City facilities proposed would be developed on either existing MTS or private transfer station sites.
- The proposed combination of facilities provides the City with redundancy in the DSNY-managed Waste system that accommodates future increases in waste generated in the City as a function of population growth. Occasional conditions that may affect certain components of the system will not disrupt future waste export.
- Use of existing private transfer station and Essex County RRF capacity: (i) allows some components to be implemented on a faster timetable; and (ii) avoids City investment in new capital projects.
- The Converted MTSs will provide capacity that could be available to containerize Commercial Waste for barge/rail export. (This advantage is addressed in more detail in Section 1.5.2.)
- The projected economics of the Proposed Action are less costly to the City than four alternative scenarios that were evaluated (see Chapter 34) and the Mayor's original plan.

Table 1.3-3 lists the support facilities that may be required for the implementation of the Long Term Export Program. These facilities include~~: (i) the 52nd Street Barge Staging Facility that would be used as a temporary mooring facility for flat bed barges being routed to maintenance facilities; and (ii)~~ several in-City intermodal facilities that are potential locations, depending on the outcome of the City's negotiations with selected waste management companies, for providing services and facilities to transload containerized waste between barges shuttling to/from the Converted MTSs and railcars or larger ocean-going barges. This F~~D~~EIS also presents an environmental review of these facilities, as applicable.

Table 1.3-3
Proposed Draft New SWMP Long Term Export – Potential Support Facilities

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Support Facilities			
~~Barge Staging Area (1)~~	~~DSNY, 52nd Street Barge Staging Area, 52nd Street and 1st Avenue, Brooklyn~~	~~Brooklyn 7~~	~~NA~~
~~Intermodal Barge-to-Rail Yard (2)~~	~~Waste Management, Harlem River Yard, East 132nd Street and St. Anns Avenue, Bronx~~	~~Bronx 1~~	~~NA~~
Intermodal Truck-to-Truck-to-Rail Yard (3)	Oak Point Rail Yard, Oak Point Avenue and Barry Street, Bronx	Bronx 2	Bronx CDs 1 through 12
~~Intermodal Barge-to-Rail Yard (2)~~	~~NYCEDC, 65th Street Intermodal Yard, 65th Street Rail Yard, Brooklyn~~	~~Brooklyn 10~~	~~NA~~
Intermodal Yard Truck-to-Truck-to-Rail (3)	LIRR, Maspeth Rail Yard, Maspeth Avenue and Rust Street, Queens	Queens 2	Queens CDs 1 through 6

Notes:

~~(1) The 52nd Street Barge Staging Area historically served the existing MTSs as a location where barge movements between individual MTSs and Fresh Kills could be staged. A replacement-in-kind of the pier structure is proposed. Its purpose in the Long Term Export Program will be more limited; principally, a supply storage facility and a location to temporarily moor barges that are scheduled for maintenance at other facilities.~~

~~(2) Two intermodal barge-to-rail facilities at Harlem River Yard and the 65th Street Rail Yard may be constructed as transload facilities to move containers between the Converted MTSs and railheads. DSNY has instituted a ministerial process to register intermodal facilities handling containerized waste that is not subject to environmental review. However, the USACE Section 10/404 permits and the NYSDEC Article 15/25 permits pertaining to waterfront construction are subject to environmental review. Note that there are other existing intermodal facilities that may be used for intermodal transfer of containers from the Converted MTSs.~~

(3) Both the East 132nd Street Truck-to-Truck-to-Rail Transfer Station in the Bronx and the Review Avenue Truck-to-Truck-to-Rail Transfer Station in Queens would dray containers between their respective transfer stations and intermodal rail yards that are in the respective project service areas but not at the same sites as the transfer stations. These intermodal yards are existing facilities that would receive non-discretionary permits from DSNY for handling solid waste and, as such, are not subject to environmental review. However, the movement of containers on tractor chassis between the transfer stations and the intermodal yard is subject to an environmental review that is reported in the FDEIS section reporting the environmental review of the respective transfer station.

~~NYCEDC = New York City Economic Development Corporation~~

LIRR = Long Island Rail Road

1.3.3 Alternatives to the Proposed Action

In July 2002, Mayor Michael Bloomberg completed an evaluation of the Long Term Export Program and directed DSNY to evaluate waste containerization and export from the City's eight existing Marine Transfer Stations (MTSs). The Long Term Export Program was an element of the City Council and State approved 2000 SWMP Modification supported by an October 2000 FEIS that analyzed long term export options at some 20 different sites with 25 different facility options across the City. (The 2000 SWMP Modification and supporting FEIS are available from DSNY on request.) The Mayor's decision to pursue containerization at the MTSs was made after a determination that insurmountable problems prevented the implementation of the Linden EBUF project. The Linden project, a key component of the 2000 SWMP Modification, would have received waste from five existing MTSs, three in Manhattan, Hamilton Avenue IN Brooklyn and North Shore in Queens. The Alternatives evaluated in the 2000 SWMP FEIS were not acceptable substitutes for Long Term Export from the three Manhattan and the North Shore MTS wastesheds, which comprised four of the five MTSs wastesheds that the Linden Project would have served.

In July 2002, the Mayor announced that the City would move in a new direction by redeveloping all eight of the MTSs as facilities capable of containerizing waste for intermodal transport by barge or rail to out-of-City disposal facilities (Converted MTSs). Since that announcement, DSNY has worked diligently with other City agencies to implement the Mayor's policy directive, while also considering other Alternatives. As a result of that effort, the Draft New SWMP proposes to implement four Converted MTS projects, not eight. Other Long Term Export options have been identified to serve the West 135th and West 59th Street wastesheds in Manhattan, and the wastesheds formerly served by the South Bronx and Greenpoint MTSs. These options are now part of the Proposed Action, because DSNY believes they can be implemented more quickly, are more cost effective than developing Alternative Converted MTSs for those wastesheds and also avoid adding new in-City waste transfer capacity, particularly in the Bronx and Brooklyn where there is a relative concentration of private waste transfer stations.

Table 1.3-4 lists the Alternatives to the Proposed Action that ~~were considered and that~~ are also reviewed in this F~~D~~EIS. These Alternatives include: (i) conversions at four other existing MTSs sites; (ii) the development of a new truck-to-rail facility in Brooklyn CD 1 that was a proposal submitted in response to DSNY's Request for Proposals (RFP) procurement for private transfer station capacity for the Brooklyn portion of the Greenpoint wasteshed; and (iii) the use of the existing MTSs, assuming substantial refurbishing of these facilities, to supply waste in open hopper barges to an enclosed barge unloading facility (EBUF) in the New York/New Jersey harbor region where it would be containerized for transport to disposal sites, although the location of such an EBUF has not been identified.

In addition to the Alternative sites referenced in Table 1.3-4, Volume V of the Commercial Waste Management Study (CWMS or Study),[5] Manhattan Transfer Station Siting Report, investigated four potential sites for truck-to-rail/barge transfer stations in Manhattan and concluded that three of these sites were technically infeasible, and that the fourth posed very significant land use constraints that would have to be overcome. None of these four sites currently serve or are permitted as waste transfer facilities. Facility conceptual designs and site plans were prepared to determine the feasibility of using each site as a minimum 1,000 tpd transfer station. Based on the conceptual designs developed for the sites, three of the four the sites were found to be technically problematic for use as waste transfer facilities for the reasons identified below. The Draft New SWMP includes the potential use of the West 13th Street (Gansevoort) site as a Recyclables processing facility. The technical difficulties with the three remaining sites, as reported in the CWMS are summarized below.

West 140th Street

- There is insufficient property to ramp trucks up to the required site level; and
- The existing rail elevation (+30') determines the building elevation (+44'). The building elevation (+44') is substantially higher than the existing road (+10') and there is insufficient room to ramp up to the facility at an acceptable grade.
- Approximately 100,000 cubic yards of backfill would be required to construct a facility at the same elevation as the existing rail line;

[5] The CWMS is available on the DSNY website: www.nyc.gov/sanitation and on a~~, in~~ compact disk ~~form as an Appendix to the Draft New SWMP and in print form at the Public Repositories listed in Table 1.6-1~~within the CWMS Study in Appendix I of this FEIS.

Table 1.3-4
New SWMP Long Term Export – Alternatives Considered

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Alternatives			
Converted MTS	DSNY, South Bronx Converted MTS, Farragut Street, Bronx	Bronx 2	Bronx CDs 1 through 12
Converted MTS	DSNY, Greenpoint Converted MTS, North Henry and Kingsland Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5; Queens CDs 1 through 6
Converted MTS	DSNY, West 135th Street Converted MTS, West 135th Street and 12th Avenue, Manhattan	Manhattan 9	Manhattan CDs 9, 10 and 12
Converted MTS	DSNY, West 59th Street Converted MTS, West 59th Street and Marginal Street, Manhattan	Manhattan 7	Manhattan CDs 1 through 4 and 7
Truck-to-Rail TS	IESI or TransRiver Marketing, Meserole Street Transfer Station, 568 Meserole Street, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5
Existing MTS	DSNY, South Bronx MTS, Farragut Street, Bronx	Bronx 2	Bronx CDs 1 through 12
Existing MTS	DSNY, Greenpoint MTS, North Henry and Kingsland Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5; Queens CDs 1 through 6
Existing MTS	DSNY, Hamilton Avenue MTS, Hamilton Avenue at Gowanus Canal, Brooklyn	Brooklyn 6	Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18
Existing MTS	DSNY, Southwest Brooklyn MTS, Shore Pkwy at Bay 41st Street, Brooklyn	Brooklyn 11	Brooklyn CDs 11, 12, 13 and 15
Existing MTS	DSNY, West 135th Street MTS, West 135th Street and 12th Avenue, Manhattan	Manhattan 9	Manhattan CDs 9, 10 and 12
Existing MTS	DSNY, West 59th Street MTS, West 59th Street and Marginal Street, Manhattan	Manhattan 7	Manhattan CDs 1 through 4 and 7
Existing MTS	DSNY, East 91st Street MTS, East 91st Street and York Avenue, Manhattan	Manhattan 8	Manhattan CDs 5, 6, 8 and 11
Existing MTS	DSNY, North Shore MTS, 31st Avenue and 122nd Street, Queens	Queens 7	Queens CDs 7 through 14

West 140th Street (continued)

- Backfilling would eliminate the existing access road;
- A new ramp providing truck access between the transfer station and West 144th Street would interfere with the current access to an existing facility in the northeast section of the site;
- On-site truck maneuvering room would be severely constrained and is considered to be insufficient -- outbound commercial trucks would have tight turning radii and minimal queuing distance prior to the outbound scale;
- Employee traffic would be mixed with collection truck traffic entering and leaving the site and there is limited on-site parking (the maximum number of parking stalls that fit on the design is seven).

Pier 42 On The East River

- Queuing would be limited to only one truck on site.
- The relatively small size of the site would cause potential problems in locating an outbound scale and parking on site, and in providing adequate maneuvering room for trucks, front-end loaders and a gantry crane.
- Since the gantry crane cannot permanently project over the U.S. Pierhead Line, the crane would need to retract when not in use.
- There is no room for ramps. Therefore, it would have to be a single level facility and containers would have to be filled with waste using a less efficient lift and load operation. this is not clear
- There is no access to the dock. This limitation will not allow for waste processing equipment stock to be located at the dock level.
- All access to the Pier 42 site is gained by a proposed access drive at the intersection of South and Montgomery Streets. The intersection is currently signalized. South Street is a local, two-way, four-lane surface street that runs parallel to the elevated FDR Drive. Montgomery Street is a two-way, two-lane roadway featuring a wide, painted, center median.
- South Street is designated by the City as a local truck route between State Street and Pike Slip. To access the site, trucks will be required to travel along South Street between Pike Slip and Montgomery Street, which is a section of South Street that is not designated as a local truck route. For these movements to occur, the designation of South Street as a local truck route will need to be extended, by the City, to the Montgomery Street intersection. This may be difficult to accomplish because the neighborhoods along the north side of South Street are heavily residential and are located in the "Zone E – Lower East Side" limited truck zone.

West 30th Street

- The City, along with Friends of the High Line and other groups, are supporting use of the High Line as a pedestrian trail before the Surface Transportation Board.
- Interconnecting with the existing elevated rail line would require construction of a processing facility and platform at the same elevation as the rail line and require providing a ramp up from the ground level.
- The site's limited size does not accommodate the structural arrangements necessary to connect to the existing overhead rail and, therefore, rail operations would not be feasible.
- There is insufficient storage area for waste;
- There is no room on site for parking;
- There is no room for container storage; and
- The available square footage of the conforming portion of the site would severely limit queuing and maneuvering space.
- West 30th Street is the only street available for the trucks to access the site. At the location of the site, West 30th Street is a one-way eastbound street. The intersection of 12th Avenue and West 30th Street is a signalized intersection. Twelfth Avenue is designated by the City as a local truck route, as well as West 30th Street between Broadway and 11th Avenue. However, the section of West 30th Street used by traffic traveling to the proposed facility is not designated as a local truck route. For operation of trucks to occur on West 30th Street between 12th Avenue and 11th Avenue, the City will need to extend the truck route designation to this section.
- The intersection of West 30th Street and 11th Avenue is a signalized intersection. Eleventh Avenue is a one-way southbound street at the intersection with West 30th Street, and is designated by the City as a local truck route. Upon exiting the facility, trucks must travel onto West 30th Street. Access to the network of local truck routes can be gained via West 30th Street, 11th Avenue, 10th Avenue and West 23rd Street. The addition of the truck traffic expected at this facility may impact the operation of the site intersections.

The fourth site, the former site of the Gansevoort MTS was found to be problematic because of land use issues but is an element of the Proposed Action for Recycling that would serve as a Recyclables Acceptance facility for Recyclables from Manhattan and as recycling education center.

During the re-procurement of Interim Export contracts for DSNY-managed Waste from Manhattan awarded in November 2004, DSNY established that the LIPCo/Covanta waste-to-energy facility in Rahway, New Jersey, had insufficient capacity to serve as a primary disposal facility. This facility was awarded an Interim Export contract for backup capacity in the amount

of 125 tpd, substantially less than is generated in any of Manhattan's three wastesheds. Moreover, the facility operates from 5:30 a.m. to 5:00 p.m. on weekdays and from 5:30 a.m. to 12 noon on Saturdays, which is not consistent with DSNY's needs.

Also, DSNY had, in the 2000 Final Environmental Impact Statement (2000 SWMP FEIS), evaluated the technical feasibility and environmental suitability of 24 export facility options on 15 different sites, as the basis for preparing the 2000 SWMP Modification. These 2000 FEIS Alternatives are listed in Table 1.3-5. In the 2000 SWMP FEIS, DSNY evaluated: (1) sites capable of accommodating an Enclosed Barge Unloading Facility (EBUF) (barge receiving with barge or rail export) as proposed by respondents to a procurement process that were identified through an RFP issued by DSNY; (2) existing truck-receiving MSW transfer sites that could export (or be modified to export) by barge, rail, or truck to rail; and (3) new sites that could be developed as truck-receiving MSW transfer sites that would be capable of exporting by barge, rail, or truck to rail. Twenty sites were initially identified but the number was reduced to 15 in an initial screening process. A total of 25 facility options at the 15 sites were evaluated in the 2000 SWMP FEIS. These site/facility alternatives are listed in Table 1.3-5. They were identifies through processes that included the following:

- Conducting a generic economic assessment that provided a comparative economic analysis of alternatives;
- Issuing a Request for Expressions of Interest that elicited 34 responses from private companies presenting conceptual proposals for export services;
- Issuing in 1997 an MTS RFP that identified the available EBUF options to receive waste from the City's existing MTSs; and
- Conducting investigations of available rail transfer station options.

In terms of alternatives considered, the development of the 2000 SWMP was an exhaustive process. Those sites that remained feasible following the Mayor's redirection of current SWMP planning in 2002 are evaluated in this FEIS. DSNY's consideration of alternatives also evaluated the information obtained through a Request for Expressions of Interest (RFEI) to Provide Waste Disposal Capacity on February 17, 2004, that sought expressions of interest to (1) sell or otherwise provide to DSNY, for its exclusive use, permitted waste disposal capacity in

Table 1.3-5
Alternatives Considered in the 2000 SWMP FEIS

Type of Facility	Location/ Borough	Export Mode	New or Permitted Facility
EBUF	Waste Management, Harlem River Yard, 132nd Street and Lincoln Avenue, Bronx	Rail	New (1)
EBUF	American Marine Rail, 500 Oak Point Avenue, Bronx	Rail	New
EBUF	Waste Management, Erie Basin, Beard and Halleck Streets, Brooklyn	Barge	New (2)
EBUF	BFI, 65th Street and upper New York Bay, Brooklyn	Rail	New
EBUF + Truck Receiving	Republic Services, Inc., 920 E. 132nd Street, Bronx	Barge or Rail	New (3)
EBUF	Port Ivory Recycling and Transfer Alliance, located on Arthur Kill along Richmond Terrace and Western Avenue, near Port Ivory	Rail	New
EBUF + Truck Receiving	Waste Management, Harlem River Yard, 132nd Street and Lincoln Avenue, Bronx	Rail	New (4)
Truck Receiving	Waste Management, Harlem River Yard, 132nd Street and Lincoln Avenue, Bronx	Rail	Permitted
Truck Receiving	Department-proposed facility, 500 Oak Point Avenue, Bronx	Rail	New (5)
Truck Receiving	Republic Services, Inc., 920 E. 132nd Street, Bronx	Rail	Permitted (6)
Truck Receiving	Republic Services, Inc., 920 E. 132nd Street, Bronx	Barge	New (7)
Truck Receiving/ MTS Replacement in Kind	DSNY South Bronx MTS, Farragut Street, Bronx	Barge	New (8)
Truck Receiving/ MTS Conversion	DSNY South Bronx MTS, Farragut Street, Bronx	Barge	New (9)
Truck Receiving/ MTS Conversion	DSNY Greenpoint MTS, N. Henry and Kingsland Avenue, Brooklyn	Barge	Permitted
Truck Receiving / Conversion to Barge	Waste Management, Inc. 485 Scott Avenue, Brooklyn on Newtown Creek	Barge	Permitted (10)
Truck Receiving/ MTS Conversion	DSNY Southwest Brooklyn MTS, Shore Parkway at Bay 41st Street, Brooklyn	Barge	Permitted (11)
Truck Receiving/ MTS Conversion	DSNY Hamilton Avenue MTS, Hamilton Avenue in the vicinity of Second Avenue at the Gowanus Canal, Brooklyn	Barge	Permitted (11)

Table 1.3-5 (continued)
Alternatives Considered in the 2000 SWMP FEIS

Type of Facility	Location/ Borough	Export Mode	New or Permitted Facility
Truck Receiving/ MTS Conversion	DSNY 59th Street MTS, West 59th St at the Hudson River, Manhattan	Barge	Permitted (11)
Truck Receiving/ MTS Conversion	DSNY 91st Street MTS, East 91st Street at the East River, Manhattan	Barge	Permitted
Truck Receiving/ MTS Conversion	DSNY 135th Street MTS, West 135th Street and 12th Avenue, Manhattan	Barge	Permitted (11)
Truck Receiving/ MTS Conversion	DSNY North Shore MTS, 31st Avenue and 122nd Street, Queens	Barge	Permitted (11)
Truck Receiving	Waste Management, Review Avenue Transfer Station, Review Avenue, Queens	Barge or Rail	Permitted (12)
Truck Receiving	DSNY, 310 West Service Road, Fresh Kills Landfill, Staten Island	Rail with Interim Truck	New (13)
Truck Receiving	Pier 42, East River, Manhattan	Barge	New
Truck Receiving	W. 30th Street and 11th Avenue, Manhattan	Rail	New
Truck Receiving	140th Street/Henry Hudson Parkway, Manhattan	Rail	New
Truck Receiving	The Elmhurst Gas Tank Site on the Conrail Hell Gate Line, 7751 through 7801 57th Avenue, Elmhurst, Queens	Rail	New

Notes:

Source: FEIS for the 2000 SWMP (Notes reflect status of sites in 2000 FEIS.)

(1) The barge receiving facility was evaluated as an addition to a permitted truck receiving/rail export facility at this site. As an EBUF, it would only receive barge-delivered waste.

(2) Two different size facility options were considered at this site.

(3) The barge receiving facility was evaluated as an addition to a permitted truck receiving rail/truck-to-rail export facility at this site. As an EBUF and truck receiving facility, it would receive waste delivered by both barge and truck. The EBUF includes two options for export by either barge or rail.

(4) The barge receiving facility was evaluated as an addition to a permitted truck receiving rail/truck-to-rail export facility at this site. As an EBUF and truck receiving facility, it would receive waste delivered by both barge and truck.

(5) The truck-to-rail facility evaluated that was evaluated at this site is neither proposed nor endorsed by AMR.

(6) The facility now exports by both rail and truck. If selected by the Department for long term export, it would be required to export all Department-managed waste by rail. Truck-to-rail export is accomplished by draying containers a short distance from the facility site to the Oak Point rail yard.

(7) This facility option was evaluated based on barge export of all waste received by truck.

(8) Formerly used by the Department as an MTS, but closed since 1997, this facility is evaluated as a replacement in-kind of the former MTS.

(9) At the Department's closed MTS site, this new facility was evaluated based on containerizing waste for export by barge. Two different size facility options were evaluated.This facility was evaluated in the 2000 FEIS based on modifications to enable operation as a truck to barge facility.

(10) The MTS conversion option evaluated the construction of a substantially modified facility for containerizing waste at the Department's existing MTS site.

(11) This facility currently exports by truck. It was evaluated based on modifications to enable export by barge or rail. The barge and rail options are evaluated as different facility types.

(12) This facility was evaluated as a new transfer station at Fresh Kills which would export by rail after the completion of interconnections with the Staten Island Railroad and freight lines in New Jersey.

This page intentionally left blank.

State that is suitable to serve as a site for a waste disposal facility; and/or (3) serve as a host community for a disposal facility located in New York State that would receive waste managed by DSNY. No practicable alternatives emerged from this RFEI.

Chapter 2 of this FDEIS provides detailed descriptions of the design features and operations of the Draft New SWMP Long Term Export Facilities, Support Facilities and Alternatives. In addition, this FEIS includes site descriptions of the 215 Varick Street truck-to-rail transfer station in Brooklyn and the Steel Style intermodal site in New Windsor, New York. These facilities were not reviewed in the DEIS, but could potentially become elements of the Long Term Export program, as outcome of the procurement processes DSNY is currently conducting. In that case, these facilities would be subject to environmental review, as required.

1.4 Proposed Action – Recycling Facilities

1.4.1 Existing Conditions/No Action

Through the first half of 2002, DSNY collected and recycled metal, glass and plastic (MGP) and Paper materials sufficient to divert 20% of the DSNY-managed Waste (curbside/containerized) waste stream from disposal. The program flourished ~~in many respects,~~ and compared favorably with the recycling programs of other major cities throughout the United States.

On July 1, 2002, the City's recycling program, having incurred budget cuts in the aftermath of the events of September 11, 2001 and the subsequent economic recession, temporarily suspended glass and plastic recycling. Diversion rates suffered; however, plastic and glass recycling programs were restored in Fiscal Year (FY) 2003 and FY 2004, respectively, and funding for composting and other services was restored in FY 2005.

1.4.2 Recycling Proposed Action

Moving forward, cost-effective recycling programs are now an even greater priority. To address this priority, the Proposed Actions for recycling will commit the City to a 20-year contract for processing MGP. This long-term commitment will facilitate the development of state-of-the-art

processing infrastructure in the City, which, in turn, will generate the consistent streams of materials necessary to foster reliable secondary materials markets. The 20-year contract also ushers in a new era of waterborne transportation of Recyclable materials, mirroring the transportation goals of the Draft New SWMP as a whole. Consistent with the commitment to emphasize waterborne transport as an element of the Draft New SWMP, the City will also develop a Recyclables acceptance facility in Manhattan that would transport Manhattan Recyclables by barge to the newly proposed Recyclables processing facility in Brooklyn.

Accordingly, the Proposed Action for recycling has the following new elements.

- Develop a materials processing facility at the 30th Street Pier (in Brooklyn Community District 7) through a public-private partnership involving a 20-year service agreement with a private Recyclables processor; and
- Develop a Recyclables acceptance facility in Manhattan.

1.4.2.1 Recyclables Processing Facility

The City plans to enter into an agreement with the Hugo Neu Corporation (HNC) for the acceptance, processing and marketing of the MGP and a portion of the mixed Paper[6] (Curbside Recyclables) collected by DSNY. As part of the agreement, HNC will finance the development of a materials processing facility on City-owned land at the 30th Street Pier in the South Brooklyn Marine Terminal (SBMT).

In addition, HNC will use its existing regional network of waterfront acceptance facilities and its own fleet of barges to transport material to the new facility at SBMT. Recyclable material will arrive at the new materials processing facility as follows:

- DSNY trucks collecting Curbside Recyclables in the Bronx will tip this material at HNC's existing acceptance facility in the Bronx, where HNC will transfer material to barge for transport to SBMT.

[6] This is the portion that is not already committed to Visy Paper (NY), Inc. (Visy), for processing in its recycled paper mill on Staten Island.

- DSNY trucks collecting Curbside Recyclables in Staten Island CDs will tip this material either at the new Staten Island Transfer Station for consolidation into transfer trailers that will drive to SBMT or at HNC's existing acceptance facility in Jersey City, where HNC will transfer material to barge for transport to SBMT.

- DSNY trucks collecting Curbside Recyclables in northern Brooklyn and Queens CDs will tip this material at HNC's existing acceptance facility in Long Island City, where HNC will transfer material to barge for transport to SBMT.

- DSNY trucks collecting Curbside Recyclables in Manhattan CDs will tip this material at a Manhattan acceptance facility. Until the new acceptance facility is on line, trucks from southern Manhattan will tip at HNC's existing acceptance facility in Jersey City; trucks from northern Manhattan will tip at HNC's existing facility in the Bronx where HNC will transfer this material to barge for transport to the 30th Street Pier at SBMT, when this facility is developed.

- DSNY trucks collecting Curbside Recyclables in southern Brooklyn CDs will drive to SBMT and tip directly at the materials processing facility.

1.4.2.2 Manhattan Recyclables Acceptance Facility

DSNY proposes to develop a Recyclables acceptance facility in Manhattan. The West 59th Street MTS is currently the transfer site for the mixed Paper which DSNY collects in Manhattan CDs and Visy Paper, Inc. barges to its ~~recycled paper~~ mill on Staten Island for recycling paper into boxboard.

As described in the Proposed Actions for Commercial Waste (see Section 1.5.2), DSNY is proposing to reserve the West 59th Street MTS to facilitate the export of a portion of Manhattan's Commercial Waste by barge. To maximize the throughput capacity required for this scenario, the truck-to-barge operation for mixed Paper would need to be relocated. To facilitate this relocation, as well as to reduce the number of vehicle miles traveled by DSNY trucks, DSNY proposes to develop a Recyclables acceptance facility in lower Manhattan. This proposal would also fulfill the goal of the Draft New SWMP to distribute waste management facilities more equitably in all five boroughs.

The most promising location for this Manhattan Recyclables acceptance facility is the former site of DSNY's Gansevoort MTS on Pier 52 in Manhattan Community District 2. The Gansevoort MTS has not been used by DSNY since 1991. For this proposed project to move forward, several issues must be resolved, such as acceptable integration of the facility design (including an environmental education center) and operation into the plans for the Hudson River Park, and amendment of the Hudson River Park Act.

Table 1.4-1 lists all of the facilities that would be elements of the Recycling Program in the Draft New SWMP, including those that are part of the Proposed Action and reviewed in this FDEIS, as well as those facilities that are elements of Existing Programs.

Table 1.4-1
Proposed Action Recycling Facilities

Facility Type	Operator/Owner, Facility Name, and Address	Community District
Recyclables Processing/Acceptance[(1)]	Hugo Neu Corporation, 30th Street Pier at the South Brooklyn Marine Terminal, Brooklyn	Brooklyn 7
Recyclables Acceptance[(2)]	DSNY, Former site of Gansevoort MTS, Pier 52, Manhattan	Manhattan 2

Notes:

(1) This 30th Street Pier at SBMT is a complex of facilities that would be designed to receive and process DSNY Curbside Recyclables. Curbside Recyclables collected in Brooklyn would be delivered by truck to this facility. Curbside Recyclables from other boroughs would be delivered by barge. Recyclables would be transferred from this facility by barge. As a recycling facility, it is not subject to regulation as a solid waste facility. However, the waterfront construction requires USACE Section 10/404 permits and the NYSDEC Article 15/25 permits that are subject to environmental review.

~~(3)~~(2) The timetable for designing, permitting and constructing this facility, which would receive truck deliveries of DSNY MGP Curbside Recyclables collected in Manhattan for barge transfer to the 30th Street Pier at SBMT for processing, is approximately seven years. Accordingly, the environmental review of this facility is deferred until more detailed design information is available. However, an analysis of the potential for off-site traffic, air quality and noise impacts from directing DSNY's Manhattan Recyclables collection vehicles to this destination was conducted.

1.4.3 Advantages of the Proposed Action – Recycling Facilities

1.4.3.1 Recyclables Processing Facility

The major advantages of the Proposed Action to develop a Recyclables processing facility are that it:

- Commits the City to maintain its Curbside MGP Program over the next 20-years.
- Creates a relationship in which the processor has economic incentives to expand product markets, and thereby increase the net recovery rate for MGP. Historically, DSNY has had considerable difficulty in establishing stable and cost-effective relationships with the contractors that have processed its Curbside MGP, in part due to the practice of contracting for a five-year term with a short-notice cancellation clause. This created economic uncertainty for the contractor and discouraged investments in facility upgrades to improve recovery rates. The 20-year term of the service agreement removes these disincentives and will create a relationship in which the processor has economic incentives to expand product markets and increase the net recovery rate for MGP processed.
- Enhances the opportunity to produce and market new products by recovering materials that are now marginal. The City's Curbside MGP have high proportions by weight of glass, particularly mixed-color broken glass, a material that does not have economic markets. Better technology to be used in the materials processing facility, in addition to aggressive research and development – both afforded by a long-term contract – will address this situation.
- Secures competitive price terms for the City and stabilizes costs over the long term.
- Creates a waterborne transportation network that is consistent with the City's goal of reducing truck traffic. An estimated 85% of the Recyclable materials will be delivered to the new Recyclables processing facility via barge, and 75% will leave post-processing via barge. This is a shift that will help reduce truck traffic on City streets. ~~and improve the local environment.~~
- Creates significant local employment opportunities through creation of an estimated 160 construction jobs and 100 permanent jobs when facility operations commence.

1.4.3.2 Manhattan Recyclables Acceptance Facility

The major advantages of the Proposed Action to develop a Recyclables acceptance facility in Manhattan are that it:

- Eliminates the need for Recyclables collection vehicles to travel from Manhattan to acceptance or processing facilities in other boroughs or New Jersey.

- Facilitates the relocation of the recycled Paper barge operation now based at the West 59th Street MTS to Gansevoort, which will enable the West 59th Street MTS site to be potentially developed for export of Commercial Waste.
- Results in a more equitable distribution of transfer facilities among the City's boroughs.

1.4.4 Alternatives to the Proposed Action

The No Action Alternative to the Proposed Action for Recycling to help develop and contract on a long-term basis with ~~an~~ centralized MGP Recyclables processing facility, built by HNC at the South Brooklyn Marine Terminal, would be the continuation of the status quo arrangement by which MGP Recyclables are delivered to several metropolitan area MGP processing facilities by DSNY collection vehicles pursuant to short-term contracts. The No Action Alternative would not involve the development of a state of the art facility with processing equipment, economies of scale, and the barge transport capability of the HNC centralized processing facility at the SBMT that is expected to improve the economics of MGP recycling. ~~for processing MGP from Curbside collection that would not result in the economic benefits to the Curbside Recycling Program afforded by the Brooklyn Recyclables processing facility.~~

Several other alternatives were considered as a result of a Request for Proposals (RFP), issued by DSNY in 2003 for services to accept, process and market MGP and Paper Recyclables. In addition to the HNC processing facility at the SBMT that is the Proposed Action, DSNY received two other proposals deemed responsive, but lacking certain advantages afforded by the HNC proposal. Therefore, these alternative proposals were not the subject of a detailed environmental review in this FEIS for the following reasons: (i) one proposal would have utilized two locations on Staten Island to receive MGP, but the delivery of MGP from the rest of the City to Staten Island presented logistical and transport problems for DSNY; and (ii) the second proposal offered two sites for acceptance facilities that were in close proximity to each other in Brooklyn, but DSNY delivery to these locations would be less efficient compared to delivery to other facilities more evenly distributed in the City. A third proposal was deemed non-responsive for technical reasons.

The Alternatives –to developing a Recyclables acceptance facility at the site of the former Gansevoort MTS would be continueding delivery of Manhattan MGP to facilities in New Jersey and the Bronx or potentially using another existing MTS facility in Manhattan. The environmental review in this FDEIS of the existing MTSs as Alternatives for Long Term Export evaluates the potential for significant adverse impacts associated with using the existing MTSs for Long Term Export. The potential for impacts associated with use of the existing MTSs as Recyclables acceptance facilities would be less than the impacts analyzed because of the lower number of DSNY collection vehicles associated with delivery of Recyclables to these sites, compared to those associated with delivery of DSNY-managed Waste to these sites. Therefore, no additional environmental review of this Alternative is required.

1.5 Proposed Action – Commercial Waste Management

1.5.1 Existing Conditions

Commercial Waste management is as complex a system as the DSNY-managed Waste counterpart. The volume of Putrescible and Non-Putrescible Commercial Waste managed in the City is even larger, accounting for nearly 75% of the City's total waste stream. Commercial Waste is managed by the private sector through a system of private carters and private transfer stations. Both elements of the systems are subject to regulation – the private carters by the City's Business Integrity Commission (BIC), and the private transfer stations by DSNY and NYSDEC. NYSDEC also regulates registered recycling facilities.

Except for that portion of Commercial Waste carted directly out of the City, waste export occurs through a network of land-based transfer stations, points at which waste from local collection trucks is transferred for long-haul export. These transfer stations are generally located in M3 districts (districts reserved for heavy industry) which are well buffered from residential communities. However, waste trucks traveling to and from these transfer stations often pass through residential communities on their way to the designated truck routes.

Local Law 74 of 2000 (LL74) amended the Administrative Code to require that DSNY contract with a consultant to conduct a comprehensive study of Commercial Waste management in the City. DSNY conducted a series of public meetings in November and December of 2002 to solicit comments, and issued a Draft Study Scope of Work on March 3, 2003 for further public comment. Comments were received and reviewed, and a Final Study Scope was issued on July 31, 2003.

In September 2002, the consultant began work on detailed analyses of a range of Commercial Waste management issues. DSNY submitted the report, including Volumes I through VI of the CWMS, to the Mayor and the City Council in March 2004. The Study extensively characterized the City's Commercial Waste management system, providing information on the quantity of Commercial Putrescible, Non-Putrescible and Fill Material generated in the City, recycled, and disposed in- and out-of-City; the locations and operations of the City's Putrescible, Non-Putrescible and Fill Material Transfer Stations;[7] and the effects of transfer stations located in geographical proximity in certain CDs in the City.

The Study included recommendations involving changes in current practices, laws and regulations affecting the design and operation of privately owned and operated transfer stations in the City. These recommendations addressed improvements in the environmental control systems and practices used at existing permitted transfer stations in the City that have the benefit of improving potential effects associated with the operation of these facilities. The complete Study can be accessed on DSNY's website: www.nyc.gov/sanitation and is also included on a compact disk as Appendix E of the Draft New SWMP. Printed copies of the Study are available at the List of Repositories in Table 1.6-1.

There are currently 58 private waste transfer station facilities in the City with 65 permits. This is down from 220 transfer stations in 1990, shortly after the 1988 increase in tipping fees for Commercial Waste at the Fresh Kills Landfill and at certain City MTSs. Approximately one third of the facilities accept Putrescible Waste, one-third accept construction and demolition (C&D) debris, and one-third accept clean Fill Material (some facilities accept more than one

[7] These types of transfer stations are permitted under DSNY's Operating Rules.

category of materials). As discussed in more detail in the Study, these facilities are located in Manufacturing Districts (M1, M2 and M3), and therefore, are not distributed evenly among the eCity's 59 CDs. For example, Community District 1 in Brooklyn has 14 facilities with 17 permits, while Bronx Community District 2 has 8 facilities and Queens Community District 7 has 5 facilities. At present, ~~only one~~ two ~~facilit~~facilities~~y~~, ~~at~~ Harlem River Yards in the Bronx and 920 East 132nd Street by draying to Oak Point Yard, uses rail to transport putrescible waste out of the City. There are two registered sites for the intermodal transfer of containerized solid waste, where sealed containers may be delivered by truck, and transloaded onto a railcar for further transport without being opened or undergoing any processing.

Two features of the current Commercial Waste management system have served as the focus of recent concern. The first is that Manhattan has no private transfer stations, despite the fact that over 40% of the City's Putrescible Commercial Waste is generated in Manhattan. As a result, although some waste is driven directly out of the City, most of Manhattan's Commercial Waste is driven to another borough before it is exported from the City. Further, because only ~~one~~ two of the City's 19 private Putrescible Transfer Stations exports waste by means other than transfer trailer, the export of waste—not just its collection—creates truck traffic.

1.5.2 Proposed Action – Commercial Waste Management

To achieve a more balanced distribution and reduce effects from Commercial Waste transfer operations in those CDs that currently have the greatest number of transfer stations, the following measures are proposed:

- Make the existing Manhattan West 59th Street MTS site available to private waste management companies to use for the transfer of Commercial Waste collected by private carters in Manhattan. The facility could be: (i) refurbished and used in conjunction with an EBUF; or (ii) redeveloped as a containerization facility.
- Design measures to encourage private carters to deliver Commercial Waste during the 8:00 p.m. to 8:00 a.m. time period to the four Converted MTSs that are elements of the Proposed Action for Long Term Export (Hamilton Avenue and Southwest Brooklyn, Brooklyn; East 91st Street; Manhattan; and North Shore, Queens).
- Negotiate arrangements with the owners/operators of the selected private transfer stations in the Bronx, Brooklyn and Queens that submitted proposals in response to the BQB RFPs and that are potential elements of the Proposed Action to require Commercial Waste (in addition to DSNY-managed Waste) processed at these facilities to be containerized and exported from the project service area by barge and/or rail.

1.5.3 Advantages of the Proposed Action

These Proposed Actions, if fully implemented, would facilitate the City's transition from an almost wholly truck-based waste export system to a predominantly rail- and/or barge-based export system for the City's Putrescible Waste.

1.5.3.1 West 59th Street MTS Site for Commercial Waste Transfer

Developing this site for transfer of a portion of Manhattan-generated Commercial Waste would:

- More equitably distribute the impacts of Commercial Waste transfer among the City's boroughs;
- Reduce the volume of transfer trailer truck traffic in the City;
- Provide the site most proximate to midtown, a major generator of Commercial Waste; and
- Shorten carters' current runtime from the end of their midtown collection route to their tipping locations in other boroughs, resulting in a decline in the overall duration of commercial collection operations and fewer vehicle miles traveled in the City.

1.5.3.2 Commercial Waste Transfer at Four Converted MTSs

The advantages of using the Converted MTSs to containerize Commercial Waste include that it:

- Capitalizes on unused capacity during the hours when private carter collection operations occur. As DSNY would tip during the day and private carters at night, there is minimal potential for conflict in terms of processing both waste streams at the Converted MTSs.
- Potentially removes approximately 178 transfer trailers from the City's streets that would otherwise be transporting waste for export. As containerization facilities, the four Converted MTSs have potentially available capacity for processing up to approximately 3,772 ~~915~~ tpd of Commercial Waste.

1.5.3.3 Containerization and Rail Export from Private Transfer Stations

1.5.3.3 Containerization and Rail Export from Private Transfer Stations

The advantages of requiring private transfer station owners/operators who are containerizing and exporting DSNY-managed Waste by barge and/or rail to also containerize and export by barge or rail any Commercial Waste processed at their respective facilities are that it:

- Reduces outbound transfer trailer traffic from the private transfer stations, thus reducing truck traffic in these communities; and
- Accelerates the conversion of the City's private transfer network towards a barge- and/or rail-based system that will have long-term economic and environmental benefits for the City.

1.5.4 Other Commercial Waste Initiatives

In addition, there are several other related actions that DSNY has taken, or will be taking, with respect to the private transfer station industry and Commercial Waste management that form an important part of the Draft New SWMP, although detailed environmental review necessarily has been or will be conducted separately, because these measures have independent utility or are the subject of ongoing litigation. Many of these measures derive from DSNY's continuing effort to ensure that the Commercial Waste management industry meets applicable regulatory and performance standards while minimizing impacts on residents and the City.

In 2003, DSNY adopted rules to encourage the use of intermodal facilities such as rail yards or port facilities where sealed containers of solid waste may be transloaded for further transport via rail or barge. By providing a process for such facilities to obtain DSNY registrations, DSNY seeks to encourage such intermodal transport and reduce the truck traffic and related impacts associated with long-haul transfer trailer transport of solid waste.

DSNY's regulation of commercial solid waste transfer stations has been the subject of litigation brought both by community groups and ~~by~~ the industry. DSNY adopted temporary rules in 2003 prohibiting the siting of most new transfer stations while the CWMS was being prepared. Following the release of the CWMS in 2004, DSNY has taken certain steps to implement many

of its recommendations and comply with judicial rulings and concerns regarding the need for additional siting restrictions on transfer stations (see DSNY~~'s~~ website, www.nyc.gov/sanitation).

1.5.4.1 New Siting Rules for Transfer Stations

In May 2004, DSNY initiated a rulemaking process~~,~~ that became final on ~~expected to be final by early~~ November 7, 2004, ~~to~~ amending the ~~rules~~ DSNY ~~administers for~~ rules on the siting of private putrescible and non-putrescible transfer stations and for potential expansions of existing facilities. A separate environmental review was undertaken for this rulemaking, which has independent utility from the Draft New SWMP and was motivated, in part, by litigation over the proper interpretation of Local Law 40 of 1990. In brief, the rules ~~will~~ create five categories of siting restrictions that vary by Community District, depending on the number of the City's transfer stations that are currently in each Community District. The rules effectively set a cap on new capacity for any kind of private transfer station in two CDs that currently have the largest number of such facilities: Brooklyn Community District 1 and Bronx Community District 2. Thus, new capacity in such districts would require a corresponding offsetting reduction in permitted transfer station capacity in the same Community District.

In addition, a buffer would be required between a new putrescible transfer station and an existing transfer station. Buffer distance requirements from a new transfer station to sensitive receptors (defined as residence districts, schools, parks and hospitals) ~~would be increased~~ are greater for districts that currently have the highest number of transfer stations. The new rules would generally allow a new transfer station in a light manufacturing (M1) district, subject to buffer requirements and zoning performance standards, as was the case until 1998. However, a new transfer station would not be permitted in an M1 district in a Community District that already has at least three transfer stations in M1 districts. The rules would apply to all applications and include more stringent standards for obtaining a variance. More information on this rule-making is available on DSNY's website at www.nyc.gov/sanitation.

DSNY's transfer station siting rule amendments encourage the use of barge or rail to transport solid waste. Specifically, an applicant would not be prohibited from siting a new transfer station within the buffer distance to another transfer station, if the new facility uses a vessel or rail to transport at least 90% of the waste received. In addition, in obtaining offset waste tonnage for

new capacity to be sited in the two CDs with an overall cap on new capacity, an applicant that uses vessel or rail to transport at least 90% of the waste received could utilize offset tonnage from a different permitted waste type. For example, existing permitted tonnage for C&D debris could be used to offset new Putrescible Waste capacity.

1.5.4.2 New Operating Rules for Transfer Stations

In addition, in August 2004, following certain recommendations outlined in the CWMS, DSNY announced proposed amendments to operating rules for new transfer stations. These rules, which were published in final form on March 17, 2005 and take effect April 16, 2005, were the subject ~~are the subject~~ of a separate environmental review, as they are independent of the Draft New SWMP. The operating rules, which would apply to existing as well as new transfer stations, ~~would~~ require putrescible transfer stations to upgrade odor and dust control and ventilation systems. Non-putrescible transfer stations ~~would~~ have to implement measures to reduce the tracking of dirt offsite, control dust, and ensure that visible air emissions from off-road diesel equipment do not exceed certain opacity standards or leave the property boundary. More information on this rule-making is also available on DSNY's website at www.nyc.gov/sanitation.

1.5.4.3 Enhanced Permit and Inspection Capability

DSNY has stated that it will work with the City Council to amend the Administrative Code to increase the fees charged for annual permits for putrescible and non-putrescible transfer stations. The additional revenue will help pay for additional expertise and training of the inspection staff to enforce air emission standards and to approve and oversee the proper facility use of enhanced odor and ventilation systems, among other things. Such legislation would be the subject of a separate environmental review.

1.5.4.4 Seek to Alleviate Transfer Station Truck Traffic near Residences

In coordination with community groups and the City Department of Transportation (NYCDOT), DSNY proposes to undertake a study of transfer station truck traffic that passes near residential areas in certain parts of the City with the greatest number of transfer stations, to identify practical

opportunities to minimize the impacts associated with such traffic. Such measures might include near-term initiatives such as enhanced enforcement of existing truck route restrictions, improved signage, targeted waste hauling truck prohibitions along designated roadways and/or other steps.

1.5.4.5 Define Authority Needed to Reduce Transfer Station Capacity in Certain Districts

Once ~~DSNY's~~ the Converted MTSs ~~conversion program becomes~~ are operational, DSNY proposes to work with community groups and the transfer station industry to explore, in a systematic way, how legal and regulatory mechanisms, whether under current law or requiring local legislation, might be used appropriately to ~~reduce~~ further reduce the number of transfer stations in areas of the City with the greatest concentration of ~~such~~ those facilities. As appropriate, any necessary environmental review would be undertaken ~~separately~~ prior to taking final action on ~~such a~~ any proposed reduction in transfer station capacity.

1.6 Public Review Process – CEQR and SEQRA

Approval of the Proposed Action will provide the basis upon which the proposed Long Term Export Program and, if applicable, other solid waste management policies or programs, can be implemented. The City's commitment of resources to these programs is predicated upon the findings presented in the F~~D~~EIS that, consistent with social, economic and other essential considerations of state and City policy, and from among the reasonable Alternatives, the Proposed Action is one that minimizes or avoids significant adverse environmental effects to the maximum extent practicable. In addition, any potential significant adverse effects disclosed would be minimized or avoided by incorporating mitigative measures that are identified as practicable (2001 CEQR Technical Manual, pages 1 through 11, Section 270, Agency Findings). Pursuant to CEQR/SEQRA rules and procedures, DSNY is lead agency for the environmental review of the Draft New SWMP; involved agencies with discretionary approval of the Draft New SWMP are the City Council and NYSDEC. The City planning Commission has discretionary approval of the Uniform Land Use Review Procedure (ULURP) applications pending for the Converted MTSs.

1.6.1 Long Term Export

Agencies interested in the Long Term Export Program elements of the Proposed Action and assessments of facilities and services related to that program that are included in the FDEIS are listed below.

1.6.1.1 Federal Agencies

- United States Army Corps of Engineers (USACE)
- United States Environmental Protection Agency (USEPA), Region 2

1.6.1.2 New York State Agencies

- Department of State
- Office of Parks, Recreation and Historic Preservation (OPRHP)
- Office of General Services (OGS)

1.6.1.3 New York City Agencies

- City Office of Environmental Coordination (OEC)
- Department of Environmental Protection (NYCDEP)
- Department of Transportation (NYCDOT)
- City Planning Commission
- New York City Economic Development Corporation (NYCEDC)
- Landmarks Preservation Commission (LPC)
- Department of Health (NYCDOH)
- Department of Parks and Recreation (NYCDPR)

1.6.2 Preparation of the FDEIS

The purpose of the FDEIS is to provide decision makers with an understanding of the potential environmental consequences of the Proposed Action so that they may make an informed decision about the actions they are asked to undertake. In addition, the FDEIS provides the basis to make reasoned comparisons of the Alternatives to the Proposed Action. ~~An~~ The initial step in the Environmental Impact Statement (EIS) process, ~~is~~ the preparation of the Draft Environmental Impact Statement (DEIS) for public comment, has been completed.

A series of Public Scoping Meetings were held between June 15 and July 1, 2004 to solicit comments and concerns from the public and regulatory agencies regarding the proposed approach to evaluation of the Proposed Action (see Section 1.8, Public Outreach Process/Environmental Justice, for a description of the public participation and outreach program). In addition to comments received at the Scoping Meetings, written comments were accepted until July 11, 2004. The Final Scoping Document was revised ~~to address~~in consideration of the public comments received.

~~An issuance of a Notice of Completion of the DEIS is required to initiate consideration of any required permit actions and approvals. A~~ As part of the Environmental Impact Statement (EIS) process, this FEIS was prepared after: (1) a public process extending from October 22, 2004 to January 24, 2005 (a period of 94 days); and (2) eight ~~P~~public ~~H~~hearing(s) on ~~to provide an opportunity for the public to comment on~~ the DEIS, held in the communities potentially affected by the Proposed Action, to solicit comments and concerns from the public and regulatory agencies on the DEIS. Additionally, public hearings on ULURP applications for the four Converted MTSs were held by the Community Boards of the Community Districts potentially affected by these elements of the Proposed Action.

Following the close of the DEIS comment period, all comments received at the public hearing and in writing were reviewed and are addressed in Chapter 40 of this FEIS. This FEIS also includes necessary revisions, additions and clarifications to the document, as well as categorized responses to comments received. Issuance of this FEIS is required for: (1) City Council adoption and NYSDEC approval of the Final New SWMP; (2) City Planning Commission approval of the pending ULURP applications; and (3) approval by the appropriate issuing authorities of other permits required to implement the Proposed Action.

~~will be~~ ~~were~~ ~~held within approximately 30 days of the distribution of the DEIS~~~~during the period of December 1 to December 20, 2004.~~ The FEIS is available at DSNY's website: www.nyc.gov/sanitation. Copies of the ~~D~~FEIS ~~will~~ can be ~~available for viewing~~viewed at ~~DSNY, Bureau of Long Term Export, 44 Beaver Street, 12th Floor, New York, New York, and at the List of~~Public Repositories listed in Table 1.6-1. Compact disks of the FEIS can be obtained by sending a mail or fax request to Assistant Commissioner, Harry Szarpanski P.E., DSNY Bureau of Long Term Export, 44 Beaver Street, New York, New York 10004, fax number (212) 269-0788.

~~Issuance of an FEIS is required for final approval of required permits.~~ These FEIS findings are ~~will be~~ used to support all other public actions and approvals inclusive of the anticipated potential permit actions listed in Chapter 1, Section 1.7 of this FEIS. Additionally, Chapter 2, Section 2.5 provides a table listing the possible applicability of permit requirements to specific sites.

1.7 Required Actions, Permits and Approvals

Potential major permit approvals for the Proposed Action that are known to be required are listed below. If subsequent approvals or permit actions are identified, a determination will be made by DSNY and the respective interested/involved agency(ies) as to what subsequent environmental assessments and determinations are required, if any.

1.7.1 Federal

1.7.1.1 U.S. Army Corps of Engineers

- Section 10 (River and Harbors Act) for structures and work in navigable waters of the United States;
- Section 103 of the Marine Protection Research & Sanctuaries Act;
- Section 404 (Clean Water Act) for discharging of dredged or fill material in waters of the United States; and
- Section 401 (Clean Water Act) Water Quality Certification.

1.7.2 New York State

1.7.2.1 Department of Environmental Conservation

- Article 27, Title 7 (6 NYCRR 360) Environmental Conservation Law solid waste permit to construct and operate a solid waste management facility;
- Article 15, Title 5 (6 NYCRR 608 – Protection of Waters) Environmental Conservation Law permit for the disturbance of a streambed or banks or excavation in or fill of navigable waters;
- Article 15, Title 5 (6 NYCRR 608 – Protection of Waters) Section 401 Water Quality Certification;
- Article 25, (6 NYCRR 661 – Tidal Wetlands Act) Environmental Conservation Law;
- Article 36 (6 NYCRR 500 – Flood Plain Management) Environmental Conservation Law permit for a facility located in a floodplain;
- Article 17, State Pollutant Discharge Elimination System (SPDES) General Permit (Section 402 of Clean Water Act) for stormwater discharges from construction activities; and

- Coastal Zone Consistency Certification (19 NYCRR 600).

1.7.2.2 Department of State

- Article 42 of the State Executive Law;
- Consistency with Federal Coastal Zone Management Act (15 CFR Part 930);
- New York State Office of Parks, Recreation and Historic Preservation (OPRHP); and
- Consultation under Section 106 (National Historic Preservation Act) and New York State Historic Preservation Act Section 14.09 compliance requirements.

1.7.2.3 Office of General Services

- Use of Lands Under Water

1.7.3 New York City

1.7.3.1 City Planning Commission

- Consistency with local Waterfront Revitalization Program (WRP); and
- Conformance with the Uniform Land Use Review Procedure (ULURP) for a Site Selection Action will be required in connection with the development of the four Converted MTSs. ~~at the existing MTS sites~~.

1.7.3.2 Department of Environmental Protection

- Sewer connection permit under Title 24 of the New York City Administrative Code (NYCAC) and Title 15 of the RCNY; and
- Industrial Pre-Treatment Approval.

1.8 Public Outreach Process/Environmental Justice

1.8.1 Introduction

NYSDEC issued policy guidance on Environmental Justice (EJ) and Permitting in March 2003 (EJ Policy). The Policy applies to certain NYSDEC permitting actions where NYSDEC is the

lead agency, including the permits for New SWMP Long Term Export facilities sought by DSNY under 6 NYCRR Part 360. This section describes DSNY's enhanced public participation and outreach program (EJ Program)~~, now underway~~ for the Draft New SWMP Long Term Export facility permitting processes that are part of the Proposed Action under consideration in this document. The EJ Program focuses on: the Public Scoping Meetings held for the Draft New SWMP DEIS; the Public Hearings that DSNY ~~will hold~~ held on the Draft New SWMP DEIS; and the Hearings expected to be held by NYSDEC on the ~~New SWMP facility permits, including~~ permits required to develop the four Converted MTSs~~, and other potential private waste containerization facilities~~.

The EJ Policy is being implemented in the potential EJ Communities that are identified in project area maps appended as Attachment A to the Final Scoping Document. These project area maps were prepared using the USEPA database, as prescribed in the EJ Policy, to identify the census block groups with populations that meet the EJ Policy criteria (EJ Community). The project area maps also identify the facilities in the project area that would be included in an environmental burden analysis conducted in the event that significant impacts from the project are found. The maps also provide information about the environmental review analyses ~~to be~~ provided in ~~the~~ this FD~~D~~EIS. The EJ Communities would be the focus of the EJ Program described herein. For reference, a copy of the NYSDEC EJ Policy is included as Attachment B to the Final Scoping Document.

The EJ Policy is specifically intended to ensure that the Draft New SWMP Long Term Export facility permitting processes and the environmental review for the Draft New SWMP Long Term Export facilities that are part of the Proposed Action consider EJ issues and promote the participation of EJ Communities in this process. Both the Draft New SWMP, and the facilities to be developed as part of the Draft New SWMP is implemented, are subject to environmental review pursuant to CEQR/SEQRA. The Converted MTSs also require permits and other authorizations that would be issued by NYSDEC, the USACE and other parties.

1.8.2 The EJ Program

DSNY, as lead agency for the FD~~D~~EIS for the Proposed Action, is implementing an EJ Program to provide opportunities for citizens to be informed about and involved in the review of the Long Term Export facility permitting portions of the Proposed Action. The EJ Program described

herein includes enhanced public outreach, information dissemination and community meetings accessible to each EJ project area. Upon completion of these activities, including outreach that will be implemented after the issuance of this FEIS, DSNY will submit a written certification to NYSDEC that it has complied with the outreach plan, and ~~will submit~~ a report detailing the activities that occurred~~ing~~ in each EJ project area.

1.8.2.1 Public Scoping Phase

DSNY, as a basis for enhancing the participation of EJ Communities in Public Scoping Meetings, has completed the following:

- Identified stakeholders to the EJ projects in the Proposed Action (including Alternatives to the Converted MTSs);
- Distributed and posted written information on the EJ projects in the Proposed Action (including Alternatives to the Converted MTSs) and related permit review processes in an easy-to-read format, and translated, as appropriate;
- Complied with the CEQR timetable for advance notice of the Scoping Meetings;
- Established easily accessible document repositories near or in potential EJ Communities at which draft Part 360 Solid Waste Facility Permit applications for the Converted MTSs are available for review by the public;
- Conducted 10 Public Scoping Meetings in project areas potentially affected by the Proposed Action or Alternatives;
- Published all comments received; and
- Issued a summary of comments and responses in Attachment C of the Final Scoping Document.

Because nine of the ten potential Long Term Export facility project areas for the Proposed Action are located within EJ Communities, DSNY implemented the EJ Program in all ten project areas, beginning with Public Scoping Meetings in locations accessible to each of the EJ project areas. Locations for written information include, but are not limited to:

- Official document repositories;
- Public libraries;
- Community liaison offices within pertinent state and federal agencies;
- Borough halls; and

- Legislative offices.

In addition, the following toll-free hotline ~~has been~~ was established: 1-888-NYC-SWMP. Messages are ~~to be~~ being documented and substantive comments considered by DSNY.

~~In the same time frame as the publication of the DEIS, DSNY will submit final permit applications for the Converted MTS projects,[8] addressing all comments received in consultation with NYSDEC. The final permit applications for the Converted MTS projects were placed in the document repositories for public review, along with any NYSDEC Notices of Complete Application or Notices of Hearing that are issued subsequent thereto.~~

1.8.2.2 DEIS Publication Phase

The DEIS ~~will identify~~identified on project area maps the facilities that potentially place an environmental burden on the EJ Community. The facilities and land uses shown on the project area maps, in addition to the Proposed Action Long Term Export facilities and Alternatives, include private waste transfer stations and major industrial or transportation facilities (including rail yards and DSNY garages) or utilities infrastructure (such as power plants, substations, water pollution control plants [WPCPs], etc.). The maps are not intended to imply that all facilities have the same potential effects on their environs, however, or that potential effects are identical to those impacts predicted for the Proposed Action Long Term Export facilities and Alternatives. The maps serve as a starting point to provide the community with information that may be relevant to the EJ process. As such, they are not intended to depict the type or extent of any environmental burden in the EJ Community.

If potentially significant adverse impacts ~~are~~ were disclosed for a Proposed Action Long Term Export facility in the DEIS, appropriate evaluation of existing facilities in the EJ project area that may impose similar environmental burdens ~~will be~~would have been presented.

On issuance of the DEIS, enhanced public participation and outreach efforts ~~will~~ continued to provide a flow of up-to-date information, ~~that will include~~ including the following:

- **One-page topical fact sheets, including frequently asked questions (FAQs):** Distributed and posted on the DSNY website and translated, at a minimum, into Spanish. Other dominant non-English languages ~~will be~~ were identified through conversations with stakeholders and materials ~~will be~~were translated, as appropriate.
- **Flyers/mailings:** Copies of mailings and public notices ~~will be~~were posted throughout potential EJ Communities. Mailings ~~will be~~were distributed to stakeholders after the Public Scoping Meetings and prior to the DEIS Hearing (three mailings in total).
- **Public notices:** These notices ~~will be~~were published in mainstream and local newspapers read both by the general public and by residents in potential EJ Communities. Lists of weekly and monthly newspapers ~~will be~~were compiled with the assistance of stakeholders and CD offices.
- **Electronic/websites:** The DSNY website (www.nyc.gov/sanitation) ~~will~~ posts project-related documents and information. ~~Other websites (including the New York City Environmental Justice Alliance, www.nyceja.org) will be invited to link to the DSNY website.~~

Public information materials are tailored to each EJ Community and: (1) describe the facility permitting activities that are part of the Proposed Action; (2) describe the design and operation of the Proposed Action Facilities, including Alternatives considered; (3) answer FAQs; and (4) present other pertinent information on the permitting process.

1.8.2.3 NYSDEC Permit Review Process Information Dissemination

Using the DEIS Hearings as an opportunity to inform the public about the NYSDEC permit review process, the format for the DEIS Public Hearings for the Converted MTSs was augmented with Power Point presentation slides and handouts that contained information about the state environmental permit applications (solid waste management facility, air and marine resources) for the Converted MTSs under review by the NYSDEC, and available at the public repositories for the Converted MTS EJ project areas. The slides provided information about the NYSDEC permit review process and details on how and when, as part of DSNY's DEIS public comment period, to submit comments on the state environmental permit applications provided for review in the public document repositories. A handout was distributed that expanded on the

[8] ~~Development of permits (where applicable) for the private transfer stations that are part of the Proposed Action is the responsibility of the companies selected to develop these facilities. These permitting activities will proceed on s a separate schedule from the permitting of the Converted MTSs.~~

information in the Power Point presentation and provided targeted information for each Converted MTS EJ project area on the location, contact information, and hours for its public document repository.

DSNY Uniform Land Use Review Procedure (ULURP) applications for each of the Converted MTSs were the subject of public hearings in January 2005 in the community boards in which the Converted MTSs are proposed to be sited. DSNY's presentation included information about the NYSDEC permit review process and the availability and contents of the state environmental permit applications on file for each of the Converted MTSs. Handouts that described the permit review process were provided to the hearing attendees. The DSNY presentations were followed by question and answer sessions at which attendees were given the opportunity to ask questions about the NYSDEC permit review process and DSNY's state environmental permit applications for the Converted MTSs.

These Permit Review Process Informational Meetings/ULURP Hearings were also the subject of Public Notices published as display advertisements in local newspapers for the Converted MTS communities in the last week of December 2004, including in Our Town (proposed East 91st Street Converted MTS, Manhattan) and the College Point/Whitestone Courier (proposed North Shore Converted MTS, Queens). A flyer targeted to each Converted MTS community was mailed to stakeholders for these communities in the last week of December 2005. The flyer provided information on the: (1) NYSDEC permit review process; (2) DSNY's state environmental permit applications on file and under review by NYSDEC; (3) public document repositories for the Converted MTS community; and (4) an invitation to the Permit Review Process Informational Meeting/ULURP Hearing held by the affected community boards. The EJ stakeholder lists were expanded to include those who provided comments on, or attended the Permit Review Process Informational Meetings/ULURP Hearings.

1.8.2.43 ~~Joint Public~~Permit Hearing Phase

The outreach ~~documents~~materials ~~have been and~~ will continue to be distributed widely through various mailings ~~and the DEIS Public Hearings that will be held within or near the~~to potential EJ

~~Community~~ Communities ~~where the Proposed Action facilities~~ in which the four proposed Converted MTSs would be located. These hearings will be ~~Joint Hearings~~ held ~~with the participation of~~by NYSDEC and ~~also invite~~will provide an opportunity for public comment on the Part 360 Solid Waste Facility Permit and other permit applications that will be before NYSDEC for consideration. The ~~Joint H~~ permit hearings will also be the subject of enhanced, targeted outreach that will comply with CEQR requirements. (Note that any permitting actions for those private transfer stations that are part of the Proposed Action will proceed on a separate schedule.) ~~It is anticipated that, after DEIS publication and prior to the DEIS Hearing, NYSDEC would issue Notices of Complete Permit Applications for the Converted MTSs that are part of the Proposed Action.~~ Key stakeholders ~~will be~~were informed of the DEIS publication, will receive notice of this FEIS, and will be informed of the ~~Joint Hearings~~ permit hearings no fewer than two weeks in advance.

This page intentionally left blank.

CHAPTER 2 DESCRIPTION OF FACILITY SITES

2.1 Introduction

2.1.1 Overview

This chapter describes the sites and operations for which the results of environmental reviews are presented in Chapters 4 through 31. Sections 2.2 through 2.4 describe each site and the facility considered for that site.

Most site descriptions contain a Site Location figure that identifies the approximate boundaries of the site and shows the surrounding neighborhood, and a Facility Footprint figure that provides an aerial view of the existing site and, where applicable, a footprint of the facility superimposed on the site. A cross-section view of the proposed processing building interior and a gantry crane section view ~~is~~ are also included, where applicable. These graphics are provided to facilitate the readers' understanding of existing site conditions and any changes that would occur with development of the facility. Renderings of the Proposed Plan Converted MTS's are also included. The site description also identifies the approximate distance of residential districts, schools and parks from the site. Zoning maps and related materials, as well as detailed information on schools and parks are in subsections of the environmental review chapters on each site. The sites under consideration may include multiple parcels under varied ownership and may extend beyond the property boundaries of parcels on which the subject facility is located. For purposes of analysis, the primary and related parcels are considered a single entity.

The site descriptions are grouped into the following sections:

- Section 2.2 presents descriptions of the Proposed Plan Facilities for the Long Term Export Program, subdivided into sites where: (1) Converted MTSs would be developed (along with site descriptions for support facilities that are subject to environmental review, such as the 65th Intermodal Yard[1] and the Harlem River Yard

[1] Note that the Converted MTSs may use other intermodal facilities than those noted here to transload containerized waste to railcars or coastal barges. These other intermodal facilities exist and do not require new or modified permits in order to service barge deliveries of DSNY-managed Waste. Although DSNY issues permits to intermodal facilities that handle containerized waste, the permit is a ministerial action not subject to environmental review under DSNY's Rules.

Barge to Rail Intermodal Yard); and (2) existing or new private transfer stations would be used, and modified or developed if necessary, to export containerized waste by barge or rail[2]. If a private transfer station's intermodal facility is located on a separate site, that site is also subject to environmental review and the description of that intermodal site is incorporated into the respective transfer station site description.

- Section 2.3 presents descriptions of the Proposed Plan Recycling Facilities for acceptance and/or processing of DSNY's Curbside Recyclables[3].

- Section 2.4 presents descriptions of Alternative sites and facilities considered for the Long Term Export Program.

Table 2.1-1 lists all of the facilities in each of the above referenced categories that are reviewed in this FDEIS or part of the New SWMP, and the wasteshed served by each facility. Note that for both the Bronx wasteshed and the Brooklyn CD 1, 3, 4, and 5 wasteshed, two private Transfer Stations are designated in each respective wasteshed as Proposed Plan Facilities. DSNY is undertaking negotiations on the terms of a 20-year Service Agreement with the companies proposing these respective sites. The outcome of the negotiations for a service contract in each wasteshed would result in a contract award to one or both companies for all, or a portion of, the waste generated in each wasteshed.

This chapter also addresses the potential applicability of the major permits referenced in Section 1.6 to the individual sites described in Sections 2.2, 2.3 and 2.4. The potential major permitting requirements for all of these sites are summarized in Section 2.5.

---

[2] These facilities are designated pursuant to an evaluation of proposals received in response to three Requests for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from the Bronx, Brooklyn and Queens, respectively, (BQB RFPs) conducted by DSNY.

[3] Note that pursuant to Title 6 of the New York Codes, Rules and Regulations (NYCRR) Sections 360-12.1 and 1.8(h), the New York State Department of Environmental Conservation (NYSDEC) authorizes recycling facilities by registration. Accordingly, recycling facilities conforming to this regulation are exempt from environmental review for purposes of solid waste facility permitting. However, the construction-related activities, such as dredging and pier construction, require permits and are subject to environmental review. Furthermore, the potential traffic, off-site air and off-site noise impacts that would be associated with changes in the delivery of Curbside Recyclables by DSNY collection vehicles from current destinations to a new facility(ies) are also evaluated in this FDEIS.

Table 2.1-1
Proposed Plan Facilities and Alternatives

Facility Type	Owner, Facility Name, and Address	Community District	Wasteshed Served – Community Districts
Proposed Plan Facilities – Long Term Export			
Converted MTS	DSNY Hamilton Avenue Converted MTS, Hamilton Avenue at Gowanus Canal, Brooklyn	Brooklyn 7	Brooklyn CDs 2, 6, 7, 8, 9, 10, 14, 16, 17 and 18

Existing MTS	DSNY, East 91st Street MTS, 91st Street and York Avenue, Manhattan	Manhattan 8	Manhattan CDs 5, 6, 8 and 11
Existing MTS	DSNY North Shore MTS, 31st Avenue and 122nd Street, Queens	Queens 7	Queens CDs 7 through 14
Truck-to-Rail TS	Waste Management, 215 Varick Avenue Transfer Station, 215 Varick Avenue, Brooklyn	Brooklyn 1	Brooklyn CDs 1, 3, 4 and 5
Intermodal Yard	Steel Style Inc. 401 South Water Street New Windsor, New York	N/A	N/A

Notes for Table 2.1-1 :

(1) The 52nd Street Barge Staging Area historically served the existing MTSs as a location where barge movements between individual MTSs and Fresh Kills could be staged. The 52nd Street Barge Staging Area may be used for temporary staging of barges between the Converted MTSs and various intermodal destinations and storage of marine supplies.

(2) Two intermodal barge-to-rail facilities, one at Harlem River Yard and one at the 65th Street Rail Yard, may be constructed as transload facilities to transfer containers between the Converted MTSs and railheads. DSNY issues a non-discretionary permit to intermodal facilities handling containerized waste that are not subject to environmental review. However, the USACE Section 10/404 permits and the NYSDEC Article 15/25 permits pertaining to waterfront construction are subject to environmental review. Note that there are other existing intermodal facilities that may be used for intermodal transfer of containers from the Converted MTSs.

(3) Pending the outcome of negotiations between DSNY and Waste Management, the Review Avenue Transfer Station would be modified to operate as either a truck-to-barge or a truck-to-truck-to-rail facility.

(4) The Essex County Resource Recovery Facility (RRF) is a permitted and operating waste-to-energy facility in Newark, New Jersey. As such, the facility itself is not subject to environmental review in this FDEIS. DSNY-managed Waste would be delivered in collection vehicles to this facility or via hopper barges from the existing MTSs if an enclosed barge unloading facility (EBUF) were to be developed in the vicinity of the Essex County RRF some time in the future. The routing of DSNY collection vehicles leaving the City is subject to environmental review and is reported in Chapter 16 of this FDEIS.

(5) The Staten Island Transfer Station was approved in the 2000 SWMP, based on an environmental review in the 2000 Plan FEIS. The facility is fully permitted and under construction. It is not reviewed in this FDEIS but is listed because it is part of the New SWMP.

(6) Both the East 132nd Street Truck-to-Truck-to-Rail Transfer Station in the Bronx and the Review Avenue Truck-to-Truck-to-Rail Transfer Station in Queens would dray containers between the respective transfer stations and intermodal rail yards that are in the project service areas, but not at the same sites as the transfer stations. These intermodal yards are existing facilities that would receive non-discretionary permits from DSNY for handling solid waste and, as such, are not subject to environmental review. However, the movement of containers on tractor chassis between the transfer stations and the intermodal yards is subject to an environmental review that is reported in this FDEIS.

(7) This 30th Street Pier at SBMT is a complex of facilities that would be designed to receive and process DSNY Curbside Recyclables. Curbside Recyclables collected in Brooklyn would be delivered by truck to this facility. Curbside Recyclables from other boroughs would be delivered by barge. Recyclables would be transferred from this facility by barge. As a recycling facility, it is not subject to regulation as a solid waste facility. However, the waterfront construction requires USACE Section 10/404 permits and the NYSDEC Article 15/25 permits that are subject to environmental review.

(8) The timetable for designing, permitting and constructing this facility, which would receive truck deliveries of DSNY MGP Curbside Recyclables collected in Manhattan for barge transfer to the 30th Street Pier at SBMT for processing, is approximately seven years. Accordingly, the environmental review of this facility is deferred until more detailed design information is available.

(9) These are existing facilities that currently receive truck deliveries of DSNY Curbside Recyclables for transfer by barge to a processing facility. As such they are not subject to environmental review and are listed here to indicate that they are facilities included in the New SWMP.

2.1.2 General Information, Plan Policies and Key Assumptions – Proposed Plan Long Term Export Facilities

All the Proposed Plan Facilities and Alternatives reviewed in this FDEIS would export DSNY-managed Waste in containers by barge or rail to out-of-City disposal sites.

All of the Converted MTS sites that are Proposed Plan Facilities are the locations of existing MTSs that would be replaced by a Converted MTS designed to containerize waste at the same site. Except for the Southwest Brooklyn site, the existing MTSs at these locations will be demolished as an element of the Proposed Action. Three Converted MTS sites[4] also contain existing incinerators—Southwest Brooklyn, Greenpoint and Hamilton Avenue. These incinerators are in the process of being demolished. These demolitions are separate actions with independent utility that have been subject to environmental review. Each Converted MTS and private transfer station in the Proposed Plan would serve a discrete wasteshed that is identified in Table 2.1-1 and in the respective site description.

2.1.2.1 General Design Features:

The four Converted MTSs that are Proposed Plan Facilities have a common three-level processing building design. Collection vehicles enter a tipping floor at the uppermost level and tip loads of waste onto the second-level loading floor approximately 12 feet below. On the loading floor, waste is sorted and pushed by front end loaders through slots in the floor slab located directly over intermodal containers, located on the first level inside the processing building. A tamper device working from the loading floor evens and densifies the waste in the containers, which are then lidded with leak-proof gasketed covers and moved by trolley to the external pier level of the facility. A gantry crane on the pier loads/unloads full/empty containers on/off of a flatbed barge moored to the pier. Each barge has a capacity for 48 containers. Tug

[4] The Hamilton Avenue and Southwest Brooklyn Converted MTSs are Proposed Plan facilities. The Greenpoint Converted MTS is an Alternative.

boats move full/empty barges directly to/from an out-of-City disposal site[5] or between the Converted MTS and an intermodal transload facility where they are loaded onto railcars or a larger barge for transport to a disposal facility.

The intermodal containers are approximately 20 feet long, 12 feet high and 8½ feet wide. They are capable of holding approximately 62 cubic yards of refuse. The density of the waste entering the container is approximately 450 pounds per cubic yard. Tamping of the waste in the container is expected to compact the waste to approximately 700 pounds per cubic yard. On average, it is estimated that each container will contain approximately 22 tons of waste.

Each Converted MTSs has four loading slots for containers. Typically, two slots would be active during periods of average waste delivery and three slots active during peak waste deliveries. One loading slot would be maintained as a spare for flexibility and redundancy within the system. Under peak operating conditions, the Converted MTS design[6] would enable ten containers to be filled within an hour using three out of four loading slots, equating to an hourly throughput rate of 220 tons.

Subject to the outcome of negotiations between DSNY and the proposers selected pursuant to the MTS Containerization RFP, containerized waste will be transported by barge from the Converted MTSs directly to: (i) a disposal site; or (ii) intermodal terminals in the New York harbor region, where the containers will be transloaded to railcars or a larger barge for transport to an out-of City disposal facility. The intermodal yards would be either existing facilities not subject to environmental review or a modified or new facility that is reviewed in this FDEIS.

[5] The procurement of transport and disposal arrangements whereby private companies would service the Converted MTSs was the subject of a DSNY Request for Proposals to Transport and Dispose of Containerized Waste from the Converted MTSs. DSNY has completed an evaluation of these Proposals but definitive contractual arrangements for transport and disposal services have not been negotiated.

[6] Due to site constraints, the design of the West 59th Street Converted MTS differs substantially from the other Converted MTSs. For details, see the site description in Section 2.4.

This FDEIS incorporates the results of a review[7] of the potential environmental impacts associated with containerizing commercial waste from the Converted MTSs and exporting it to an out-of-City disposal facility by barge or rail. This environmental review concludes that varying quantities of commercial waste can also be processed at each of the ~~converted~~ Converted MTSs without significant adverse impacts.

The design and operation of each of the Proposed Plan private transfer stations varies. At the Harlem River Yard and 78 Scott Avenue-594 Scholes Street facilities, containerized waste would be loaded onto on-site rail cars. At the East 132nd Street and Review Avenue (truck-to-rail option[8]) facilities, waste would be containerized at the transfer station and drayed to an intermodal facility located within the same wasteshed as served by the facility. At the 485 Scott Avenue and the Review Avenue (truck-to-barge) facilities, containers would be loaded on site onto flatbed barges for shipment to another intermodal transfer facility. More specific details are provided in each site description.

DSNY's BQB RFPs established a policy objective of requiring private transfer stations that are awarded DSNY Long Term Export Contracts to also export by barge or rail any commercial waste they process at such a facility. DSNY's ability to achieve this policy will be determined in future negotiations between the DSNY and the BQB Proposers.

All of the private Transfer stations included as Proposed Plan Facilities are existing permitted facilities. With the exception of HRY Truck-to-Rail TS,[9] these transfer stations would require varying types of modifications. These modifications may involve both expansion of existing permitted capacities and physical changes to the site and facilities to enable containerization and barge or rail export.

---

[7] See Volume III, Commercial Waste Management Study, Summary Report: Commercial Waste Processing and Analysis of Potential Impacts, included as Appendix D to this FDEIS.

[8] See Note #6 in Table 2.1-1 on the environmental review status of these facilities.

[9] Note that the Harlem River Barge-to-Rail Intermodal Yard is a new facility (separate from the HRY Truck to Rail TS) that would transload containers delivered from the Converted MTSs from barge to rail.

2.1.2.2 Capacities of Converted MTSs in the ~~Proposed~~ New SWMP

To define the average and peak hourly capacity parameters for design of the Converted MTSs,~~,~~ historical data regarding truck and tonnage arrival rates from FY 1998 were evaluated and analyzed. Based on this analysis, it was determined that a Converted MTS would be designed with a tipping floor to accommodate 30 collection vehicles per hour and a loading level to process and containerize 220 tons of MSW per hour. If the facility were to operate at full capacity over an entire day (that is 3 shifts with productivity of 6.5 hours per shift) it would process 4,290 tons of waste. Under normal or average conditions, the Converted MTS would not approach this level of processing.

For this F~~D~~EIS, scale-house data from 1998 (1997 in the South Bronx) were used to identify the Average Peak ~~Daily tonnage~~ton per day (average of the highest day in each of 52 weeks – typically Monday or Tuesday). A 20% contingency was applied to that Average Peak ~~Daily Tonnage~~ ton per day to allow for fluctuations in waste deliveries. The purpose of applying this contingency was to build in an element of conservatism in the environmental review. In addition, each Converted MTS was evaluated for the capability to receive deliveries of commercial waste as determined in the Commercial Waste Study mandated by Local Law 74 (LL74) of 2000.[10] This evaluation assumed that commercial waste deliveries were limited to the hours of 8:00 p.m. to 8:00 a.m. to avoid conflicts with processing of DSNY-managed Waste, which is primarily collected and delivered in the 8:00 a.m. to 8:00 p.m. time period. This evaluation also considered the noise impacts of collection vehicle traffic passing sensitive receptors located on truck routes and local streets used to access the Converted MTSs. At several Converted MTSs the evaluation identified hours, typically the quietest nighttime hours, during which it would be necessary to limit commercial collection vehicle traffic to avoid noise impacts. Accordingly, the tonnages of commercial waste that are shown as containerized at certain Converted MTSs reflect reduced deliveries to avoid noise impacts at sensitive receptors (typically residential buildings on the routes leading to an MTS or on lots located near the

[10] See Volume III, Commercial Waste Management Study, Summary Report: Commercial Waste Processing and Analysis of Potential Impacts, included as Appendix D to this F~~D~~EIS.

Converted MTSs). This FDEIS is not definitive on the issue of processing commercial waste at the Converted MTSs, however, because the feasibility of exporting commercial waste from the Converted MTSs is primarily driven by economic and institutional factors that would be addressed in policy measures to facilitate the use of these facilities by commercial carters that would be adopted in the Proposed New SWMP.

Although the design capacity of the Converted MTSs is 4,290 tpd,[11] Table 2.1-2 presents expected average throughput capacities at the Converted MTSs in the Proposed New SWMP for DSNY-Managed managed Waste and Commercial Waste. It also shows the Average Peak Day tonnagetons per day with including a 20% contingency that is used in this FDEIS analyses for purposes of conservatism. There would be occasions, subject to permit limits, when the full design capacity of the Converted MTSs would be required to deal with upset conditions in the City's waste management system. The classic example of this is a snow emergency. Also, unanticipated outage conditions in one element of the system could require temporary shifts in waste deliveries among the Converted MTSs.

Table 2.1-2
Expected Converted MTS Average Throughputs
Proposed Draft New SWMP Facilities

Converted MTS Location	DEIS FEIS Evaluated Off-Site Average Peak Day with Contingency TPD	Commercial Tonnage (Noise Constrained) TPD	Total
Hamilton Avenue	2,248	1,306 1,274	3,554 3,522
SW Brooklyn	1,388	828 718	2,216 2,106
East 91st Street	1,093	780	1,873
North Shore	2,672	1,000	3,672

[11] The West 59th Street Converted MTS in Manhattan has a design capacity of 2,145 tpd because of a unique site configuration.

~~2.1.2.2~~ 2.1.2.3 *Capacities of Private Transfer Stations*

All but one[12] of the seven private transfer stations included in the Proposed Plan or considered as Alternatives is an existing facility. Of the five existing facilities, four would require permit modifications to facilitate barge or rail export and/or expansions of their existing permitted capacities. Several of these facilities have been the subject of environmental reviews in recent years. Where past environmental reviews have been performed, it is possible to limit scope of the environmental review that is required in this F~~D~~EIS. Table 2.1-3 provides a summary of the permitted status of these facilities, proposed capacity expansions (if applicable), other required permit modifications (if applicable), and DSNY wastesheds served. It also includes the average peak tpd of DSNY-managed Waste deliveries assumed in the environmental review, and the tpd capacities evaluated in this F~~D~~EIS for both on- and off-site potential impact analyses, taking into account the applicability of prior environmental reviews.

[12] Meserole Street Truck to Rail TS would be a new facility and was considered as an Alternative.

Notes:

(1) Approval of currently permitted capacities at Harlem River Yard, considering the on-site effects of processing DSNY-managed Waste, was based on Negative Declarations in prior EAS reviews. Therefore, no additional review is required.

(2) This is the potential tpd increment between the average of what is currently exported from the Harlem River Yard and, pending the outcome of contract negotiations between DSNY and the company, the potential to export all Bronx waste from this site.

(3) Approval of currently permitted capacities at East 132nd Street, considering the on-site effects of processing DSNY-managed Waste, was based on Negative Declarations in prior EAS reviews.

Notes for Table 2.1-3 (continued)

(4) This is the potential tpd increment between the average of what is currently exported from East 132nd Street and, pending the outcome of contract negotiations between DSNY and the company, the potential to export all Bronx waste from this site.

(5) The export of containers by barge from 485 Scott Avenue would reduce out-bound transfer trailer impacts, thus reducing impacts associated with on-site traffic. Details on the barge loadout design will be developed by Waste Management and may require a supplemental EIS in the future to support required permit modifications.

(6) 485 Scott Avenue currently provides Interim Export service to DSNY for the same wasteshed, based on a Negative Declaration in a prior EAS review. Under Long Term Export, the number of outbound truck trips would be less, reducing the potential impacts. Therefore, no additional review is required.

(7) 38-50 Review Avenue currently provides Interim Export service for the same Queens wasteshed. However, the increment in proposed permitted capacity and development of a container-to-barge loadout design will require a new environmental review.

(8) This is the potential tpd increment between the average of what is currently exported from the Review Avenue TS and, pending the outcome of contract negotiations between DSNY and the company, the potential to export Queens waste from CDs 1through 6 from this site.

2.2 Site Descriptions – Proposed Plan Facilities Long Term Export

2.2.1 Hamilton Avenue Converted MTS, Brooklyn

2.2.1.1 Description of Existing Site

The existing Hamilton Avenue MTS site is located off of Hamilton Avenue, at the mouth of the Gowanus Canal in Brooklyn. The site is bounded by the elevated Gowanus Expressway to the north and east, 17th Street to the south and the Gowanus Canal to the west. Figure 2.2.1-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 625 and Lot 2, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

The gross acreage of the DSNY-owned lot is approximately 7.4 acres and consists largely of upland. In addition to the existing MTS, the site is also occupied by other existing DSNY facilities, including the former Hamilton Avenue incinerator. A contract has been awarded to demolish the incinerator and work is commencing; an environmental remediation program was conducted prior to demolition. The Hamilton Avenue MTS site is roughly triangular in shape. The northeastern boundary of the site follows the configuration of the elevated Gowanus Expressway and is approximately 650 feet in length. The southern boundary of the site is approximately 850 feet in length. The western side of the site is approximately 225 feet in length and follows the Gowanus Canal shoreline.

The site is located within an M3-1 zoning district, which allows for heavy industrial uses. This district is bounded by Gowanus Canal and Bay to the north and northwest and the Gowanus Expressway/Hamilton Avenue and 3rd Avenue to the east and southeast. This M3-1 zoning district extends to the south, terminating at 58th Street. The M3-1 zone is bounded by M1-2 and M2-1 zones to the north of the site, which allow for light and medium industrial uses, respectively. To the east and south of the site, the M3-1 zone is bounded by an M1-2D zoning district, which allows residential uses with the authorization of the City Planning Commission.

Site delineations are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Further east and south of the site are the R6 and R5 zoning districts that characterize the Gowanus/Sunset Park neighborhoods. North and west of the site, in Red Hook, is another M3-1 zoning district that follows the north side of the Gowanus Canal into New York Bay.

The site is bordered by transportation and municipal functions on the northeast and eastern edges and commercial activities on the south side. An active City Department of Transportation (NYCDOT) asphalt plant and storage yard is located northeast of the site. Hamilton Avenue, a heavily-traveled arterial, and the elevated Gowanus Expressway define the eastern boundary of the site, and a large, two-story parking lot/garage associated with a Home Depot on 19th Street borders the site on the south side. Various businesses providing automotive services and warehouses are located on the northeastern side of Hamilton Avenue, including DSNY's Brooklyn 2 Garage. A new Lowe's Home Improvement store opened earlier this year on the Gowanus Canal near 12th Street, a few blocks north of the site.

For the area between ¼-mile and ½-mile of the site, large-lot industrial uses line both sides of Gowanus Bay and Canal southwest and northeast of the site. The area southeast of 3rd Avenue, in Park Slope, is almost exclusively residential, with ground-floor commercial uses located on the avenues. The large Red Hook Houses complex is located west of Clinton Street, between Lorraine Street and West 9th Street, where it dominates the northwestern portion of the ¼-mile to ½-mile area. Vacant lots and large parkland areas surround the complex. A small portion of the large Carroll Gardens/South Brooklyn (Gowanus) neighborhood is included in the area northwest of the canal.

There are no City, state or nationally designated landmarks or historic districts within ½-mile of the site, or archaeological resources on the site.

2.2.1.2 Hamilton Avenue Converted MTS

The Hamilton Avenue Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.2.1-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the Converted MTS superimposed on the site. Figure 2.2.1-3 illustrates the final rendering of the Hamilton Avenue Converted MTS. Figures 2.2.1-~~3~~ 4, -5 and -6 (Plan ~~and~~ View, Section View, and Gantry Section View) shows the processing building interior and details of the gantry cranes.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

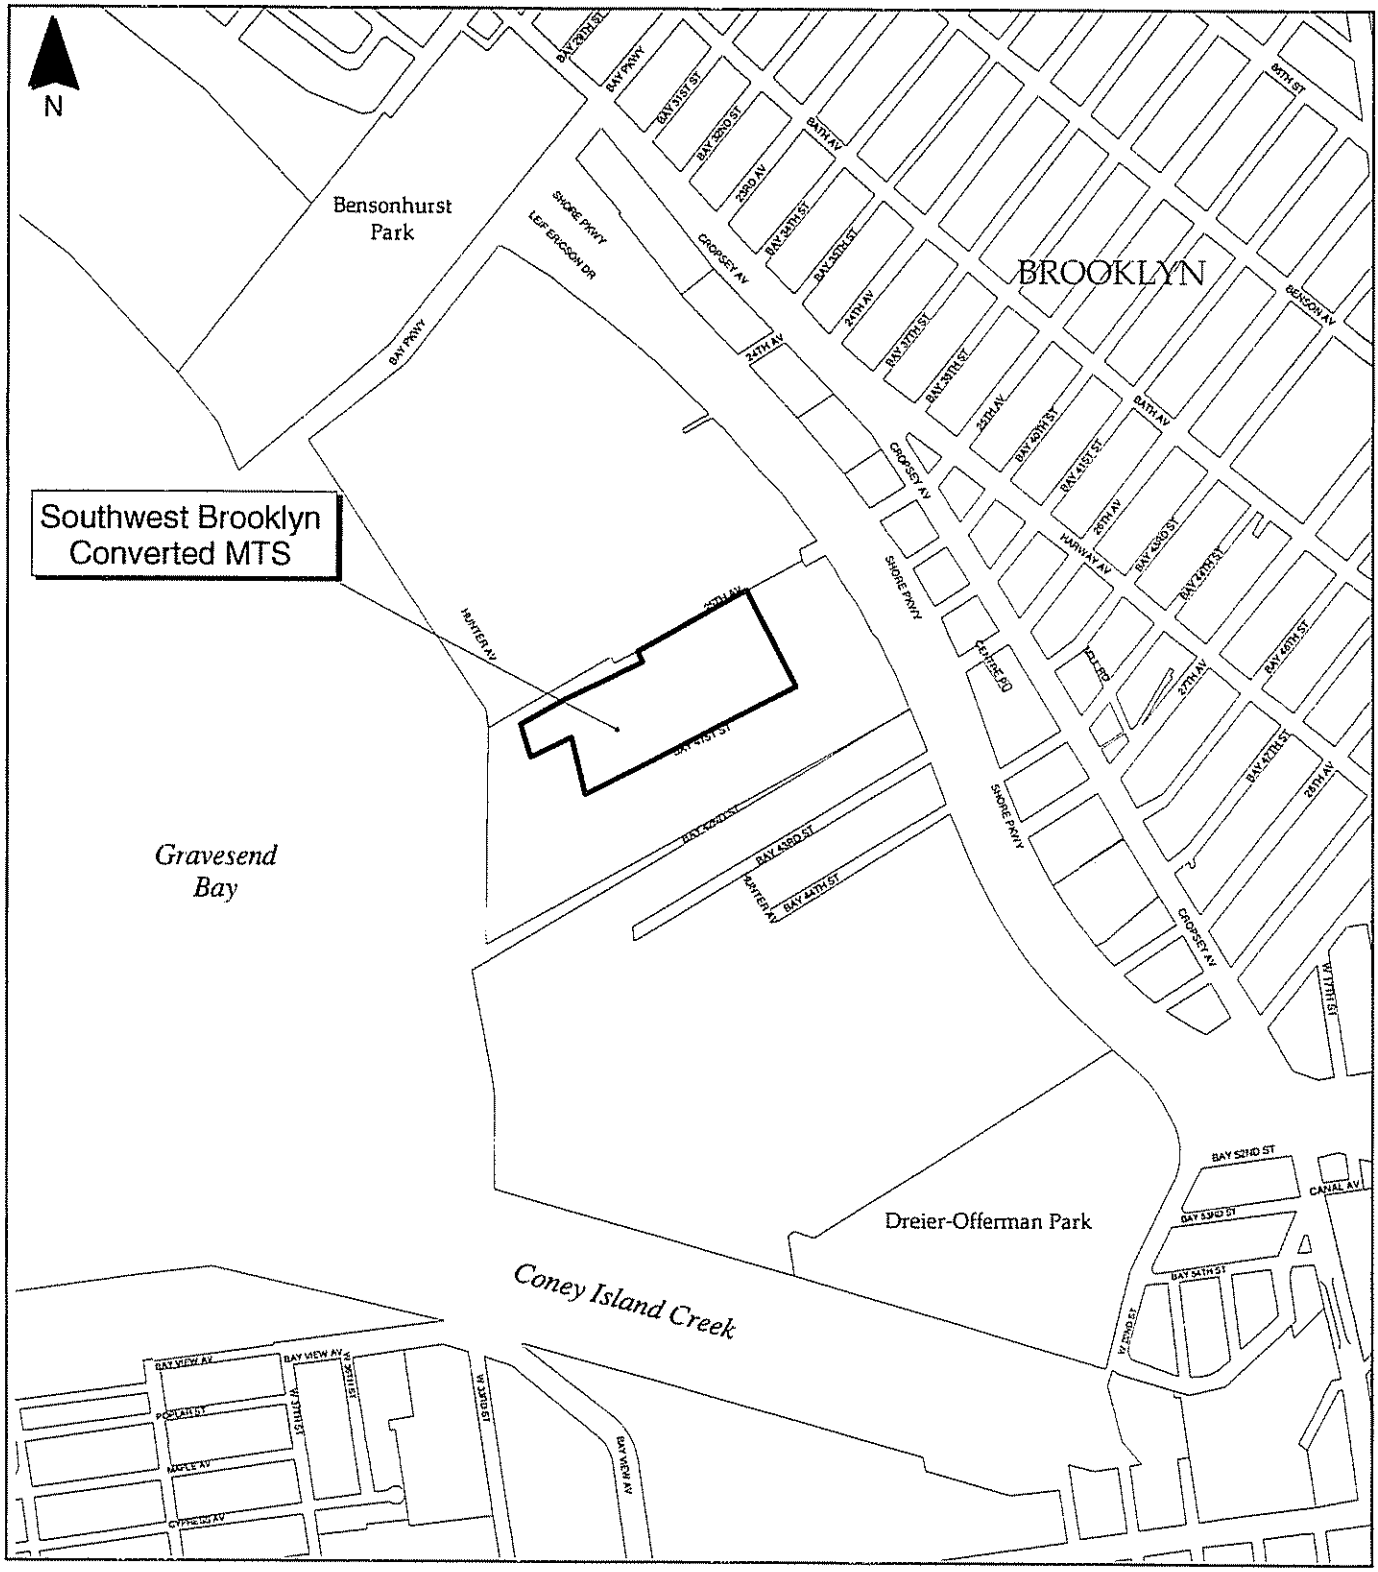
DSNY-managed Waste would be delivered to the Hamilton Avenue Converted MTS by a variety of collection vehicles, primarily consisting of packer and dual-purpose trucks, including collection vehicles operated by DSNY and other City agencies (e.g., City Department of Parks and Recreation [NYCDPR], City Housing Authority [NYCHA] and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building, at the entrance to the tipping-floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

The loading floor would be 12 feet below the tipping floor. On the loading floor, front-end loaders would push the waste into slots in the floor slap located over open-top containers. The containers would be mounted on shuttle cars that would move on tracks at the pier level of the building, 16 feet below the loading floor. A tamper device working from the loading floor would even and densify the waste in the containers. When loading is complete, the open-top containers would be moved into position at the enclosed lidding area of the processing building and would be securely lidded with a gasketed steel lid via pressure from a bridge crane with a spreader device. Then, the overhead door to the lidding area would open, and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and gross payload of 1,308 tons) would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

2.2.2 Southwest Brooklyn Converted MTS, Brooklyn

2.2.2.1 Description of Existing Site



The existing Southwest Brooklyn MTS site is located at Bay 41st Street and the service road of the Shore (Belt) Parkway in the Bensonhurst section of Brooklyn in Community District 11. The site is bounded to the north by 25th Avenue (extended), to the south by Bay 41st Street (extended), to the east by the DSNY CD 11 garage facility and to the west by Gravesend Bay.

Figure 2.2.2-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 6943, Lot 30, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

The site location is approximately 6.4 acres of the total 23.5-acre DSNY-owned lot, running an average of approximately 350 feet along its north-south parallel and approximately 600 feet from east to west. The existing Southwest Brooklyn MTS, located within Lot 30, is roughly rectangular in shape and covers an additional 0.6 acres along the Gravesend Bay waterfront. The existing incinerator, located adjacent to the existing MTS within the upland portions of the site, currently occupies approximately 1.3 acres. The incinerator is in the process of being demolished; an environmental remediation program was conducted prior to demolition. The DSNY CD 11 garage facility, two salt storage sheds and a self-help site (SHS) occupy the remainder of the DSNY-owned lot.

The site is located at the southern end of an M3-1 zoning district that extends about ½-mile along the waterfront from Bay Parkway to Bay 41st Street. Immediately south of the site is a small M1-1 zoning district and further south is a C3 commercial zoning district. Beyond these industrially-zoned waterfront areas, most of the surrounding residential communities (Bensonhurst, Gravesend and Coney Island [east and south of the site]) are zoned for medium density residential uses (R4, R5 and R6) and contain a mix of housing types, parks and marinas. Within the larger residentially-zoned district to the northeast is a small C8-1 zoning district that allows automotive-related uses in a few blocks between Cropsey and Bath Avenues.

Directly to the northeast and east of the site are DSNY facilities, including one salt shed and DSNY garage. Other land uses within ¼-mile of the site include the Nellie Bly Amusement Park, a neighborhood feature for decades, which is on the same block and fronting Shore Parkway, 500 feet east of the site. Fuel oil tanks and buildings associated with the Bayside Fuel Oil Corporation are located north of the site near Shore Parkway, as are the Atlantic Express Bus Company and various other automobile repair services. Further north-northwest of the site is a variety of commercial uses surrounded by fairly large parking areas. These uses include several banks; a shopping area with regional retail establishments, such as Best Buy and Toys "R" Us; several automobile service establishments; and a motel on the equivalent of 24th Avenue south of the Bay Parkway-Shore Parkway intersection.

Figure 2.2.2-1 Site Location

Southwest Brooklyn Converted MTS

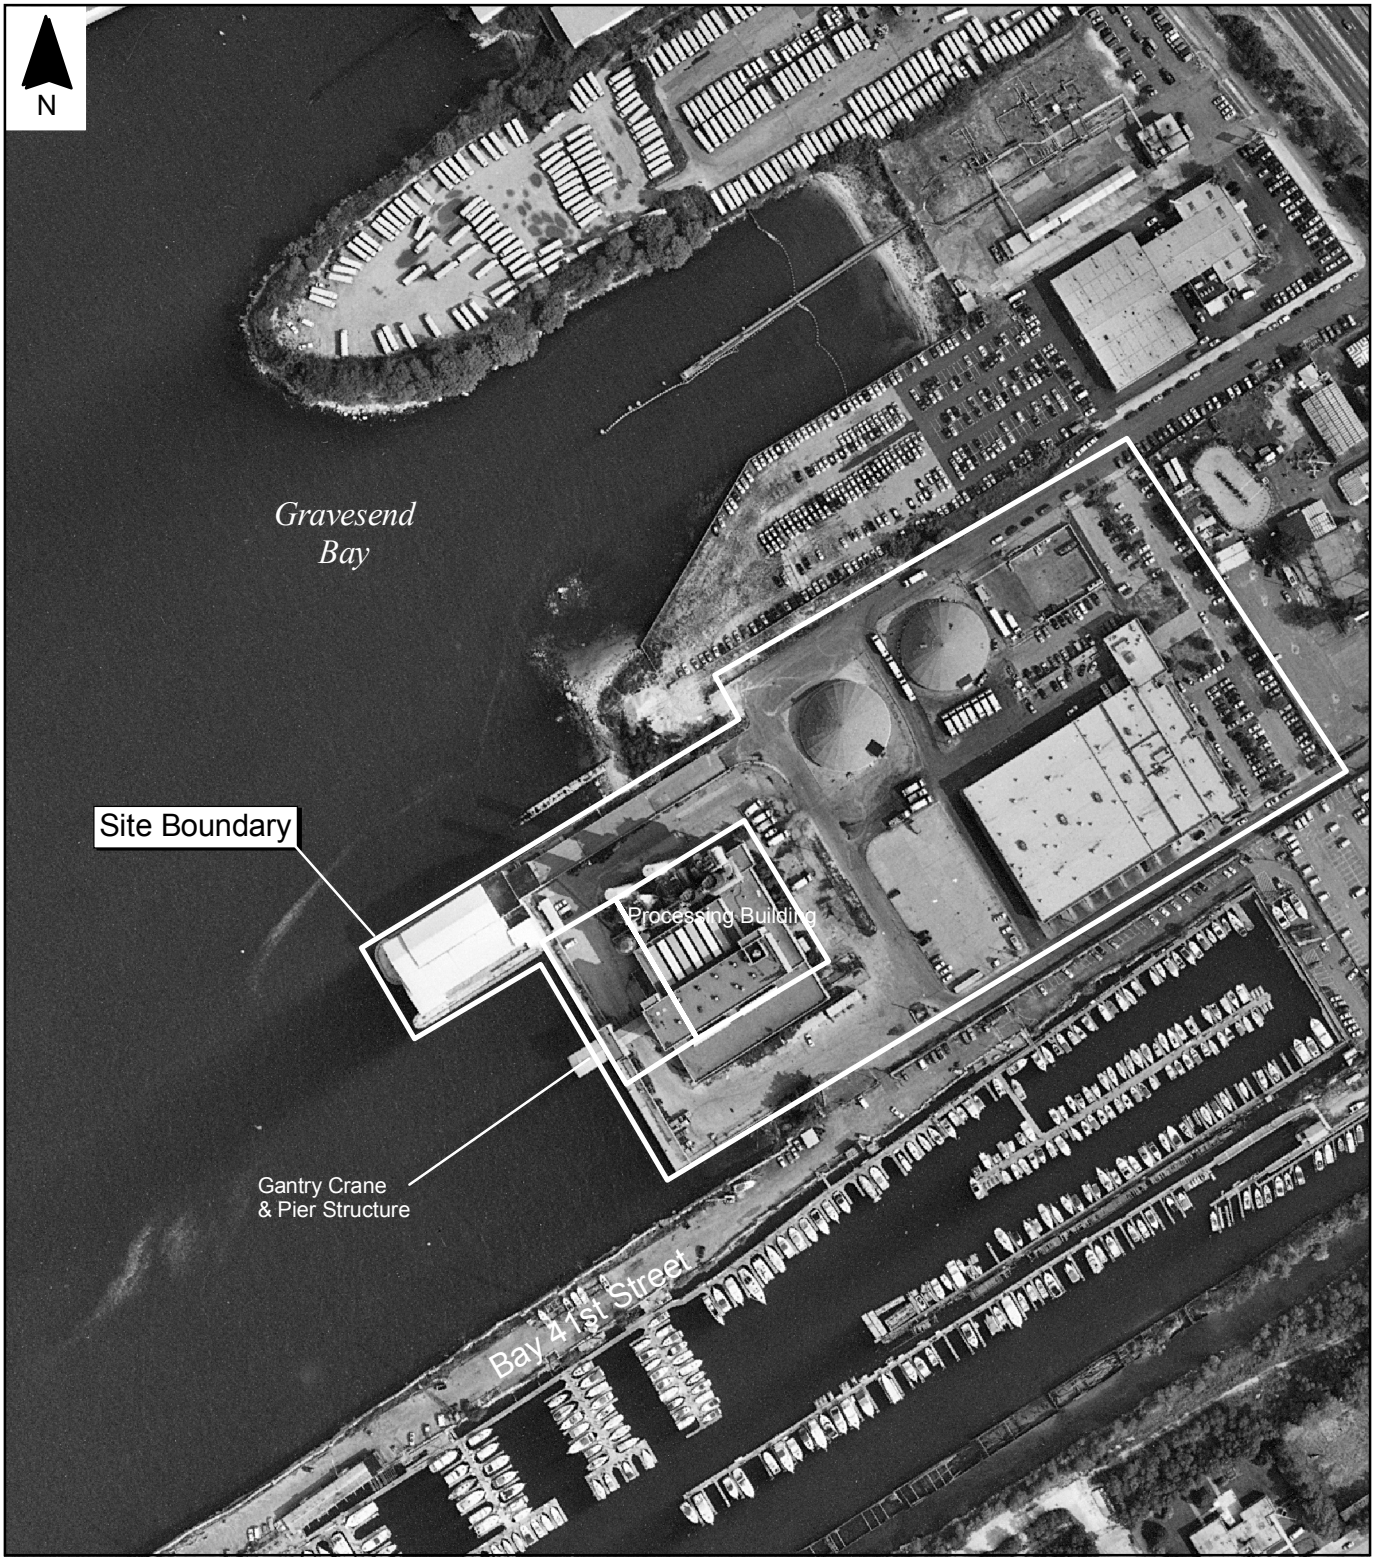
CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

East of Shore Parkway within the ¼-mile area is a dense residential area, including the 167-unit Regina Pacis Residence for Senior Citizens on Bay 37th Street, various apartment houses and three-story row houses.

South of the site are several yacht clubs, including the Williamsburg Yacht Club and Marina where boats are moored south of Bay 41st Street. On Bay 44th Street and Hunter Avenue is a home for handicapped children. Across Hunter Avenue to the east are another assisted living facility and the Brooklyn School for Special Children. An unfinished residential development once known as "Rose Cove" stands within the primary study area north of and adjacent to Dreier-Offerman Park at Bay 44th Street and West Shore. This residential development was designed originally to include three buildings and some town homes, the remains of which are not publicly accessible. The model structures now stand vacant and dilapidated. The property is not being developed at this time.

The area between ¼-mile and ½-mile is characterized by waterfront, municipal parks and largely residential uses inland to the east. Bensonhurst Park is located southwest of the southern end of the Leif Ericson Drive Shore Road park system north of Bay Parkway and northwest of the site, while Dreier-Offerman Park, a large 73-acre waterfront public park, and the Coney Island Boat Basin are located south of the site along Coney Island Creek.



The remainder of the area lies northeast of Shore Parkway, where the land use pattern is primarily residential, consisting of single- and multi-family housing, mostly detached and semi-detached homes. The area also contains apartment towers, such as the Contello Towers Co-op, Sections I and II (between Shore Parkway and Cropsey Avenue at Bay 44th Street); senior housing; schools; and religious institutions; as well as some local professional offices, light industrial uses and automotive services, with a concentration along Bath Avenue. East of Cropsey Avenue on either side of 25th Avenue are the buildings, storage areas and parking areas associated with New York City Transit's (NYCT's) Ulmer Park bus depot.

To reduce the potential for damage to the seawall of the Marine Basin Marina, a property adjacent to the MTS site to the east, as a result of increased wake resulting from the construction of the Converted MTS or tugboat operations associated with the facility, a DSNY consultant recommended the installation of a kingpile bulkhead wall. Consequently, the Converted MTS project would include the construction of a kingpile bulkhead wall to ensure that the marina is not impacted by pile driving activities, construction-related dredging and tugboat prop wash (wake) during Converted MTS operations. The proposed kingpile bulkhead wall extends 290 feet south into the ocean from the southeast corner of the existing pier to an existing channel buoy. The buoy delineates the limits of the navigable channel for tugs coming to the Converted MTS and is the eastern limit for the proposed dredge area. To improve the stability of the Marina seawall, the top of the sheeting between the kingpiles would be close to the existing ocean bottom and rip-rap or concrete groins would be installed perpendicular to the kingpile wall the Marina seawall. In addition, the angle of the proposed wall was designed to decrease the probability that tide, current and waves would erode the base of the Marina seawall.

There are no City, state or nationally designated landmarks or historic districts within a ½-mile radius of the site, nor are there any archaeological resources on the site.

2.2.2.2 Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.2.2-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the Converted MTS superimposed on the site. Figure 2.2.2-3 depicts the current rendering of the Southwest Brooklyn Converted MTS. Figures 2.2.2-~~3,~~ 4, -5 and -6 (Plan ~~and~~ View, Section View and Gantry Section View) shows the processing building interior and details of the gantry crane.

DSNY-managed Waste would be delivered to the Southwest Brooklyn Converted MTS by a variety of waste collection vehicles, primarily consisting of packer and dual-purpose trucks, including collection vehicles operated by DSNY and other City agencies (e.g., the NYCDPR, NYCHA and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building, at the entrance to the tipping-floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

The loading floor would be 12 feet below the tipping floor. On the loading floor, front-end loaders would push the waste into slots in the floor slab located over open-top containers. The containers would be mounted on shuttle cars that would move on tracks at the pier level of the building, 16 feet below the loading floor. A tamper device working from the loading floor would even and densify the waste in the containers. When loading is complete, the open-top containers would be moved into position at the enclosed lidding area of the processing building and would be securely lidded with a gasketed steel lid via pressure from a bridge crane with a spreader device. Then, the overhead door to the lidding area would open, and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and a gross payload of 1,308 tons), would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

2.2.3 East 91st Street Converted MTS, Manhattan

2.2.3.1 Description of Existing Site

The existing East 91st Street MTS site is located in the Upper East Side of Manhattan in Community District 8. The site is bounded by the East River to the north and east, Carl Schurz Park to the south and the Franklin D. Roosevelt (FDR) Drive to the west. Figure 2.2.3-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 1587, Lot 27, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

Site delineations and study areas are approximate.
Base Map Source: New York City Department of City Planning

500 0 500 Feet

HDR URBITRAN EEA Hydroqual PB Cambridge Environmental Inc

Figure 2.2.3-1 Site Location

East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The gross acreage of the DSNY-owned lot is approximately 3.07 acres. The East 91st Street MTS site is roughly rectangular in shape. The western boundary of the site conforms to the existing configuration of the FDR Drive. The northern boundary of the MTS site extends approximately 240 feet in an east-west direction to meet the U.S. Pierhead Line, the eastern border along the U.S. Pierhead Line is approximately 1,000 feet in length, the western border along the U.S. Bulkhead Line measures approximately 1,400 feet in length and the southern border measures approximately 128 feet in length.

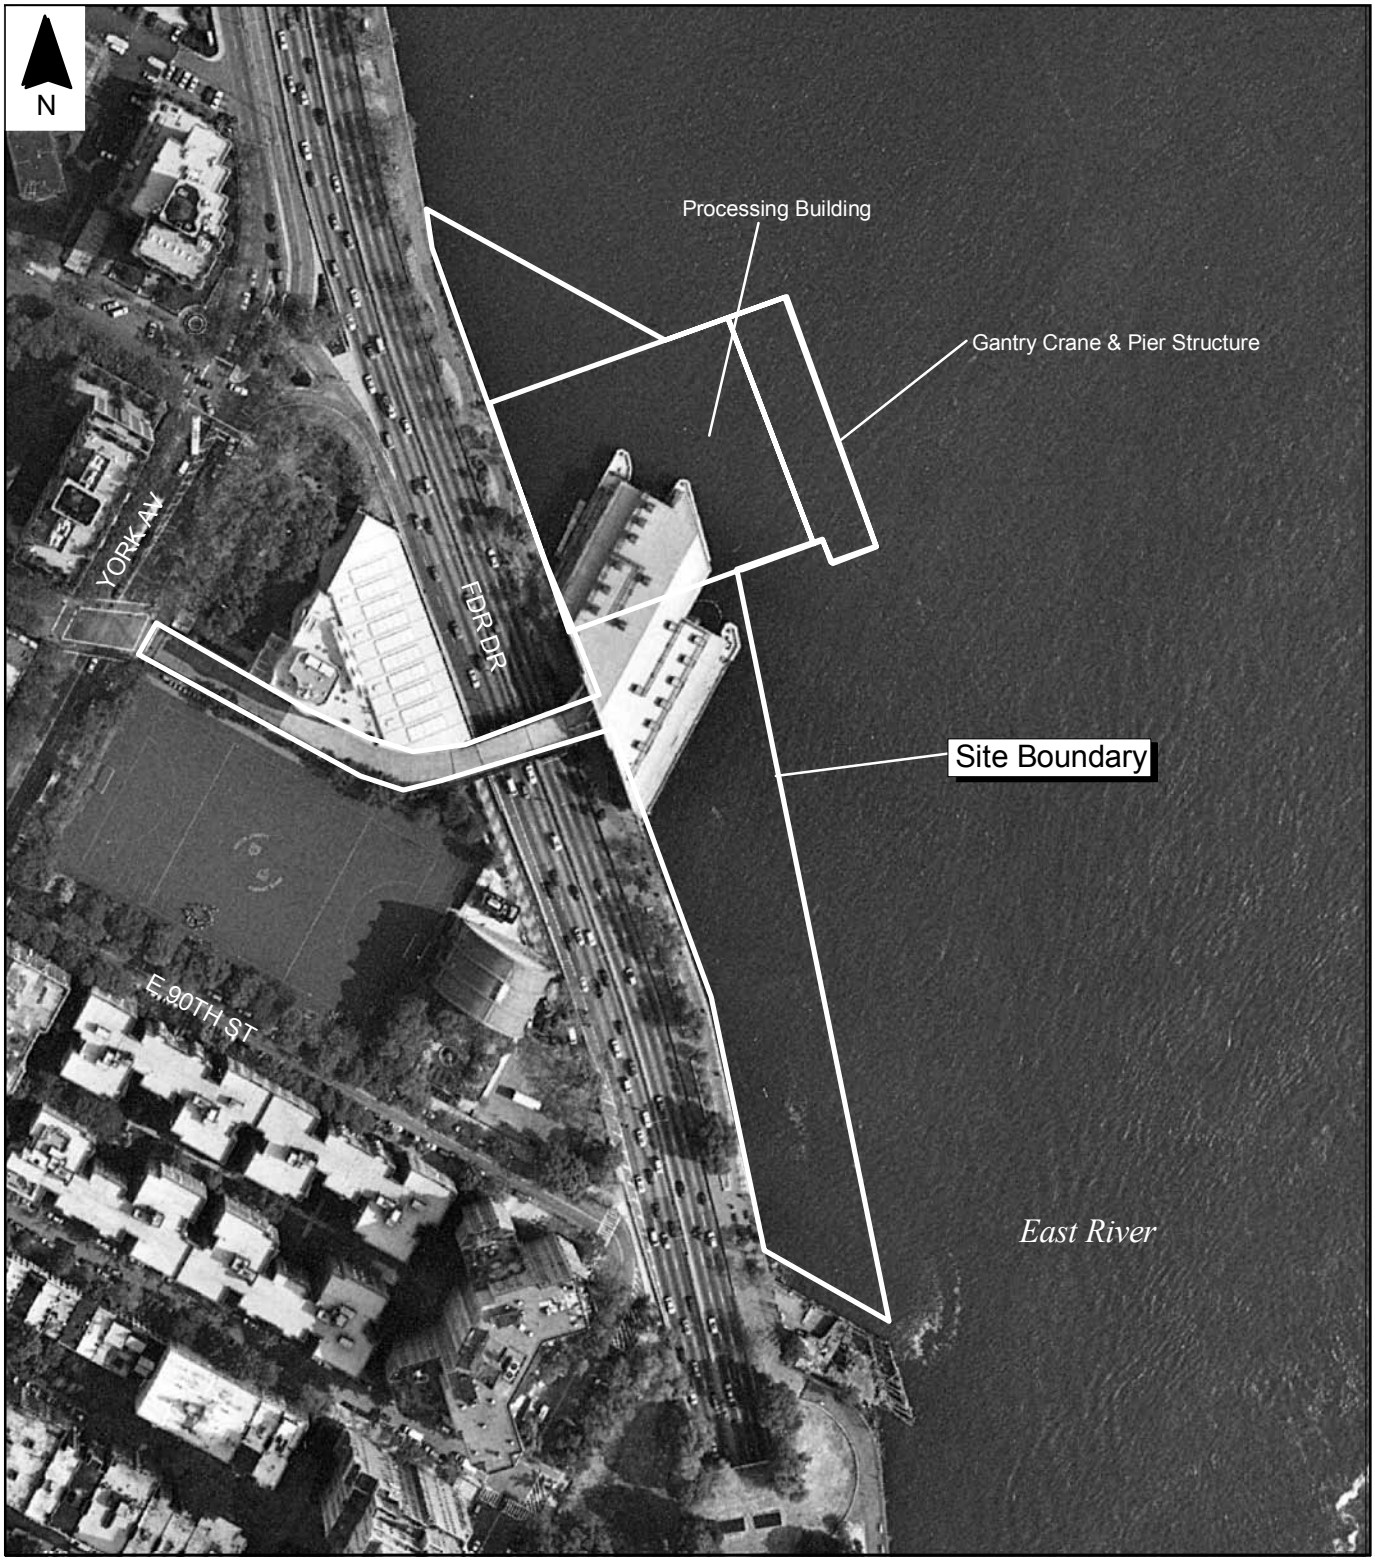
The MTS site is located within a small irregularly-shaped M1-4 (light industrial) zoning district, which extends from East 90th to East 93rd Streets along the shoreline, between the FDR Drive and the East River waterfront. It continues west of the site to York Avenue between East 90th and East 92nd Streets to encompass most of the Asphalt Green Recreational Center. Beyond the site on all sides are high-density residential zoning districts that allow for high-rise development. The northern portion of Asphalt Green is situated within a large R7-2 zoning district that extends about one mile to the north. Immediately south of the site is an R10A high-density residential district and is surrounded by other high-density residential districts (R8, R8B and R10) within a ½-mile radius. There are also a wide array of discrete commercial (C84, C28, C1-9, C4-6) zones further west and northwest of the site throughout the ½-mile radius.

The area within a ¼-mile radius of the site is comprised of open space and recreational land uses, with fairly dense residential and commercial areas. The site is on the waterfront with the FDR Drive separating it from the mainland street network, which in the vicinity of the site includes the northern termini of East End Avenue and York Avenue. Carl Schurz Park, the setting of Gracie Mansion, the mayor's formal residence, lies immediately to the south of the site and runs adjacent to the western side of the FDR Drive to East 84th Street. The park provides a buffer to residential uses adjacent to it on East End Avenue. At its northern end nearest the site, the park extends over the FDR Drive to the waterfront, where public access to the waterfront is provided adjacent to the site via a waterfront promenade, which crosses beneath the existing MTS access ramp. A commuter ferry pier is located just south of the existing MTS at East 90th Street. The park and promenade extend south along the water beyond the primary study area.

Asphalt Green, another major open space within the ¼-mile-radius area, stretches between East 90th and East 92nd Streets east of York Avenue. It is a sports and training complex, featuring indoor and outdoor facilities, including a soccer field, basketball courts, running track, aquatic center and fitness center. Access to the existing MTS site is provided by an unmapped drive that crosses through the Asphalt Green complex from the intersection of East 91st Street and York Avenue. The landmark Municipal Asphalt Plant, which now houses a gymnasium, is also part of the complex. (See Section 6.6 for additional discussion of cultural resources in the study area).

The remainder of the ¼-mile-radius area is primarily residential, with multi-story towers on the west side of East End Avenue facing the river and row houses lining the cross-streets. A few blocks feature ground-floor commercial space along York Avenue and First Avenue. The study area's strongly residential nature is only somewhat interrupted by the presence of a few warehouses and auto-related uses between East 89th Street, East 92nd Street and York and First Avenues. A gourmet grocery (Eli's) with a restaurant above (The Vinegar Factory) and an arts and crafts shop are located on the north side of East 91st Street (a local route for DSNY and other agency collection vehicles leaving the site) just west of York Avenue, and a pizzeria is located on the south side of the street. On the local inbound truck route (East 90th Street between York and First Avenues) there is a combination of residential buildings and automobile-related uses (e.g., car rental, automobile repair and parking garages). Beth Israel Hospital (North) is located in the area on East End Avenue and East 87th Street, and the High School of Teaching and P.S. 66 are located on East 88th Street, between York and First Avenues. Stanley M. Isaacs Park is located on both sides of East 91st Street, east of First Avenue.

Land use within the ¼-mile- to ½-mile-radius area is generally characterized by residential uses, with ground-floor commercial uses lining the avenues except for the portion of the study area north of East 95th Street, where Metropolitan Hospital and associated parking is located at East 97th Street, along with J.H.S. 99 and other institutional uses east of First Avenue, north of the Metropolitan Hospital complex, and the School of Cooperative Technical Education at East 97th Street, to the south.



One historic district and 13 other historic properties are located within ½-mile of the site, representing different stages of the neighborhood's development over the last 200 years. The two closest historic resources are: (1) Asphalt Green Recreation Center (New York City Landmark [NYCL] and National Register of Historic Places [NR]), across the FDR Drive from the site; and (2) Gracie Mansion (NYCL, New York State Register of Historic Places [NYSR or SRHP] and NR), located south of the site at East 88th Street. Asphalt Green, built in 1944, was the Municipal Asphalt Plant. It was the first successful American use of the parabolic arch form in reinforced concrete. Gracie Mansion was built at the turn of the 19th century as a country house for Archibald Gracie, a successful Scottish merchant who settled in New York. It was acquired by the City in 1896 and later became an official residence for the New York City mayor in 1942.

No archaeologically significant resources are located on the site.

2.2.3.2 East 91st Street Converted MTS

The East 91st Street Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.2.3-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the Converted MTS superimposed on the site. The East 91st Street Converted MTS extends beyond the water grant line, which will require an underwater land grant from the NYS Office of General Services. Figure 2.2.3-3 depicts the current rendering of the East 91st Street Converted MTS. Figures 2.2.3-~~3, 4~~, -5 and -6 (Plan ~~and~~ View, Section View and Gantry Section View) shows the processing building interior and details of the gantry crane. The ramp that carries collection vehicle traffic across Asphalt Green Park and the FDR Drive is part of the existing MTS. The existing ramp would be demolished and replaced with a new one with wider dimensions and a higher grade (slope) to accommodate queuing DSNY collection vehicles, utilities and appropriate noise barriers. (See Figure 2.2.3-7. Ramp Section View.) The new ramp would require a structural support that would result in a larger depth of the structure to support the wider ramp, utilities, appropriate noise barriers and a new outbound scale, but that would maintain the same clearance over the FDR Drive that exists today.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

DSNY-managed Waste would be delivered to the East 91st Street Converted MTS by a variety of waste collection vehicles, primarily consisting of packer and dual-purpose trucks, and including collection vehicles operated by DSNY and other City agencies (e.g., NYCDPR, NYCHA and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building at the entrance to the tipping-floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

The loading floor would be 12 feet below the tipping floor. On the loading floor, front-end loaders would push the waste into slots in the floor slab located over open-top containers. The containers would be mounted on shuttle cars that would move on tracks at the pier level of the building, 16 feet below the loading floor. A tamper device working from the loading floor would even and densify the waste in the containers. When loading is complete, the open-top containers would be moved into position at the enclosed lidding area of the processing building and would be securely lidded with a gasketed steel lid via pressure from a bridge crane with a spreader device. Then, the overhead door to the lidding area would open, and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and a gross payload of 1,308 tons), would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

2.2.4 North Shore Converted MTS, Queens

2.2.4.1 Description of Existing Site

The existing North Shore MTS site is located in the College Point section of Queens in Community District 7. It is bounded by 30th Avenue to the north, 31st Avenue and 120th -Street to the east and Flushing Bay to the west. Figure 2.2.4-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 4346 and Lot 75, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

HDR URBITRAN EEA Cambridge Environmental Inc

Figure 2.2.4-1 Site Location
North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The gross acreage of the DSNY-owned lot, which includes the site and is bounded by 122nd Street, is approximately 12.5 acres, of which approximately 7.5 acres are upland. DSNY's District 7 garage occupies the majority of this acreage; the remaining five acres are made up of water that extends to the U.S. Pierhead Line. The North Shore MTS site is roughly rectangular in shape, with a bend beyond the U.S. Bulkhead Line extending south. The northern boundary of the MTS site measures approximately 1,000 feet in length to the U.S. Pierhead Line, the southern boundary is approximately 800 feet in length, the eastern border along 120th Street is approximately 550 feet in length and the western border along the U.S. Pierhead Line is approximately 560 feet in length.

The site is located on the western edge of a heavy industrial M3-1 zoning district along Flushing Bay, which extends north approximately to 30th Avenue and east to Ulmer Street. Bordering the M3-1 zone to the north is an M1-1 zone, which allows for light industrial uses and extends from Flushing Bay to beyond ½-mile from the site. M1 zoning districts, often buffers for adjacent residential and commercial districts, serve this function to the residentially-zoned areas north of the site. These include a variety of residential zoning districts such as R4, R5B, R4-1 and R3X.

The area within a ¼-mile radius of the site is primarily characterized by heavy industrial land uses, with some residential uses located in the northern section. The western half of the primary study area is part of Flushing Bay, while the eastern half contains a variety of land uses, mostly industrial. Industrial and manufacturing uses and their associated offices, warehouses/storage facilities and parking areas are concentrated to the south and east of the site. Commercial establishments are found throughout the primary study area, with a large number of automobile parts and service shops lining both sides of College Point Boulevard between approximately 27th and 28th Avenues and around 119th and 120th Streets, north of the site. East of and adjacent to the site is the DSNY Queens District 7 garage and, north of the garage, Vassilaros Coffee Roasting Company. A large Consolidated Edison facility is located on the block due east of the site and the district garage, with storage and parking on the western end, closest to the site. Residential uses are located north of the site from 29th Avenue to 28th Avenue west of 120th Street and north of 28th Avenue, where it is almost entirely residential between College

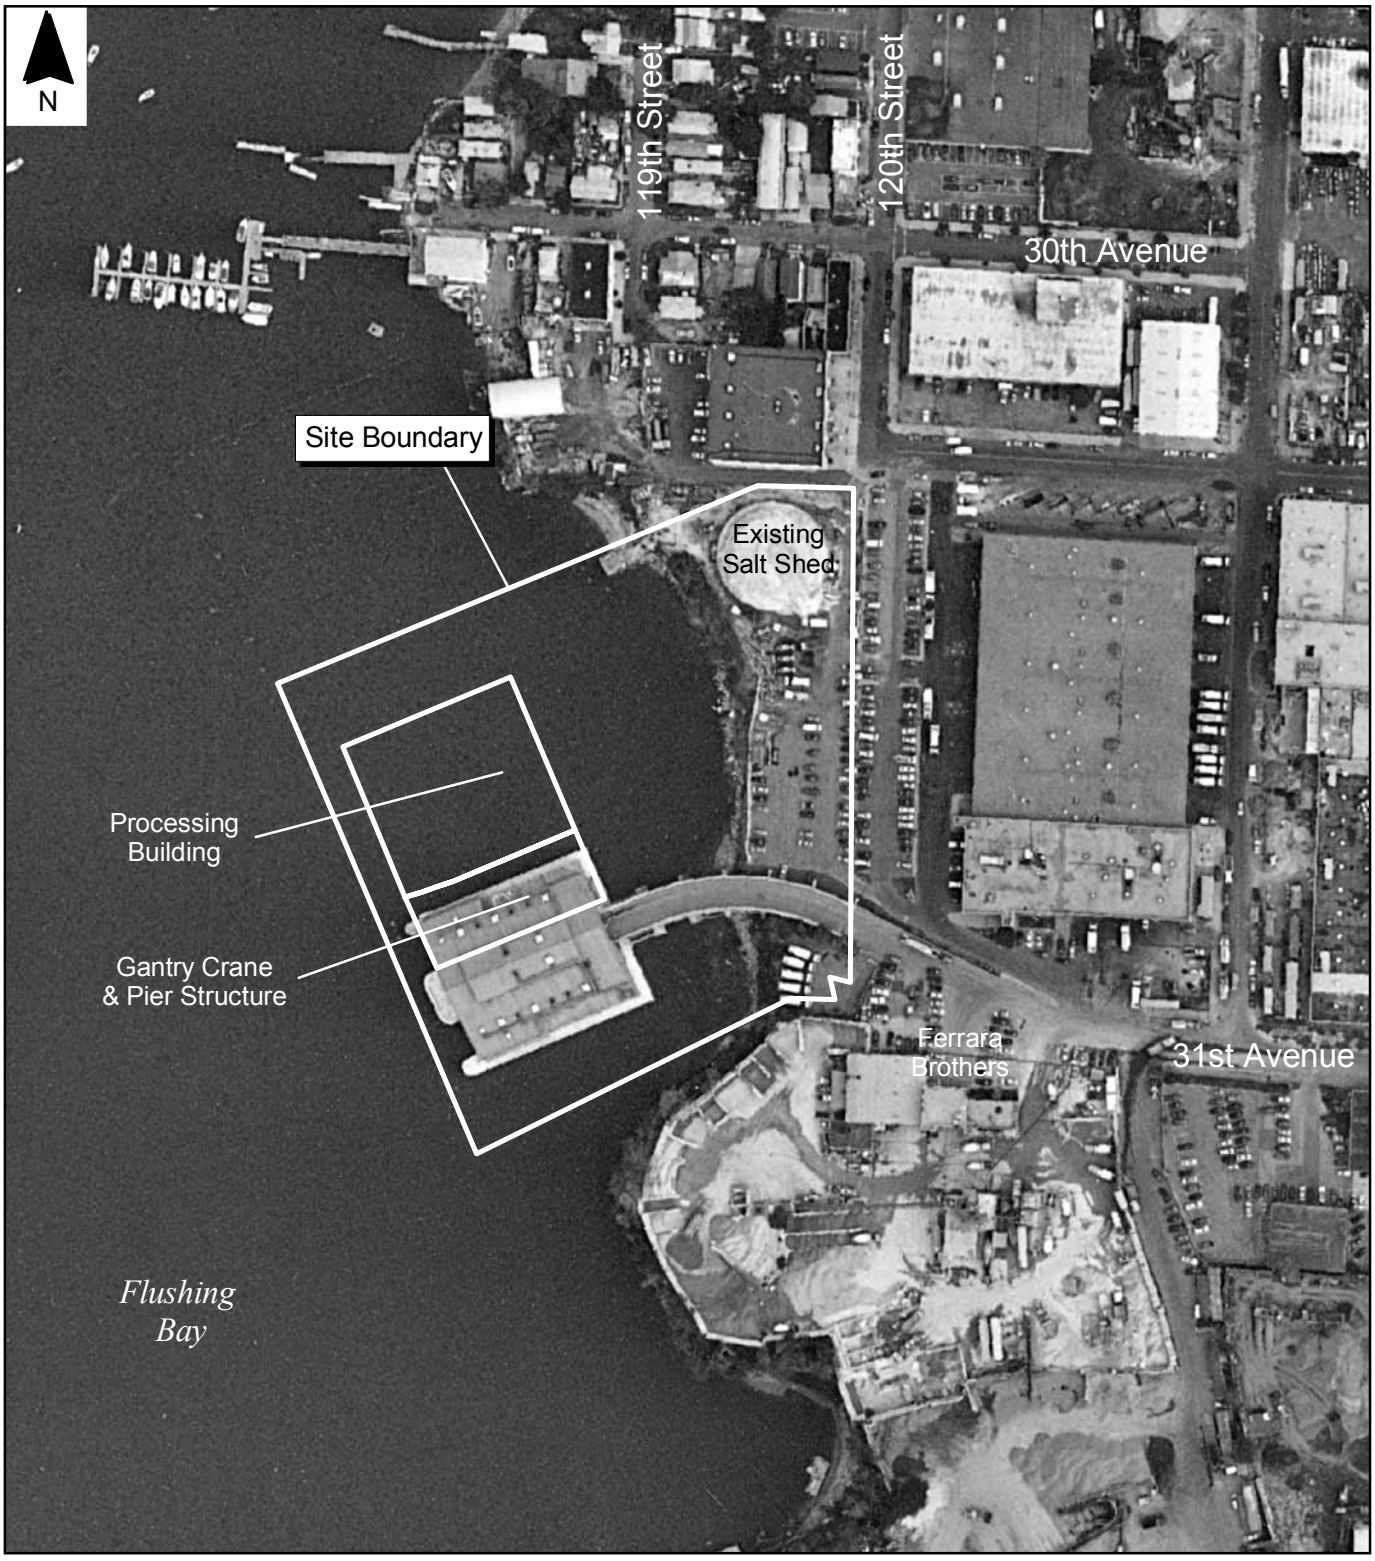
Point Boulevard and the bay. The residential area contains single-family detached housing, two-family housing and some late 20th-century row housing. Nursing home facilities built between 1955 and 1971 are located on the western ends of the three blocks between 25th Avenue and 27th Avenue.

South of and adjacent to the site is the Ferrara Brothers Building Materials Company on 31st Avenue. Behind their offices is the materials storage and truck loading area. Several of the mapped streets in the area are not open to the public, but instead serve the concrete and asphalt companies located there. A Home Depot store has been recently constructed east of Ferrara Brothers near College Point Boulevard, introducing large-scale retail activity to the area.

A portion of the College Point Industrial Park to the east of the site lies in the primary study area. The park begins at College Point Boulevard and extends eastward and southward from about 26th Avenue to about 31st Avenue. Warehouses, busing facilities and storage/parking areas are located within that portion of the park within the study area, while the remainder of the park features such prominent businesses as The New York Times printing facility.

The northern portion of the ¼-mile- to ½-mile-radius area is almost exclusively residential with the exception of major industrial uses in the area between 120th Street and the shore. Enterprises such as Sunrise Oil and an active boat yard and parking are found there. The northern residential portion of the study area east of 119th Street contains more multi-family apartment housing than in the residential areas nearer to the site. Machine shops and small manufacturers are scattered throughout. Public School No. 29, built in 1928, is located just outside the study area, on the south side of 23rd Avenue between 125th and 126th Streets. As mentioned, a new Home Depot is situated west of College Point Boulevard, south of 31st Avenue. Except for the Full Gospel New York Church at 130-30 31st Avenue, industrial uses, including the City's impound lot south of 28th Avenue, characterize most of the remaining secondary study area east of College Point Boulevard. Large manufacturers, such as The New York Times printing facility, are located to the east on the perimeter of the secondary study area.

Southeast of the site, the area consists of large privately owned lots of industrial waterfront and warehouses as well as the former Metropolis nightclub at the southern end of 124th Street. Most of these properties are accessible only via private drives. The secondary study area also includes the southern shore of Flushing Bay, where the City Bureau of Highways' Queens asphalt plant is located, as is the Flushing Meadows Corona Park, which extends south of the bay. The study area extends westward across the bay to include a small portion of the eastern edge of LaGuardia Airport.



No designated historic landmarks or districts are within the study area nor are there archaeologically significant resources located on the site.

2.2.4.2 North Shore Converted MTS

The North Shore Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.2.4-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the Converted MTS superimposed on the site. Figure 2.2.4-3 depicts the current rendering of the North Shore Converted MTS. Figures 2.2.4-~~3, 4~~, -5 and -6 (Plan ~~and~~ View, Section View and Gantry Crane View) shows the processing building interior and details of the gantry crane.

DSNY-managed Waste would be delivered to the North Shore Converted MTS by a variety of waste collection vehicles, primarily consisting of packer and dual-purpose trucks, and including collection vehicles operated by DSNY and other City agencies (e.g., NYCDPR, NYCHA and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building, at the entrance to the tipping floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

The loading floor would be 12 feet below the tipping floor. On the loading floor, front-end loaders would push the waste into slots in the floor slab located over open-top containers. The containers would be mounted on shuttle cars that would move on tracks at the pier level of the building, 16 feet below the loading floor. A tamper device working from the loading floor would even and densify the waste in the containers. When loading is complete, the open-top containers would be moved into position at the enclosed lidding area of the processing building and would be securely lidded with a gasketed steel lid via pressure from a bridge crane with a spreader device. Then, the overhead door to the lidding area would open, and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and a gross payload of 1,308 tons), would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

2.2.5 52nd Street Barge Staging Area, Brooklyn

The 52nd Street Barge Staging Area may serve as a support facility for the Converted MTSs. Its principal uses would be for storage of marine supplies required by the Converted MTSs, temporary mooring of -barges scheduled for maintenance, and temporary staging of container barge movements between the Converted MTSs and intermodal transload facilities (barge-to-barge operations).

2.2.5.1 Description of Existing Site

The existing 52nd Street Barge Staging Area is located within the Sunset Park section of the industrial Brooklyn waterfront in Community District 7, just south of Bush Terminal and north of the Brooklyn Army Terminal. It is bounded on the east by First Avenue and on the north, south and west by the Upper New York Bay. Figure 2.2.5-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 803, Lot 5 based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

Site delineations and study area boundaries are approximate

Figure 2.2.5-1 Site Location

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Currently, the site contains a DSNY vehicle maintenance facility and a storage facility for sand and salt, as well as a parking lot for employees.

The site and most of the area within a ¼-mile of site lie within a large M3-1 zone, which extends southward to 57th Street. This M3-1 zone extends east toward Second Avenue, west to the shoreline and northward to the South Brooklyn Terminal. A mixed-use M1-2D zoning district and a small M1-2 zoning district on 54th Street are located east of Second Avenue. Immediately south of this light industrial district is an R6 zoning district, which encompasses Lutheran Medical Center. Small portions of R6A and R6B zoning districts allowing medium contextual residential development are situated southeast of the site along Second Avenue.

Along First Avenue, the land uses are characterized by light industrial activities, warehousing and some commercial space. A series of five- to six-story warehouses is located between First Avenue and the waterfront, north of 51st Street. These structures include loading piers and parking areas for trucks and autos.

Warehouses, factories, automotive repair shops, parking lots and several vacant lots are located between First and Second Avenues. The First Avenue Rail Yard north of 51st Street includes several unused railroad spurs that run parallel to First Avenue. South of the site is the Brooklyn Wholesale Meat Market, consisting of three buildings at 5600 First Avenue, between 55th and 56th Streets. Individual meat and poultry wholesales occupy two of the buildings and a processor and distributor of frozen meals leases the third.

Residential uses within ¼-mile of the site consist of two- and three-story single- and multi-family attached structures east of Second Avenue. Similarly, community facilities within ¼-mile of the site are generally located east and southeast of the site, along Second Avenue. The Lutheran Medical Center (including its associated mental health clinic), the Augustana Lutheran elder care facility, a five-story parking structure and the Martin Luther Playground are located at Second Avenue at 55th and 56th Streets.

The general land use pattern found within ¼-mile of the site extends to ½-mile from the site. Industrial uses housed in large industrial loft buildings are located on the blocks nearest the waterfront, while a mix of residential, commercial and lighter industrial activities characterize the blocks east of Second Avenue. Rows of single-family attached homes and two- and three-story row houses line most of the blocks, along with isolated storefronts and auto repair shops between Second and Third Avenues, between 42nd and 46th Streets.

No significant elements of architectural or historical significance are located on the site, but several historic resources are located within ½-mile of the site. Bush Terminal, to the north, consists of a collection of red brick buildings built in the early 1900s to serve the bustling intermodal industrial complex. They are clustered on either side of 43rd Street, between Marginal Street and First Avenue. SHPO determined that Bush Terminal (not the deteriorated piers) is eligible for listing on the New York State and National Registers of Historic Places (NYSR and NR), and the Landmarks Preservation Commission (LPC) concurs that the complex is eligible for City landmark designation.

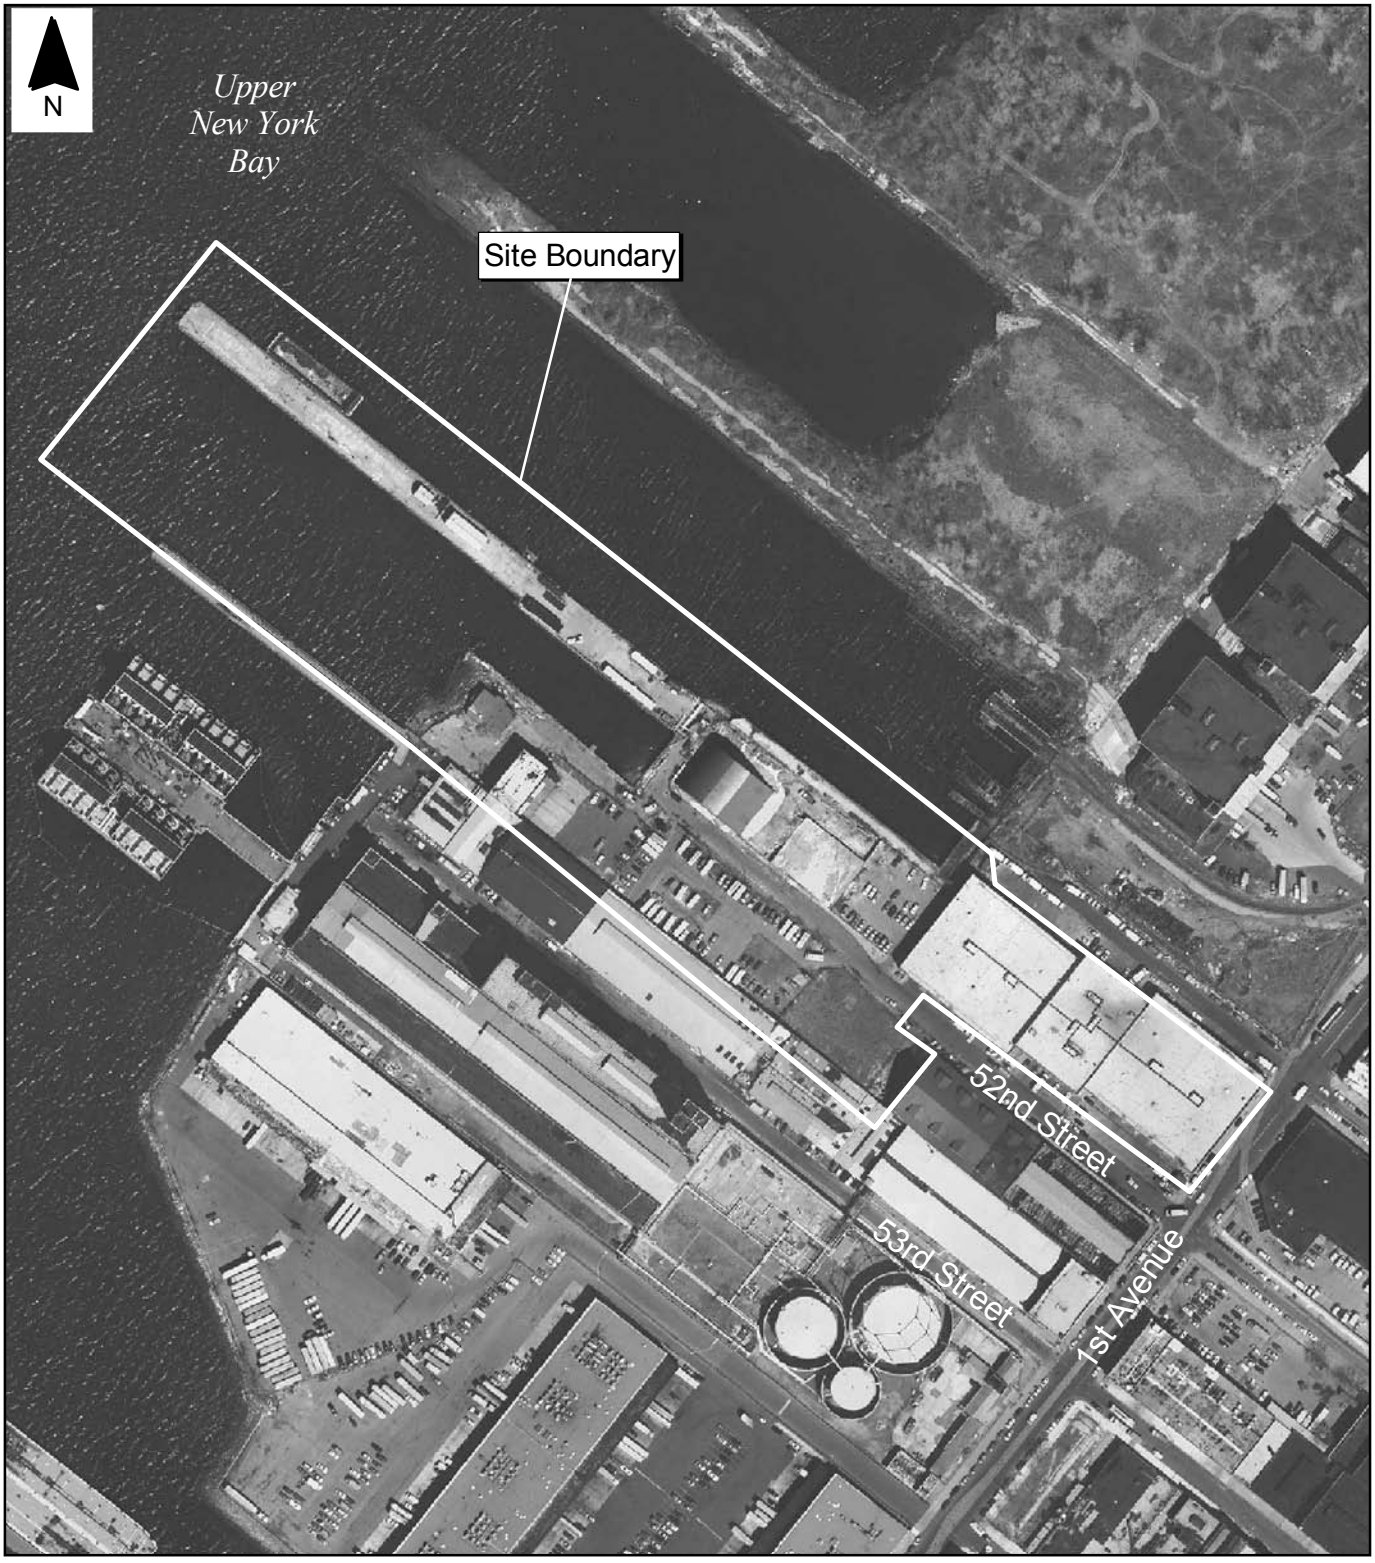
The Brooklyn Army Terminal south of the site is listed on NYSR and NR and appears to be eligible for LPC designation. The original complex of eight structures (two remain) was designed by Cass Gilbert, architect of the Woolworth Building and other City landmarks.

The expansive Sunset Park Historic District, which is listed on the NR for its uniform 19th-century residential development, is a large district roughly bounded by Fourth Avenue, 38th Street, Seventh Avenue and 64th Street, approximately ½-mile east of the site.

The former 18th Police Precinct House and Stable (4302 Fourth Avenue), approximately 4,000 feet northeast of the site, currently houses the Sunset Park School of Music. A designated City landmark, it is one of several station houses in Brooklyn designed by City Police Department (NYPD) architect George Ingram in the late 19th century to resemble a medieval fortress.

2.2.5.2 *52nd Street Barge Staging Area*

The 52nd Street Barge Staging Area would be a replacement-in-kind of the existing pier. It would be used for storage of marine supplies, temporary mooring of barges needing repair, and temporary staging of container barge movements between the Converted MTSs and intermodal transload facilities (barge-to-barge operations). The existing pier structure consists of a concrete deck supported by timber piles and substructure elements. Figure 2.2.5-2 (Facility Footprint) provides an aerial view of the existing site, including the existing pier. Figure 2.2.5-3 (Plan View) shows the plan for the reconstructed pier.



2.2.6 Harlem River Yard Barge to Rail Intermodal Yard

The Harlem River Yard (HRY) Barge to Rail Intermodal Yard may serve as a support facility for the Converted MTSs. It would function as an intermodal transload facility where barges with containerized waste from the Converted MTSs would be unloaded, containers placed on railcars, and train sections for transport to out-of-City disposal facilities assembled. Returned empty containers would be loaded on barges and towed back to the Converted MTSs.

2.2.6.1 *Description of Existing Site*

On a property contiguous to the existing HRY TS, a new facility would be developed to transload containers of DSNY-managed Waste delivered by barges from Converted MTSs to rail cars in the HRY. The new facility would be located south of the existing HRY TS. Figure 2.2.8-1 in the HRY Truck to Rail TS section shows the approximate boundaries of the site and surrounding neighborhood.

This site was evaluated as the location of a proposed enclosed barge unloading facility (EBUF) in the 2000 SWMP FEIS. The gross acreage of the lot is approximately 18 acres. The site is bounded on the northeast side by a primary branch of the through-track rail line to the Oak Point Link running through the development, on the west by the Harlem River, and on the south and southeast by the Harlem River.

Site Delineations are approximate.

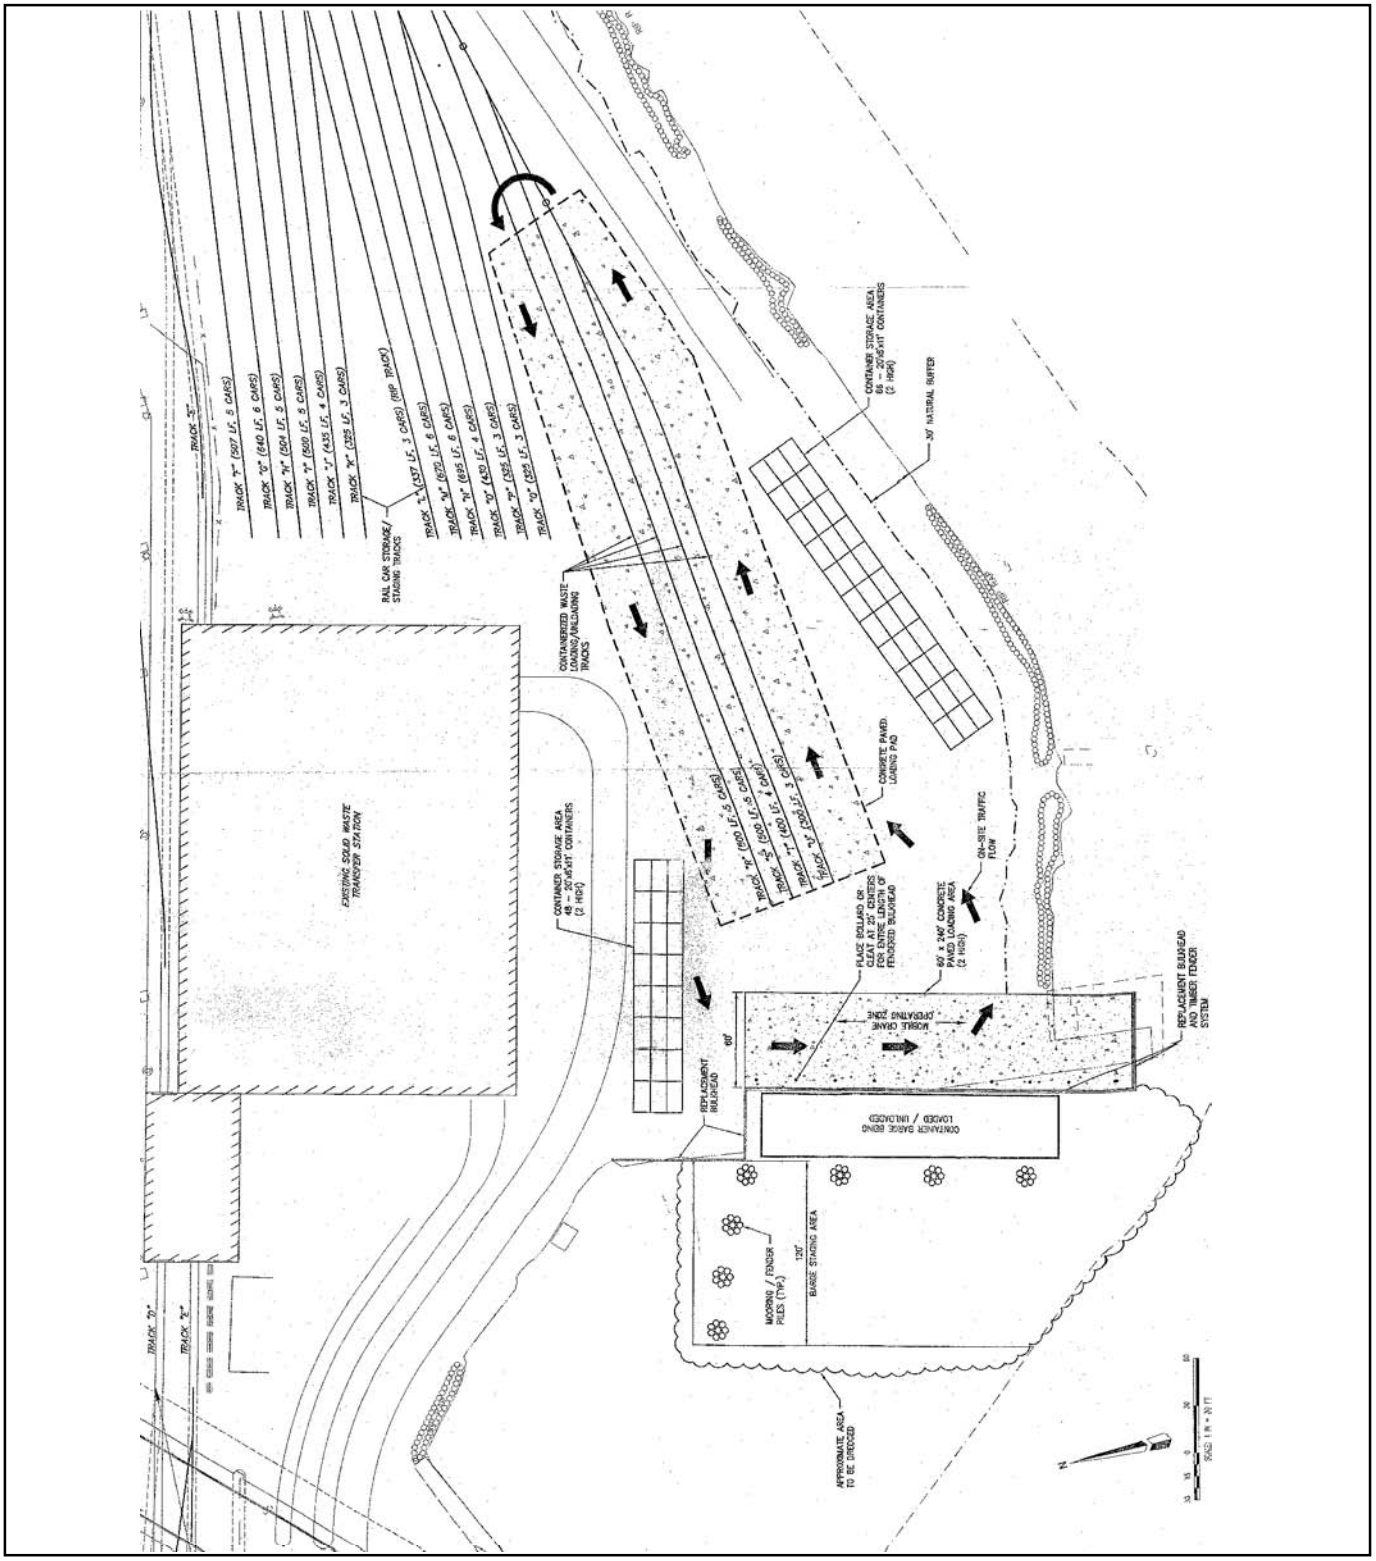
Figure 2.2.5-3 Plan View

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The site is located in a heavily industrialized area that is zoned M3-1. Across 132nd Street to the northeast lies a light manufacturing zone (M1-2), with a residential zone (R6) beyond the Major Deegan Expressway more than ½-mile from the site. Across the Harlem River in Manhattan lies the Harlem River Drive, bordered by light manufacturing (M1-2) and medium-density apartment-house (R7-2) zones. Land use on Randalls Island to the south across Bronx Kill is also designated R7-2.

2.2.6.2 HRY Barge to Rail Intermodal Yard



The site development would include a barge staging area with pile fendering, a barge mooring area adjacent to a replacement bulkhead for servicing barges, an adjacent 60-foot by 200-foot concrete pad for crane operations in unloading and loading barges, four rail spurs with capacity for 17 rail cars, and two designated storage areas for intermodal containers with capacity for 114 container units. A crane would unload containers from a barge moored at the bulkhead onto a yard jockey (tractor) that would move the container into position where a container handler unit would move the container from the chassis to a rail car. When a section of cars is loaded with full containers, it would be switched to a train-assemble track elsewhere in the HRY complex. Figure 2.2.6-1 (Plan View) shows the layout for this facility.

2.2.7 65th Street Intermodal Yard, Brooklyn

The 65th Street Intermodal Yard, Brooklyn may serve as a support facility for the Converted MTSs. It would function as an intermodal transload facility where barges with containerized waste from the Converted MTSs would be unloaded, containers placed on railcars, and train sections for transport to out-of-City disposal facilities assembled. Returned empty containers would be loaded on barges and towed back to the Converted MTSs.

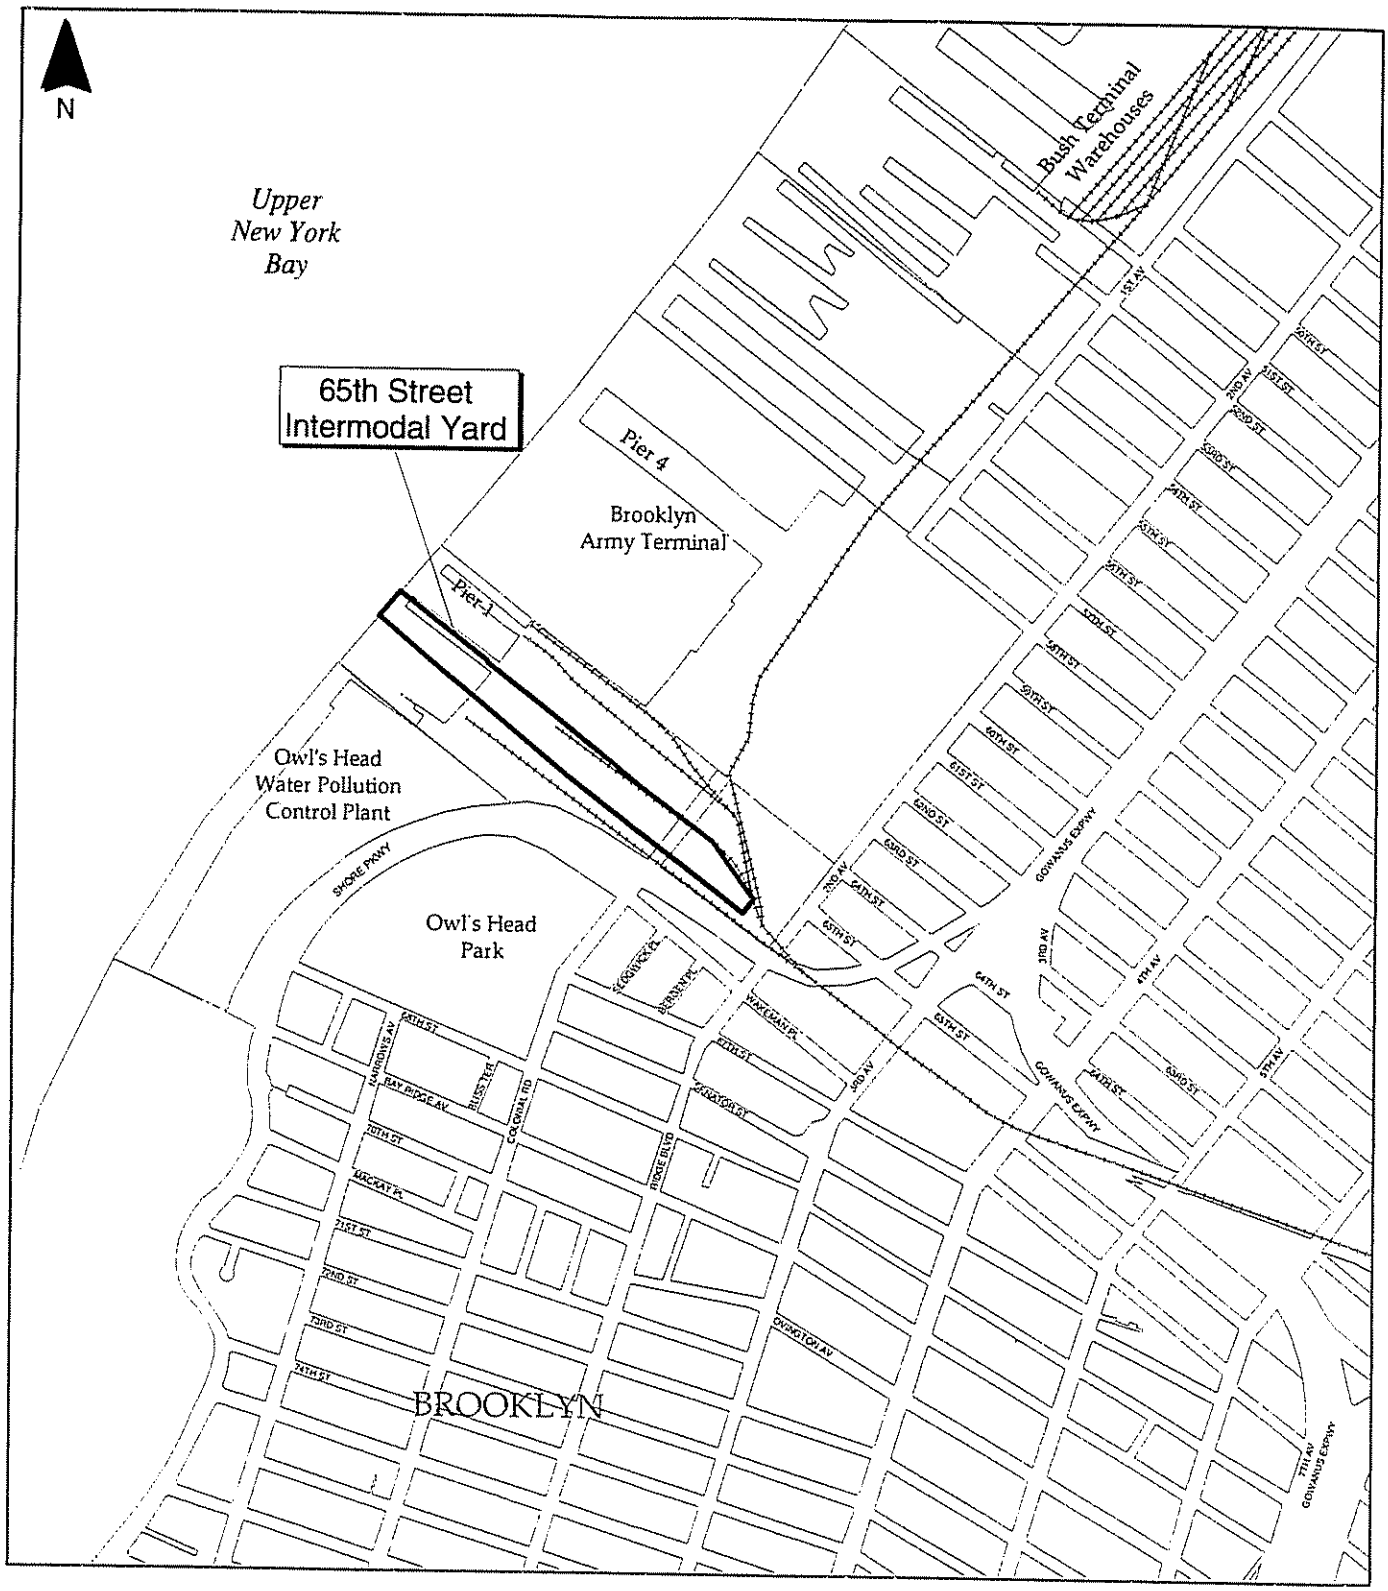
2.2.7.1 Description of Existing Site

The 65th Street Intermodal Yard is an existing intermodal yard owned by and under the control of NYCEDC, and currently leased by Canadian Pacific Railway. Under a proposal responding to DSNY's MTS-RFP, a waterfront area of the existing intermodal transload facility would be sublet to an MTS proposer and developed to service barges from the Converted MTSs.

Source: Earth Tech, April 30, 2004

Figure 2.2.6-1 Plan View
Loading Area
Harlem River Yard Barge to Rail Intermodal Yard

CITY OF NEW YORK
DEPARTMENT OF SANITATION



NYCEDC has completed an $8 million improvement program to upgrade rail facilities at this property. This program included the construction of two new gantry float bridges and the installation of 10 tracks on the south side of the site, and three tracks on the north side. NYCEDC will issue an RFP for a long-term lease shortly.

The 65th Street Intermodal Yard is in the industrial waterfront area bordering Bay Ridge and Sunset Park, Brooklyn. It is in Brooklyn CD 10 near the border of Brooklyn CD 7. Based on City tax maps, the site is comprised of Lot 2 of Block 5804. The yard interconnects with the Bay Ridge Line, a freight line that crosses Brooklyn to interconnect with the CSX and CP rail systems at Fresh Pond Yard in Queens. The Bay Ridge Line is owned by the Long Island Rail Road (LIRR) and is operated by the New York & Atlantic Railway (NY&A) under a lease agreement for use for freight traffic.

The intermodal site is comprised of approximately 12 upland acres of the 33-acre City property managed by NYCEDC and five acres over water between the U.S. Bulkhead Line and the U.S. Pierhead Line that would be developed for barge staging. The site is zoned M2-1 and is on the Upper New York Bay waterfront adjacent to the Brooklyn Army Terminal. The waterfront portion of the site is occupied by the ruins of two railroad float bridges and timber piles that would have to be removed before the waterfront could be dredged for barge reception.

Figure 2.2.7-1 (Site Location) shows the location of the 65th Street intermodal site. On the west, the property is bounded by the Upper New York Bay. It is bounded on the north, east and south by the 65th Street Rail Yard facilities. Immediately to the east, NY&A is planning to develop a rail-to-truck intermodal facility. Immediately to the south are a series of tracks that lead to the waterfront, where a float bridge terminal is being developed. Further to the south is the Owl's Head Water Pollution Control Plant (WPCP) and the Shore Parkway.

The site is level and unpaved except for the gravel service roads that run through it. In some areas near the water and the Owl's Head facility, the surface growth has been stripped away to reveal bare soil. The waterfront edge of the site is overgrown with grasses and scrub, and remains of piers protrude through the water's surface. The only existing on-site structures aside from a chain-link fence around the perimeter are five 80-foot-tall rail yard lighting fixtures.

Site delineations are approximate

Figure 2.2.7-1 Site Location

65th Street Intermodal Yard

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Designated parklands – Shore Road Park and Owl's Head Park – are located to the southeast of the site. The closest of these, Shore Road Park, is land located under Shore Parkway and, as such, is a visual resource to the community, but not useable parkland. Owl's Head Park would be approximately 800 feet from the location of the transload facility. The Brooklyn Army Terminal Day Care Center (58th Street and 1st Avenue) is approximately 500 feet from the site boundary. Residentially-zoned areas interspersed within commercial and industrial zones are located to the northeast of the site.

2.2.7.2 65th Street Intermodal Yard

Figure 2.2.7-2 (Facility Footprint) is an aerial photograph of the existing site. As indicated in this figure, development of the 65th Street Intermodal Yard would not affect any existing structures. Figure 2.2.7-3 (Plan View) depicts the proposed facility. DSNY containers delivered by barge from Converted MTSs would be transloaded to rail. This would occur on an existing bulkhead at the facility and would probably require some refurbishing and new container handling equipment. The 65th Street Intermodal Yard facility would be capable of handling an average of 190 containers per day, or a capacity of 4,000 tpd.

At the intermodal facility, barges with loaded containers would be moored into position. The hostler driver would then be signaled to pull into the load/offload position next to the barge. Loaded containers would be placed on the chassis of the hostler for drayage to the rail loading area, where the intermodal equipment operator would signal the next hostler to move into loading/unloading position adjacent to the next railcar in the block of railcars with empty containers. Transloading of the loaded container from the chassis to the next open position on the railcar would then occur. Empty containers are placed on the truck chassis for drayage to the barge loading/offloading area. Empty containers would be placed on the barge for return to the MTS.

Site delineations are approximate.

2.2.8 Harlem River Yard Truck to Rail TS

2.2.8.1 Description of Existing Site

The Harlem River Yard (HRY) Site is an existing permitted transfer station located at 98 Lincoln Avenue. The site is located in the southwestern portion of the Harlem River Yard Intermodal Transportation and Distribution Center (HRYITDC) property in the south Bronx. The entrance to the site is at Lincoln Avenue. The HRY Site is bounded on the northeast side by a primary branch of the through-track rail line to the Oak Point Link running through the development, on the west by the Harlem River, and on the south and southeast by the Harlem River. Figure 2.2.8-1 (Site Location) shows the location of the site. Figure 2.2.8-2 (Facility Footprint) shows an aerial map with major features of the site.

The property is located directly northeast of the Harlem River and Bronx Kill. As such, the aquifer at this site is tidally influenced, brackish in quality and as a result, is not used as a potable water source. No wetlands are located on the site; however, tidal wetlands are present along the north shore of the Bronx River.

The site is located in a heavily industrialized area that is zoned M3-1. Across 132nd Street to the northeast lies a light manufacturing zone (M1-2), with a residential zone (R6) beyond the Major Deegan Expressway more than ½-mile from the site. Across the Harlem River in Manhattan lies the Harlem River Drive, bordered by light manufacturing (M1-2) and medium-density apartment-house (R7-2) zones. Land use on Randalls Island to the south across Bronx Kill is also designated R7-2.

Site delineations are approximate

Figure 2.2.8-2 Facility Footprint

Harlem River Yard

CITY OF NEW YORK
DEPARTMENT OF SANITATION

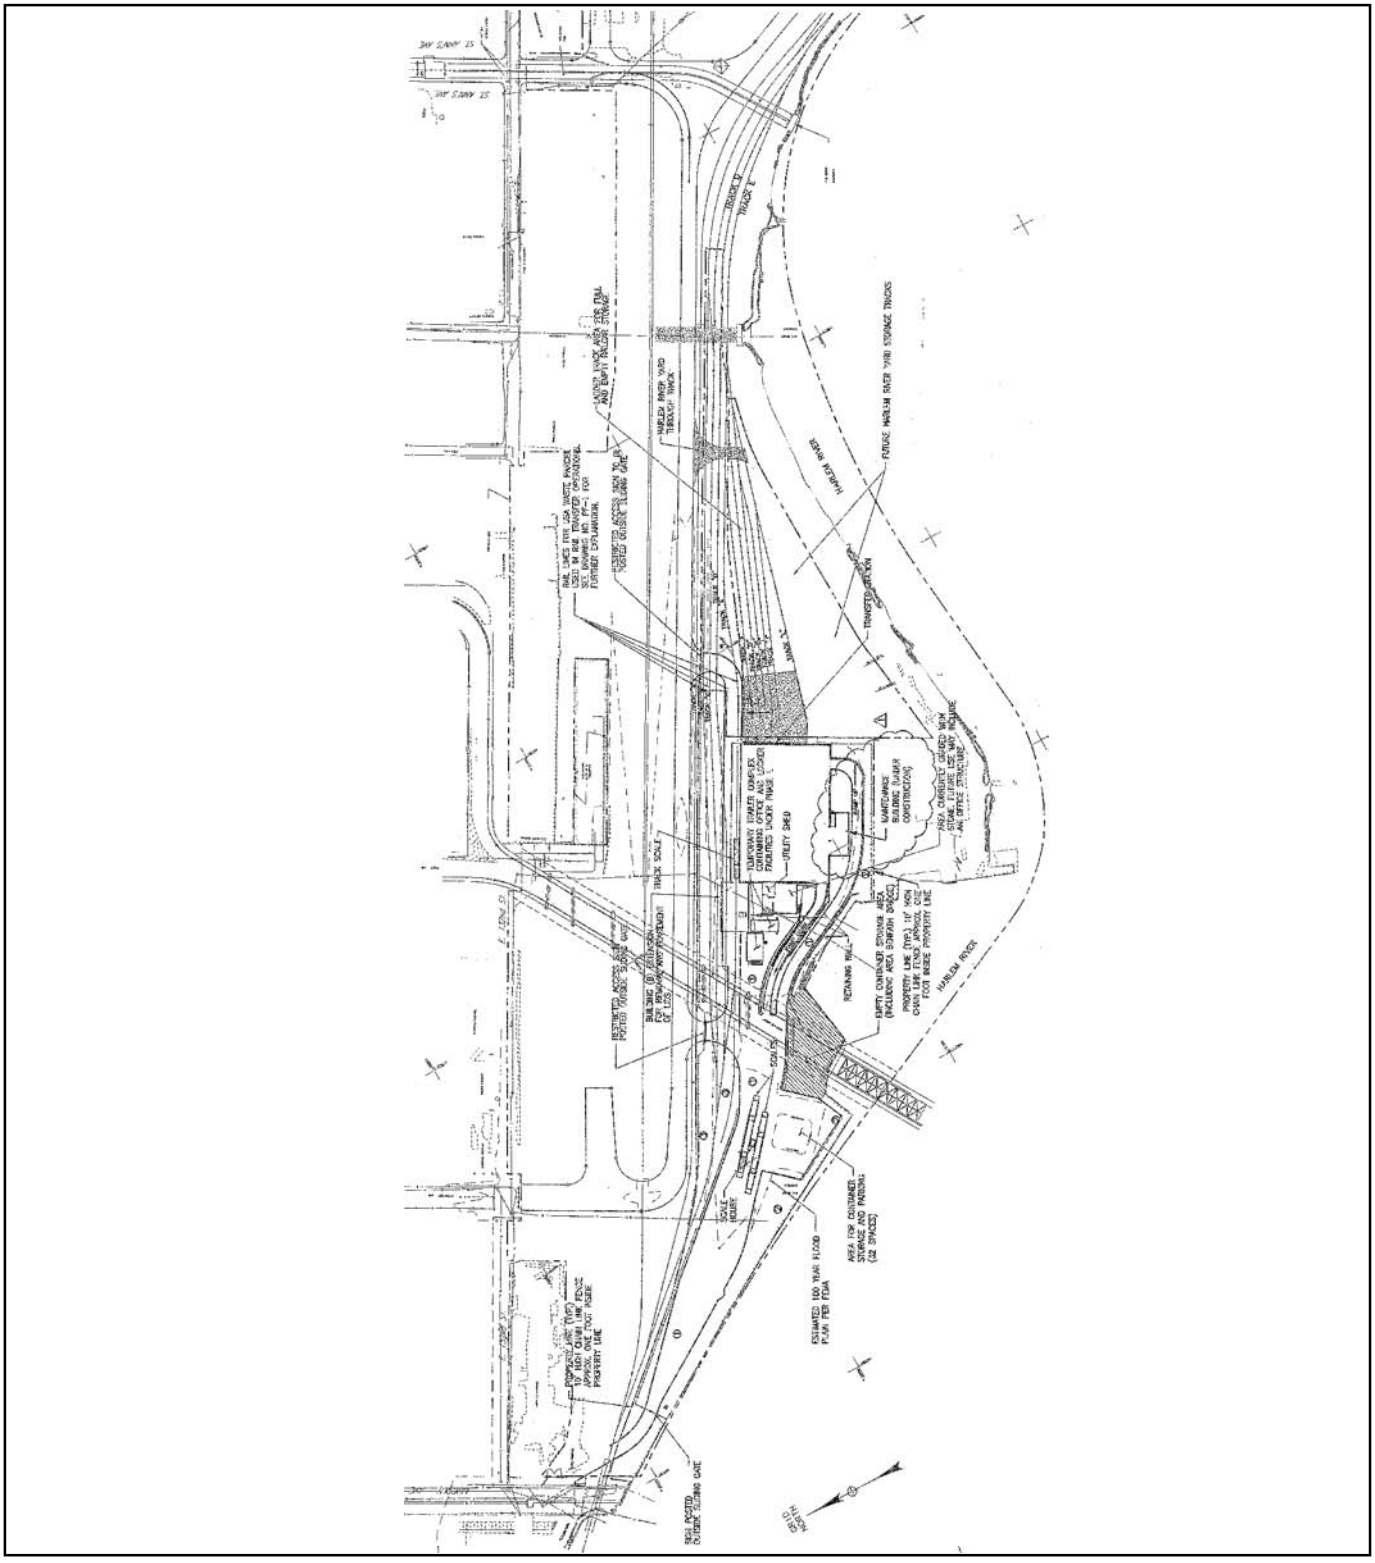
This page intentionally left blank.

The property is situated at an approximate elevation of 10 feet NGVD. The 100-year tidal surge or 100-year floodplain is at elevation 11 feet NGVD. All waste handling components of the facility's operation have been placed at elevation 12 feet NGVD or higher, leaving a minimum one-foot buffer. In addition, the tipping floors are located in an elevated building so that uncontained solid waste is handled well above the floodplain at elevation 19 to 21 feet NGVD.

Access to the site is via designated truck routes, including Bruckner Boulevard between Third Avenue and Willis Avenue, Bruckner Boulevard north of East 138th Street, East 138th Street, East 149th Street, Third Avenue, and Willis Avenue.

As reported in the 2000 SWMP FEIS, the study area for the Harlem River Yard Barge to Rail Intermodal Yard is very industrial in nature as it is part of one of the city's few remaining active industrial waterfronts. The area has not noticeably changed in terms of land use, population or zoning in the four years since publication of the 2000 SWMP FEIS. No significant adverse environmental impacts were predicted on the area's land use, socioeconomics, community facilities, open space, cultural resources, neighborhood character or urban design in the 2000 SWMP FEIS, which evaluated an intermodal EBUF at this site. Therefore, the less intensive Harlem River Yard Barge to Rail Intermodal Yard reported on in this FDEIS would, likewise, be expected to have no impacts.

NYCDCP, in March of 2005, approved a rezoning of approximately 15 blocks in the Port Morris section of the Bronx to allow mixed use development on underutilized blocks north of the HRY site. Development related to this potential rezoning is projected to occur by 2014 at the earliest, well beyond 2006 when the Proposed Action is expected to be implemented. Therefore, this rezoning and development were not included in the Future No-Build Condition analyzed in this FDEIS.



2.2.8.2 *HRY Truck to Rail TS*

The HRY Truck to Rail TS is permitted at 4,000 tpd. A 1993 FEIS supported permit approvals of the original 3,000 tpd facility. An application for a 1,000 tpd increase in capacity (to 4,000 tpd total) in October 2003, with an EAS dated August 2003 to support the 1,000 tpd increase has been approved. The EAS includes an evaluation of the $PM_{2.5}$ impacts associated with the 1,000 tpd increment in capacity. A Negative Declaration finding for that EAS has been issued by DSNY as the lead agency. NYSDEC has also approved the permit expansion.

The facility is currently contracted to accept up to 1,800 tpd of Bronx DSNY-managed Waste under interim export and DSNY delivers approximately 1,381 tpd on an average peak day. In response to DSNY's Bronx RFP, the HRY Truck to Rail TS proposes to accept all of the Bronx DSNY-managed Waste long term, which is approximately 2,337 tpd (average peak day analyzed in this FDEIS, increased by an additional 20% contingency). To accomplish this, the HRY Truck to Rail TS requires no increase in capacity, but does require a minor modification for additional equipment.

The HRY Truck to Rail TS was also the subject of an EAS in 2001 for Interim Export that evaluated the receipt of all of the Bronx DSNY-managed Waste (56 collection vehicles during the peak hour of 11:00 a.m. to 12:00 p.m.). Traffic analyses were completed at multiple locations and PM_{10} analyses were completed at two intersections. $PM_{2.5}$ was not analyzed and CO and mobile noise analyses were screened out.

The existing facility is a direct truck-to-rail facility where putrescible waste is loaded directly from the tipping and processing floor into containers on rail cars within the transfer station building. The complete transfer facility consists of an enclosed 69,600-square-foot steel-framed transfer building that includes an extension for lidding operations, maintenance and utility buildings, access roads and ramps, weigh station and scales, and employee and visitor parking lots. Figure 2.2.8-3 provides a plan view of the existing facility.

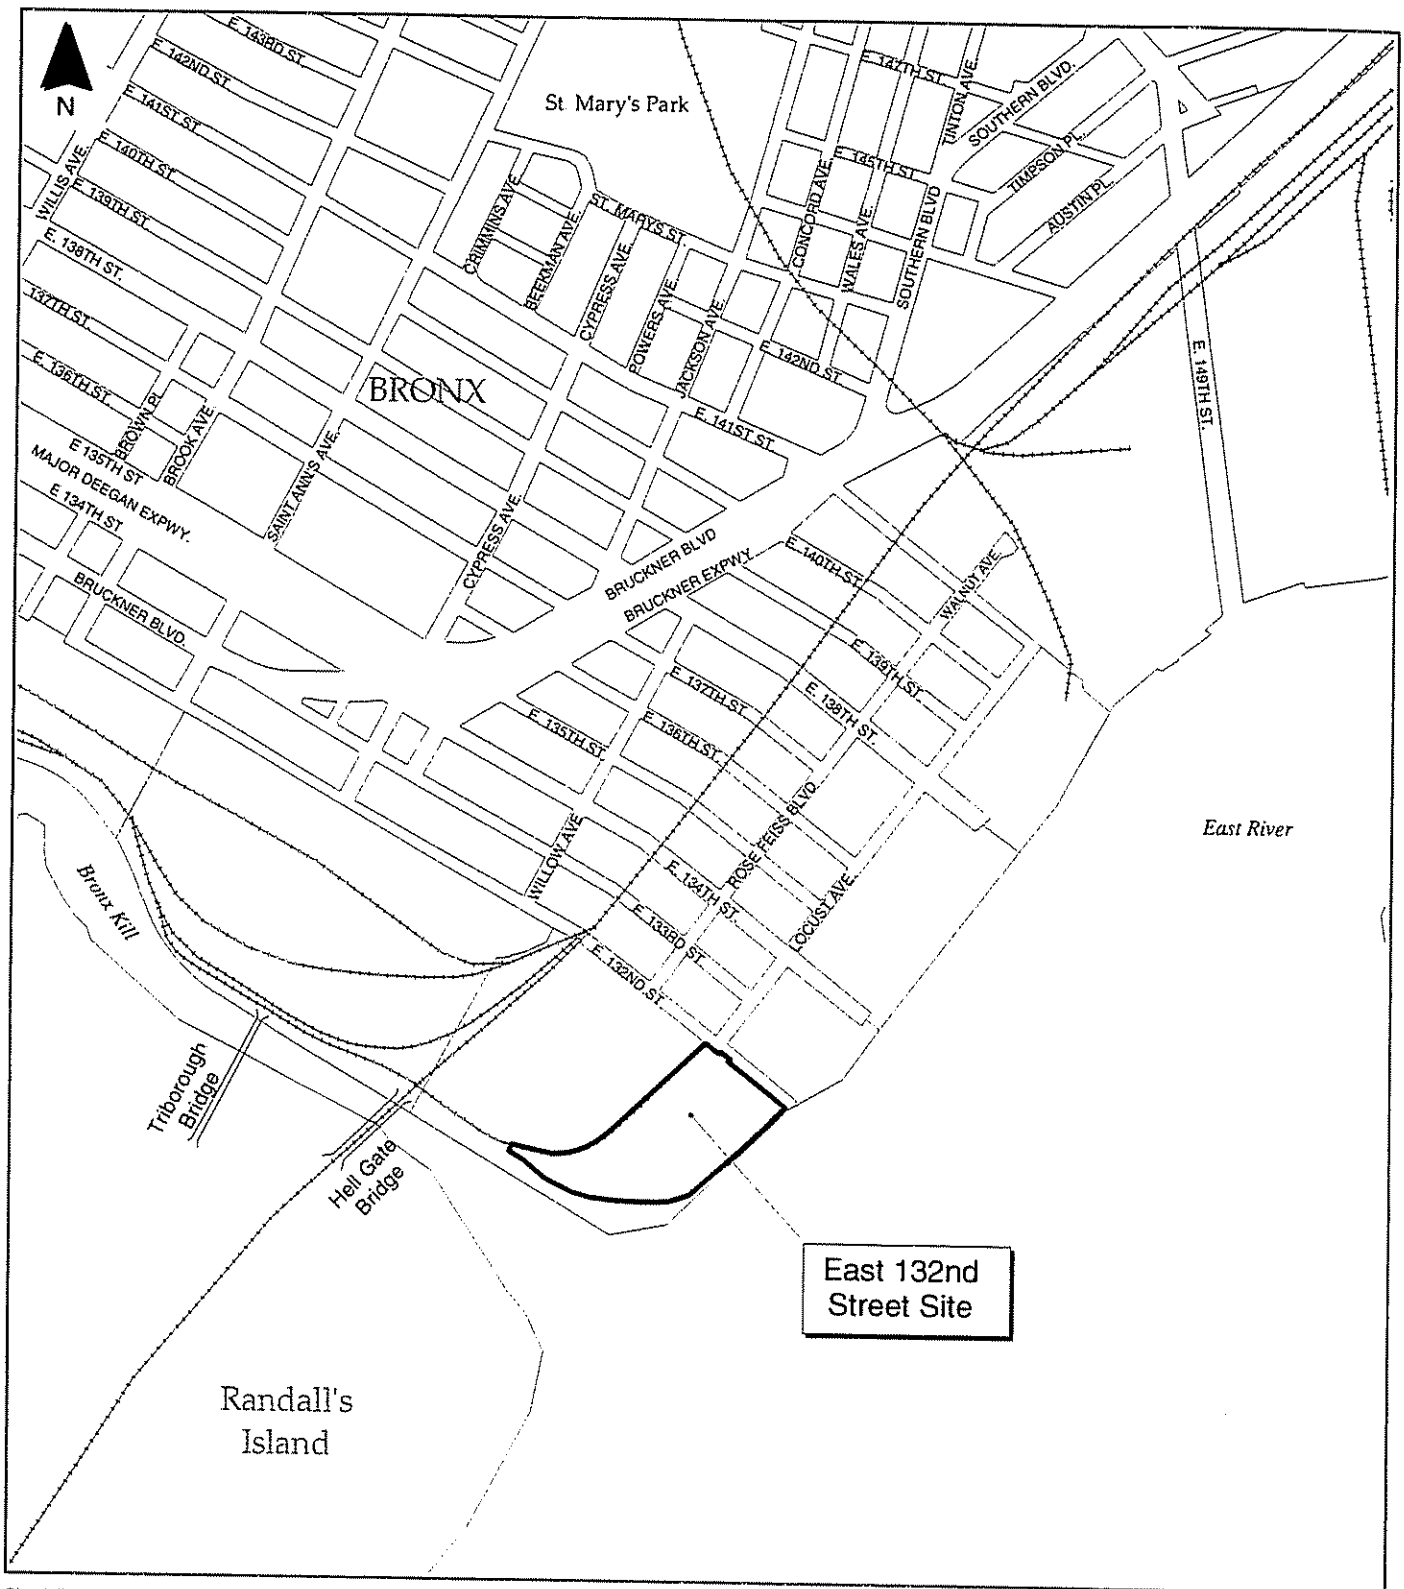
Figure 2.2.8-3 Plan View (Overall Site)

Harlem River Yard

CITY OF NEW YORK
DEPARTMENT OF SANITATION



2.2.9 East 132nd Street TS

2.2.9.1 Description of Existing Site

The East 132nd Street TS is an existing permitted facility in the Port Morris section of the South Bronx in CD 1, which is in the extreme southeastern corner of the Bronx. The site is bounded on the north by 132nd Street, on the east by the East River, on the south by the Bronx Kills and on the west by the Harlem River Yard. Based on City tax maps, the site is comprised of Lots 30 and 62 in Block 2538 and Lot 650 in Block 2538. The site and immediately surrounding area is zoned M3-1 for heavy industry. There are no residentially zoned districts, schools or parks within an approximate 2,000-foot radius of the site. There are no registered historic structures or significant architectural resources in the area. Figure 2.2.9-1 (Site Location) shows the location of the East 132nd Street Site.

East 132nd Street serves as the access road for the site. Employee parking is on the northern side of the property, where the site entrances and exits are located. The used portion of the site is entirely paved. The site is enclosed by fencing and has direct access to the East River.

Out-of-service rail tracks traverse the southwestern boundary and the middle of the site. These rails could not be used for direct rail export to an out-of City disposal facility because the East 132nd Street facility does not currently have rail access to the Harlem River Yard due to an agreement between the developer of the Harlem River Yard complex and the original developer of the truck-to-rail transfer station there. Under Long Term Export, DSNY-managed Waste would be containerized and then drayed to the Oak Point Rail Yard where containers would be loaded onto rail cars.

Site delineations are approximate

Figure 2.2.9-1 Site Location

East 132nd Street Site

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Figure 2.2.9-2 (Facility Footprint) provides an aerial view of the site and its features. Figure 2.2.9-3 (Plan View) depicts a layout of the existing facility. The processing building, which is approximately 450-foot-long and varies in width from 100 to 200 feet, provides approximately 67,500 square feet of space. It includes a two-story administrative wing on its western side. A 10,200-square-foot elevated tipping gallery on the eastern side of the processing building is accessed by collection vehicles via an inclined ramp. There are eight truck bays within the gallery for unloading. The building provides a 44,000-square-foot processing floor, 10 feet below the tipping gallery. Front-end loaders and excavators move waste dumped on the processing floor to conveyors feeding two baling units or a compactor.

On-site container storage areas can accommodate approximately 800 empty/full containers, each being approximately 20 feet long, 8 feet wide and 9½ feet high.

The facility currently exports waste by truck. The waste is hauled directly to a disposal facility by:

- Compacting waste into bales (with approximate dimensions of 45 inches by 40 inches by 40 inches) that are then placed on flatbed tractor-trailers and covered.
- Loading waste into walking floor or tipping transfer trailers that deliver to a disposal destination.

2.2.9.2 East 132nd Street Truck to Rail TS

The East 132nd Street Truck to Rail TS is currently permitted at 2,999 tpd based upon a negative declaration finding on an EAS completed in 1994 for that capacity. It is currently contracted to accept up to 1,500 tpd of Bronx DSNY-managed Waste under interim export. The quantities of DSNY-managed Waste delivered to this facility for interim export average approximately 1,033 tpd. In response to the DSNY's RFP to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from the Bronx (Bronx RFP), the East 132nd Street Truck to Rail TS proposes to accept all of the Bronx DSNY-managed Waste long term, which is approximately 2,337 tpd (the average peak day analyzed in the MTS Environmental Evaluation increased by an additional 20% contingency).

Site delineations are approximate.

HDR, HydroQual, URBITRAN, PB, EEA, Cambridge Environmental Inc	**Figure 2.2.9-3 Plan View** **East 132nd Street Site** **CITY OF NEW YORK** **DEPARTMENT OF SANITATION**	THE CITY OF NEW YORK DEPARTMENT OF SANITATION

To accomplish this, the East 132nd Street Truck to Rail TS requires no increase in capacity, but does require a minor permit modification to add container lidding outside of the building. Lids would be placed on the open-top containers that are loaded inside of the processing building and driven a short distance on site (less than 250 feet) from the enclosed truck loading area to the intermodal lidding station, where a crane would place a lid on the container. The lid would be secured with latches by facility personnel. There would be no increase in air emissions from the facility because no diesel-generating equipment is associated with the lidding operation. Since containers would be lidded shortly after exiting the processing building, any increase in odors that may occur during this period would not be significant. Noise generated from this lidding operation was measured at a facility with a similar operation. See Chapter 12 for a discussion of the on-site noise analysis results.

This facility was also the subject of an EAS in 1997 for interim export that evaluated the receipt of all Bronx DSNY-managed Waste. At that time, no off-site PM_{10} or $PM_{2.5}$ analyses were performed. The 2000 SWMP FEIS evaluated on-site, but not off-site, impacts related to delivery of all Bronx waste to this site under a variety of different export scenarios, e.g., EBUF, truck-to-barge, truck-to-rail. The EAS for Interim Export, updated in 2001, evaluated sending only a portion of the Bronx waste (24 collection vehicles during the peak hour between 11:00 a.m. to 12:00 p.m.) to the East 132nd Street Truck to Rail TS because that EAS focused more on analyzing all of the Bronx waste to Harlem River Yard. Traffic analyses were completed at multiple locations, and PM_{10} analyses were completed at two intersections. $PM_{2.5}$ was not analyzed, and CO and mobile noise analyses screened out. The increment of waste to be analyzed for off-site impacts in this FDEIS is 1,565 tpd (2,337 tpd minus 1,033 tpd plus 20% contingency).

2.2.9.3 Oak Point Rail Yard

Under Long Term Export, DSNY-managed Waste would be containerized and then drayed to the Oak Point Rail Yard, where the containers would be loaded onto rail cars. The Oak Point Rail Yard is approximately 2½ miles from the East 132nd Street Truck to Rail TS site in Bronx Community District 2. (See Figure 2.2.9-4, Site Location). Access to the Oak Point Rail Yard is provided via Oak Point Avenue off of Bruckner Boulevard. At the Oak Point Rail Yard, the

Site delineations are approximate

Figure 2.2.9-4 Site Location

Oak Point Railyard

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

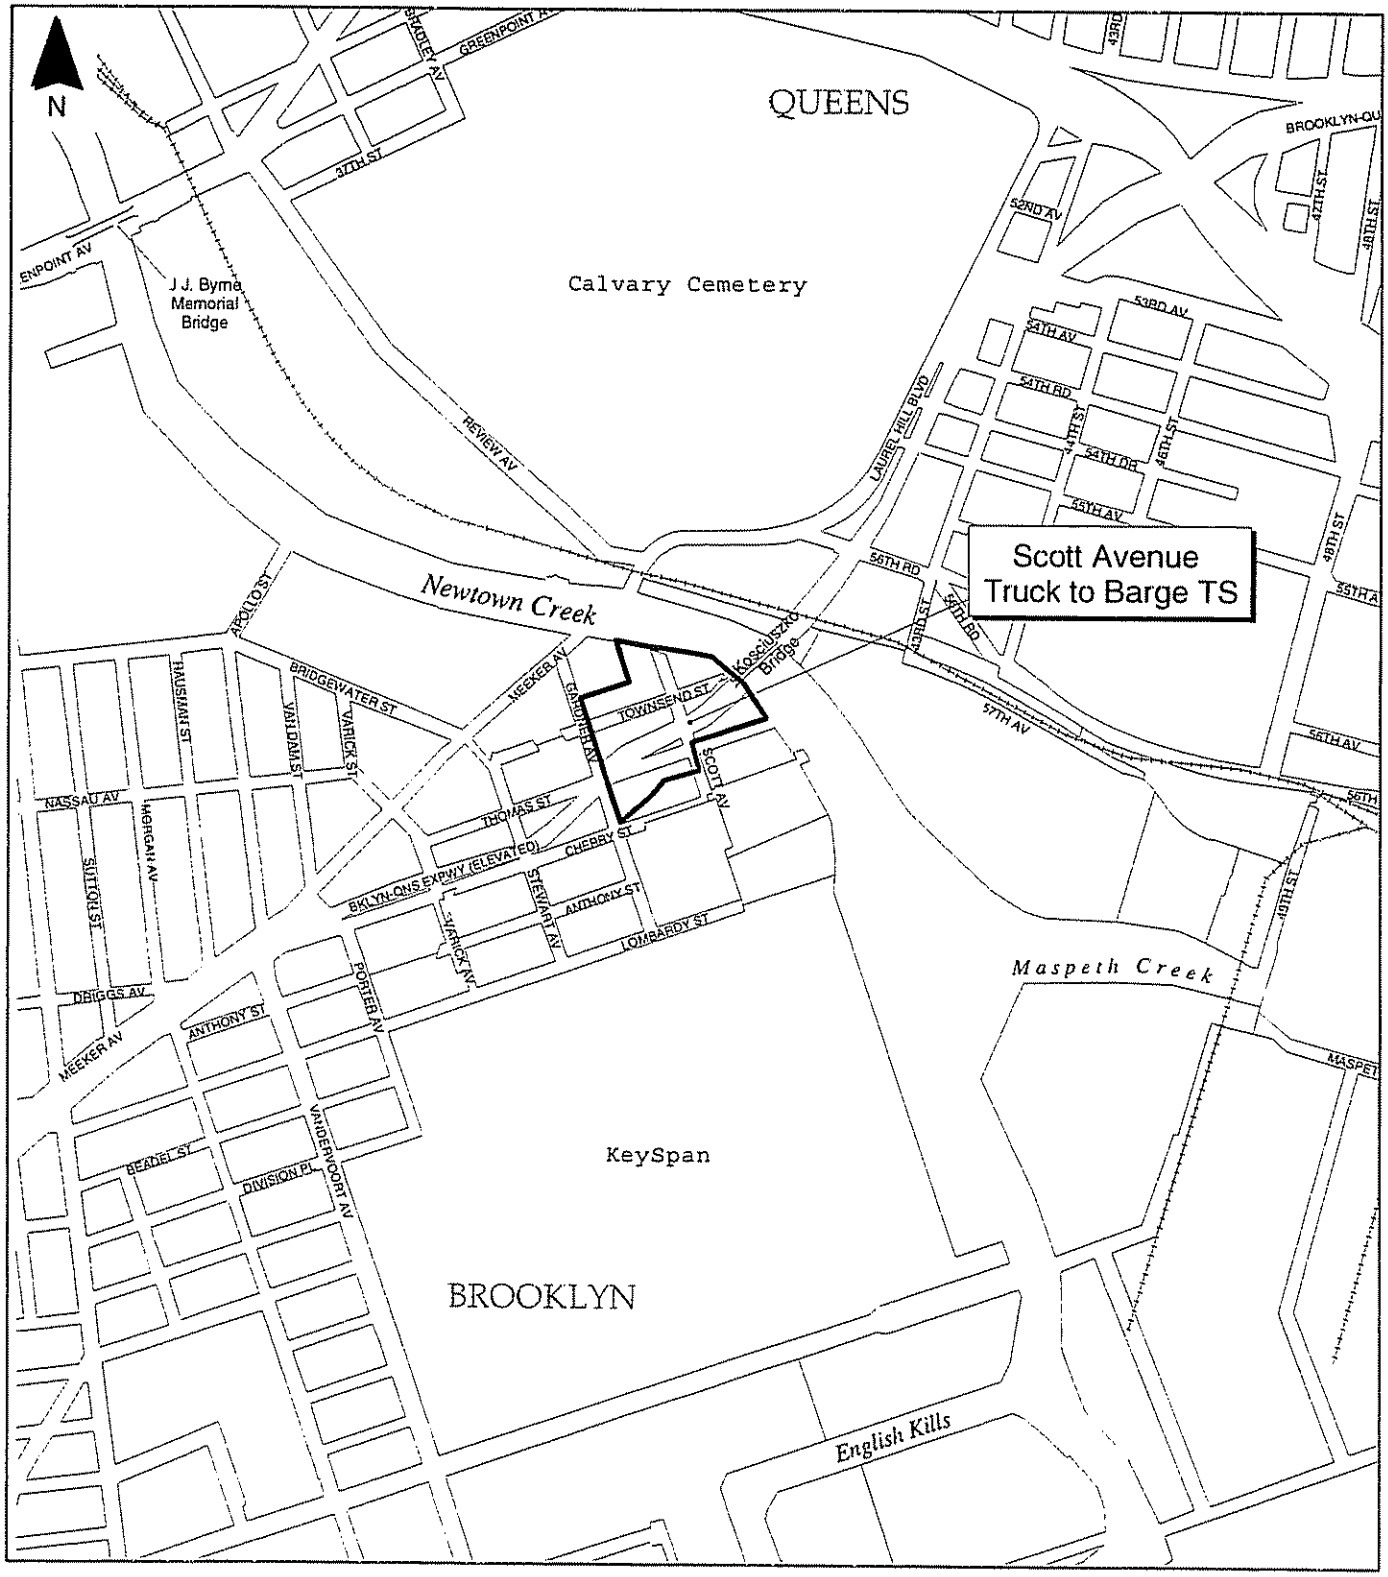
container would be loaded onto a rail car and a train section dispatched daily to an out-of-City disposal destination. Empty containers returned by train to the Oak Point Rail Yard are drayed back to the transfer station and stored at the site. Each train travels to a disposal facility and returns empty in an approximate seven-day or more cycle.

The trucking of containers of DSNY-managed Waste to Oak Point Rail Yard is considered part of this FDEIS, since, at present, all waste from the 132nd Street Truck to Rail TS goes out by transfer trailer. However, the review is limited to off-site impacts of draying to the Oak Point Rail Yard, since the Oak Point Rail Yard has been permitted as an intermodal yard, and any changes in this permit would be subject to DSNY's new rules as a non-discretionary action. The Bronx RFP issued by the DSNY requires that proposers commit to exporting all waste (both DSNY and commercial) processed at their facility by rail or barge. Although historically some waste processed at the East 132nd Street Truck to Rail TS was containerized and drayed to Oak Point Yard for export by rail, currently all waste moves out via transfer trailer. Thus, the draying of full containers of waste and return of empty containers between the East 132nd Street Truck to Rail TS and the Oak Point Rail Yard equivalent to the fully permitted capacity of the facility (2,999 tpd) would be a change in the existing condition.

2.2.10 Scott Avenue Truck to Barge TS, Brooklyn

2.2.10.1 Description of the Existing Site

The existing Scott Avenue Truck to Truck TS is a permitted facility located at 485 Scott Avenue. The site comprises several buildings, open lots and processing areas, and covers an area of 9.75 acres. The facilities and property are owned by Waste Management. The site is located in the Williamsburg Industrial Park section in Brooklyn, New York. The entrance to the site is at the intersection of Gardner Avenue and Thomas Street. The elevated Brooklyn-Queens Expressway (BQE) Kosciusko Bridge traverses the eastern portion of the site. Figure 2.2.10-1



(Site Location) shows the location of the site. Figure 2.2.10-2 (Facility Footprint) shows an aerial map with major features of the site.

The property abuts Newtown Creek. As such, the aquifer at this site is tidally influenced, brackish in quality and, as a result, is not used as a potable water source. No wetlands are located on the site or in the surrounding area.

The site is located in a heavily industrialized area that is zoned M3-1. The northern perimeter of the property is bounded by Newtown Creek. Properties to the south include warehouses, open lots, truck parking lots and other heavy manufacturing and industrial facilities. Properties to the east include factories, truck parking lots, construction yards and other properties associated with heavy industrial uses. Properties to the west include Newtown Creek, a building supply and equipment rental facility, importer warehousing and related truck parking and other heavy industrial uses.

Access to the site is via designated truck routes including Vandervoort Avenue, Lombardy Street, Metropolitan Avenue, Grand Street, Norman Avenue and McGuinness Boulevard. The blocks and lots which comprise the site and the functions they are used for are listed below.

- Block 2798, Lot 1 – Vehicle parking and recyclables storage.
- Block 2798, Lot 30 – One-story building with office and space for equipment repair and storage; two-story building which houses offices, toilets and equipment repair, and storage.
- Block 2799, Lot 1 and Block 2803, Lot 1 – The outdoor yard is used for glass crushing operations and C&D processing operations.

Site delineations are approximate

- Block 2803, Lots 14 and 25 – Material storage and truck parking.

- Block 2802, Lot 1 – Access area.

- Block 2802, Lots 10, 11 and 14 – Three-story building which houses the mixed solid waste processing and transfer; processing, baling and transfer of commingled recyclables.

- Block 2808, Lots 3 and 25 – Baled recyclables storage and bale washing.

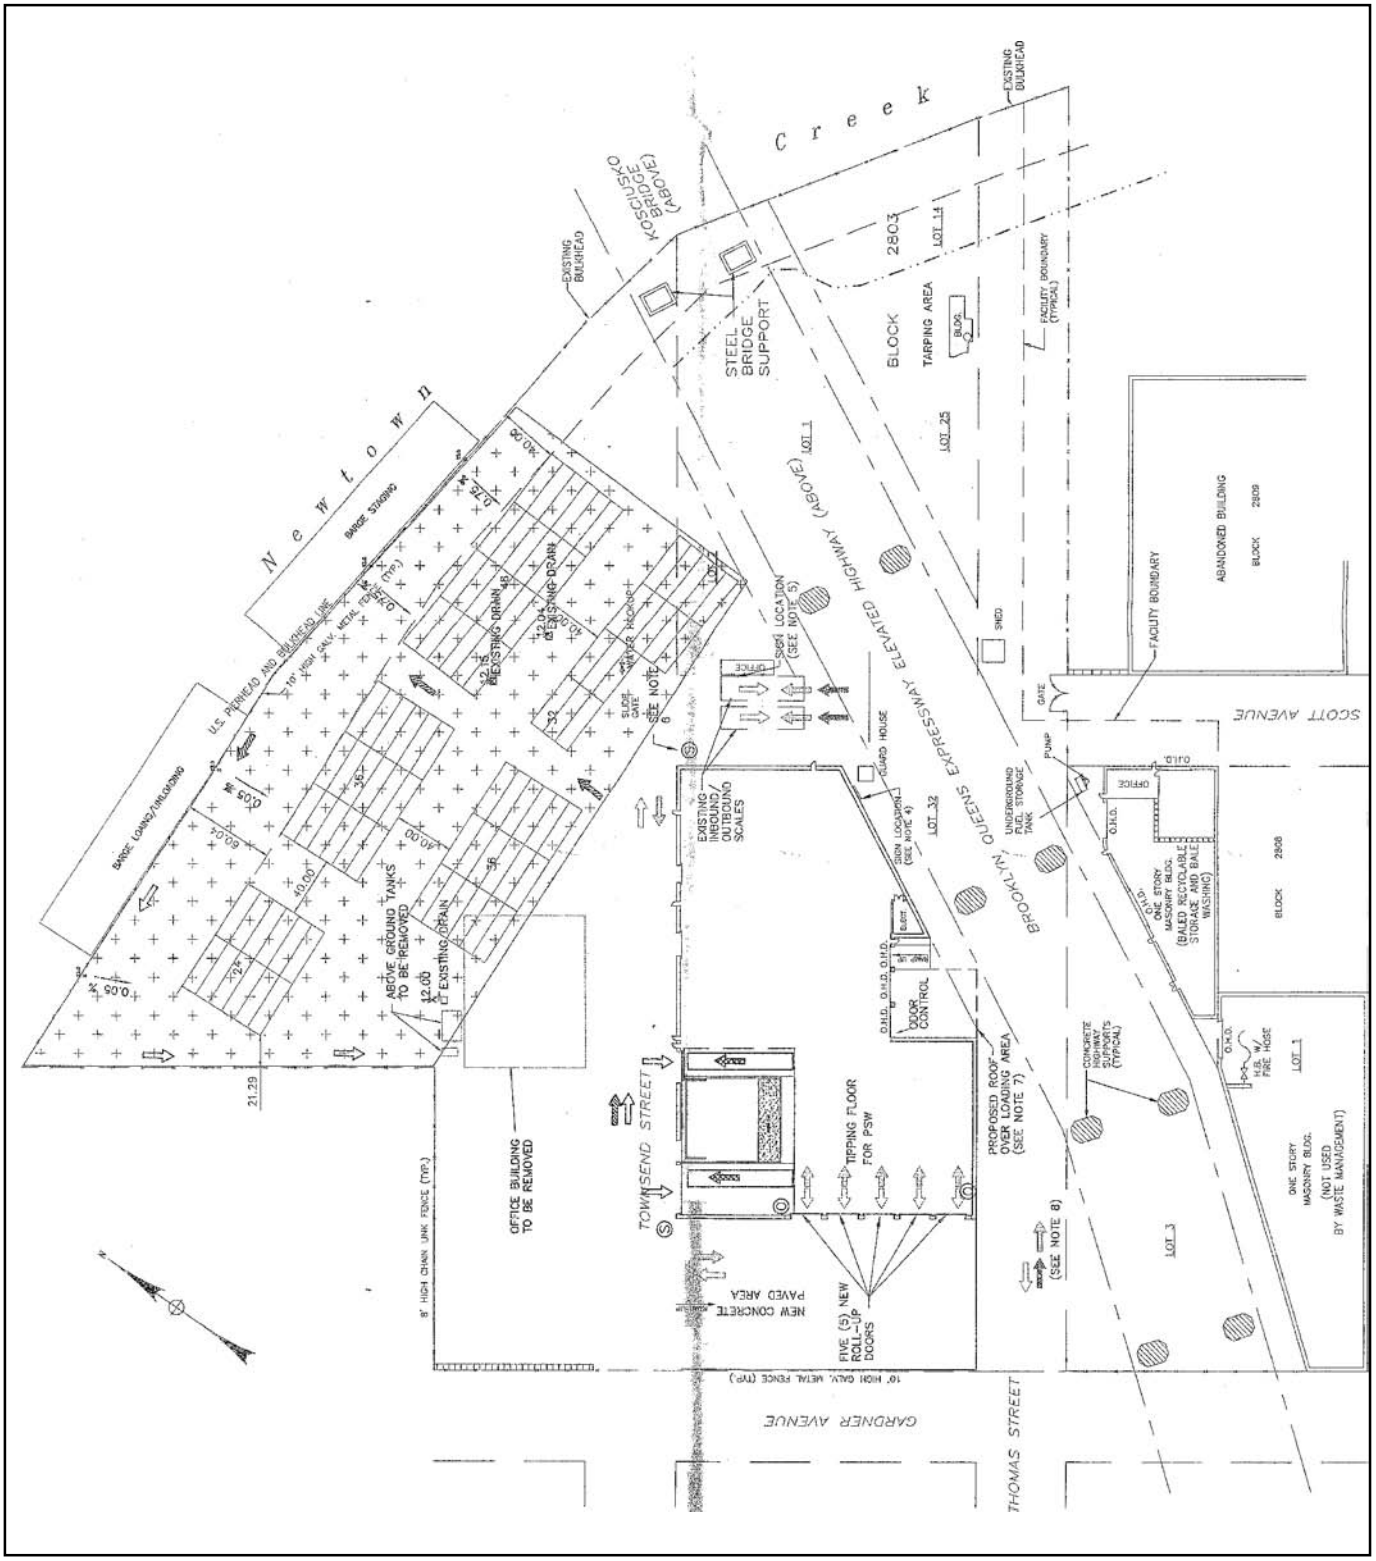
Newtown Creek is a NYSDEC-designated littoral zone. The existing property is currently situated between 7.5 feet and 22 feet Brooklyn Highway Datum (BHD) or 10.06 to 24.56 feet mean sea level (MSL). The 100-year tidal surge or 100-year floodplain is at elevation 10 feet MSL (7.44 feet BHD). All waste handling components of the facility's operation have been placed at elevation 7.5 feet BHD or higher to minimize the risk of flooding at the site.

2.2.10.2 Scott Avenue Truck to Barge TS

The existing Scott Avenue Truck to Truck TS is currently permitted at 1,500 tpd with a negative declaration and EAS for that capacity dated January 2003. The Scott Avenue Truck to Truck TS is currently contracted to accept up to 1,400 tpd of DSNY-managed Waste under Interim Export. In response to the DSNY's Request for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from Brooklyn Formerly Delivered to the Greenpoint Marine Transfer Station (Brooklyn RFP), the Scott Avenue Truck to Truck TS proposes to accept all of the Brooklyn DSNY-managed Waste long term, which is approximately 900 tpd. To accomplish this, the Scott Avenue Truck to Truck TS requires no increase in capacity, but does require a minor modification for barge loading and container lidding to operate as a Truck to Barge TS.

This facility was also the subject of an EAS in 1998/1999 for Interim Export. At that time, no off-site $PM_{2.5}$ analysis was performed and there is not enough available information to determine if a PM_{10} analyses was performed. The EAS for Interim Export, updated in 2002, assumed

continuation of the 1998/1999 EAS action, so no traffic, $PM_{2.5}$, CO or mobile noise analyses were completed since there was no net change. PM_{10} was analyzed at four locations. The 2000 SWMP FEIS evaluated this facility as a truck-to-barge operation.



The quantities of DSNY-managed Waste delivered to the facility under Interim Export average approximately 1,114 tpd. The Scott Avenue Truck to Barge TS would take 900 tpd, which is a decrease in tonnage. Therefore, no off-site analyses are required.

The Scott Avenue Truck to Barge TS would be a direct container-to-barge facility, where putrescible waste is loaded directly from the tipping and processing floor into containers and then transported from the transfer building across the property to waiting shuttle barges for transport to a container handling facility. At the container handling facility, containers would be loaded onto ocean going barges for long-haul transport to a final disposal facility.

The facility consists on an enclosed 52,492-square-foot masonry transfer building, including maintenance and office areas; access roads; tipping bays; loading bays; two scales, a scale house and a loading scale inside the building; and employee and visitor parking areas. Figure 2.2.10-3 (Plan View) shows the existing facility. All waste is received, handled and processed within the transfer station building.

Modifications to the facility would be made to accommodate containerizing the waste, and container handling and barge loading operations. Site features changed would include demolition of the office and maintenance building, relocating the functions to the main transfer building, and removing recycling areas from the main building (which would be replaced by an additional enclosed loadout area in the north side of the building).

The putrescible waste processing building, which also houses various pieces of mobile and stationery equipment used in the transfer process, is one story, approximately 30 feet high, with new roll-up doors, a 12,000-sq-ft tipping floor, unauthorized waste storage areas, a concrete paved floor, ramps, loading docks and processing equipment. The access ramp consists of 12 inches of concrete with reinforcing bars, and the sections of floor in the building subject to the heaviest loading conditions are concrete.

Source: TAMS Consultants, Inc, March 29, 2004

Figure 2.2.10-3 Plan View

Scott Avenue Truck to Barge TS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

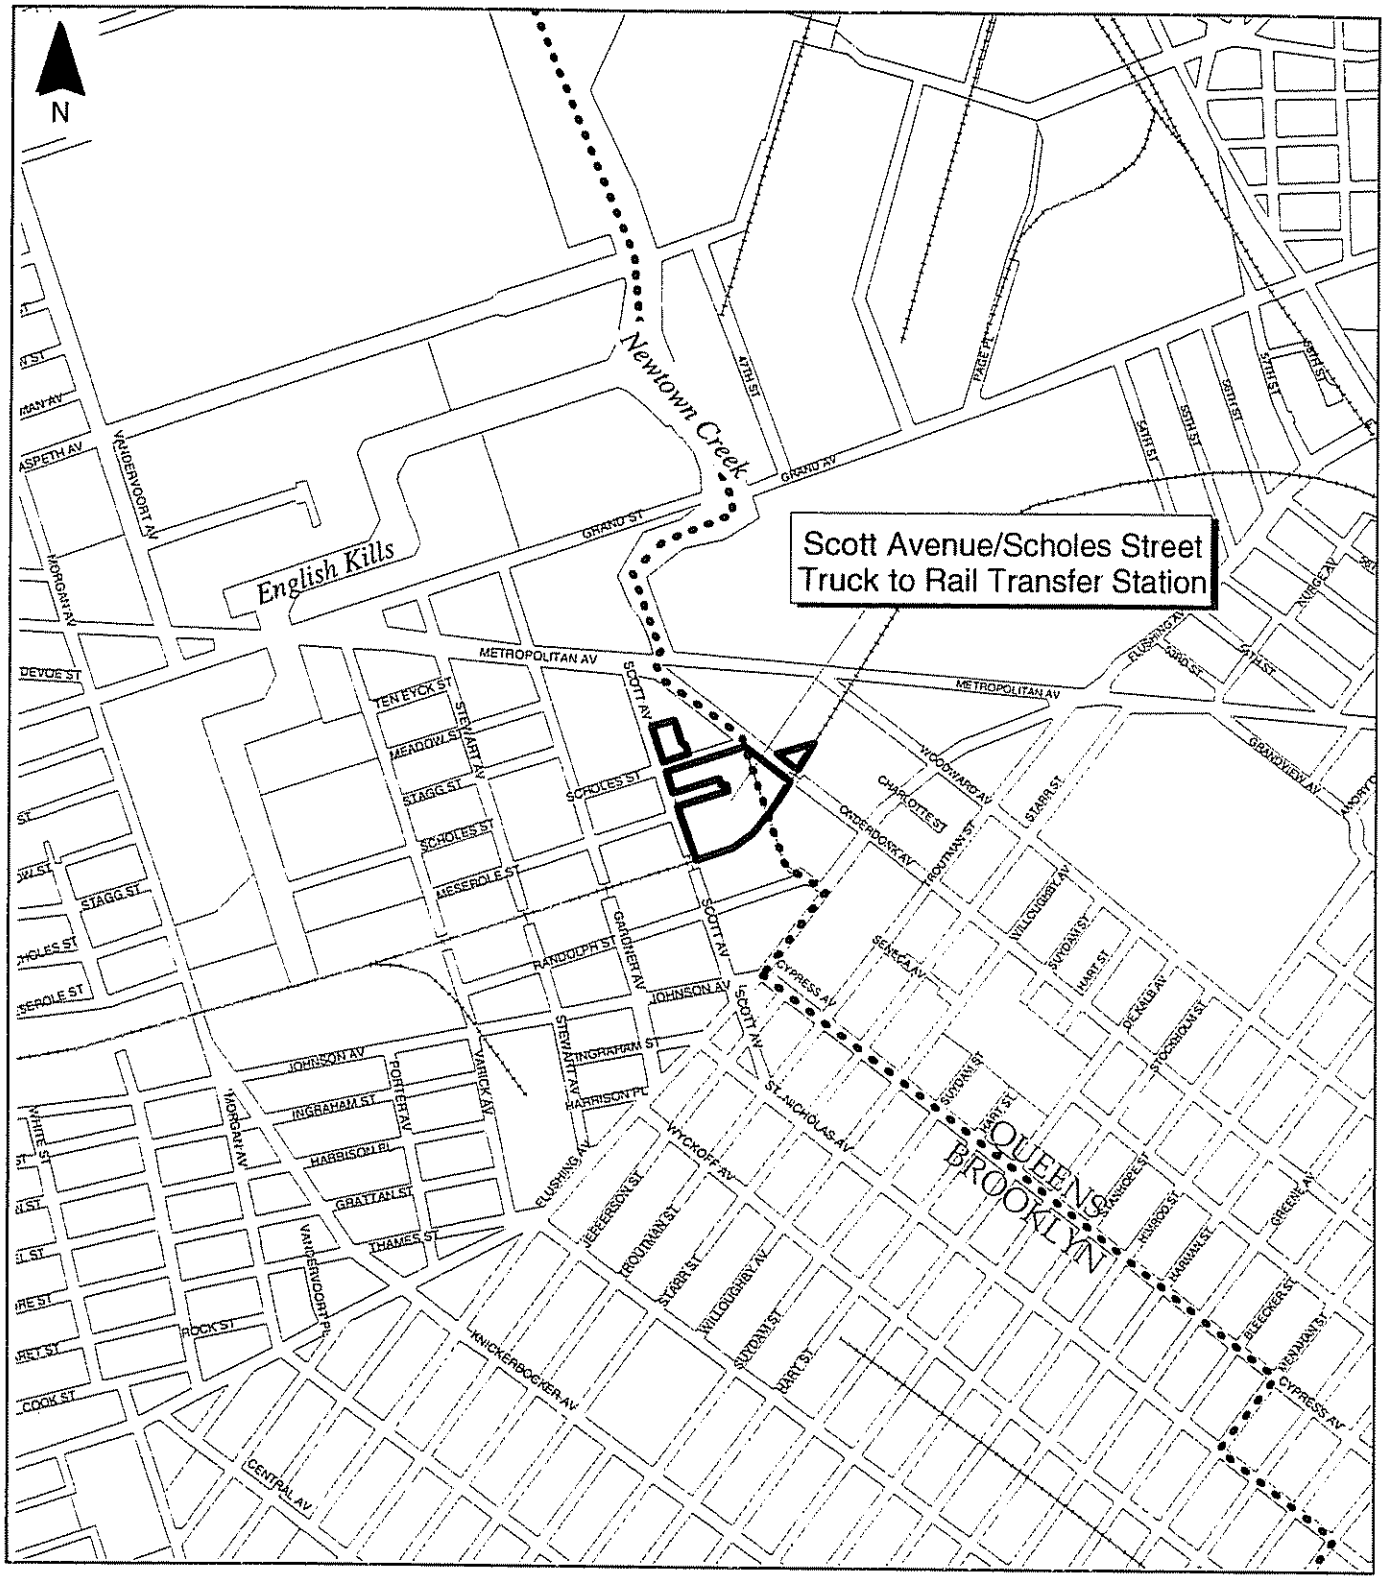
The putrescible waste processing area consists of five tipping bays for simultaneous processing of waste. Modifications to the facility would include the addition of a bay, equipped with a scale for loading purposes. Crushed and compacted putrescible waste would be loaded into containers on chassis in these bays and weighed prior to being moved to the barge link across the yard.

Vehicular access and egress to the facility is at Thomas Street at the intersection of Gardner Avenue. Incoming trucks queue off the street and on the facility along the inbound access road beneath the elevated BQE. Approximately 10 to 12 vehicles can safely be queued single-file along the access road without encroaching on Gardner Avenue. Since the scale house can process up to 45 vehicles per hour, including movement on and off each of the scales, the peak volume can be managed safely and efficiently. Once unloading is completed, the truck pulls forward and exits the processing building, proceeds to the outbound scale to be weighed, and then exits the facility.

After weighing, the driver is directed to unload at the designated unloading area. A wheel loader and/or grapple pushes and spreads the tipped waste. Refuse in the processing area is then crushed and/or compacted. Movable container chassis equipped with containers will be positioned in scale-equipped container pits. Wheel loaders or grapples lift the loose crushed or compacted putrescible waste into containers, which are then covered securely with lids. The container is then moved on a chassis to the barge loading area on Newtown Creek. The barge loading area would have a reconstructed bulkhead and fender system, and the adjacent Newtown Creek area would be dredged to allow for barge operations. Reach stackers would be used to lift the containers from the chassis, which are then either staged for loading onto shuttle barges or loaded directly onto the shuttle barges for transport.

Shuttle barges would be used to initially remove containerized waste from the facility. The shuttle barges would be towed to and from American Stevedoring (ASI) in Red Hook, Brooklyn. At ASI, the lidded containers are transferred, using overhead cranes, onto ocean-going barges, which would be towed to and from Port Weanack in Virginia. There, lidded containers would be unloaded and either temporarily staged or loaded directly onto tractor-trailer chassis for transfer to the Charles City County Landfill for disposal.

2.2.11 Scott Avenue/Scholes Street Truck to Rail TS



2.2.11.1 Description of Existing Site

The Scott Avenue/Scholes Street Truck to Rail TS site is located at 72 Scott Avenue/598 Scholes Street in Community District 1 near the Brooklyn/Queens border, in the predominantly industrial section of East Williamsburg, Brooklyn. It is generally surrounded by English Kills on the west, Newtown Creek on the east and LIRR tracks to the east and south. The area is also characterized by abundant parking lots and garage facilities, some of which are leased by DSNY for trucks and other equipment storage. Figure 2.2.11-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 2990, Lot 1 and Tax Block 2979, Lot 5, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

Currently, the site contains a processing facility for commingled recyclables, putrescible waste processing area, and wastepaper baling plant, owned by Allied Waste Services. The 598 Scholes Street site is currently permitted to handle 1,450 tpd of source-separated recyclables, and 220 tpd of putrescible waste. The buildings occupy a 106,700-square-foot area with several loading docks and rail access to the southeast.

The site is located within an M3-1 zoning district. This M3-1 zone extends north of the site along English Kills, east into Queens and south of the site where there are M1-2 and M1-1 zoning districts as well. The M1 zones act as a buffer between the residential and the heavier manufacturing districts and feature both residential and light manufacturing (e.g., distribution) activities. The nearest residential district, R5B, is located approximately ¼-mile east of the site.

The Scott Avenue/Scholes Street site is situated on the Brooklyn/Queens border which separates East Williamsburg, Brooklyn to the west and Maspeth, Queens to the east. South of the site are several private waste transfer stations (including BFI Waste Systems facilities on Scholes Street and Gardner Avenue, and Waste Management of New York facilities on Stewart Avenue and Varick Avenue), as well as a DSNY parking lot on Meserole Street, a new CD 1 and 4 garage under construction on Varick Avenue and an existing garage on Johnson Avenue.

Figure 2.2.11-1 Site Location
Scott Avenue/Scholes Street
Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The English Kills canal located ¼-mile east of the site is approximately 200 feet wide and connects with Newtown Creek at the Brooklyn/Queens boundary. The LIRR tracks pass immediately south of the site between Meserole and Randolph Streets. The NY&A operates freight trains on these tracks, with a terminal nearby in Bushwick (to the west).

North and south of the existing site are scrap metal yards and plastic manufacturing facilities, window and door manufacturing, lumber yards and hydraulic equipment leasing companies. Development surrounding the site is primarily low density with open parking lots and low-scale masonry buildings ranging from two to four stories in height.

The area surrounding the Scott Avenue/Scholes Street site includes some vacant land to the north on Gardner and Stewart Avenues, as well as lots undergoing construction. Some sites have been rehabilitated to accommodate new industrial loft space and community facilities such as a Peter Jay Sharp Center for Opportunity on Porter Street. The other community facilities include a fire station on Morgan Avenue and a daycare center on Knickerbocker Street.

There is a mix of residential, industrial and some commercial uses further from the site. Industrial uses located nearly ½-mile from the site tend to be of lighter intensity than those found within ¼-mile of the site. These uses include printers, auto salvage and repair shops and food product manufacture and distribution companies. The nearest residential area, Bushwick, which is ½-mile east of the site along Willoughby and Starr Streets, is characterized by three- and four-story apartment buildings as well as single-family homes and townhouses.

According to published sources, no historic structures are located on the site. However, within ½-mile of the site there are three early 20th-century historic districts and one individual property that are listed on the NYSR and NR. The Vander Ende-Onderdonk House (a.k.a., The Adrian and Anne Wyckoff Onderdonk House), located nearly ¼-mile east of the site, is a City landmark and listed on the NYSR and NR. It is the oldest Dutch-American fieldstone house in the City, and houses the Greater Ridgewood Historical Society. The three historic districts within ½-mile of the site (or just beyond) are all intact groupings of late 19th-century/early 20th-century working class rowhouse and tenement housing. They are all in the bisected neighborhood of Ridgewood,

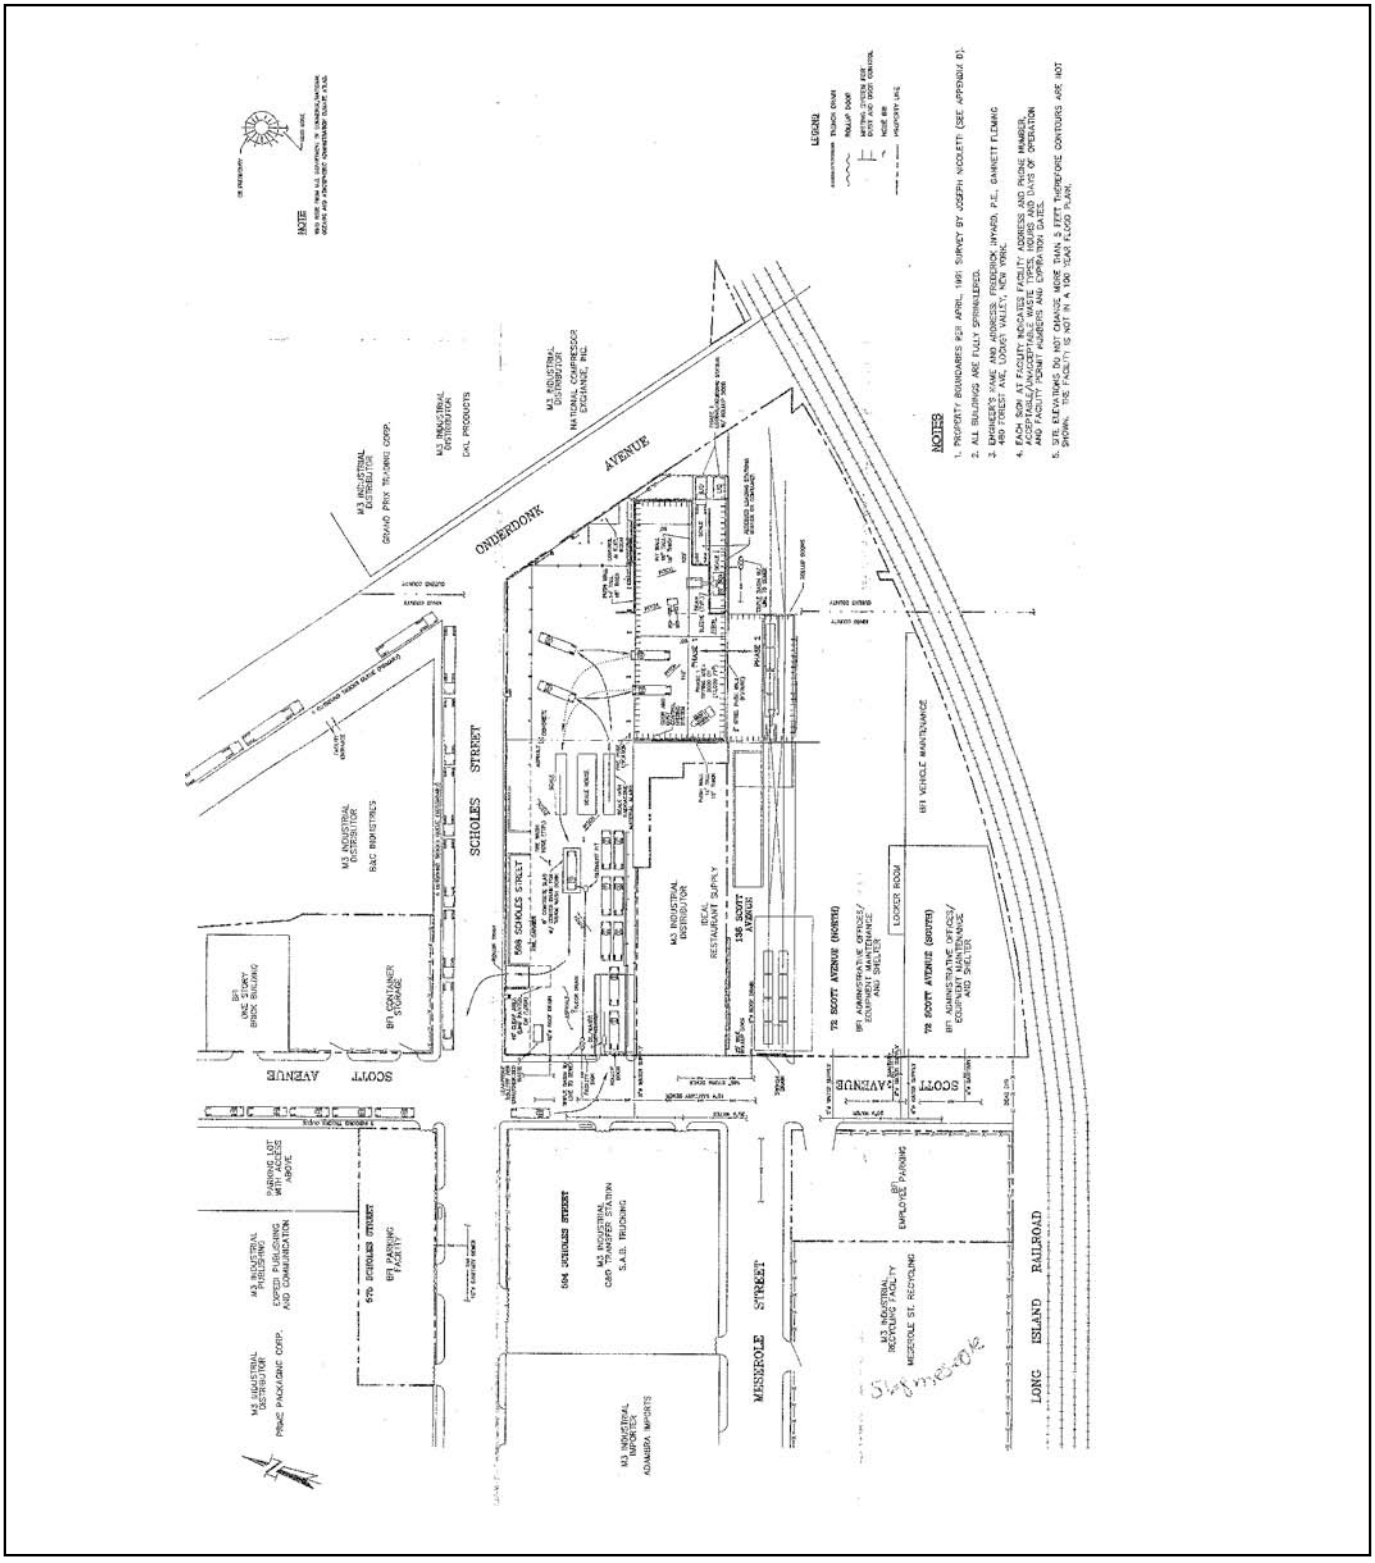
which spans the Queens and Brooklyn border. The Willoughby-Suydam Historic District covers 1½ blocks composed of 50 three-story brick tenements built between 1904 and 1906. Located more than ¼-mile southeast of the site, the district is listed on the NYSR and NR. The Stockholm-DeKalb-Hart Historic District covers 2½ blocks, approximately ½-mile east of the site. The central portion of this district is designated by LPC as the Stockholm Street Historic District.

2.2.11.2 Scott Avenue/Scholes Street Truck to Rail TS

The Scott Avenue/Scholes Street Truck to Rail TS would require an increase in its currently permitted putrescible waste capacity and would add rail export to the facility's waste shipping capabilities. Figure 2.2.11-2 (Facility Footprint) shows the features of the site on an aerial photograph. Figure 2.2.11-3 (Plan View) depicts a layout of the existing facilities on the site.

The capacity of the facility would be increased to 1,368 tpd. This would include the 560 tpd of putrescible capacity that would be transferred to the Scott Avenue/Scholes Street Truck to Rail TS from a nearby facility on Thames Street that would be shut down. In addition, Allied proposes that the permitted capacity of 388 tpd of C&D at 594 Scholes Street and 200 tpd from glass, tire and yard waste at 575 Scholes Street be transferred to the Scott Avenue/Scholes Street Truck to Rail TS. The permit application and EAS for the expansion to 1,368 tpd was submitted in September 2003, with supplemental traffic analyses submitted in March 2004 to support the expansion. The site is currently contracted to accept up to 220 tpd of DSNY-managed Waste under Interim Export, and has proposed to accept 891 tpd of DSNY-managed Waste under Long Term Export.

This facility was also the subject of an EAS in 1998-1999 for Interim Export at its permitted 220 tpd capacity. At that time, no off-site $PM_{2.5}$ analysis was performed. The updated EAS in 2002 assumed a continuation of the previous tonnage, so no traffic, $PM_{2.5}$, CO or mobile noise analyses were completed. PM_{10} was analyzed at four locations. This analysis will, therefore, provide a complete on- and off-site environmental review for 1,368 tpd capacity, reflecting the proposed phase-in from truck to on-site rail export.



Site Delineations are approximate.

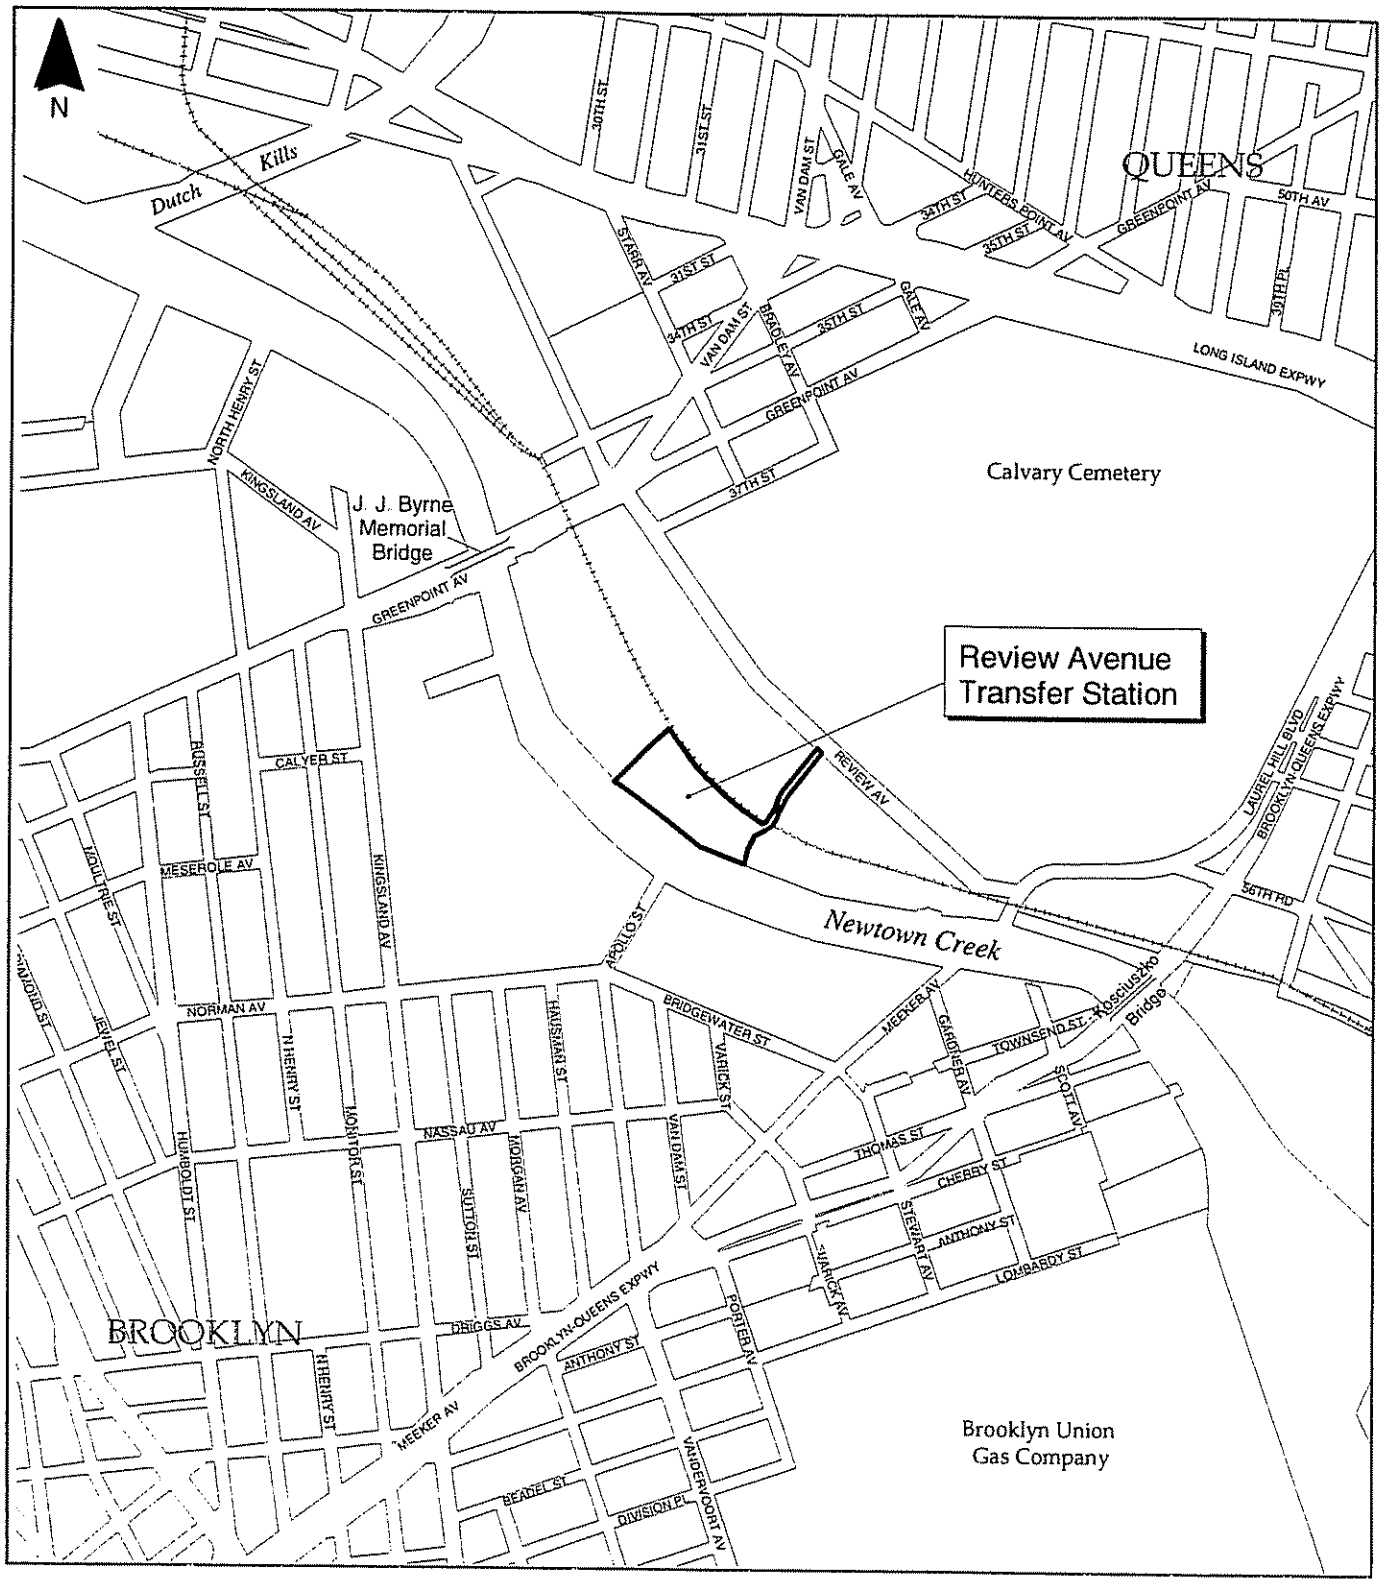
2.2.12 Review Avenue Truck to Rail/Barge TS



2.2.12.1 Description of Existing Site

The Review Avenue TS site is located at 38-50 Review Avenue in Queens and is adjacent to Newtown Creek. The facility and property are owned by Waste Management of New York. The site is in the West Maspeth section of Queens in Queens Community District 2 in a heavily industrialized area across Newtown Creek from the Greenpoint section of Brooklyn. It is bounded by the Montauk branch of the LIRR on the north and Newtown Creek to the south. Industrial and warehouse buildings are on the site's eastern and western borders. Laurel Hill Boulevard is farther to the east and Greenpoint Avenue is farther to the west. Calvary Cemetery is approximately 520 feet to the north of the site. There are no schools or parks within a ¼-mile radius.

The site is comprised of approximately four upland acres. Access to the site is via an easement that extends from Review Avenue between two warehouses and over the LIRR right-of-way. Based on City tax maps, the site is comprised of all or portions of Lots 300, 308, 309 and 1366 within Block 312. Figure 2.2.12-1 (Site Location) shows the location of the site.

The site and the immediately surrounding area are zoned M3-1 for industrial/heavy manufacturing use under a "Use Group 18" designation. The site is currently permitted to handle 958 tpd of putrescible solid waste as a truck-transfer facility. Newtown Creek is an NYSDEC-designated littoral zone and a portion of the existing property is within the 100-year floodplain.

DSNY's Request for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from Queens Formerly Delivered to the Greenpoint Marine Transfer Station (Queens RFP), requires that proposers commit to exporting all waste processed at their facility (both DSNY and commercial) by rail or barge. In its response, the proposer offered two alternatives, one for barge and one for rail.

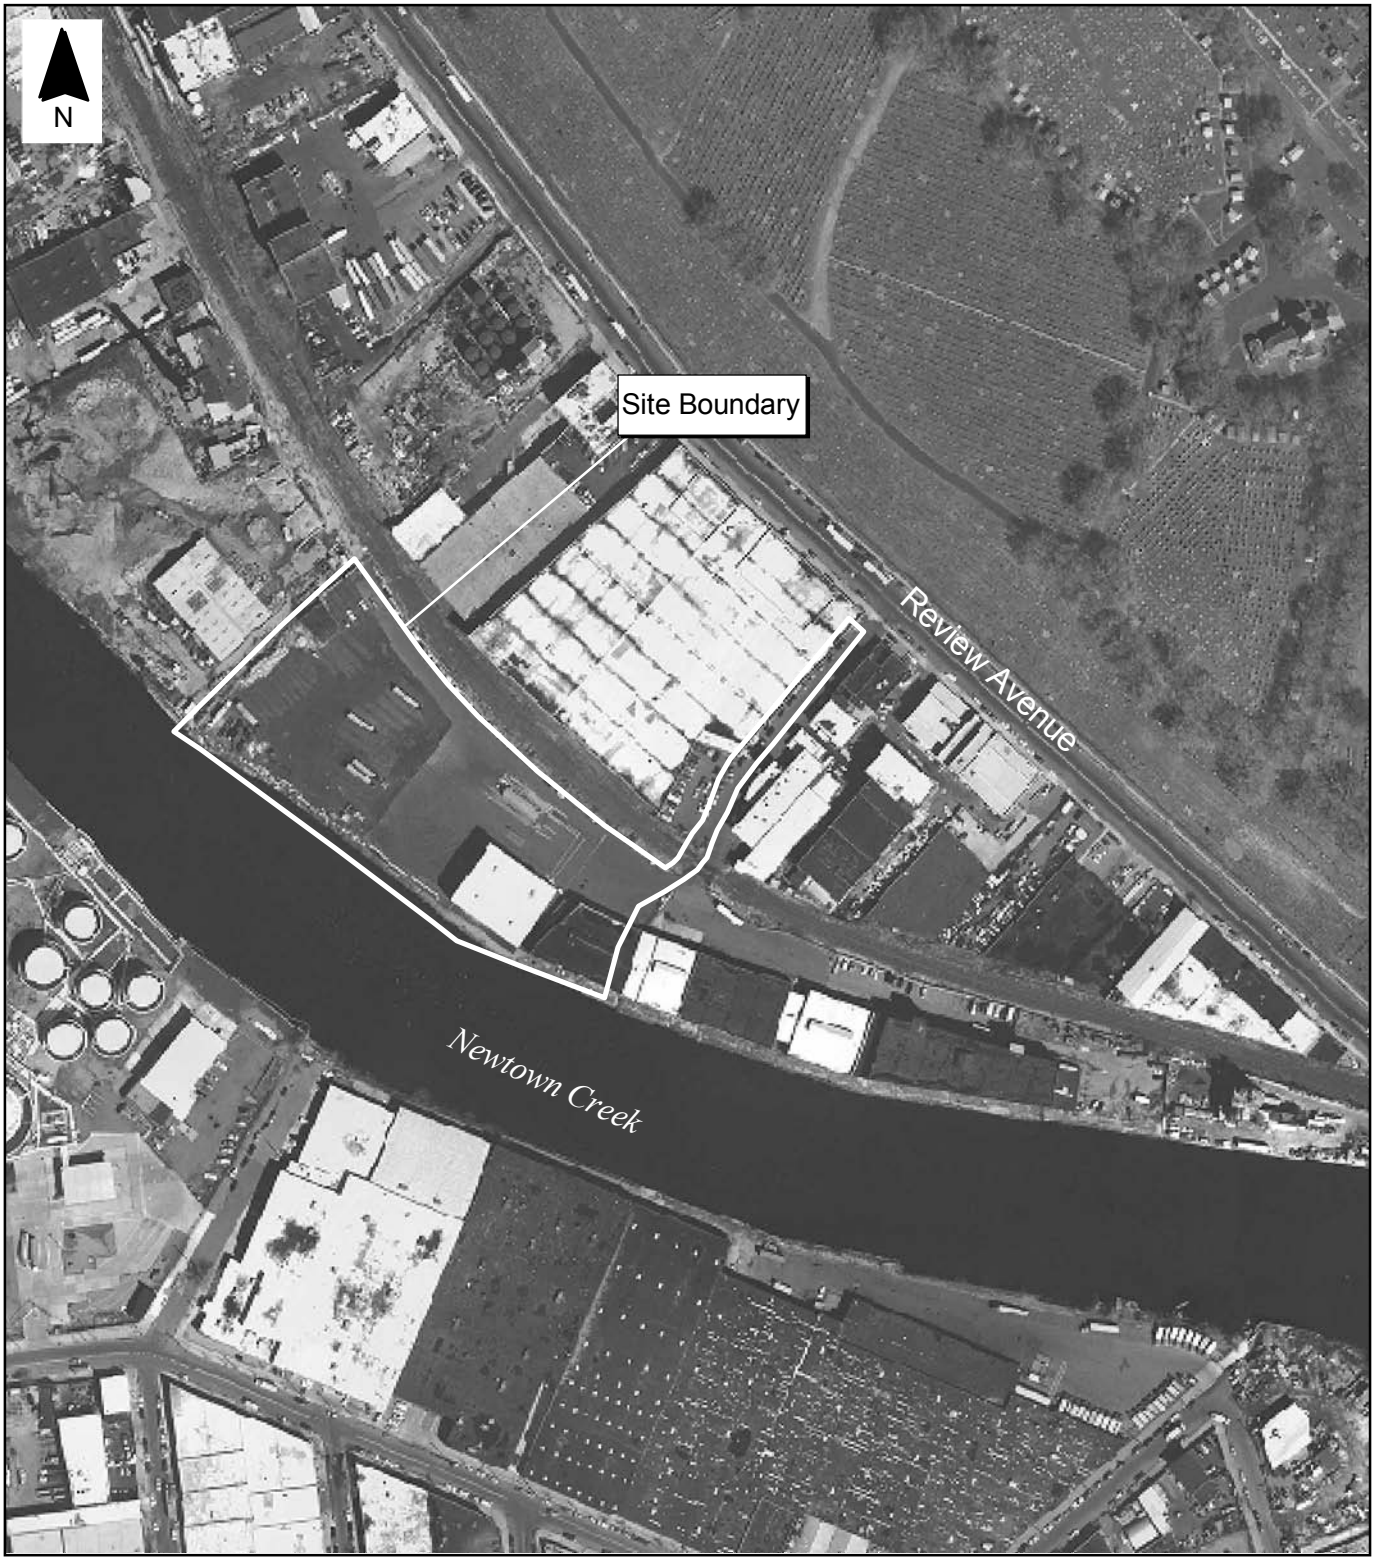
Review Avenue Site

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION



2.2.12.2 *Review Avenue Truck to Barge TS*

Review Avenue is currently permitted as a Truck to Truck TS at 958 tpd. The existing facility has a 13,800-square-foot processing building that includes a 1,600-square-foot tipping floor, access roads, inbound and outbound scales, on-site queuing for up to 25 vehicles, and employee and visitor parking areas. The existing facility is currently used for interim export of DSNY-managed Waste. Waste is unloaded onto the tipping floor using wheel loaders. The waste is pre-crushed by wheel loaders and placed into transfer trailers for out-of-City disposal.

A permit application to modify the facility for barge transport and a capacity expansion from 958 to 1,200 tpd is proposed and was submitted in January 2003. The facility was subject to EAS review for Interim Export in June 2000, which did not evaluate $PM_{2.5}$. The facility would be modified to enable lidding of containers and transport of containerized waste by barge and would require a permit modification to do so. Since Review Avenue was evaluated in the 2000 SWMP FEIS as a truck-to-barge operation at a planned average peak capacity of 1,200 tpd (37 collection vehicles during the peak hour), no on or off-site analysis is required except for $PM_{2.5}$,which was not evaluated in the 2000 SWMP FEIS.

Waste Management, in its response to the DSNY's Request for Proposals to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from Queens Formerly Delivered to the Greenpoint Marine Transfer Station (Queens RFP), has proposed Review Avenue as a Truck to Barge TS to accept all of the DSNY-managed Waste generated in Queens CDs 1 through 6, an average of approximately 1,200 tpd. Figure 2.2.12-2 (Facility Footprint) shows the existing facility on an aerial photograph of the existing site. Figure 2.2.12-3 (Plan View) depicts the layout of the facility equipment and structures.

Development of the Review Avenue Truck to Barge facility would involve expanding the processing building to include a lidding operation, the addition of a stick crane for loading/unloading barges, a container handler, the repair/rehabilitation of the bulkhead, and dredging of material from Newtown Creek.

Site delineations are approximate.

Figure 2.2.12-3 Plan View

Review Avenue Truck to Barge Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Collection vehicles would access the facility via an existing easement from Review Avenue. The easement is approximately 30 feet wide, accommodating two lanes of traffic at the Review Avenue entrance, and narrows to 16-feet and a single lane to cross over the LIRR right-of-way. The LIRR crossing has automated signalized crossing gates. In addition traffic signals would be installed on either side of the LIRR right-of-way to control the passing movements of inbound and outbound collection vehicles. The LIRR grade crossing is also the means of access used by existing businesses located on the south side of the LIRR and to the east of the facility.

Two inbound queuing lanes, one running parallel to the LIRR right-of-way/easement on the south side of the LIRR, and the second running towards the northeast corner of the modified processing building, provide queuing space for approximately 25 inbound collection vehicles between the scalehouse and the LIRR crossing. After weighing, collection vehicles would enter the 40-foot wide by 40-foot long tipping floor via entrances on both the north and south sides of processing building. There is adequate space on the tipping floor for vehicles to tip completely inside the processing building. Wheel loaders would move the waste from the tipping gallery to the storage area on the east side of the building. The waste would be loaded from the storage area into empty containers (40' long by 8' wide by 9'- 6" high) on chassis that are stationed on the north side of the building. Each container holds approximately 18 tons of waste. An overhead electric crane would place the lids on the containers while inside the processing building. Vehicles would exit the processing building, cross the outbound scale and the LIRR grade crossing and then follow the easement onto Review Avenue. The design of the modified facility includes room for storage of 144 containers on the site in the paved area located on the northwest area of the site.

Yard tractors would move the containers approximately 200 feet to the on-site barge loading/unloading area. Reach stackers would be used to: lift the container from the chassis and place the container either: (1) on a shuttle barge that would transport the containers along Newtown Creek to the ASI Terminal in Red Hook, Brooklyn; or (2) onto the on-site container staging area for loading onto barges for out-of-City transport using stick cranes. Dredging of Newtown Creek would be required to provide sufficient draft to moor harbor barges at the bulkhead. Refurbishing of, and improvements to, the bulkhead would be required to provide moorings for the barges.

2.2.12.3 Review Avenue Truck to Rail TS

Collection vehicles would access and exit the Review Avenue Truck to Rail TS along the same route as the Review Avenue Truck to Barge TS via an existing easement from Review Avenue.

Two inbound queuing lanes, one running parallel to the LIRR right-of-way/easement on the south side of the LIRR and the second running towards the northeast corner of the modified processing building, provide queuing space for approximately 25 inbound collection vehicles between the scalehouse and the LIRR crossing. After weighing, collection vehicles will enter the 40-foot wide by 40-foot long tipping floor via entrances on both the north and south sides of processing building. There is adequate space on the tipping floor for vehicles to tip completely inside the processing building. Wheel loaders will move the waste from the tipping gallery to the storage area on the east side of the building. The waste will be loaded from the storage area into empty containers (20' long by 8'-6" wide by 11' high) on chassis that are stationed on the north side of the building. An overhead electric crane will place the lids on the containers while inside the processing building. Vehicles will exit the processing building, cross the outbound scale and the LIRR grade crossing, and then follow the easement onto Review Avenue. The design of the modified facility includes room for storage of 144 containers on the site in the paved area located on the northwest area of the site.

Figure 2.2.12-4 (Facility Footprint) shows the existing facility on an aerial photograph of the existing site. Figure 2.2.12-3 (Plan and Section View) depicts the layout of the Review Avenue Truck to Barge TS facility equipment and structures. The Review Avenue Truck to Rail TS would require the same modifications as the Review Avenue Truck to Barge TS for lidding containers that would be drayed to the Maspeth Rail Yard; however, there would be no improvements for barge loading/unloading.

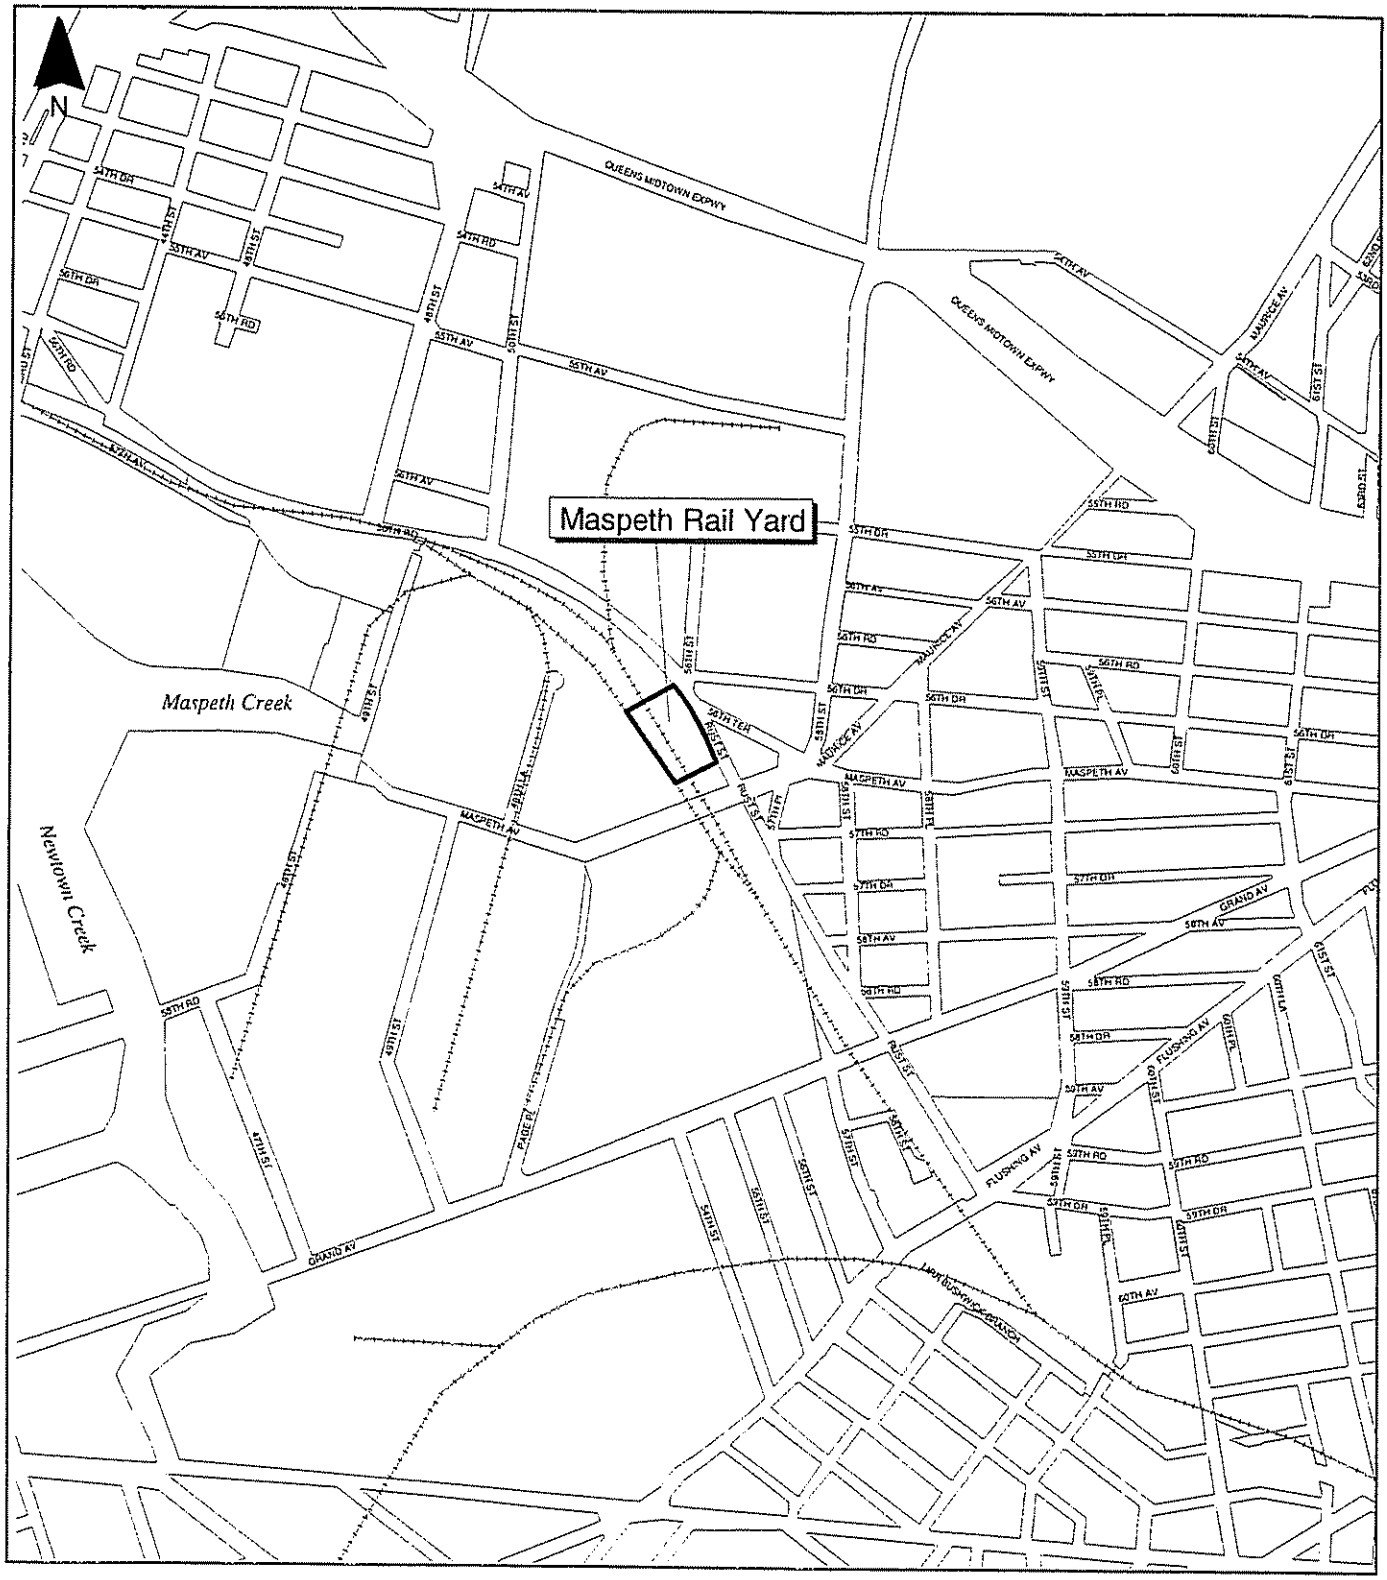
Figure 2.2.12-4 Facility Footprint

Review Avenue Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION



This page intentionally left blank.

2.2.12.4 Maspeth Rail Yard

Under the Review Avenue Truck to Rail TS Alternative, DSNY-managed Waste would be containerized and then drayed on chassis by yard tractors to the Maspeth Rail Yard, where the containers would be loaded onto railcars. The Maspeth Rail Yard is approximately 1½ miles from the Review Avenue Truck to Rail TS site in Queens Community District 2. Figure 2.2.12-5 (Site Location) shows the location of the Maspeth Rail Yard site.

Access to the Maspeth Rail Yard is provided via Maspeth Avenue off of Rust Street. At the Maspeth Rail Yard, containers would be unloaded from the chassis and placed onto railcars. Full containers would be brought to the rail yard only when a train is available for loading and would not be stored at the Maspeth Rail Yard. Once a group of railcars is fully loaded, a locomotive would be used to pull the string of railcars off site to a final out-of-City disposal destination. Empty containers returned by train to the Maspeth Rail Yard would be either staged or placed directly on chassis for the return dray back to the Review Avenue Truck to Rail TS and stored at the site. On average, trains carrying empty containers would be returned to the transfer station once per day. In addition, one loaded train would leave the Maspeth Rail Yard per day of operation. With a daily throughput of 1,200 tpd and a railcar capacity of 72 tons, approximately 17 cars can be loaded per day at maximum capacity. Each train travels to an out-of-City disposal facility and returns empty in an approximate 13-day or more cycle.

The trucking of containers of DSNY-managed Waste to Maspeth Rail Yard is considered part of this FDEIS, since, at present, all waste from the Review Avenue Truck to Rail TS goes out by transfer trailer. However, the review is limited to off-site impacts of draying to the Maspeth Rail Yard, since the Maspeth Rail Yard has been permitted as an intermodal yard and any changes in this permit would be subject to DSNY's new rules, as a non-discretionary action. The Queens RFP issued by the City requires that proposers commit to exporting all waste (both DSNY and commercial) processed at their facilities by rail or barge. Thus, the draying of full containers of waste and return of empties between the Review Avenue Truck to Rail TS and the Maspeth Rail Yard equivalent to the proposed fully permitted capacity of the facility (1,200 tpd) would be a change in the Existing Condition. Off-site traffic and noise impact analyses were performed for the equivalent of 1,200 tpd in round-trip truck traffic and results are reported in this FDEIS.

Site delineations are approximate

Figure 2.2.12-5 Site Location

Maspeth Rail Yard

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The 2000 SWMP FEIS analyzed a truck-to-barge design for this site at a capacity of 2,300 tpd, which included off-site air quality (PM_{10} and CO), traffic and noise analyses assuming 56 collection vehicles during the peak hour. The 56 collection vehicles assumption is equivalent to operating at 1,200 tpd and draying containers to the Maspeth Rail Yard. The 2000 FEIS will be referred to as sufficient for evaluating impacts associated with the current proposal, except for $PM_{2.5}$, which is reported in this FDEIS.

2.2.13 Collection Vehicle Transport to Essex County WTE Facility

2.2.13.1 Description of the Action

The out-of-City waste-to-energy (WTE) facility is the Essex County Resource Recovery Facility (RRF) located on Raymond Boulevard in Newark, New Jersey, off the New Jersey Turnpike South. It is an existing permitted facility with a capacity of 2,800 tpd that can accept waste from the City, and, as such, no environmental review of this site is required in this FDEIS. Currently DSNY-managed Waste from Manhattan is disposed there under Interim Export contracts.

Any required environmental review would be limited to the evaluation of off-site impacts associated with collection vehicle traffic as it leaves the City to reach the Essex County WTE Facility in New Jersey.

2.2.13.1.1 Traffic

Under CEQR, the objective of a traffic analysis is to determine whether a proposed action can be expected to have a significant impact on street and roadway conditions and on parking facilities. According to the 2001 CEQR Technical Manual, a proposed action that would typically result in fewer than 50 new peak hour passenger car (or equivalent) trip ends is unlikely to have significant traffic impacts. The CEQR guidelines for traffic analysis state that a waste collection vehicle is roughly equivalent to 1.5 passenger cars. Hence, the threshold for potential impacts becomes 33 collection vehicles.

DSNY does not envision a change in post collection routing of DSNY collection vehicles now going to the Essex County WTE Facility. Implementation of this Proposed Action under a 20-year service agreement will not materially change DSNY collection operations While it would change the post-collection destinations of some DSNY collection vehicles, truck routes and dumping schedules would remain substantially the same under the Long Term Plan as under existing Interim Export contracts. This is because DSNY collection vehicles would still be routed to the nearest Hudson River crossing on their way to New Jersey.

Although no change in daily loads is projected, this FDEIS assumes a 20% increase in loads by the implementation year of 2006. Since the average peak number of daily loads in Manhattan is 222 (as of FY 2003), the 20% increase represents just 88 two-way trips over the entire day. When divided between the three Hudson River crossings and converted to an hourly basis, peak hour volume increases at any one intersection would always be below the 33-truck threshold. Therefore, no traffic impacts are anticipated and no traffic analysis is required.

2.2.13.1.2 Air Quality

Carbon Monoxide. The 2001 CEQR Technical Manual contains screening criteria to determine whether a proposed action is likely to significantly increase levels of CO. That criteria level is set at 100 vehicles. If the number of vehicles generated by a proposed action does not exceed 100 vehicles in a single peak hour, no further air quality analysis of CO is required to conclude that the action would not significantly increase CO levels. As noted previously, the maximum additional increment of DSNY trucks assumed was 88 for the entire day, so no CO analysis is required.

Particulate Matter. The 2001 CEQR Technical Manual does not contain screening criteria for mobile sources of PM_{10} or $PM_{2.5}$. To measure the effects of PM_{10} emissions, DSNY modeled existing traffic and anticipated project generated-traffic at four worst-case intersections to determine if the project would contribute to any exceedances of ambient air quality standards for PM_{10}. For $PM_{2.5}$, the NYCDEP has established an interim screening threshold of

21 diesel-fueled vehicles per hour. The Proposed Action generates fewer than 21 heavy-duty diesel-fueled vehicles at any facility or intersection, or on any street segment, so no further analysis of $PM_{2.5}$ is required to conclude that it would not have a significant adverse impact on air quality.

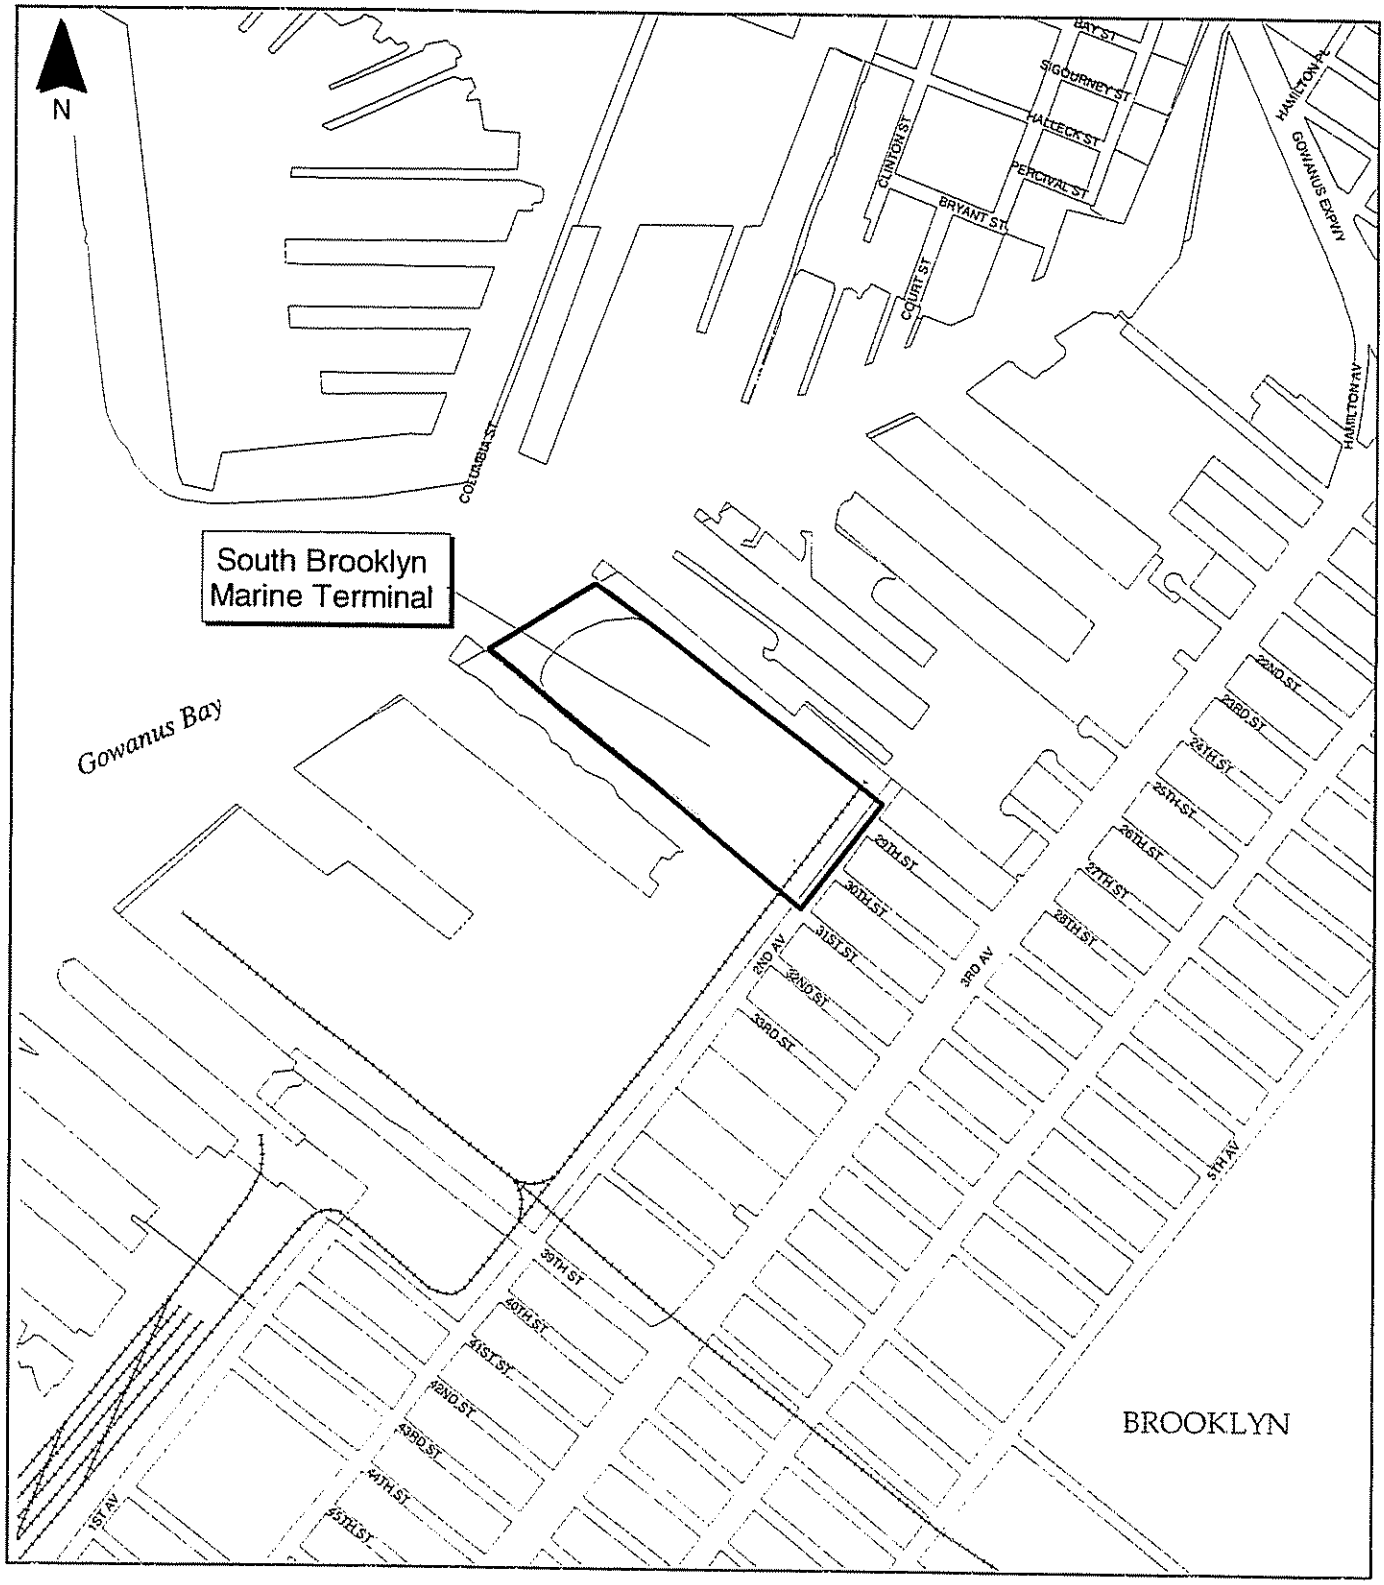
2.2.13.1.3 Noise

The Long Term Plan would generate a small number of additional truck trips (a 20% increase) over Existing Conditions. The 2001 CEQR Technical Manual establishes criteria for determining noise impacts. According to CEQR guidelines, an initial screening can be performed using passenger car equivalents (PCEs). For noise analysis, a waste collection vehicle is equivalent to 47 collection vehicles. If the ratio of PCEs between the Future Action and Existing Conditions is equal to or greater than two at any receptor location selected (a 100% increase), a detailed noise analysis is warranted at that location. This FDEIS assumes a 20% increase in loads and, therefore, a similar increase in truck trips. This increase, however, is well below the 100% increase required to trigger a more detailed noise analysis. Therefore, no significant adverse noise impacts are anticipated and no further noise analysis is necessary.

In summary, no environmental review of this element of the Proposed Plan is required in this FDEIS.

2.3 Proposed Plan Recycling Facilities

2.3.1 30th Street Pier at the South Brooklyn Marine Terminal



2.3.1.1 Description of the Existing Site

Located along Gowanus Bay in the South Brooklyn Marine Terminal (SBMT) in Tax Block 662, Lot 1, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data,* the 30th Street Pier site is bounded by Second Avenue to the east and the U.S. Pierhead Line to the west. The 29th Street Pier and the 31st Street Pier abut the site to the north and south, respectively. The site is zoned M3-1 between Second Avenue and the U.S. Bulkhead Line, M2-1 between the U.S. Bulkhead Line and the U.S. Pierhead Line, use group 18 (which allows for all manufacturing uses) The site is located in Brooklyn CD 7. The site was used for loading and off-loading marine vessels and long-term import/export cargo storage and processing, office space, and trailer inspections and repair. Figure 2.3.1-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood.

Development of the 30th Street Pier at the SBMT for the acceptance and processing of Recyclables would involve removal of an undetermined amount of piling remnants and other underwater debris from the recent demolition of the finger piers that formerly abutted the 30th Street Pier, and dredging of an estimated 40,000 cubic yards of material. The 30th Street Pier at the SBMT would require construction of two, 400-foot-long-by-60-foot-wide docks constructed on 100'- to 120'-deep piles to support equipment, a fendering system, and sheetpiling to prevent washout.

2.3.1.2 Description of the 30th Street Pier at the SBMT

As shown in Figure 2.3.1-2 (Plan View), the preliminary site plan for the proposed 30th Street Pier at the SBMT consists of:

Site delineations are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

- An approximately 50,000-square-foot enclosed receiving building and tipping area capable of unloading two barges with an overhead crane and receiving truck loads of recyclables;

- An approximately 60,000-square-foot processing area for segregating mixed recyclables, and a 50,000-square-foot area for baling and storage of plastics, paper, non-ferrous metal and residue;

- An approximately 96,000-square-foot area for metals processing, and an approximately 76,000-square-foot glass processing area;

- An approximately 32,000-square-foot loading area for outbound barges, capable of loading two barges with an overhead crane. Note that the area for loading outbound barges would not be enclosed in the current plan. This area is for metal and glass.

- On-site container storage for approximately fifty 20-foot-long shipping containers;

- Loadout docks for outbound transfer trailers;

- Two, 80-foot-long truck scales for weighing inbound and outbound vehicles; and

- An approximately 20,000-square-foot, three-story administration/visitor's center with space for visitor and bus parking.

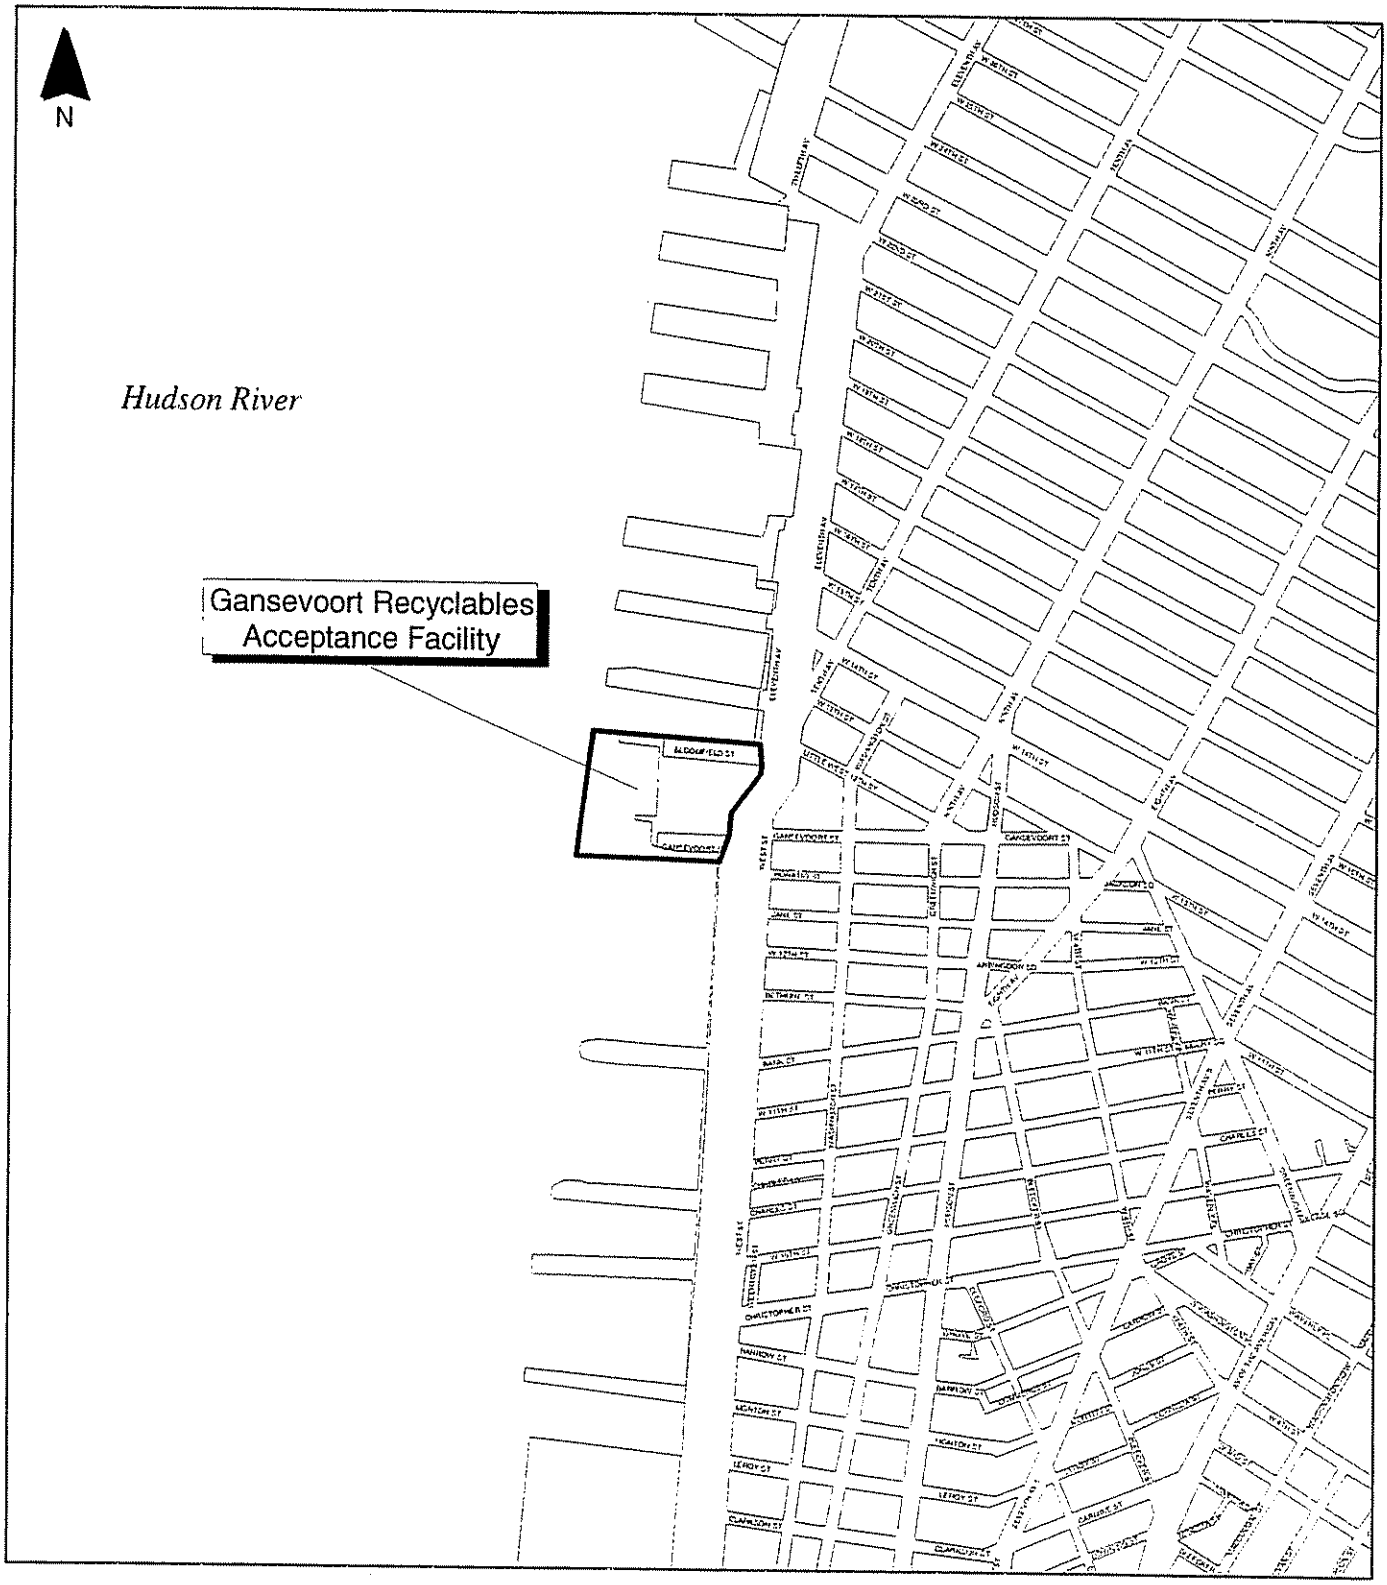
- To prevent the escape of litter into the surrounding water body, the enclosed barge unloading building would be equipped with the following:

- Enclosed processing areas wherever wind-blown litter could present a problem;

- Fencing and regular housekeeping of the site perimeter as needed to prevent the escape of litter into the waterway;

- Booms and/or a skimmer boat as needed and operating personnel using dip nets to control litter in the enclosed barge unloading/loading area.

In addition, inbound barges carrying mixed MGP will be equipped with netting/fencing to avoid windblown litter from full barges.



The majority of inbound recyclables (an estimated 85%) are expected to be delivered to the 30th Street Pier Recycling Facility at SBMT by barge. Some recyclables from South Brooklyn collection districts may be delivered directly in DSNY collection vehicles. It is expected that most glass and ferrous metals will be exported from the facility by barge (these two materials comprise an estimated 75% of mixed MGP). Depending on market conditions, plastics, non-ferrous metals and residue from processing operations may leave the site by truck.

2.3.2 Gansevoort Recyclables Acceptance Facility

2.3.2.1 Description of the Existing Site

Located on Block 651, Pier 52 along the Hudson River, the former Gansevoort Street MTS site is bounded by a pedestrian walkway along the West Side Highway to the east and the U.S. Pierhead Line to the west. Bloomfield Street and Gansevoort Street abut the site to the north and south, respectively. The site is located in Manhattan CD 2. The site is zoned M3-2, Use group 18, which allows for all manufacturing uses. The site was formerly used as an MTS, but was closed down in July 1991. Figure 2.3.2-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood.

Development of a new facility at Gansevoort Street for the acceptance and processing of Recyclables would involve the removal of the existing structures on the site. The NYCEDC is currently in the planning stages for converting much of the Gansevoort property into parkland with recreational activities. These recreational areas will include a rocky beach, open market along Bloomfield Street, concession stand, a lawn area, a boat drop off and marina, and a stop for water taxis. . This plan is a part of a larger plan to convert the waterfront from Battery Park City to West 59th Street into park facilities between the U.S. Pierhead Line and the western boundary of West 11th and West 12th Streets. Fire Department Marine Company One, Manhattan's only remaining waterside fire station, will remain on Pier 53 adjacent to the Gansevoort property to the north.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

Figure 2.3.2-1 Site Location

Gansevoort Recyclabels Acceptance Facility

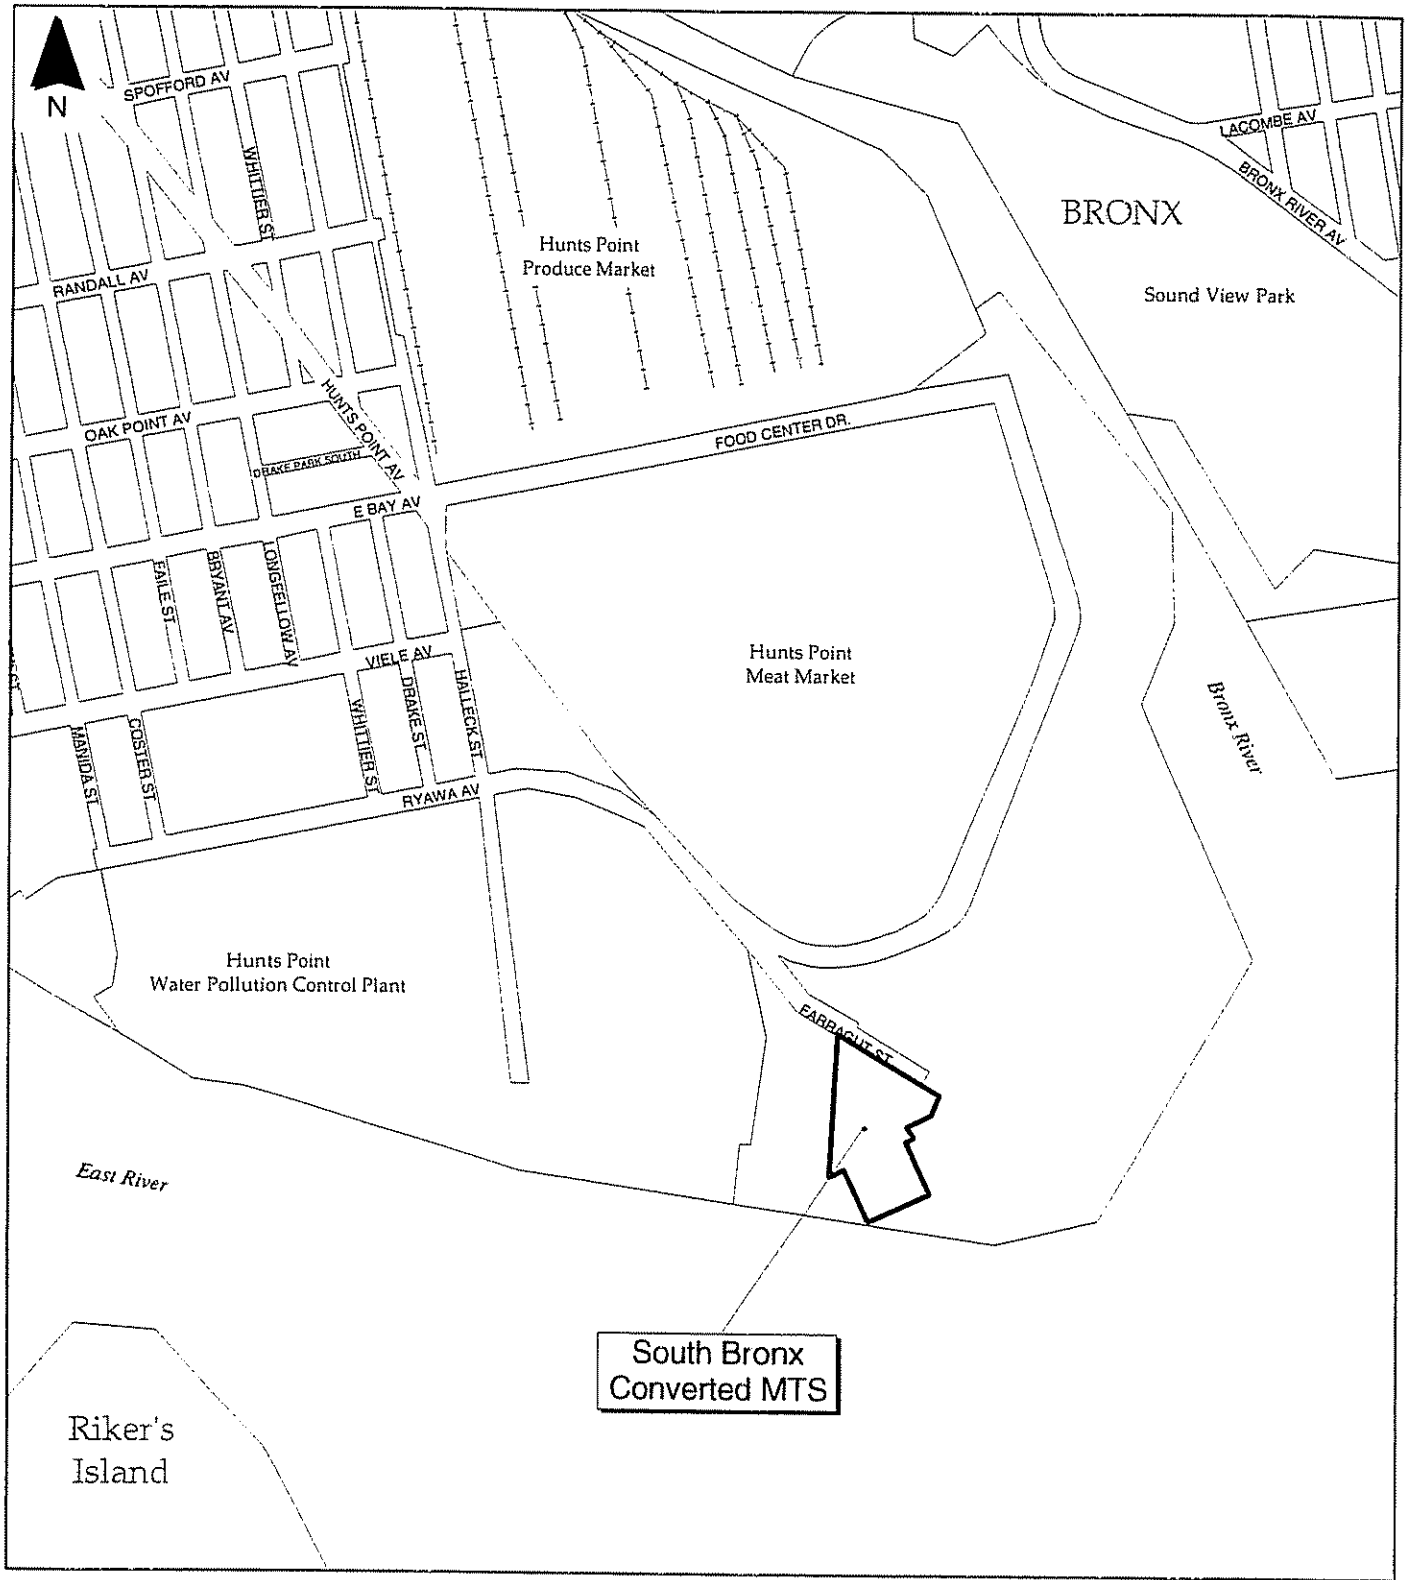
CITY OF NEW YORK
DEPARTMENT OF SANITATION

The site is adjacent to public parks on Pier 51 that include a new maritime-themed playground, a water play area, climbing equipment and slides and viewing scopes, which have been open to the public since Spring 2003.

2.3.2.2 Description of the Gansevoort Recyclables Acceptance Facility

NYCEDC is in the planning stages for the Gansevoort Recyclables Acceptance Facility. Once a design is developed, the Gansevoort Recyclables Acceptance Facility will be the subject of a future environmental review. The facility is not subject of permitting as a solid waste facility; however, its construction will likely require Section 10/404 permits from the USACE and Article 15.25 permits from NYSDEC. The environmental review of this facility is be limited to the impact analyses required to support these permit applications and also addresses the off-site impacts associated with traffic, air quality and noise.

2.4 Alternatives Considered – Long Term Export Facilities



2.4.1 South Bronx Converted MTS, Bronx

2.4.1.1 Description of Existing Site

The existing South Bronx MTS site is located in the Hunts Point area of the South Bronx in Community District 2. This site is bounded by Farragut Street (formerly Hunts Point Avenue) to the north, the East River to the east and south, and the 30-acre site of the relocated Fulton Fish Market (now under construction), to the west. Figure 2.4.1-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The gross acreage of the DSNY-owned lot is approximately 8.6 acres of upland area. In addition to the MTS, other existing DSNY facilities, including a salt storage shed and a DSNY SHS, occupy the roughly triangular project site. An active SHS on the site is comprised of a paved area surrounded by concrete walls topped with cyclone fencing. Accessed through a 30-foot sliding gate facing Farragut Street, the SHS accepts materials such as tires, metal, wood, C&D materials and glass from non-commercial vehicles. An office trailer is also located within this area.

The northern boundary follows Farragut Street and is approximately 400 feet in length. The eastern boundary is approximately 420 feet in length. The southern boundary is located along the East River and is approximately 380 feet in length. The site is located within Tax Block 2781, Lots 301 and 306, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

Most of the Hunts Point peninsula is zoned for manufacturing, the heaviest industrial uses allowed along the Bronx River and East River waterfronts. The Hunts Point Food Market dominates the eastern portion of the peninsula and is the primary distribution point for meat and produce in the City.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

HDR | HydroQual | URBITRAN | PB | EEA Cambridge Environmental Inc

Figure 2.4.1-1 Site Location
South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The site and surrounding properties within both the primary and secondary study areas fall within an M3-1 heavy industrial district that extends north to approximately East Bay Avenue and Randall Avenue, where it abuts an M1-1 light industrial district. The M1-1 light industrial zoning district provides a buffer between the M3-1 district and the Hunts Point neighborhood (zoned R6) located in the northeastern section of the peninsula. This residential area is comprised of approximately 20 blocks, located roughly between Longfellow, Garrison, Tiffany and Randall Avenues, about one mile from the site.

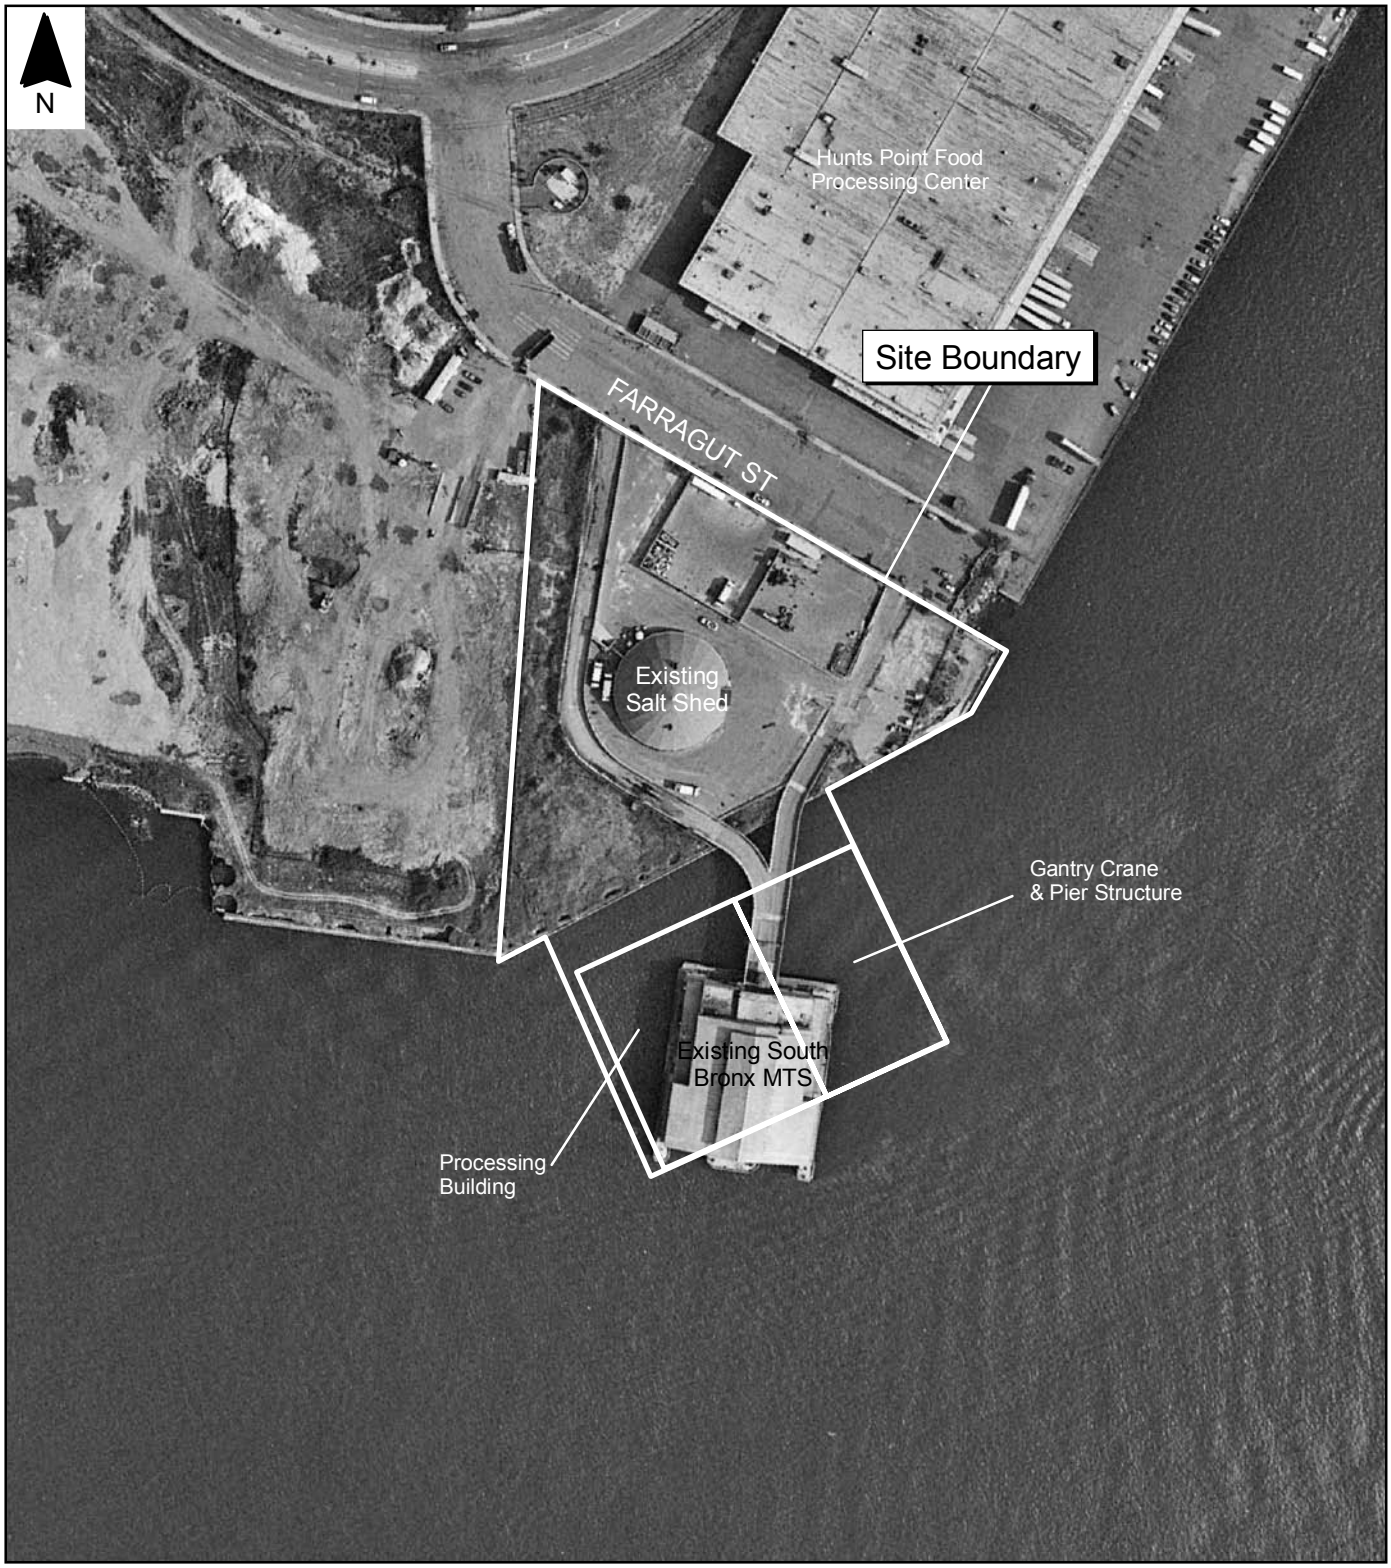
All property immediately adjacent to the site is owned by the City or its agencies (e.g., DSNY, Department of Correction, NYCDEP and NYCEDC). The relocated Fulton Fish Market is under construction on the parcel west of the site, and scheduled to open in early 2005. When completed, all 50 of the wholesale fish companies that operate in Lower Manhattan will move to the new state-of-the-art facility in Hunts Point.

Other land uses within ¼-mile of the site include a one-story, vacant goods distribution warehouse operated formerly by National Foods located opposite the site, across Farragut Street. This facility is part of the City-owned Hunts Point Market, the wholesale food market and distribution center built in the 1970s that covers approximately the entire eastern half of the Hunts Point peninsula. The Hunts Point Market serves as the primary distribution point for meat and produce within the tri-state area. The meat market is located within the primary and secondary study areas, while the produce market extends north from East Bay Avenue.

Moored at the foot of Halleck Street, south of the Fish Market, is the Vernon C. Bain Center (Prison Barge). It is a reserve facility that can accommodate up to 80 inmates. Abutting the east side of the MTS site is a small paved area near the East River's edge that is used informally by local residents as a point of public access for fishing and viewing the water.

Several one-story market buildings and a two-story cold storage warehouse building are located in the ¼-mile to ½-mile area, north-northeast of the site within the Hunts Point Market. Paved storage and parking areas that surround these distribution warehouses are separated from Farragut Street by wire fencing. Major food distribution businesses including National Foods, Krasdale Foods, and Bazzini Nut Corporation are located off Food Center Drive.

Additional Department of Correction vacant property is to the west of the site. Further west, just within the ½-mile area, is the Hunts Point WPCP operated by NYCDEP. Private industrial and heavy commercial uses, such as auto salvage yards, are located on Ryawa Avenue, Halleck Street, Drake Street and Whittier Street.



There are no City, state or nationally designated landmarks or historic districts within a ½-mile radius of the site.

Beyond the ½-mile area to the northwest and east, respectively, the Hunts Point peninsula contains additional industrial uses and the Hunts Point residential community (with approximately 11,400 residents).

2.4.1.2 South Bronx Converted MTS

The South Bronx Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.4.1-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the South Bronx Converted MTS superimposed on the site. Figure 2.4.1-3 (Plan and Section View) depicts its layout and the processing building interior.

DSNY-managed Waste would be delivered to the South Bronx Converted MTS by a variety of waste collection vehicles, primarily consisting of packer and dual-purpose trucks, including collection vehicles operated by DSNY and other City agencies (e.g., NYCDPR, NYCHA and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building, at the entrance to the tipping-floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

The loading floor would be 12 feet below the tipping floor. On the loading floor, front-end loaders would push the waste into slots in the floor slab located over open-top containers. The containers would be mounted on shuttle cars that would move on tracks at the pier level of the building, 16 feet below the loading floor. A tamper device working from the loading floor would even and densify the waste in the containers. When loading is complete, the open-top containers would be moved into position at the enclosed lidding area of the processing building and would be securely lidded with a gasketed steel lid via pressure from a bridge crane with a spreader device. Then, the overhead door to the lidding area would open, and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and a gross payload of 1,308 tons), would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

2.4.2 Greenpoint Converted MTS, Brooklyn

2.4.2.1 Description of Existing Site

The existing Greenpoint MTS site is located on the heavily industrial Newtown Creek in the Greenpoint section of Brooklyn in Community District 1. The site is bounded by Newtown Creek to the north, Whale Creek Canal to the west, Kingsland Avenue (Green Street) to the south and North Henry Street to the east. Figure 2.4.2-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 2508 and Lot 1, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

The gross acreage of the DSNY-owned lot is approximately 6.3 acres, of which approximately 3.5 acres is upland. The existing Greenpoint MTS and the former Greenpoint incinerator occupy most of the irregularly-shaped site. A contract has been awarded to demolish the incinerator and work is commencing. An environmental remediation program was conducted prior to

Site delineations are approximate

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

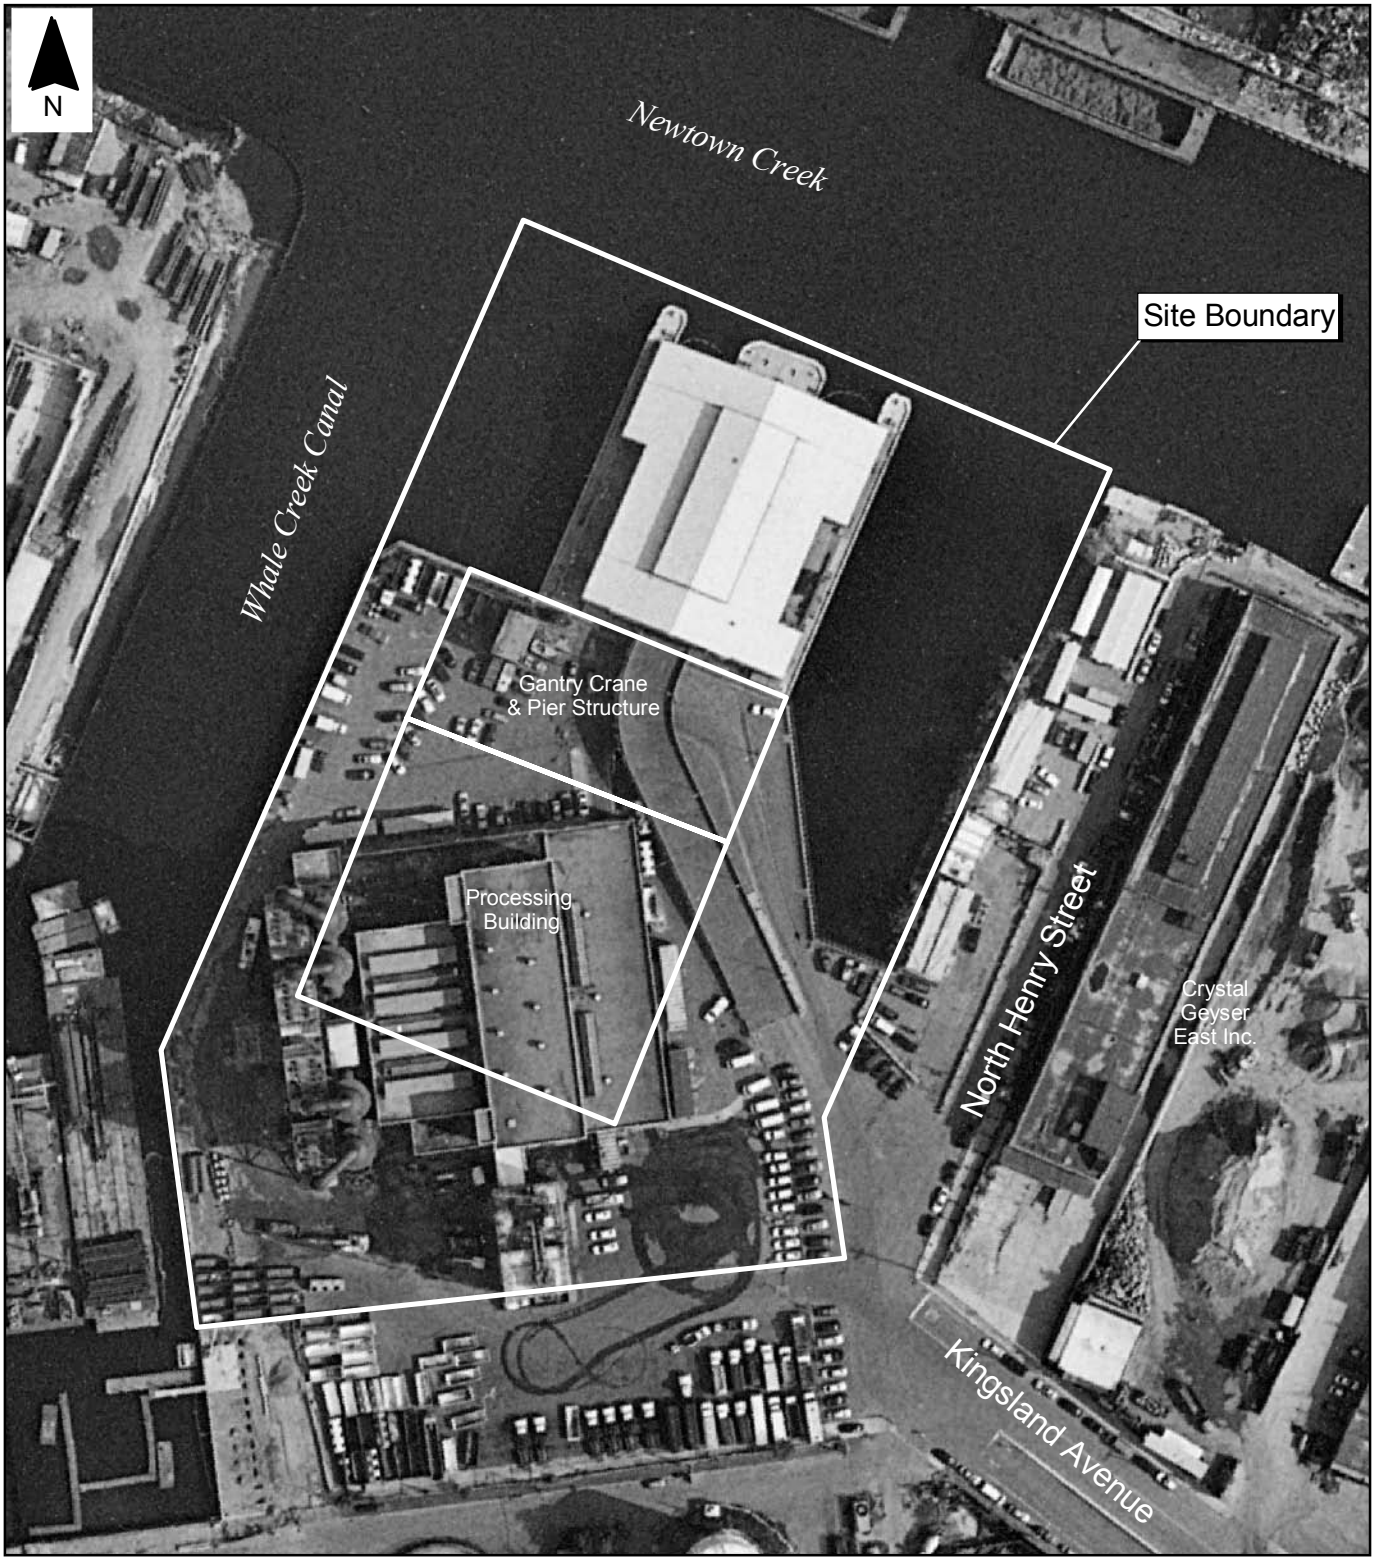
demolition. The remaining 2.8 acres consist of water that extends to the pier and bulkhead line. The northern boundary of the site along the U.S. Pierhead Line measures approximately 400 feet, the southern boundary along Green Street is approximately 350 feet in length, the eastern boundary along North Henry Street is approximately 500 feet in length and the western and northern boundary along Whale Creek is approximately 750 feet in length.

The site is located in a large M3-1 zoning district, which allows for heavy industrial uses along the entire length of Newtown Creek. This zoning district encompasses NYCDEP's expanded Newtown Creek WPCP, situated to the south and west of the site, as well as an active NYCDOT asphalt plant to the east of the site. In Queens, an M3-2 zoning district spans the Newtown Creek shoreline from the northern border of Dutch Kills to Manhattan Avenue, and an M3-1 zoning district extends from the eastern shore of the Dutch Kills, for about a mile south to Metropolitan Avenue. In Brooklyn, the M3-1 zoning district is primarily bordered by additional light and medium manufacturing zoning districts (M1-1 and M1-2) providing a buffer area between the heavier industrial uses on the waterfront and the residential districts further inland. On the northern side of the Creek, in Queens, the heavy M3-1 and M3-2 zoning districts are also bounded by M1-1, M1-3, M1-4 and M2-1 manufacturing zones, specifically. A small R6A district is located ½-mile northwest of the site at the edge of the Long Island City Mixed Use Special Purpose District and a small portion of a larger R4 zoning district (which encompasses Calvary Cemetery) is located ½-mile southeast of the site.

The area within ¼-mile of the site is comprised almost exclusively of heavy industrial uses concentrated along Newtown Creek and dominated by the Newtown Creek WPCP. The WPCP, which occupies a large area immediately south of the site, is currently being expanded to the east and to the north (west of Whale Creek Canal), across from the site. An NYCDOT asphalt production facility and private recycling center for construction debris and fill are located east of the site on Kingsland Avenue. The Queens side of Newtown Creek is also characterized by industrial uses such as Case Paper Manufacturers, The Exhibit Company and numerous warehouses fronting on Borden and Review Avenues across from the site.

In addition to the uses bordering the site, the blocks south of the site along the west side of Provost Street are almost exclusively warehouses. Most of these are active, though there are some vacant warehouse buildings and vacant lots scattered throughout. Southeast of the site beyond a private recycling center and WPCP sites are Metro Fuel Oil Depot petroleum outdoor-loading facilities.

Within the ¼-mile to ½-mile area, heavy industrial uses are concentrated along both sides of Newtown Creek and Dutch Kills, and in about half of the area in Brooklyn, particularly south of Greenpoint Avenue. West of the site within the ½-mile area is a residential area comprised mostly of three- to four-story apartment buildings, whose ground-floor commercial uses line McGuinness Boulevard and Manhattan Avenue. In this area, an apartment building recently converted from industrial uses stands west of Provost Street on Dupont Street. South of Meserole Avenue, in the southern portion of the study area, residential uses are interspersed with active warehouses.



The portion of the ½-mile area that lies north of the site in Queens is comprised almost entirely of industrial uses and warehouses with the exceptions of the Salvation Army Veterans Residence northwest of the site at 21st Street and Borden Avenue, and some commercial uses north of the site along 49th Avenue and east of the site along Greenpoint Avenue.

There are no City, state or nationally designated landmarks, historic districts within ½-mile of the site or archaeological resources on the site.

2.4.2.2 Greenpoint Converted MTS

The Greenpoint Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.4.2-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the Greenpoint Converted MTS superimposed on the site. Then, the overhead door to the lidding area would open, and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and a gross payload of 1,308 tons), would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

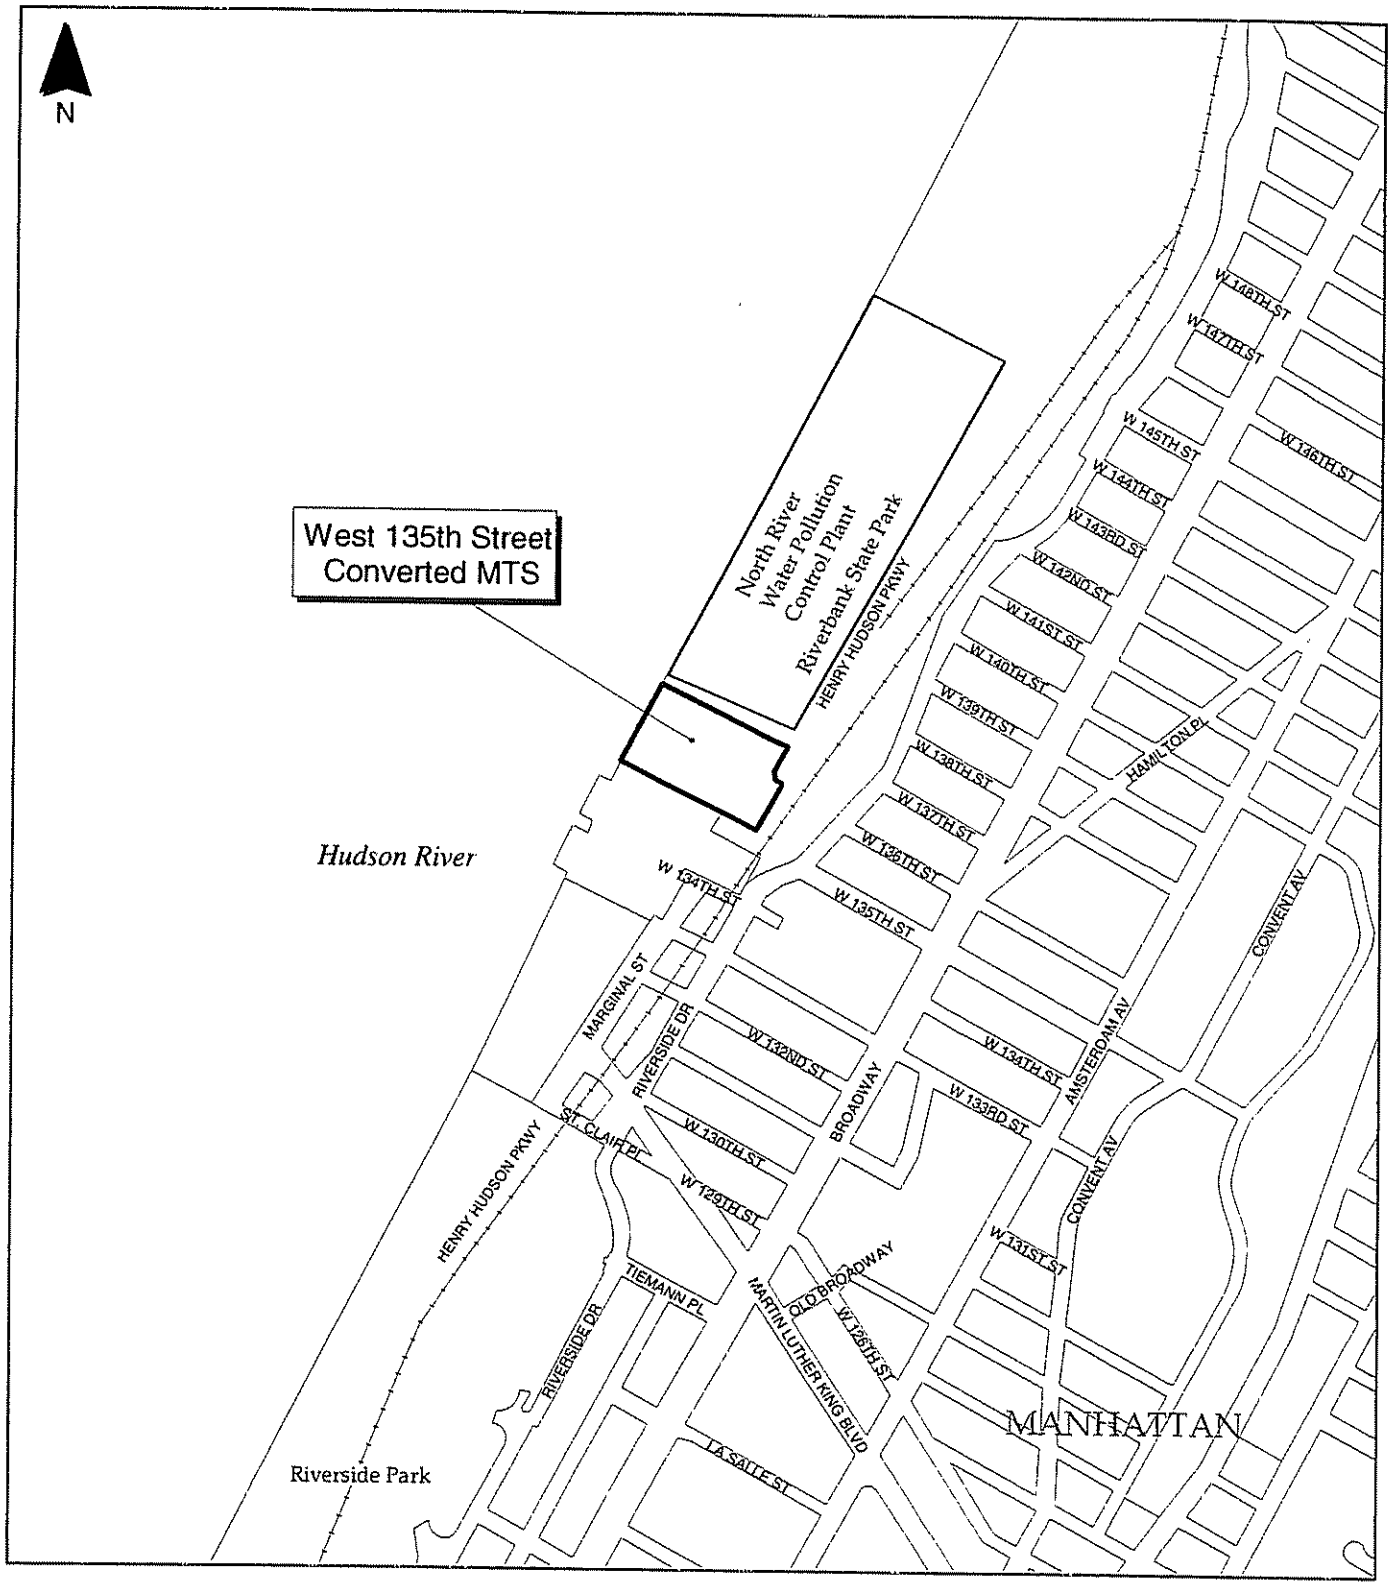
2.4.3 West 135th Street Converted MTS, Manhattan

2.4.3.1 Description of Existing Site



The existing West 135th Street MTS is located at the end of West 135th Street, west of the elevated Henry Hudson Parkway on the Hudson River, in the Manhattanville section of Manhattan in Community District 9. It is constructed almost entirely over water on a

pile-supported structure, just south of the North River WPCP, which has Riverbank State Park on its roof. Figure 2.4.3-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 2101 and Lots 117 and 120, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

The gross acreage of the site is approximately five acres. The northern boundary of the MTS site measures approximately 600 feet in length to the U.S. Pierhead Line, the eastern border along U.S. Bulkhead Line is roughly 400 feet in length, the site's southern border is approximately 700 feet in length and the western site border along the U.S. Pierhead Line is approximately 420 feet in length.

The site is located in an M1-1 zoning district, which allows light industrial uses. This zoning district extends along the waterfront from West 133rd to West 145th Streets and east to Riverside Drive, and includes the North River WPCP/Riverbank State Park. South of West 133rd Street and east of the site there are several industrial zoning districts (M2-3, M1-2 and M3-1) that extend south to St. Clair Place and inland east of Broadway (between West 133rd and West 135th Streets). Beyond the immediate industrial zoning districts are high-density residential zoning districts (R8 and R7-2), with commercial overlays along Broadway and Amsterdam Avenue.

The area within a ¼-mile radius of the site is characterized by light industrial land uses with some residential, with open space and recreational uses adjacent to the site. Two major roadways, the Henry Hudson Parkway and Riverside Drive, separate the site from upland elevated areas to the east by providing a buffer of about 450 feet between the site and residential uses. In addition, these residential upland areas sit at a higher elevation than the site and do not have direct access to it via the cross streets. Most streets around the site are dead-end or one-way and directed away from the site. Essentially, the only way to access the site is to approach West 135th Street from the south via 12th Avenue, which runs between St. Clair Place and 137th Street under Riverside Drive.

Site delineations are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

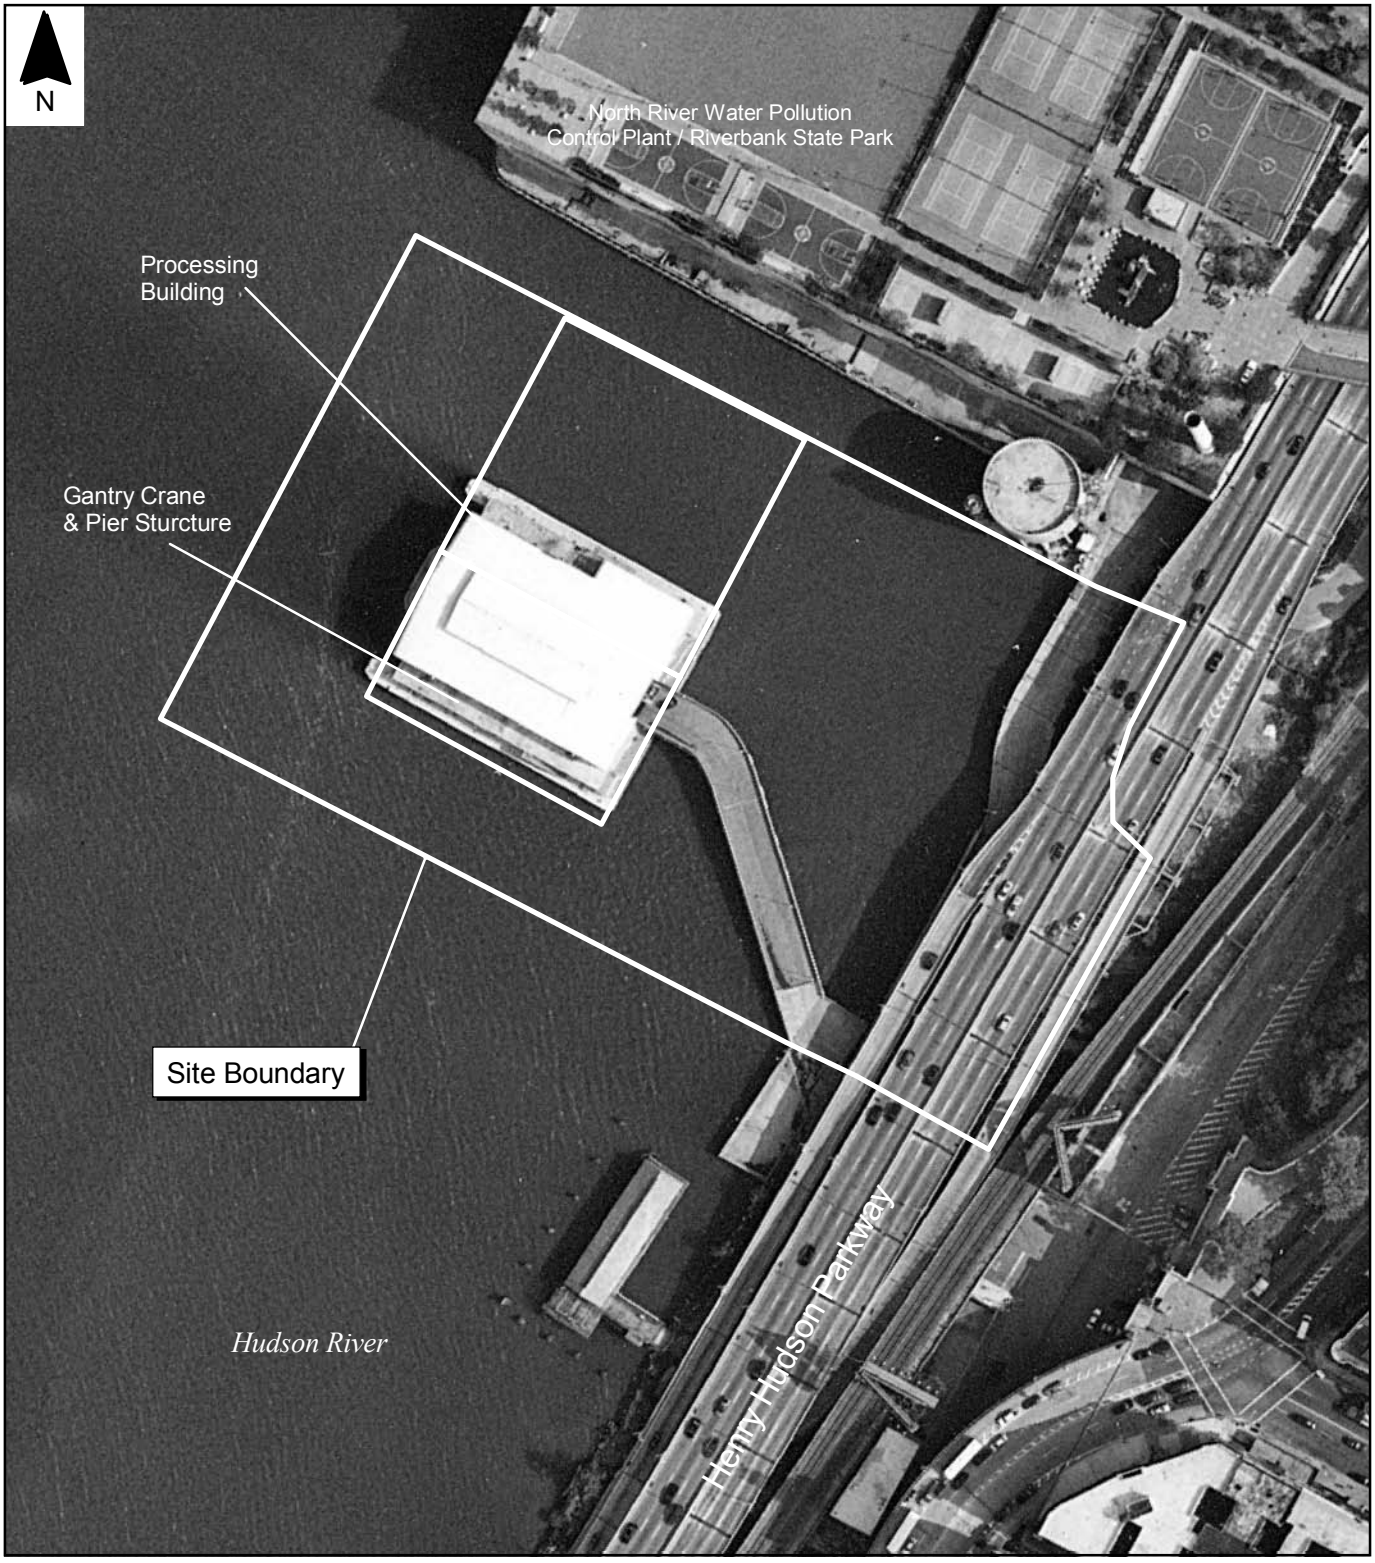
THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Immediately north of and adjacent to the site is the City's North River WPCP between West 135th and West 145th Streets, upon which Riverbank State Park is located. The park is an active recreation facility encompassing 28 acres of playing fields and courts, a café, cultural center and amphitheater. (See Section 21.5 for more detail on the park.) Adjacent to the WPCP, at grade level below the Henry Hudson Parkway, is a staging area used by the NYCDEP for ongoing construction at the plant. A variety of other uses are also below the parkway, including the 26th Precinct Police Station at West 135th Street, various warehouses, vacant buildings and commercial establishments. Immediately to the south of the site is a Consolidated Edison natural gas pumping facility. A narrow portion of Riverside Park runs just to the east of the site, along the western edge of Riverside Drive and at the same elevation as Riverside Drive and the residential area adjacent to it.

The undeveloped piers and shore area south of the site located between West 125th and West 133rd Streets, known as "Harlem Piers," are publicly owned property currently used as informal public waterfront access and the subject of a current NYCEDC redevelopment plan.

East of Riverside Drive the area is almost entirely residential. These upland areas are comprised of apartment buildings generally six to seven stories tall except for River View Towers on Riverside Drive north of West 139th Street, which is 24 stories tall. Toward the southern portion of the primary study area, particularly around Broadway, there are ground-level commercial uses and various automotive repair, garage and warehouse storage spaces on the cross streets, including NYCT's Manhattanville Bus Depot (between West 132nd and West 133rd Streets).

Additional land uses located between a ¼-mile and ½-mile radius of the site are generally characterized as residential, with related uses such as schools, churches and libraries, and commercial uses along Broadway and Amsterdam Avenue, the north-to-south arteries. City College, located east of the site on Amsterdam Avenue, covers the area along the eastern perimeter of the secondary study area from about West 130th to West 140th Streets. Grant's Tomb, a national landmark and tourist attraction, is located south of the secondary study area at West 122nd Street and Riverside Drive.



One historic district and several historic properties are located within approximately ½-mile of the site. These properties are designated City landmarks and listed on the State Registers of Historic Places. These properties are: the Hamilton Heights Historic District (including the Alexander Hamilton House), northeast of the MTS; the Croton Aqueduct Gatehouse, at the junction of West 135th Street and Convent Avenue; the IRT Manhattan Valley Viaduct, on Broadway between West 135th and West 122nd Streets; Our Lady of Lourdes Roman Catholic Church, northeast of the site on West 142nd Street; the New York Public Library, Hamilton Grange Branch, northeast of the site on West 145th Street; City College, City University of New York, on Convent Avenue between West 138th and 140th Streets; St. Mary's Protestant Episcopal Church, southeast of the site near West 126th Street; the Hamilton Theater on Broadway and West 146th Street; Riverside Park and Drive south of 129th Street; and the 137th Street IRT Subway on Broadway, east of the site.

No archaeologically significant resources are located at the site or within the study area.

2.4.3.2 West 135th Street Converted MTS

The West 135th Street Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.4.3-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the West 135th Street Converted MTS superimposed on the site. Figure 2.4.3-3 (Plan and Section View) shows the processing building interior.

DSNY-managed Waste would be delivered to the West 135th Street Converted MTS by a variety of waste collection vehicles, primarily consisting of packer and dual-purpose trucks, and including collection vehicles operated by DSNY and other City agencies (e.g., NYCDPR, NYCHA and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building, at the entrance to the tipping floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

2.4.4 West 59th Street Converted MTS, Manhattan

2.4.4.1 Description of Existing Site

The existing West 59th Street MTS site is located in the Clinton section of Manhattan in Community District 4, at the end of West 59th Street and the Hudson River. Figure 2.4.4-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 1109, Lot 99, based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

The gross acreage of the DSNY-owned lot is approximately 2.8 acres. The site boundary extends approximately 780 feet from the U.S. Pierhead Line to 12th Avenue and approximately 160 feet from north to south along the U.S. Pierhead Line. Approximately 0.3 acre of the site is located on land and 2.5 acres are located over the Hudson River.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

Figure 2.4.4-1 Site Location

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The site is located at the northern edge of an M2-3 manufacturing zone, which extends south along the Hudson River waterfront to the Gansevoort Peninsula and then continues south to Battery Park City. Adjacent to the site's northern boundary is a large R10 zoning district that covers the waterfront and the residential portion of the new Riverside South Development.

Directly northeast of the site is a C4-7 zoning district and an M1-6 zoning district. Beyond these immediate districts, much of the area within ½-mile northeast of the site is zoned for high-density residential uses (R8) and a varied mix of commercial and industrial activities.

Southeast of the site, the immediate area is predominantly zoned for a range of industrial uses (M1-5 and M3-2). Within ½-mile of the site there is a mix of commercial and high-density residential (R8 and R9) districts, further to the east and south. In addition, there are two Special Purpose Districts that are in the general site vicinity: (1) the Clinton Special Purpose District, which extends west to 12th Avenue and West 59th Street; and (2) the Lincoln Square Special Purpose District, which extends south to West 60th Street and 10th/Amsterdam Avenues. These Districts were created to preserve and strengthen the residential character of the Clinton neighborhood and to preserve, protect and promote the unique cultural and architectural character of the Lincoln Center area.

Land uses in the site's immediate vicinity are varied and in flux. While the areas to the south and east remain largely dominated by transportation and utility uses, much of the waterfront is being redeveloped for public park use and mixed residential and commercial uses to the northeast and east. The site itself is within the designated Hudson River Park boundary, and plans for the park extend as far north as Pier 97 (at West 57th Street).

The elevated Miller Highway dominates the study area immediately surrounding the site (as it touches down to grade at West 57th Street), as does the massive Consolidated Edison generating plant across 12th Avenue and the large surface parking lot north of West 59th Street. In addition to the plant, Consolidated Edison occupies Pier 98 at the end of West 58th Street immediately south of the site for fuel transfer operations. Just south of Consolidated Edison's pier is Pier 97, which DSNY uses for vehicle parking and various storage operations. Pier 97 is also planned to

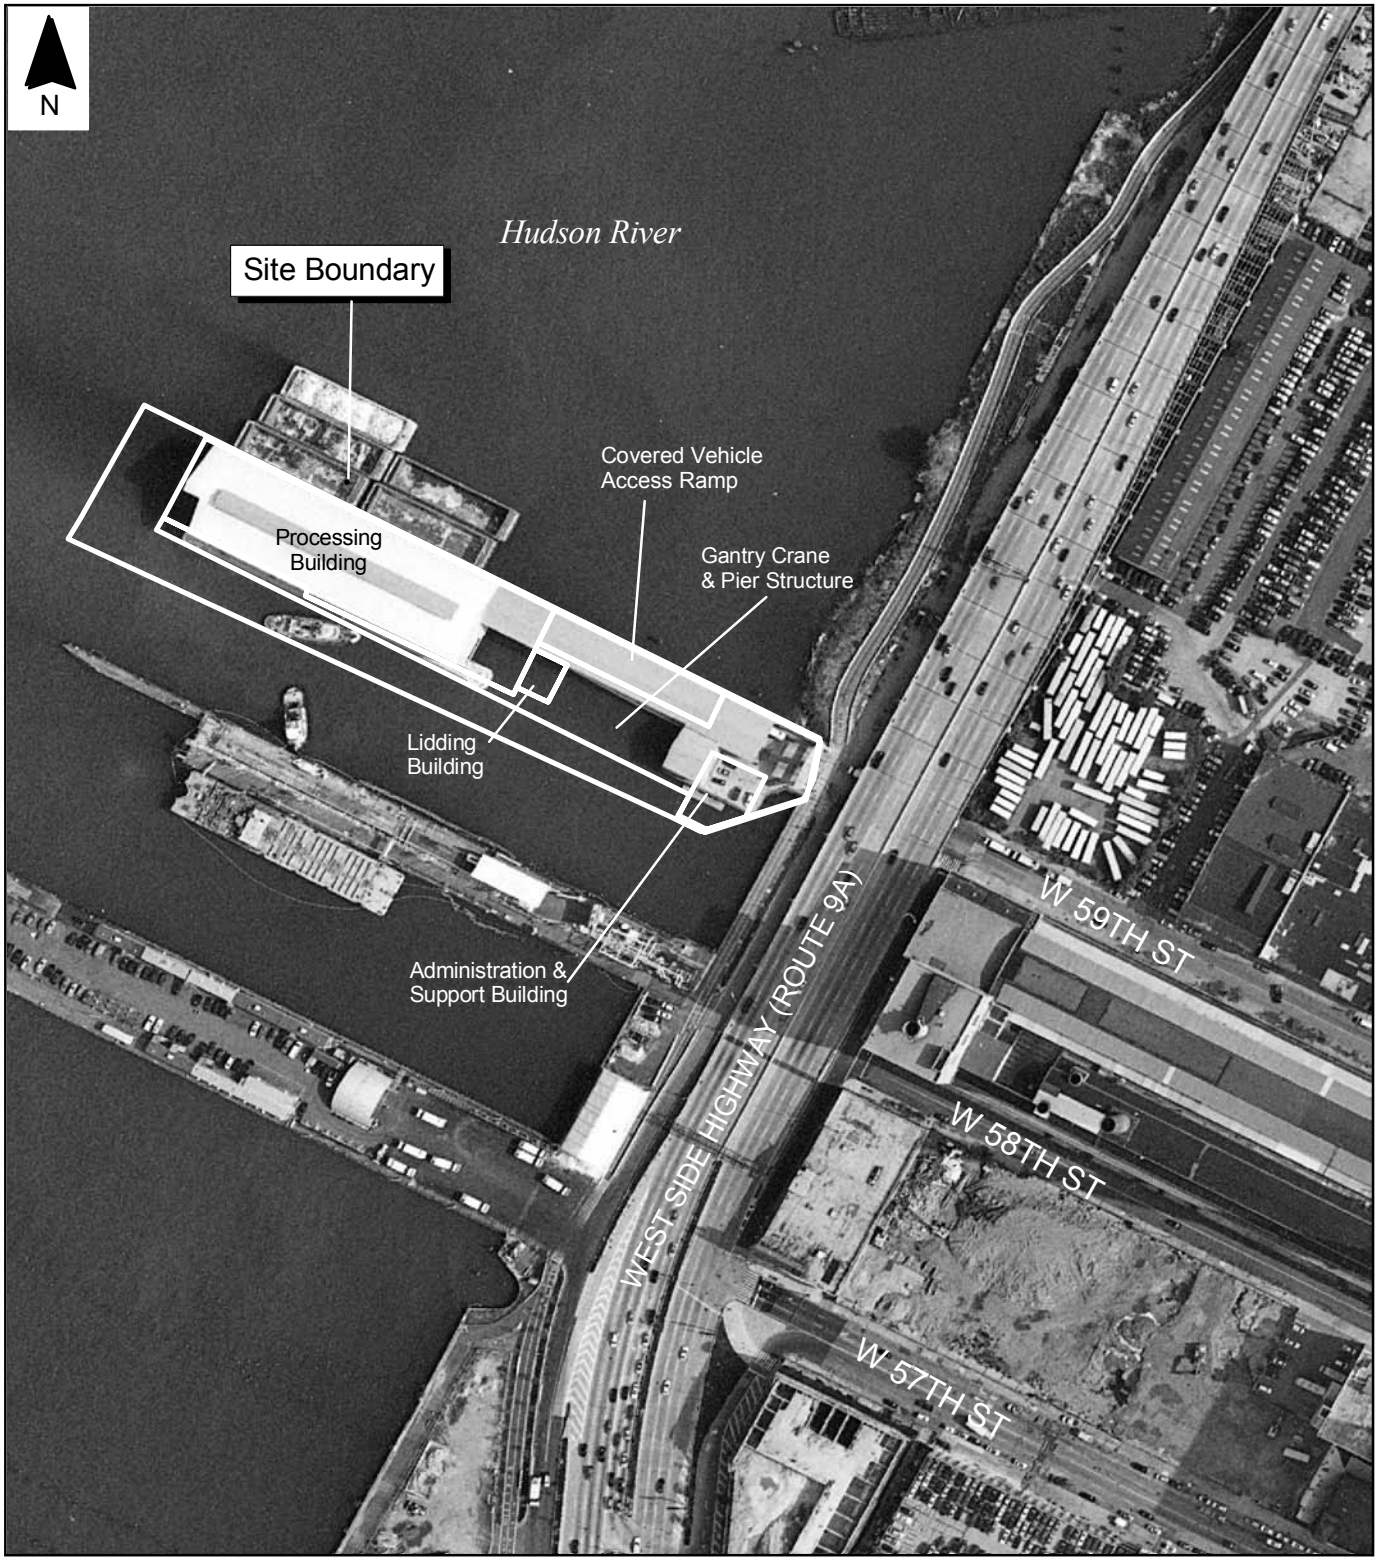
be rehabilitated in the future as part of the Clinton Cove Park and may include passive and active recreational areas. Piers 95 and 96 at the end of West 55th and West 56th Streets, respectively, are under construction as part of the Hudson River Park's "Clinton Cove Park," which will feature a boathouse and other waterfront amenities. This section of park is scheduled to open in 2005.

East of 12th Avenue between West 58th and West 57th Streets is the expansive ArtKraft Sign Corporation Factory, as well as other industrial activities located along the side streets. Interspersed with these one- and two-story warehouses are parking garages and surface lots. A large site has been cleared for the new DSNY District (4 and 7) Garage construction across 12th Avenue and spanning West 55th to West 57th Streets. It is scheduled to be completed by 2005. Further east, the pattern changes with a mix of century-old low-rise tenement buildings and recent high-rise apartment towers that have come to characterize the Clinton neighborhood.

Directly north of the site is an unbuilt section of Riverside Park South, which will connect the developing upland residential and commercial development north of West 59th Street to the waterfront under the elevated Miller Highway structure. The northern section, between West 66th and West 72nd Streets, is already completed and features expansive lawn areas, landscaped waterfront walkways and seating. The park segment between West 62nd and West 66th Streets (Phase 3) is actively under construction and due to be completed in 2005. The proposed park ends at West 59th Street, where the upland area is restricted to street right-of-way such that the adjacent bicycle/pedestrian path is the only physical and visual link between Riverside Park South and the emerging Hudson River Park to the south.

The West End Towers Park is a relatively new park on West End Avenue between West 63rd and West 64th Streets that is privately owned, though open to the public,. De Witt Clinton Park is located south of the site between West 52nd and West 54th Streets and 11th and 12th Avenues.

The Riverside South Development will ultimately extend from West 59th to West 72nd Streets on the site of the former Penn Central Yards. In conjunction with the park, the northern segments between West 66th and West 72nd Streets were completed first. Construction continues as a new ABC studio is rising at West 66th Street.



Several landmarks are located within a ½-mile radius of the site. The original Interborough Rapid Transit Company powerhouse is located on West 59th Street approximately 600 feet east of the site. The Church of St. Paul the Apostle is located along West 59th Street, approximately ½-mile east of the site, and the 69th Street Transfer Bridge/New York Central Railroad is located at West 69th Street and the West Side Highway, approximately ½-mile north of the site. The rehabilitation of the 69th Street Transfer Bridge as a ferry terminal is currently being considered as part of the overall development of the Riverside South Complex. This ferry terminal would alleviate commuter congestion problems along the subway lines that serve the area (along 8th Avenue).

No archaeologically significant resources are located on the site.

2.4.4.2 West 59th Street Converted MTS

The West 59th Street Converted MTS would be designed and built with the capability to containerize DSNY-managed Waste for export to out-of-City disposal facilities for the foreseeable future. Figure 2.4.4-2 (Facility Footprint) provides an aerial view of the existing site with a footprint of the West 59th Street Converted MTS superimposed on the site. Figure 2.4.4-3 (Plan and Section View) shows the processing building interior.

DSNY-managed Waste would be delivered to the West 59th Street Converted MTS by a variety of waste collection vehicles, primarily consisting of packer and dual-purpose trucks, and including collection vehicles operated by DSNY and other City agencies (e.g., NYCDPR, NYCHA and non-profit institutions). To enter the Converted MTS, waste delivery vehicles would ascend a ramp to an elevated tipping floor. Waste would be weighed and recorded on an inbound scale located inside of the building at the entrance to the tipping-floor level. After weigh-in, trucks would be directed to one of six tipping bays to discharge waste onto the loading floor. Empty vehicles would exit the building and cross over an outbound scale at the bottom of the ramp.

Site delineations are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

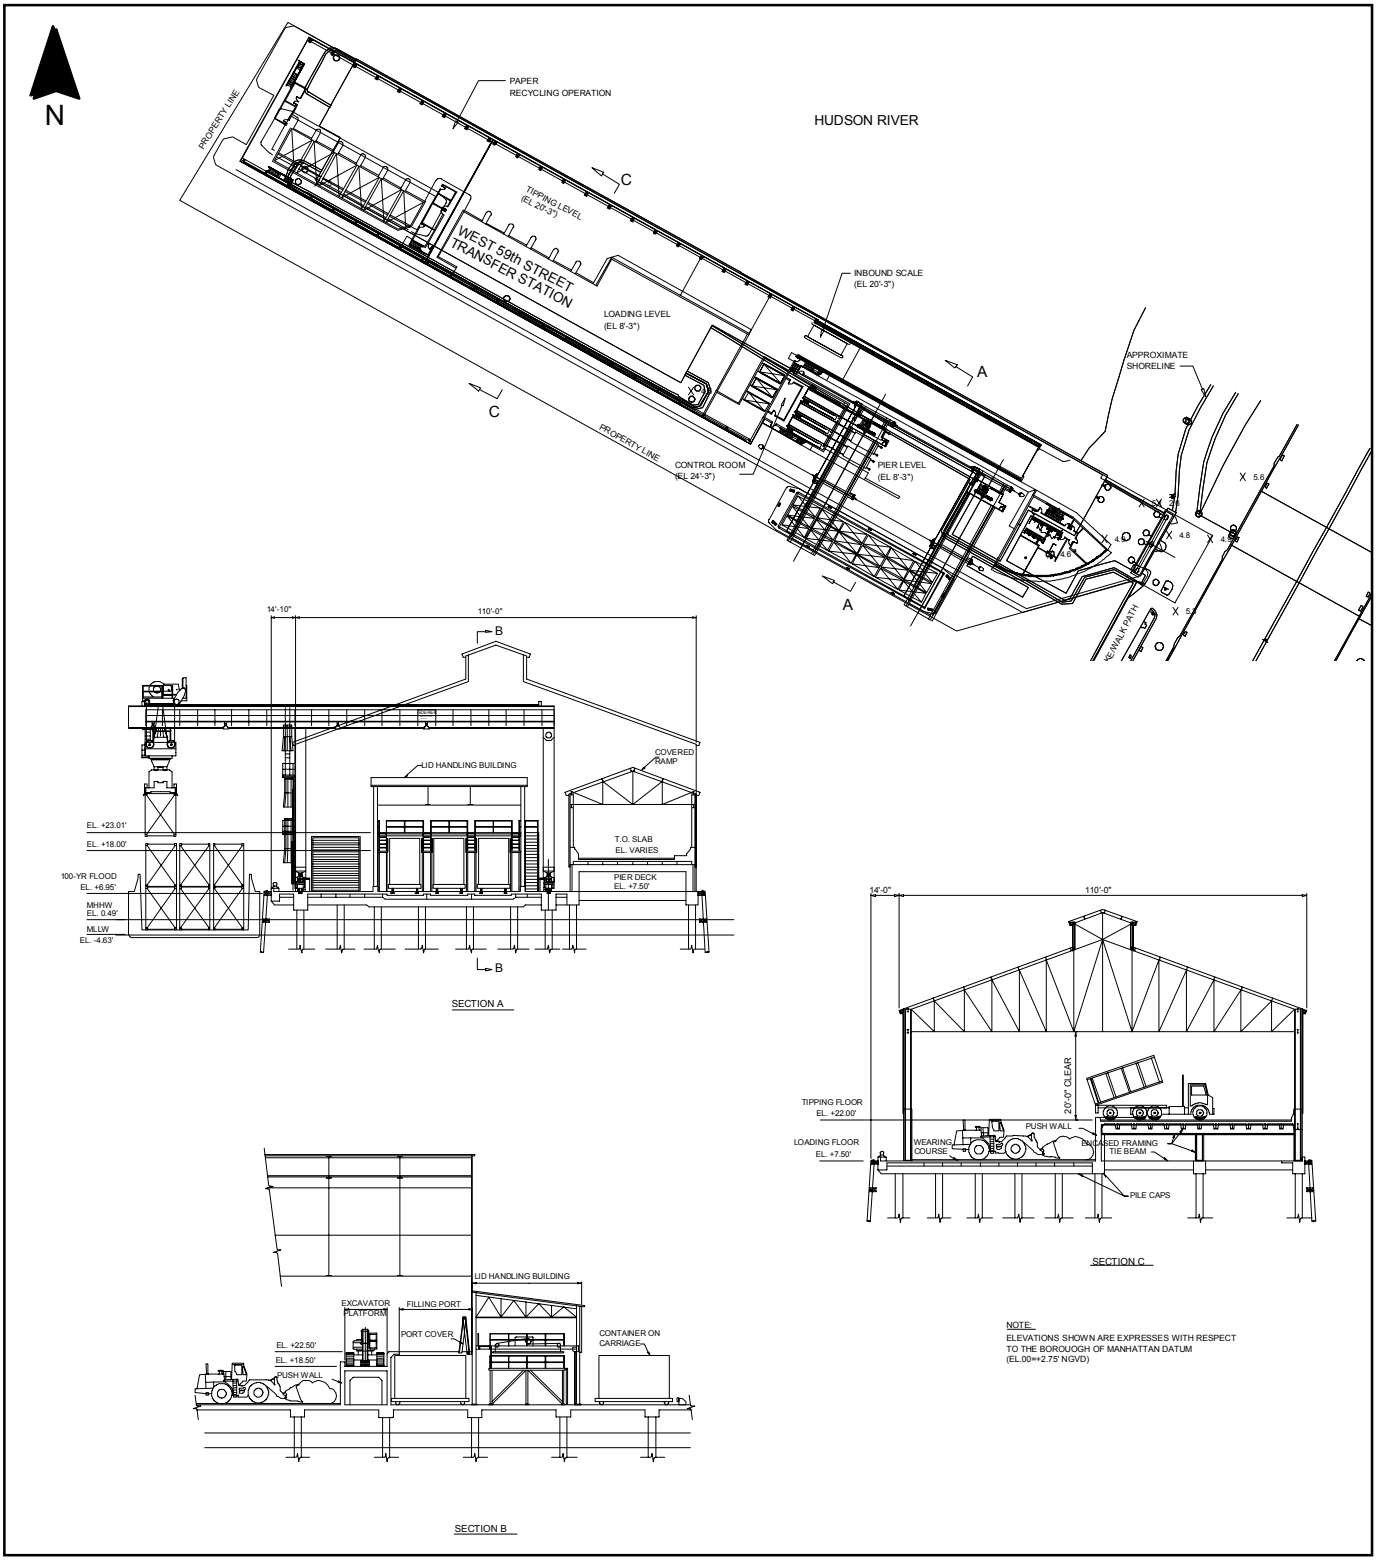

Figure 2.4.4-3 Plan and Section View

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The Converted MTS would also accept recyclable paper from DSNY collection vehicles and private haulers. The recyclable material would be handled in a separate area from the solid waste processing and storage area. The delivery vehicles for recycling operations would share the inbound and outbound ramp with solid waste delivery vehicles.

The loading floor would be 12 feet below the tipping floor. On the loading floor, front-end loaders would push the waste towards the eastern push wall. After the waste has been moved, an excavator located on an elevated platform 12 feet above the loading floor at the eastern push wall would load and tamp the waste into slots in the floor slab located over open-top containers. The containers would be mounted on shuttle cars that would move on tracks at the pier level at the same elevation as the loading floor. A tamper device working from the loading floor would even and densify the waste in the containers.

When loading is complete, the open-top containers would be moved into position at the enclosed lidding area of the processing building and would be securely lidded with a gasketed steel lid via pressure from a bridge crane with a spreader device. Then, the overhead door to the lidding area would open and the sealed containers would move via motorized shuttle cars onto the outdoor pier level. Gantry cranes would then load the containers onto a barge moored to the pier. The barges, with a containerized waste payload of approximately 1,056 tons (and a gross payload of 1,308 tons), would be towed to intermodal facilities, where the containers would then be transloaded to either trains or ocean-going vessels for transport to out-of-City disposal facilities.

The West 59th Street MTS site is evaluated in this FDEIS with: (1) a Converted MTS for the acceptance and processing of both DSNY-managed Waste and Commercial Waste; and (2) an existing MTS facility that would receive waste delivered in DSNY collection vehicles and load the waste into hopper barges for out-of-City disposal. If the site were selected to receive, transfer and transport commercial waste only, a supplemental environmental review would reassess the potential for adverse impacts based on a more complete understanding of Commercial Waste transfer operations at this site.

2.4.5 Existing South Bronx MTS, Bronx

2.4.5.1 Description of Existing Site

See Section 2.4.1.1, Description of Existing Site, for the Existing South Bronx MTS site.

2.4.5.2 Existing South Bronx MTS

The Existing South Bronx MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming collection vehicles and to monitor the Existing South Bronx MTS operation.

The Existing South Bronx MTS would require complete refurbishment to become operational.

A scale is located at the Existing South Bronx MTS building entrance to record and report the weight of the solid waste prior to its receipt. The scale, which has a 30-foot-long platform, is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. Leading to the Existing South Bronx MTS building is a ramp that is sized to accommodate the loadings exerted by the collection vehicles and to provide passage of vehicular traffic in both directions.

The Existing South Bronx MTS building is supported by a series of pilings embedded below the East River. The pilings, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams in turn support a steel frame that supports the reinforced concrete slab that forms the tipping floor.

The design of the 12-bay tipping floor provides for the accommodation of traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 120 feet wide by 140 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the Existing South Bronx MTS. In addition, the internal height of the structure allows sufficient headroom for the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

Provisions have been included to ensure that the tipping procedure occurs in a safe and efficient manner. Along the entire length of the tipping floor, a truck wheel curb, approximately 1 foot by 1 foot, has been installed. In addition, each bay is separated by a barrier. These features allow each collection vehicle to back up and deliver its contents directly into the barge. Signs are also posted in visible areas to remind drivers of potential safety hazards.

All solid waste delivered to the Existing South Bronx MTS would be placed directly into the barges. Each barge undergoing the loading procedure would be moored internally and covered by the Existing South Bronx MTS structure. The structure provides sufficient protection from outside forces until the waste can be secured with netting.

To provide a comfortable working environment, the Existing South Bronx MTS is equipped with an air conditioning system in its administrative areas. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a solution pump, an odor-suppressant pump and related piping. To provide fresh outside air, the tipping area is equipped with supply air fans, exhaust air fans and related supply duct work.

To prevent traffic to and from the Existing South Bronx MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp, scale and on-site roadway leading to the scale. The width of the facility roadway allows for two-way traffic flow and for cars to proceed to the South Bronx Existing MTS parking area.

The parking lot includes space for approximately 12 vehicles. This is more than adequate room for the number of employees assigned to the Existing South Bronx MTS.

2.4.6 Existing Southwest Brooklyn MTS, Brooklyn

2.4.6.1 Description of Existing Site

See Section 2.2.2.1, Description of Existing Site, for the Existing Southwest Brooklyn MTS site.

2.4.6.2 Existing Southwest Brooklyn MTS

The Existing Southwest Brooklyn MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming collection vehicles and to monitor the Existing Southwest Brooklyn MTS operation.

The existing ramp is sized to accommodate the loadings exerted by the collection vehicles and to provide passage of vehicular traffic in both directions. It has a load-bearing capacity of 40 tons. A scale is located at the Existing Southwest Brooklyn MTS to record and report the weight of solid waste prior to its receipt. The scale is connected to a computerized data record keeping system that maintains an accurate accounting of all weights.

The Existing Southwest Brooklyn MTS structure is supported by a series of pilings embedded within Gravesend Bay. The pilings, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams in turn support a steel frame that supports the reinforced concrete slab that forms the tipping floor. The tipping floor has a slight pitch to allow drainage to inlets and piping located under the tipping floor, which has a load bearing capacity of 40 tons.

The design of the six-bay tipping floor provides for the accommodation of the traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 48 feet wide by 114 feet long. This size provides adequate room for the collection vehicles to enter, back up, unload and exit the Existing Southwest Brooklyn MTS. In addition, the internal height of the structure allows for sufficient headroom so the collection vehicles can end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

All solid waste delivered to the Existing Southwest Brooklyn MTS would be placed directly into the barges. Each barge undergoing the loading procedure would be moored internally and covered by the Existing Southwest Brooklyn MTS structure. The structure provides sufficient protection from outside forces until the waste can be secured with netting.

To provide a comfortable working environment, the Existing Southwest Brooklyn MTS is equipped with an air conditioning system in its administrative areas. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a solution pump, an odor-suppressant pump and related piping. To provide fresh outside air, the tipping area is equipped with supply air fans, exhaust air fans and related supply duct work.

To prevent traffic to and from the Existing Southwest Brooklyn MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp, scale and on-site roadway leading to the scale. The width of the facility ramp allows for two-way traffic flow and for cars to proceed to the Existing Southwest Brooklyn MTS parking area. The parking lot includes space for approximately 10 vehicles.

The asphalt road surface design is adequate to withstand the expected loads and is sloped to facilitate drainage. To accommodate stormwater runoff, catch basins and underground/under ramp piping are provided.

2.4.7 Existing Greenpoint MTS, Brooklyn

2.4.7.1 Description of Existing Site

See Section 2.4.2.1, Description of Existing Site, for the Existing Greenpoint MTS site.

2.4.7.2 Existing Greenpoint MTS

The Existing Greenpoint MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming collection vehicles and to monitor the Existing Greenpoint MTS operation.

The ramp is sized to accommodate the loadings exerted by the collection vehicles and to provide passage of vehicular traffic in both directions. To record and report the weight of the solid waste prior to receipt at the Existing Greenpoint MTS, a scale is located at the Existing Greenpoint MTS entrance. The 30-foot-long scale is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. Scale capacity is limited to the existing ramp and tipping floor maximum capacity of 40 tons.

The Existing Greenpoint MTS structure is supported by a series of pilings embedded within Newtown Creek. The pilings, which form the foundation, support a steel frame that supports the reinforced concrete slab that forms the tipping floor. The tipping floor has a slight pitch to allow drainage to a holding tank, then to a sump pit that discharges to the municipal sewer system.

The design of the 12-bay tipping floor provides for the accommodation of the traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 80 feet wide by 160 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the Existing Greenpoint MTS. In addition, the internal height of the structure provides sufficient headroom for the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

To provide a comfortable working environment, the Existing Greenpoint MTS is equipped with an air conditioning system in its administrative areas. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a solution pump, an odor-suppressant pump and related piping. To provide fresh outside air, the tipping area is equipped with supply air fans, exhaust air fans and related duct work.

To prevent traffic to and from the Existing Greenpoint MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp, scale and on-site roadway leading to the scale. The de-mapped portion of Kingsland Avenue can also accommodate vehicles, if required. The width of the Existing Greenpoint MTS roadway allows for two-way traffic flow.

The asphalt road surface design is adequate to withstand the expected loads and is sloped to facilitate drainage. To accommodate stormwater runoff, catch basins and underground/under ramp piping are provided.

2.4.8 Existing Hamilton Avenue MTS, Brooklyn

2.4.8.1 Description of Existing Site

See Section 2.2.1.1, Description of Existing Site, for the Existing Hamilton Avenue MTS site.

2.4.8.2 Existing Hamilton Avenue MTS

The Existing Hamilton Avenue MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming collection vehicles and to monitor the Existing Hamilton Avenue MTS operation.

To record and report the weight of the solid waste prior to receipt at the Existing Hamilton Avenue MTS, a scale is located at its entrance. The scale, which has a 30-foot-long platform, is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. Beyond the scale is the ramp that provides access to the tipping floor. The existing ramp is sized to accommodate the loading exerted by the collection vehicles and to provide passage of vehicular traffic in both directions. The existing ramp and tipping floor maximum loading capacity is 40 tons.

The Existing Hamilton Avenue MTS structure is supported by a series of pilings embedded within Gowanus Canal. The pilings, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams, in turn, support a steel frame that braces the reinforced concrete slab that forms the tipping floor.

The design of the 12-bay tipping floor (six per slip) provides for the accommodation of traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 185 feet wide by 178 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the Existing Hamilton Avenue MTS. In addition, the internal height of the structure allows sufficient headroom for the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

Provisions have been included to ensure that the tipping procedure occurs in a safe and efficient manner. Along the entire length of the tipping floor, a truck wheel curb, approximately 1 foot by 1 foot, has been installed. In addition, each bay is separated by a barrier. These features allow each collection vehicle to back up and deliver its contents directly into the barge. Signs are also posted in visible areas to remind drivers of potential safety hazards.

All solid waste delivered to the Existing Hamilton Avenue MTS would be placed directly into the barges. Each barge undergoing the loading procedure would be moored internally and covered by the Existing Hamilton Avenue MTS structure. The structure provides sufficient protection from outside forces until the waste can be secured with netting.

To provide a comfortable working environment, the Existing Hamilton Avenue MTS is equipped with a portable air conditioner in the office. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a dust control solution pump, odor-suppressant pumps and related piping. To provide fresh outside air, the tipping area is equipped with supply air fans, exhaust air fans and related duct work.

To prevent traffic to and from the Existing Hamilton Avenue MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp and scale. The width of the Existing Hamilton Avenue MTS roadway allows for one-way traffic flow and for cars to proceed to the Existing Hamilton Avenue MTS parking area. The parking lot includes space for approximately 10 vehicles. This is adequate room for the number of employees assigned to the Existing Hamilton Avenue MTS.

The asphalt road surface design is adequate to withstand the expected loads and is sloped to facilitate drainage. To accommodate stormwater runoff, catch basins and underground/under ramp piping are provided.

2.4.9 Existing West 135th Street MTS, Manhattan

2.4.9.1 Description of Existing Site

See Section 2.4.3.1, Description of Existing Site, for the Existing West 135th Street MTS site.

2.4.9.2 *Existing West 135th Street MTS*

The Existing West 135th Street MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming collection vehicles and to monitor the Existing West 135th Street MTS operation.

To record and report the weight of the solid waste prior to entering the tipping floor, a scale is located just inside the entrance of the Existing West 135th Street MTS. The scale, which has a 30-foot-long platform and a 60-ton capacity, is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. Scale capacity is more than adequate as the ramp and tipping floor maximum loading capacity is 40 tons.

The Existing West 135th Street MTS is supported by a series of piles embedded within the Hudson River. The piles, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams in turn support a steel frame that supports the reinforced concrete slab that forms the tipping floor. The tipping floor has a slight pitch to allow drainage to an oil/water separator and then to a sludge tank that discharges to the municipal combined storm-sewer system.

The design of the 12-bay tipping floor provides for the accommodation of traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 120 feet wide by 140 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the Existing West 135th Street MTS. In addition, the internal height of the structure allows for sufficient headroom allowing the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

Provisions have been included to ensure that the tipping procedure occurs in a safe and efficient manner. Along the entire length of the tipping floor, a truck wheel curb, approximately 1 foot by 1 foot, has been installed. In addition, each bay is separated by a barrier. These features allow each collection vehicle to back up and deliver its contents directly into the barge. Signs are also posted in visible areas to remind drivers of potential safety hazards.

All solid waste delivered to the Existing West 135th Street MTS would be placed directly into the barges. Each barge undergoing the loading procedure would be moored internally and covered by the Existing West 135th Street MTS structure. The structure provides sufficient protection from outside forces until the waste can be secured with netting.

To provide a comfortable working environment, the Existing West 135th Street MTS is equipped with an air conditioning system in its administrative areas. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a solution pump, an odor-suppressant pump and related piping. To provide fresh outside air, the tipping area is equipped with supply air fans, exhaust air fans and related duct work. This system is enhanced by the MSA Gas Monitors (Model Toxguard SX), which measure the level of CO within the tipping area.

A parking lot is located just south of the ramp entrance, and can accommodate roughly 10 to 12 cars. To prevent traffic to and from the Existing West 135th Street MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp, scale and on-site roadway leading to the scale. The width of the facility roadway allows for two-way traffic flow.

2.4.10 Existing West 59th Street MTS, Manhattan

2.4.10.1 Description of Existing Site

See Section 2.4.4.1, Description of Existing Site, for the Existing West 59th Street MTS site.

2.4.10.2 Existing West 59th Street MTS

The Existing West 59th Street MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming refuse vehicles and to monitor the Existing West 59th Street MTS operation.

To record and report the weight of the solid waste prior to receipt at the Existing West 59th Street MTS, a scale is located at the existing MTS entrance. The scale, which has a 30-foot-1½-inch-by-15-foot platform and a 40-ton capacity, is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. Beyond the scale is a covered ramp that provides access to the tipping floor. The ramp is sized to accommodate the loadings exerted by the collection vehicles and to provide passage of vehicular traffic in both directions.

The Existing West 59th Street MTS structure is supported by a series of pilings embedded within the Hudson River. The pilings, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams in turn support a steel frame that braces the reinforced concrete slab that forms the tipping floor. The tipping floor (elevation 22.5 feet) has a slight pitch to allow drainage to a sump pit, which discharges to the city sewer system. The loading capacity of the existing floor and ramp is 40 tons.

The design of the 14-bay tipping floor, of which 12 bays are functional and/or utilized, provides for the accommodation of traffic flow. The dimensions of the floor are approximately 50 feet wide by 300 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the facility. In addition, the internal height of the structure allows for sufficient headroom for the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

Provisions have been included to ensure that the tipping procedure occurs in a safe and efficient manner. Along the entire length of the tipping floor, a truck wheel curb, approximately 1 foot by 1 foot, has been installed. In addition, each bay is separated by a barrier. These features allow each collection vehicle to back up and deliver its contents directly into the barge. Signs are also posted in visible areas to remind drivers of potential safety hazards.

To provide a comfortable working environment, the Existing West 59th Street MTS is equipped with an air conditioning system in its enclosed areas that are normally occupied, excluding the tipping floor. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a solution pump, an odor-suppressant pump and related piping. To provide fresh outside air, the tipping area is equipped with supply air fans, exhaust air fans and related duct work. This system is enhanced by an MSA Gas Monitor, Model 516, which measures the percent lower explosive limit (LEL) and the level of CO within the tipping area.

To prevent traffic to and from the Existing West 59th Street MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the 30-foot-wide ramp scale and on-site roadway leading to the scale. The width of the facility roadway allows for two-way traffic flow and for cars to proceed to the Existing West 59th Street MTS parking area. The parking lot includes space for approximately six vehicles. This is adequate room for the number of employees assigned to the Existing West 59th Street MTS.

2.4.11 Existing East 91st Street MTS, Manhattan

2.4.11.1 Description of Existing Site

See Section 2.2.3.1, Description of Existing Site, for the Existing East 91st Street MTS site.

2.4.11.2 Existing East 91st Street MTS

The Existing East 91st Street MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the facility. The function of the tipping floor level is to offload all incoming refuse vehicles and to monitor the Existing East 91st Street MTS operation.

To record and report the weight of the solid waste prior to receipt at the Existing East 91st Street MTS, a scale is located at the facility entrance. The scale, which has a 30-foot-long platform and a 40-ton capacity, is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. The existing ramp and tipping floor maximum loading capacity is 40 tons.

The Existing East 91st Street MTS structure is supported by a series of pilings embedded within the East River. The pilings, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams in turn support a steel frame that supports the reinforced concrete slab that forms the tipping floor. The tipping floor has a slight pitch to allow drainage to the municipal sewer system.

The design of the tipping floor provides for the accommodation of traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 50 feet wide by 300 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the Existing East 91st Street MTS. In addition, the internal height of the structure allows for sufficient headroom allowing the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one would be processed at a time. Along the entire length of the tipping floor, a truck wheel

curb, approximately 1 foot by 1 foot, has been installed in order to ensure that the tipping procedure occurs in a safe and efficient manner. In addition, each bay is separated by a barrier. These features allow each collection vehicle to back up and deliver its contents directly into the barge. Signs are also posted in visible areas to remind drivers of potential safety hazards.

All solid waste delivered to the Existing East 91st Street MTS would be placed directly into the barges. Each barge undergoing the loading procedure would be moored internally and covered by the Existing East 91st Street MTS structure. The structure provides sufficient protection from outside forces until the waste can be secured with netting.

To provide a comfortable working environment, the Existing East 91st Street MTS is equipped with an air conditioning system in those areas that are occupied, excluding the tipping floor. A dust control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a solution pump, an odor-suppressant pump and related piping. To provide fresh outside air, the tipping area is also equipped with supply air fans, exhaust air fans and related duct work.

To prevent traffic to and from the Existing East 91st Street MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp, scale and on-site roadway leading to the scale. The width of the facility roadway allows for two-way traffic flow.

2.4.12 Existing North Shore MTS, Queens

2.4.12.1 Description of Existing Site

See Section 2.2.4.1, Description of Existing Site, for the Existing North Shore MTS site.

2.4.12.2 Existing North Shore MTS

The Existing North Shore MTS is a two-story structure with the lower level designated as the barge level and the upper level identified at the tipping floor level. The function of the barge level is mainly to secure all barges to the MTS. The function of the tipping floor level is to offload all incoming refuse vehicles and to monitor the Existing North Shore MTS operation.

At the entrance to the Existing North Shore MTS is a 35-foot-wide ramp that provides worker/vehicle access from street level. The existing ramp is sized to accommodate the loadings exerted by the collection vehicles and to provide passage of vehicular traffic in both directions. The existing ramp has a load capacity of 40 tons.

To record and report the weight of the solid waste prior to receipt at the Existing North Shore MTS, a scale is located at the tipping floor entrance. The scale, which has a 30-foot-long platform, is connected to a computerized data record keeping system that maintains an accurate accounting of all weights. The weighing system is located within the Weighmaster Room. Materials from the SHS would be weighed upon delivery to the Existing North Shore MTS or at the vendor's facility.

The Existing North Shore MTS structure is supported by a series of pilings embedded within Flushing Bay. The steel pilings, which form the foundation, are connected by reinforced concrete pile caps and beams. The caps and beams, in turn, support a steel frame that braces the reinforced concrete slab that forms the tipping floor. The tipping floor has a slight pitch to allow drainage to a collection tank which, in turn, discharges to the municipal sewer system.

The design of the 12-bay tipping floor provides for the accommodation of the traffic flow in a safe and efficient manner. The dimensions of the floor are approximately 80 feet wide by 130 feet long. This size provides adequate room for the collection vehicles to enter, back up, discharge and exit the Existing North Shore MTS. In addition, the internal height of the structure provides sufficient headroom for the collection vehicles to end dump without hitting an overhead structure. Several collection vehicles can be accommodated simultaneously, but generally only one or two would be processed at a time.

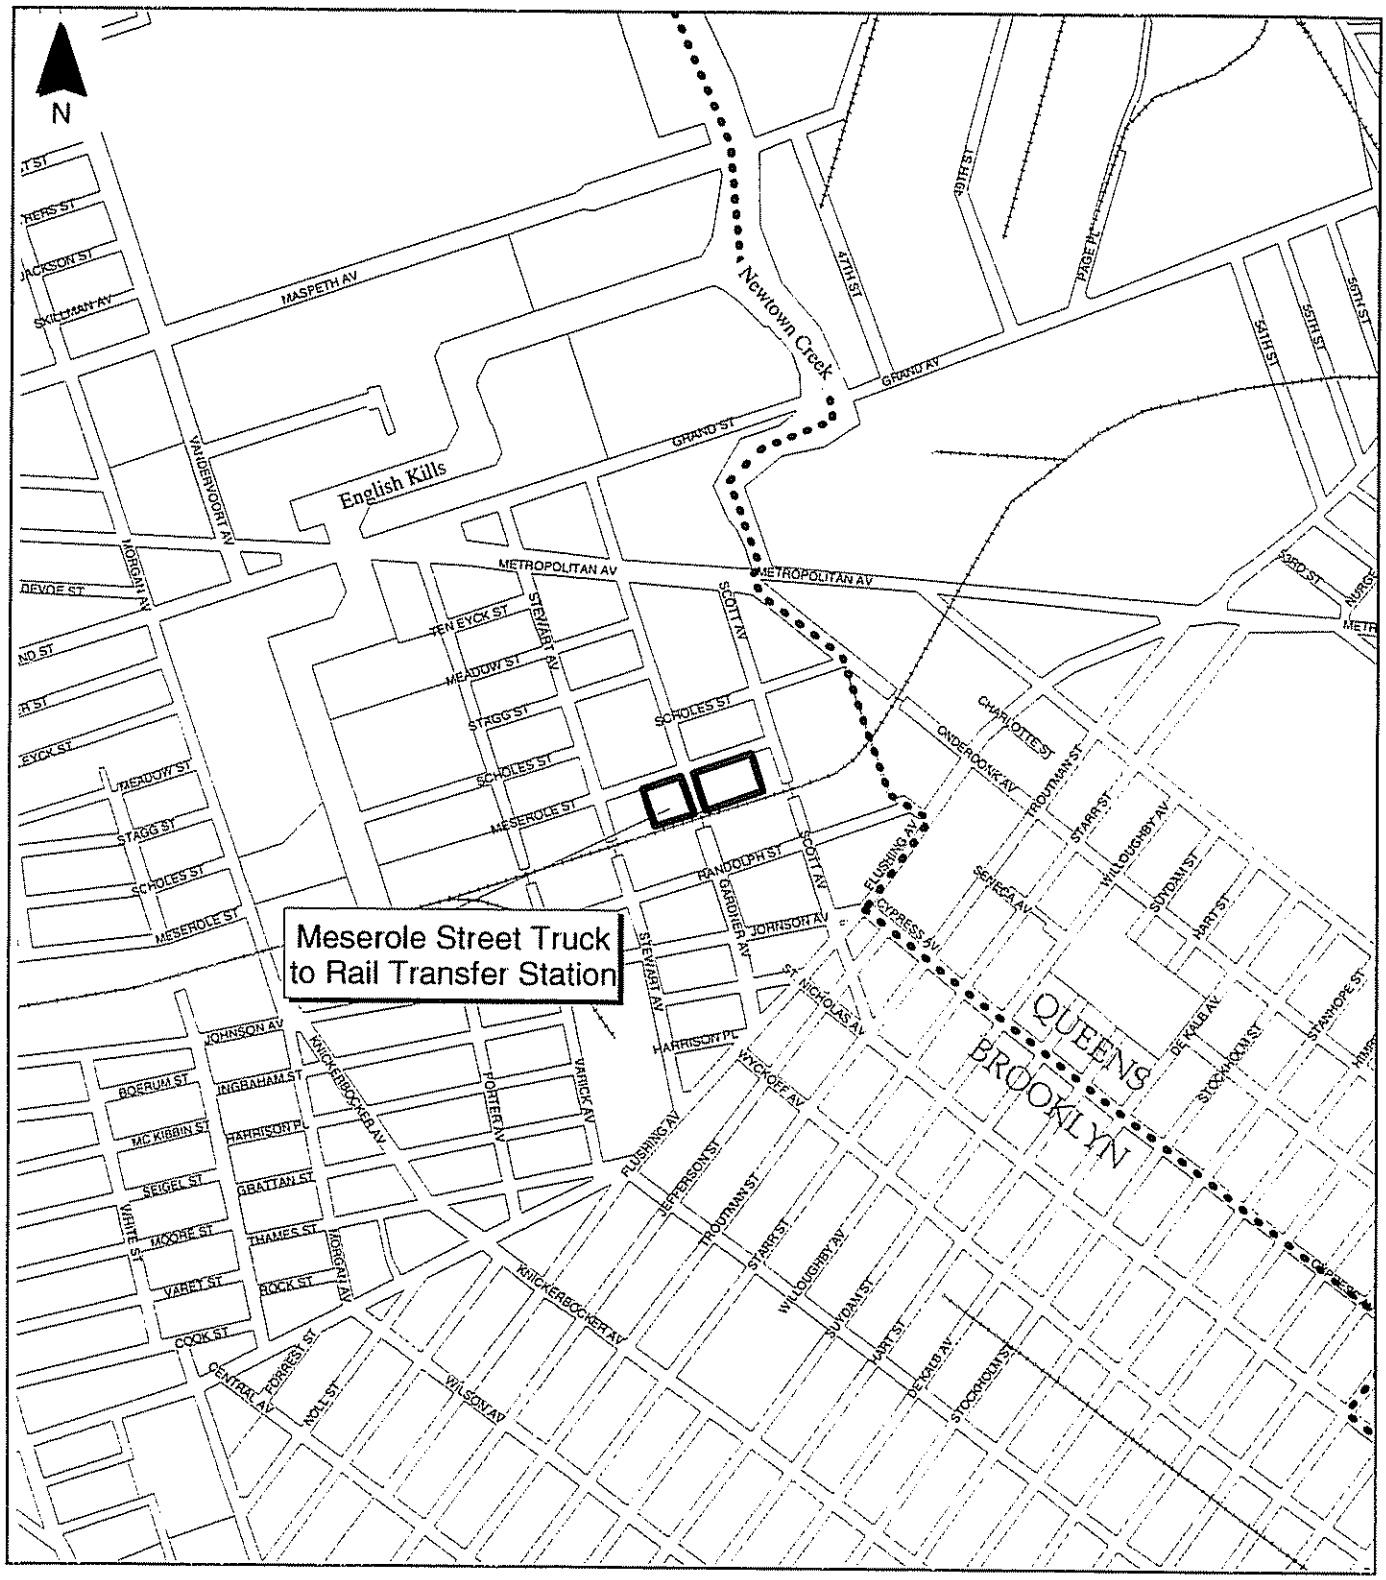
Provisions have been included to ensure that the tipping procedure could occur in a safe and efficient manner. Along the entire length of the tipping floor, a truck wheel curb has been installed. In addition, each bay is separated by a barrier. These features allow each collection vehicle to back up and deliver its contents directly into the barge. Signs are also posted in visible areas to remind drivers of potential safety hazards.

All solid waste delivered to the Existing North Shore MTS would be placed directly into the barges. Each barge undergoing the loading procedure would be moored internally and covered by the Existing North Shore MTS structure. The structure provides sufficient protection from outside forces until the waste can be secured with netting.

To provide a comfortable working environment, the Existing North Shore MTS is equipped with an air conditioning system in its administrative areas. A dust-control system is provided within the tipping area to suppress the airborne transport of fugitive dusts. This system includes a spray pump, a deodorizer pump and related piping. The tipping area is equipped with supply air fans, exhaust air fans and related duct work.

To prevent traffic to and from the Existing North Shore MTS from impeding the surrounding environs, space is available on site for the staging of collection vehicles. The space includes the ramp, scale and on-site roadway leading to the scale. The width of the Existing North Shore MTS roadway allows for two-way traffic flow and for cars to proceed to the Existing North Shore MTS parking area. The parking lot includes space for approximately 15 vehicles, which is adequate room for the number of employees assigned to the Existing North Shore MTS.

2.4.13 Meserole Street Truck to Rail TS



2.4.13.1 Description of the Existing Site

The Meserole Street Truck to Rail TS site is located in Community District 1 near the Brooklyn/Queens border, in the predominantly industrial section of East Williamsburg, Brooklyn. It is generally surrounded by English Kills on the west, Newtown Creek on the east and LIRR tracks to the east and south. The area is also characterized by abundant parking lots and garage facilities, some of which are leased by DSNY for trucks and other equipment storage. Figure 2.4.13-1 (Site Location) shows the approximate boundaries of the site and the surrounding neighborhood. The site is located within Tax Block 2978, Lot 1 and Tax Block 2977, Lot 1 based on a review of 2002 New York City Department of Finance *Real Property Assessment Data*.

The site contains two parcels on either side of Gardner Avenue. 568 Meserole Street contains the Meserole Street (paper) Recycling Facility on the southeast corner of Gardner Avenue and Meserole Street. The Filco Carting Company's truck parking lot occupies most of the lot at 111 Gardner Avenue, on the southwest corner of Gardner Avenue. The existing buildings on the site would be demolished to accommodate new facility construction.

The site is located within an M3-1 zoning district. This M3-1 zone extends north of the site along English Kills, east into Queens and south of the site where there are M1-2 and M1-1 zoning districts as well. The M1 zones act as a buffer between the residential and the heavier manufacturing districts and feature both residential and light manufacturing (e.g., distribution) activities. The nearest residential district, R5B, is located approximately ¼-mile east of the site.

The site is situated just west of the Brooklyn/Queens border, which separates East Williamsburg, Brooklyn, to the west and Maspeth, Queens, to the east. South of the site are several private waste transfer stations (including Allied Waste Systems facilities on Scholes Street and Gardner Avenue, and Waste Management of New York facilities on Stewart Avenue and Varick Avenue), as well as a DSNY parking lot on Meserole Street, a new CD 1 and 4 garage under construction on Varick Avenue and an existing garage on Johnson Avenue.

Site delineations are approximate

Figure 2.4.13-1 Site Location

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The English Kills canal located ¼-mile east of the site is approximately 200 feet wide and connects with Newtown Creek at the Brooklyn/Queens boundary. The LIRR tracks pass immediately south of the site between Meserole and Randolph Streets. The NY&A operates freight trains on these tracks, with a terminal nearby in Bushwick (to the west).

North and south of the existing site are scrap metal yards and plastic manufacturing facilities, window and door manufacturing, lumber yards and hydraulic equipment leasing companies. Development surrounding the site is primarily low density with open parking lots and low-scale masonry buildings ranging from two to four stories in height.

The area surrounding the site includes some vacant land to the north on Gardner and Stewart Avenues, as well as lots undergoing construction. Some sites have been rehabilitated to accommodate new industrial loft space and community facilities, such as a Peter Jay Sharp Center for Opportunity on Porter Street. The other community facilities include a fire station on Morgan Avenue and a daycare center on Knickerbocker Street.

There is a mix of residential, industrial and some commercial uses further from the site. Industrial uses located nearly ½-mile from the site tend to be of lighter intensity than those found within ¼-mile of the site. These uses include printers, auto salvage and repair shops and food-product manufacture and distribution companies. The nearest residential area, Bushwick, which is ½-mile east of the site along Willoughby and Starr Streets, is characterized by three- and four- story apartment buildings as well as single family homes and townhouses.

According to published sources, no historic structures are located on the site. However, within ½-mile of the site there are three early 20th-century historic districts and one individual property that are listed on the NYSR and NR.

The Vander Ende-Onderdonk House (a.k.a., The Adrian and Anne Wyckoff Onderdonk House), located nearly ¼-mile east of the site, is a City landmark, and listed on the NYSR and NR. It is the oldest Dutch-American fieldstone house in the City, and houses the Greater Ridgewood Historical Society.

The three historic districts within ½-mile of the site (or just beyond) are all intact groupings of late 19th-century/early 20th-century working class rowhouse and tenement housing. They are all in the bisected neighborhood of Ridgewood, which spans the Queens and Brooklyn border.

The Willoughby-Suydam Historic District covers 1½ blocks composed of 50 three-story brick tenements built between 1904 and 1906. Located more than ¼-mile southeast of the site, the district is listed on the NYSR and NR.

The Stockholm-DeKalb-Hart Historic District covers 2½ blocks, approximately ½-mile east of the site. The central portion of this district is designated by LPC as the Stockholm Street Historic District.

2.4.13.2 Meserole Street Truck to Rail TS

Two different companies have proposed to develop a truck-to-rail transfer station at the site. TransRiver Marketing Company, LLP is proposing a completely new truck to on-site rail facility, with 2,000 tpd of capacity. Waste received at the Meserole site would be transported by rail to a proposed American Ref-Fuel WTE facility located in Niagara, New York. The on-site operations would include truck tipping, use of a grapple to load the waste into intermodal shipping containers, and the loading of full containers onto waiting rail cars located inside the transfer facility. Of the proposed capacity, only 1,000 tpd would be utilized by DSNY-managed Waste, with the balance used by commercial accounts. No permit applications or environmental review documents have been filed for the site. Therefore, this FDEIS evaluates the facility at the proposed 2,000 tpd capacity. A new 200-foot-by-200-foot building would be constructed with a concrete tipping floor, push walls, rail line loading dock and two scales. All tipping and loading operations would occur inside the building. Figure 2.4.13-2 (Facility Footprint) shows the site boundary on an aerial photograph. Figure 2.4.~~14~~13-3 (Plan and Section View) shows the building interior.

Site Delineations are approximate.

Figure 2.4.13-3 Plan and Section View

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

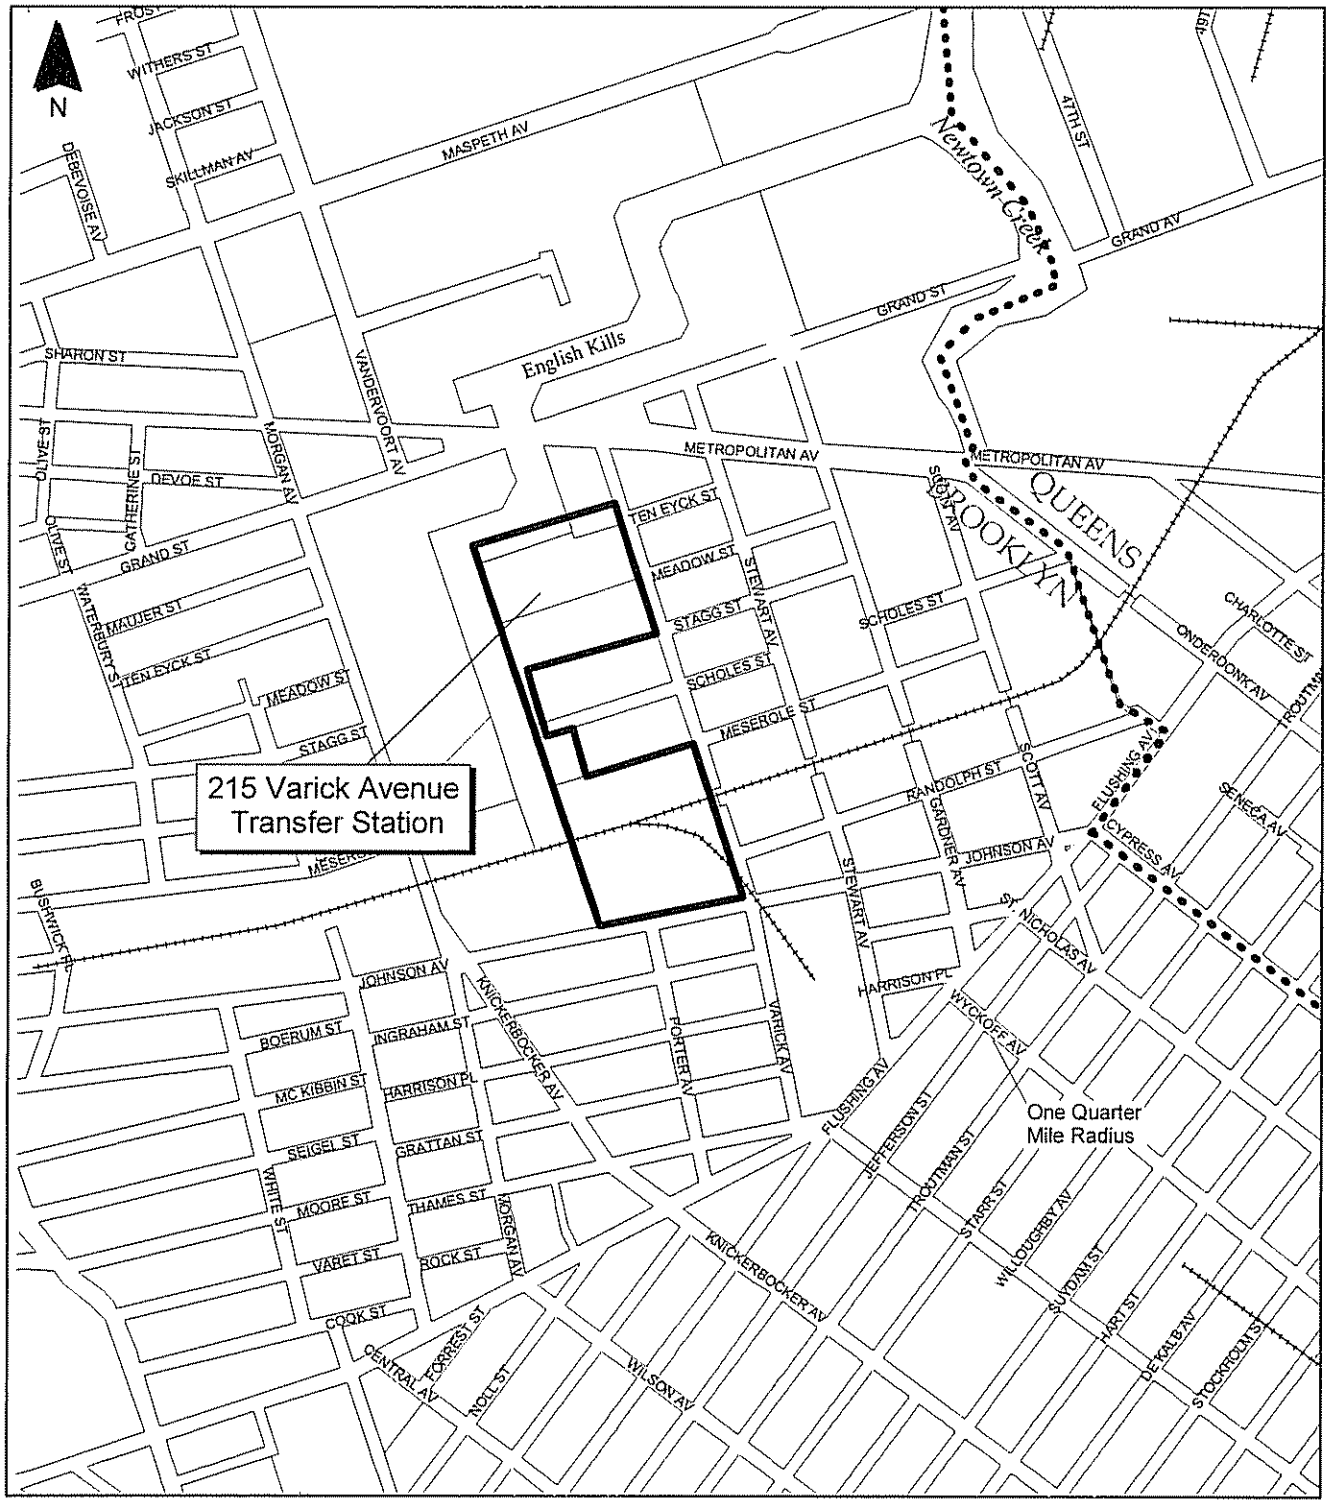
IESI is proposing a new truck to on-site rail facility, with 2,000 tpd of capacity. Limited design, permit or EAS information has been provided; therefore the analysis of this proposal will utilize the TransRiver Marketing Company's proposed design as the basis for environmental review. If IESI is the selected proposer and a modified design is identified, the modifications will be evaluated in a supplemental EIS.

2.4.14 215 Varick Avenue Transfer Station

This site is an Alternative that could potentially be selected by DSNY for Long Term Export by rail of DSNY-managed Waste from the former Brooklyn portion of the Greenpoint MTS wasteshed, Brooklyn CDs 1, 3, 4 and 5. It was not reviewed in the DEIS, because at the time of DEIS publication, it had not yet been identified as a potential rail export site. As part of the Long Term Export procurement being conducted by DSNY, in February 2005, a request for best and final offers was issued in connection with the negotiation of contracts with one or more private transfer stations in this wasteshed for Long Term Export services. In response to this request, the 215 Varick Avenue Transfer Station site was proposed as a truck-to-rail facility for this wasteshed. Because it has not been evaluated in this FEIS, a future decision to contract for the use of this site would be subject to environmental review before DSNY could implement a Long Term Export contract. Furthermore, any final decision on this site, assuming adoption and approval of the New SWMP, would result in termination of the existing Interim Export under which waste from Brooklyn CDs 4, 8 and 15, 17 and 18 is exported via transfer trailer from this site to out-of-City disposal facilities.

2.4.14.1 Description of Existing Site

The 215 Varick Avenue Transfer Station site is an existing permitted facility in the East Williamsburg section of Brooklyn, in Brooklyn Community District #1 on Varick Street near the intersection of Metropolitan Avenue. The facility and property are owned by Waste Management and it currently receives DSNY-managed Waste under Interim Export. No wetlands are located on the site or in the surrounding area. The site is bounded by industries on the north, south and east and by the English Kills on the west. Flushing Avenue is farther to the south and southeast and Metropolitan Avenue is farther to the north. There are no schools within a ¼-mile radius.



The 6.4 acre Cooper Park is located approximately ¼ mile from the site to the northwest; occupying an entire block between Morgan Avenue, Sharon Street, Maspeth Avenue and Olive Street.

The site is comprised of approximately 4.6 acres and is located between Varick Street and the English Kills, a tributary of Newtown Creek. Of the 4.6 acres of property, approximately 1.5 acres are occupied by buildings. Based on City tax maps, the site is comprised of all or portions of Lots 1, within Block 2950.

The site and the surrounding properties are zoned M3-1 for industrial/heavy manufacturing use under a "Use Group 18" designation. Figure 2.4.14-1 (Site Location) shows the location of the site. Figure 2.4.14-2 (Facility Footprint) shows an aerial view of the site and its major features.

The existing property is currently situated between 6 and 10 feet Brooklyn Highway Datum (BHD). The 100-year tidal surge or 100-year flood plain is at elevation 7.44 feet BHD according to FEMA floodplain maps. All waste handling components of the facility's operation have been placed at elevation 7.5 feet BHD or higher.

Access to the site is via NYCDOT-designated truck routes, including Varick Avenue, Meadow Street and Ten Eyck Street. Designated NYCDOT through truck routes between the transfer station and other regions of the service area include the Long Island Expressway and the Brooklyn-Queens Expressway. All vehicles accessing the site use the Varick Avenue entrance gate.

Site delineations are approximate

2.4.14.2 Varick Avenue Transfer Station

The Varick Avenue Transfer Station is currently permitted to handle 4,250 tpd of putrescible solid waste as a truck-to-truck transfer facility. Of this 4,250 tpd, the facility currently accepts and processes approximately 1,400 tpd of DSNY-managed Waste under Interim Export from Brooklyn CDs 4, 8, 15, 17, and 18 for export by transfer trailer, and also processes approximately ,1,100 tpd of construction and demolition (C&D) debris at 123 Varick Avenue (C&D permit for 5,249 tpd) and exports the C&D debris that goes to a landfill for disposal out by rail (80-90% of C&D processed). On February 11, 2005, DSNY issued a Best and Final Offer (BAFO) to Receive, Transfer, Transport and Dispose of Department of Sanitation-Managed Waste from Brooklyn Formerly Delivered to the Greenpoint Marine Transfer Station (Brooklyn BAFO). Among other things, DSNY's Brooklyn BAFO requires that proposers commit to exporting all waste processed at their facility (both DSNY-managed Waste and commercial waste) by rail or barge. In response to the BAFO, the proposer offered the Varick Avenue Transfer Station to accept the anticipated average peak day volume of 1,140 tpd of DSNY-managed waste and export it by rail. Currently, putrescible waste processed at the Varick Avenue Transfer Station is processed into transfer trailer trucks for transport it to one of Waste Management's disposal facilities

Under the proposed operation, the facility would operate as a truck-to-container-to-rail facility, where precrushed and/or compacted waste would be loaded into containers. The containers would be transported by tractors with flatbed chassis from the transfer building on Waste Management property along English Kills to an existing expanded on-site rail yard, less than of a mile away. There, the containers would be loaded onto railcars and transferred to the New York and Atlantic Railroad's Metropolitan Yard for transport to one of Waste Management's disposal facilities. Figure 2.4.14-3 provides a Plan View of the proposed facility. Since the proposed facility and its operations are the subject of current, ongoing negotiations with DSNY, the facility description is presented in this FEIS based on available information to date.

HDR, HydroQual, URBITRAN, PB, EEA, Cambridge Environmental Inc	**Figure 2.4.14-3 Plan View** **215 Varick Avenue Transfer Station** **CITY OF NEW YORK** **DEPARTMENT OF SANITATION**	THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The complete transfer facility consists of an enclosed, 64,300-square-foot area, access roads, nine scales and two scale houses, office space and various storage areas. All waste is received, handled, and processed within the transfer station building.

Incoming waste hauling vehicles are weighed at one scale house, located at the southwest corner of the property, while outbound vehicles are weighted at the second scale house located at the exit onto Varick Avenue at Ten Eyck Street. There are four scales inside the enclosed processing building for weighing empty and loaded trucks. There are roll-up doors at the entrances to the truck unloading areas and the loading dock area.

The main processing area consists of a 29,000 square foot tipping and loading area floor. The floor is sloped from the edge of the tipping and loading area toward a trench drain to allow water to drain. The enclosed building is equipped with five roof exhaust fans and a high pressure atomizing mist deodorant system is operated throughout the building.

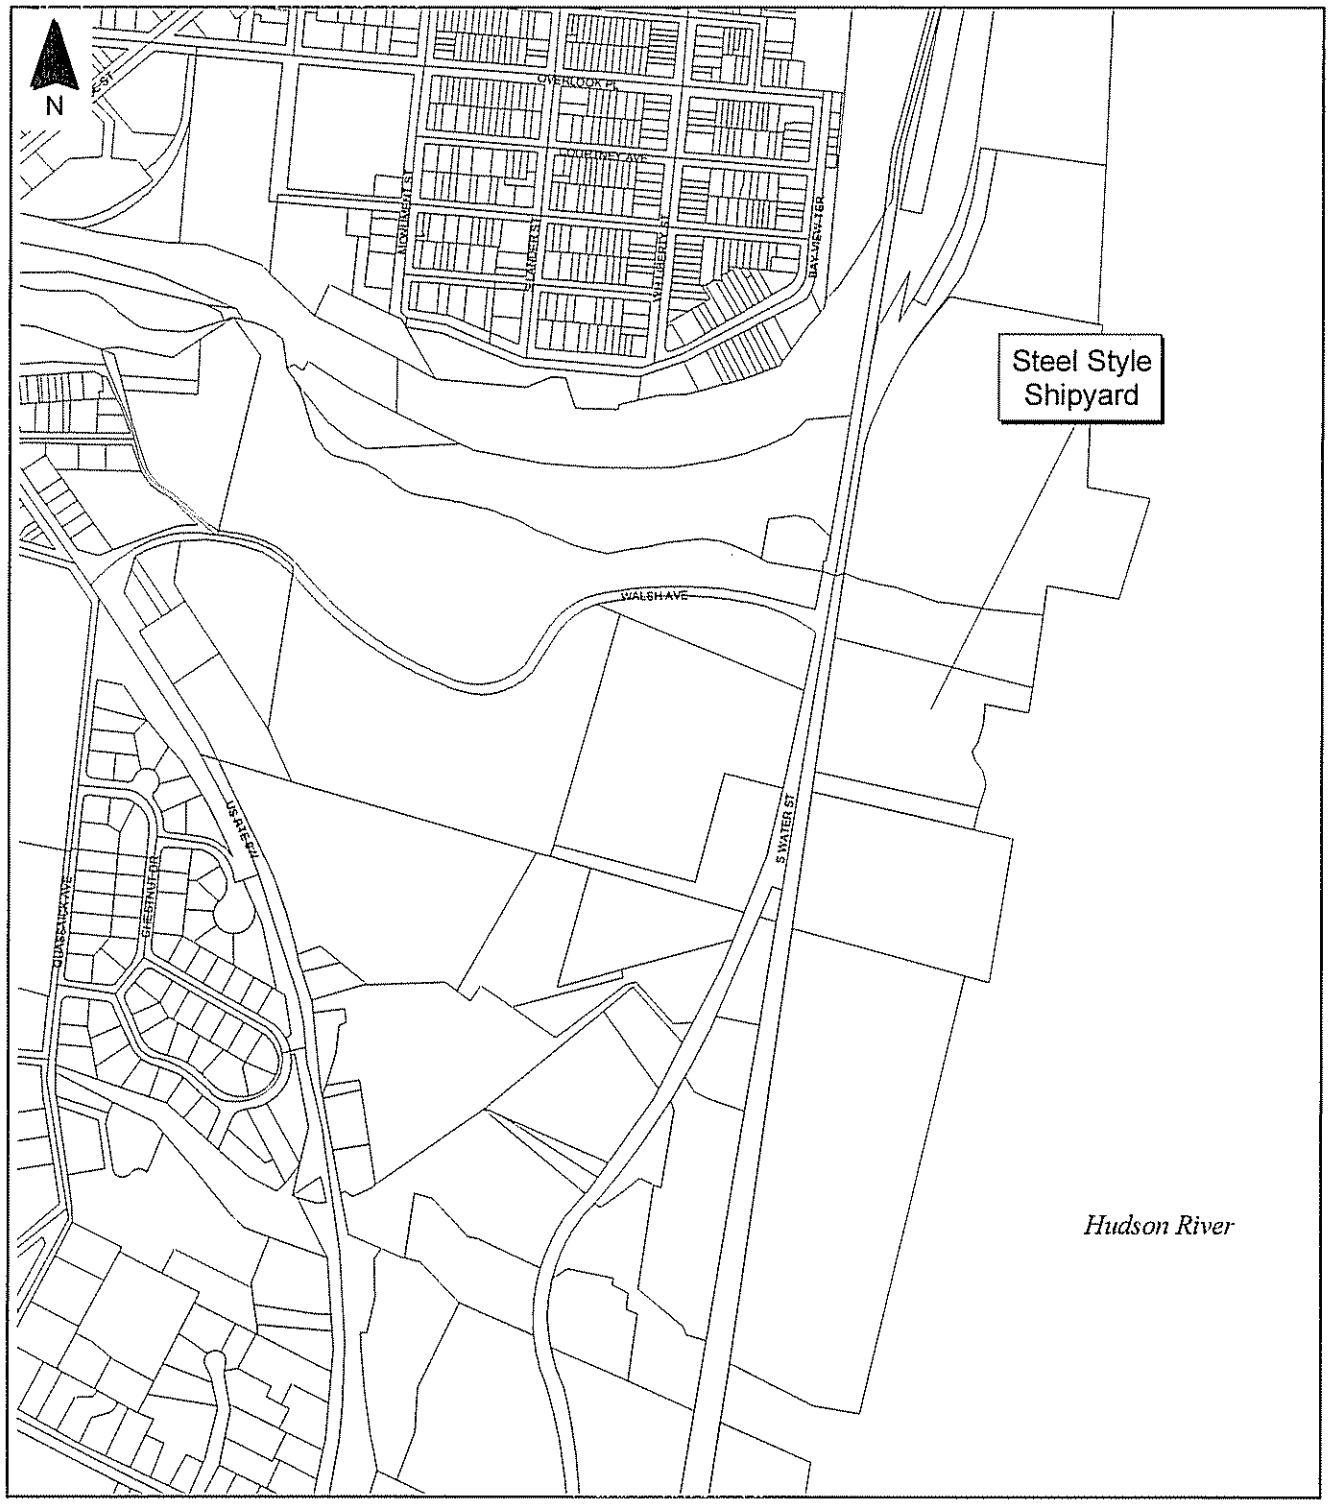
Traffic flow is and would remain one-way. Collection vehicles access to and egress from the transfer facility is currently via Varick Avenue. Collection vehicles enter the site via the entrance at the intersection of Varick Avenue and Meadow Street. Under the proposed operation, outgoing collection vehicles would exit the site via the driveway closest to Ten Eyck Street at the northeast section of the property. Tractor chassis carrying empty containers would approach the building by heading north on Varick Avenue from the rail yard 1,200 feet away, then turn left into the property at the Varick Avenue/Meadow Street entrance, and exit with loaded containers at the southwest corner of the property to travel parallel to English Kills to the on-site Varick Avenue Transfer Station rail yard.

All incoming vehicles entering the facility would be weighed prior to proceeding to the truck unloading areas or to the tipping and loading area. Upon entering the facility, waste hauling vehicles would queue along the south side of the transfer station building in two rows leading to the scales. Once weighed, they would be directed to the truck unloading areas on the north side of the processing building for inspection and unloading. After visual inspection for unauthorized materials, the waste hauling vehicles would unload, and exit the facility by passing over scales on the north side of the building and turning onto Varick Avenue.

Tipped waste is currently pushed from the tipping floor using wheel loaders. The proposed operation would use the same wheel loaders to load empty containers located on chassis within the processing building where outbound transfer trailers are currently positioned. Tractor chassis would move containerized waste from the transfer station to the on-site railyard, exiting the transfer building and proceed to the southwest corner of the property, travel along the western border of the property adjacent to English Kills where they would turn south and travel along English Kills to the on site Varick Avenue Transfer Station rail yard.

At the on-site Varick Street Transfer Station rail yard, the loaded containers would be placed onto railcars, from which empty containers would be unloaded. Proposed modifications to the on-site rail yard include construction of approximately 600 feet of additional track, parallel and to the south of, the existing on-site track. New York and Atlantic Railroad would send a shuttle railcar to connect to and move the train sections from Varick Avenue east to Fresh Pond Yard. From Fresh Pond Yard, CSX would pull the rail cars to the Oak Point junction in the Bronx. At Oak Point, CSX would classify the rail cars and pull the rail cars to Petersburg, Virginia, where Norfolk Southern would pick up the train and pull the rail cars for the last portion of the trip to the Atlantic Landfill in Waverly, Virginia.

Empty, sealed containers would be returned to the Varick Avenue Transfer Station on site railyard. Yard jockeys with empty containers would enter the facility through the existing southernmost door fronting Varick Avenue and pass over a scale inside the building for weighing. Next, the lids would be removed from the containers within the processing building using either an overhead crane or mobile equipment. The yard jockeys would move the open containers to the loading area where waste would be loaded into the containers. The containers would be securely relidded, the outside of the containers would be cleaned, and the loaded yard jockeys would be reweighed on a relocated scale, located at the rear of the transfer station building.



2.4.15 Steel Style Shipyard

DSNY is procuring transport and disposal services for containerized waste from the Converted MTSs. This will require barge delivery of containers to an intermodal terminal where the containers can be transloaded to ocean-going barge or railcars. Any intermodal facilities in New York State that would be used for this purpose and that would also require permit modifications are subject to environmental review. The Steel Style site had not been identified as a potential intermodal terminal at the time of the DEIS publication. If this site were to be selected as a facility for intermodal transfer of barged containers to rail, assuming permits were required for on-site construction, it would be subject to environmental review.

2.4.14.1 Description of Existing Site

The Steel Style Shipyard site is located on the west bank of the Hudson River at 401 South Water Street in New Windsor, New York. The facility and property are owned by Steel Style, Inc. The site is a 35-acre site located, approximately 25 miles north of New York Harbor. Figure 2.4.15-1 shows the location of the site. Figure 2.4.15-2 shows an aerial view of the site and its major features. Currently, limited information is available on the site. If this site were selected by DSNY as part of the Proposed Action, further information would be required and would be the subject of a future environmental review.

Currently, there are two piers at the site approximately 700 feet long and 70 feet wide. Some repairs to these piers would be required to operate a barge handling facility. The depth at the piers is approximately eight feet, so dredging would be required in order to berth harbor barges. According to the terminal operator, if both rail and marine improvements were made, there would be sufficient capacity to move about 132 one-way containers per day of DSNY-managed Waste by rail to and from Steel Style Shipyard to the CSX River Line for movement to the final destination.

2.4.15.2 Steel Style Facility

The existing Steel Style facility has two short rail spurs that are located on the northern portion of the property. The CSX River Line is a single track railroad (on a double track right-of-way) as it passes the site. Just south of Steel Style, there is a double-ended passing siding on the location of the second main track. The lead track onto the Steel Style site comes off the north end of the passing siding and runs north by the main gate of Steel Style to the small two-track facility on the north end of Steel Style.

A proposed conceptual design for the potential modifications to the site is not currently available. At this time, it is assumed that containers would not be able to be unloaded directly from barges onto railcars at the piers. The containers would be moved to the on-site rail sidings and loaded onto railcars. However, to accommodate the loading and unloading of railcars by either a sideloader or gantry crane, it would be necessary to configure at least two long tracks at the site. Based on the available space for tracks, there would be sufficient capacity to move approximately 132 one-way containers per day of DSNY-managed Waste by rail to and from Steel Style Shipyard to the CSX River Line for movement to the final destination.

2.5 Summary of Potentially Applicable Permits for Sites Considered

Table 2.5-1 and Table 2.5-2 provide a summary of the major permits that will or may be required to undertake the development of each site/facility described in this chapter.

(5) Consistency with Local Waterfront Revitalization Program.

(6) Existing MTSs may require permit modifications and/or renewal for operations.

CHAPTER 3 OVERVIEW OF STUDY METHODOLOGIES FOR SITE-SPECIFIC ANALYSES

3.1 Introduction

This SWMP FDEIS documents the assessment of the potential social, economic and environmental effects that may result from the Proposed Action and Alternatives, as applicable, and identifies measures that could be applied to mitigate potentially adverse impacts. These impact assessments were guided by standards, regulations and guidelines established under SEQRA (6 NYCRR Part 617) and CEQR (Executive Order No. 91, Chapter 5: Rules of Procedure for CEQR, the 2001 CEQR Technical Manual). The effects of the Proposed Action are assessed against the Existing Conditions, as defined below, and Future No-Build Conditions (2006) at the specific sites and the respective study areas (defined later in this chapter). For purposes of evaluating the effect of the Proposed Action on DSNY's waste collection and transfer operations (exclusive of waste disposal operations), Future No-Build Conditions are assumed to be the same as Existing Conditions. Where other developments or changes outside of the Proposed Plan Facilities, and Alternatives, when applicable, are expected to occur at a site by 2006, they are discussed in the applicable sections of Chapters 4 through 31.

This chapter describes the issues pertaining to and the data collection and analysis methods used for each type of environmental analysis documented in this SWMP FDEIS. The assumptions made and methods used for each type of environmental analysis were applied consistently to all sites, as applicable, except as noted otherwise in Sections 3.2 through 3.19. Discussions of methodology are not repeated in Chapters 4 through 31, which document the site-specific environmental analyses. A copy of the technical backup for the analyses in this FDEIS is available upon request in *.pdf and *.txt format on compact disk.

3.2 Analysis Years and Future No-Build Conditions

An environmental evaluation typically determines the potential impacts of implementing a proposed action in a particular build year by comparing that action to the conditions that would likely exist in that build year if the action were not implemented (Future No-Build Condition). A Future No-Build Condition is a projected baseline for the Build year (which, in this case, is 2006) that assumes the continuation of relevant Existing Conditions, realization of other known planned development activity and expected changes in population and traffic.

The City has been taking interim export actions to assure that all DSNY-managed Waste is exported out of the City following the closure of Fresh Kills Landfill in December 2001. Existing Conditions reflect interim export of waste from each of the five boroughs to out-of-City disposal sites as of January 2003 when the DEIS analysis commenced. The Future No-Build Condition developed for the SWMP FDEIS consists of: (1) Existing Conditions; (2) known planned development activity; and (3) updated traffic and population data. Future No-Build Conditions are the conditions against which potential site-specific impacts associated with the Proposed Plan Facilities or Alternatives are identified and to which they are compared for each site (presented in Chapters 4 through 31).

3.3 Definition of Sites and Study Areas

3.3.1 Site Definition

As noted in Section 2.1.1, the definition of site boundaries for purposes of environmental review may extend beyond the boundaries of the primary parcel in which the Proposed Plan Facilities, or Alternatives, as applicable, would be located.

The sites are illustrated in the figures presented in Chapter 2. These site boundaries may differ from the sites described in permits for the existing MTS facilities, as provided in DSNY engineering reports. It is also important to note that the sites for the Converted MTSs may not include all DSNY facilities and/or operations in contiguous properties, such as salt sheds and garages.

3.3.2 Study Area Delineation

Assessments of Existing Conditions, anticipated Future No-Build Conditions and potential effects of the Proposed Action and Alternatives, as applicable, focused on study areas and sensitive receptors. Study areas for each type of environmental analysis were defined to include areas and sensitive receptors that could be affected by the Proposed Action and Alternatives, as applicable, and, therefore, vary among the different environmental assessments performed.

For the analysis of land use, zoning, and public policy; community facilities and services; open space; and cultural resources, the study areas were delineated in a conventional manner according to a radial distance measured from the boundaries of each site. For land use, zoning, and public policy; and community facilities, the primary study area is defined as the area within a ¼-mile radius of the site, and a secondary study area is defined as the area between ¼-mile and ½-mile of the site. Detailed descriptions are provided and detailed analyses were performed for the primary study areas, while generalized descriptions are given and generalized analyses were performed for secondary study areas. Open space and cultural resources conditions are analyzed within a single study area defined by a ½-mile radius.

There are some deviations to these conventional study areas, however. If community facilities, historic resources, and open spaces and parklands were within 250 feet (the length of the short side of a typical city block) of the outside boundary of the secondary study area, they were included in the inventory. The study area for archaeological sensitivity and potential impact — one component of the cultural resources analysis — is comprised of only the site, however, because any project-related subsurface disturbance would be limited to the site.

The study areas for the remaining analyses vary from these limits to comply with specific regulatory requirements and to reflect the reasonable foreseeable potential for significant impacts, given the sensitivity of existing land uses. Study areas for socioeconomic conditions, urban design, and neighborhood character analyses were defined in a manner that is consistent within each type of analysis, as appropriate to the available data (e.g., census data) and/or to encompass the area of potential impact in its entirety. Methods of defining these particular study areas are described in greater detail in Sections 3.5, 3.9 and 3.10.

Analyses of traffic and transportation, air quality, odor, and noise were performed without the utilization of such study areas, per se. Rather, these environmental analyses were undertaken in a manner that incorporates data describing various points. These may be the locations of sensitive receptors related to specified screening criteria or modeling protocol, as in the case of on-site noise, air quality and odor or, as in the case of traffic and off-site noise and air quality analyses, of critical intersections within a reasonable distance of the site.

The study areas for the remaining analyses — infrastructure, solid waste and sanitation services, and energy; natural resources; water quality; waterfront revitalization; and hazardous materials — vary to comply with specific regulatory requirements and to reflect the reasonable foreseeable potential for significant impacts, given the sensitivity of Existing Conditions.

Sections 3.4 through 3.19 provide descriptions of analytical methodologies for each category of environmental analysis. Some methods of defining study areas are also described in greater detail where necessary.

3.3.3 Maps and Figures

The graphic figures illustrating this SWMP FDEIS are derived from computerized GIS base maps developed by the NYCDCP. This mapping information, contained on the BYTES of the BIG APPLE™ disks, was initially compiled for government use by NYCDCP. The City and NYCDCP make no representation as to the accuracy of the information or its suitability for any purpose. The City, NYCDCP and DSNY disclaim any liability for errors that may be contained therein.[1]

[1] • Map Sources: The files on these disks are derived from the tax block/lot geography files. The tax lot files are digitized and maintained by the NYCDCP Computer Information Services/Geographic Systems Section. The primary sources for these files are the City Department of Finance (NYCDOF) tax maps, the Borough President topographic maps, and the NYCDCP sectional maps. These files are schematic representations of the tax lot outlines and should not be used for applications that require precise measurements.

• Spatial Accuracy: The tax lot files were created for thematic mapping for planning applications at the NYCDCP. Spatial accuracy was not of primary concern in their creation. A limited set of control points was used to loosely fit the lines to the New York East State Plane Coordinate System.

• Legal vs. Physical features: These files are a representation of the City's tax blocks. Tax blocks are not identical to physical blocks. Boundaries of tax blocks are not usually located at the curb line of a street. Many properties include areas under bodies of water. Most highways and many other features are not represented in these files because their depiction does not arise from the delineation of tax blocks.

3.4 Land Use, Zoning, and Public Policy

Land uses, zoning and development trends on the site and in the primary and secondary study areas, as well as pertinent public policies, are characterized and then assessed to determine whether the Proposed Action and Alternatives, as applicable, would be compatible with and/or could affect these conditions. If necessary, mitigation measures were then identified.

Data were collected on existing land uses, zoning patterns, recent development trends and proposed developments in the sites' primary and secondary study areas through consultation with the Borough offices of the NYCDCP, community district liaisons and the NYCEDC; research of published sources of information; and field reconnaissance. The descriptions of Future No-Build Conditions reflect the development potential of underdeveloped sites in the study areas, as well as information obtained from the DSNY, NYCDCP and the City Office of Environmental Coordination (OEC) concerning planned and programmed improvements in the study areas.

The Converted MTSs are considered "Use Group 18" land uses according to the City Zoning Resolution. According to the zoning code, "Use Group 18 consists primarily of industrial uses that: (1) either involve considerable danger of fire, explosion or other hazards to public health or safety, or cannot be designed without appreciable expense to conform to high performance standards with respect to the emission of objectionable influences; and (2) normally generate a great deal of traffic, both pedestrian and freight."

Maps of existing land uses and zoning on the sites and within the primary and secondary study areas appear in the site-specific discussions in Chapters 4 through 31. Table 3.4-1 provides information from the City Zoning Resolution summarizing the characteristics of the types of zoning districts that are found at the sites analyzed. It is presented here as a reference for all zoning discussions in the subsequent chapters.

Table 3.4-1
Zoning District Characteristics

Manufacturing Districts								
Zone	**Type of Zone**	**Description**	**Typical Uses**	**Max. Permitted Floor Area Ratio (FAR)**	**Initial Setback Distance**	**Max. Permitted Height of Front Wall of Building within Permitted Setback (Standard)**	**Sky Exposure Plane (ratio) Dictating Max. Permitted Height of Front Wall or Building beyond Setback (Standard)**	**New Community Facility and Residential Uses Permitted**
M3-2	Central manufacturing area	M3 districts permit heavy industries that generate noise, traffic and pollutants Usually located near the waterfront, they are buffered from residential areas by light and medium industrial M1 and M2 districts.	In theory, nearly all industrial uses can locate in any manufacturing zone if they meet the respective performance standards required in the Zoning Resolution for each M1, M2 or M3 zone. For example, more noise and vibration are allowed in M2 districts than M1 districts except when they border on a residential district; smoke is permitted and industrial activities need not be entirely enclosed.	2.0 for commercial or manufacturing	15-foot setback for wide streets; 20 feet for narrow streets	60 feet high (or 4 stories)	5.6 to 1 vertical distance for wide streets; 2.7 to 1 for narrow streets	No
M3-1	Heavy manufacturing use							
M2-3	Typically located only in Manhattan Central Business District (CBD)	M2 districts occupy the middle ground between light and heavy industrial areas Permits commercial and general industrial uses.		5.0 for commercial or manufacturing		85 feet high (or 6 stories)		
M2-2	Waterfront manufacturing area							
M2-1	Most widely mapped M2 districts; mainly in older manufacturing areas			2.0 for commercial or manufacturing		60 feet high (or 4 stories)		
M1-4	Located mainly in Manhattan CBD	M1 permits low-bulk commercial and light industrial uses and requires high performance standards that limit impacts from noise, vibration, smoke and other effects		2.0 for commercial or manufacturing 6.5 for community facilities				Yes
M1-3	Older industrial areas			5.0 for commercial or manufacturing 6.5 for community facilities		85 feet high (or 6 stories)		
M1-2	Light industrial district			2.0 for commercial or manufacturing 4.8 for community facilities		60 feet high (or 4 stories)		
M1-1	Located adjacent to low density residential areas			1.0 for commercial or manufacturing 2.4 for community facilities		30 feet high (or 2 stories)	1 to 1 vertical distance for narrow and wide streets	

Table 3.4-1 (continued)
Zoning District Characteristics

Commercial Districts								
Zone	**Type of Zone**	**Description**	**Typical Uses**	**Max. Permitted FAR**	**Initial Setback Distance**	**Max. Permitted Height of Front Wall of Building within Permitted Setback (Standard)**	**Sky Exposure Plane (ratio) Dictating Max. Permitted Height of Front Wall or Building beyond Setback (Standard)**	**New Community Facility and Residential Uses Permitted**
C8-3	Automobile showrooms and offices	C8 districts form a bridge between commercial and manufacturing uses, and are appropriate for heavy uses that are land-consuming but not labor intensive. These districts are mainly mapped along major traffic arteries where concentrations of automotive uses have developed.	Automobile showrooms, automotive service facilities and warehouses Housing is not permitted.	2.0 for commercial 6.5 for community facilities	15-foot setback for wide streets; 20 feet for narrow streets	85 feet high (or 6 stories)	5.6 to 1 vertical distance for wide streets; 2.7 to 1 for narrow streets	New community facilities are permitted No new residential uses
C8-1	Automotive sales and service			1.0 for commercial 2.4 for commercial facilities		30 feet high (or 2 stories)	1 to 1 vertical distance for narrow and wide streets	
C3	Waterfront recreation areas	C3 zones permit waterfront recreation and uses related to boating and fishing	Marinas, boat repair shops and public or private beaches (with dressing rooms and refreshment stands)	0.5 for commercial 1.0 for community facilities 0.5 for residential				Yes
C2-2 on R8	Commercial overlay	C2 zones are Local Service Districts	Residential and Commercial (Retail and Services)	2.0 for commercial; 6.5 for community facilities; 4.8 to 6.0 for residential		85 feet high (or 6 stories)	5.6 to 1 vertical distance for wide streets; 2.7 to 1 for narrow streets	
C2-2 on R7-2				2.0 for commercial; 6.5 for community facilities; 2.8 to 3.4 for residential		60 feet high (or 4 stories)		
C2-2 on R7-1								
C2-2 on R5				1.0 for commercial; 2.0 for community facilities; 1.0 to 1.25 for residential		30 feet high (or 2 stories)	1 to 1 vertical distance for narrow and wide streets	
C2-2 on R4								
C1-2 on R8		C1 zones are Local Retail Districts		2.0 for commercial; 6.5 for community facilities; 4.8 to 6.0 for residential		85 feet high (or 6 stories)	5.6 to 1 vertical distance for wide streets; 2.7 to 1 for narrow streets	
C1-2 on R7-2				Same as C2 on R7		60 feet high (or 4 stories)		
C1-4 on R7-1								
C1-2 on R7-1								
C1-4 on R6				2.0 for commercial; 4.8 for community facilities; 2.0 to 2.4 for residential				
C1-3 on R6B								
C1-3 on R6								
C1-1 on R6								
C1-3 on R5				Same as C2 on R5		30 feet high (or 2 stories)	1 to 1 vertical distance for narrow and wide streets	
C1-1 on R5								

Table 3.4-1 (continued)
Zoning District Characteristics

Residential Districts							
Zone	**Type of Zone**	**Description**	**Max. Permitted FAR**	**Initial Setback Distance**	**Max. Permitted Height of Front Wall of Building within Permitted Setback (Standard)**	**Sky Exposure Plane (ratio) Dictating Max. Permitted Height of Front Wall or Building beyond Setback (Standard)**	**New Community Facility and Residential Uses Permitted**
R8	General residence district	R8 is a high-density district – the highest density mapped in the Bronx – served by mass transit	4.8 to 6.0	15-foot setback for wide streets; 20 feet for narrow	85 feet high (or 9 stories)	5.6 to 1 vertical distance for wide streets; 2.7 to 1 for narrow streets	Yes
R7-2	General residence district	R7 is a medium density apartment house district.	2.8 to 3.4		60 feet high (or 6 stories)		
R7-1	Differs from R7-2 only in the amount of parking required for new dwelling units						
R6	General residence district	R6 districts are appropriate for medium density housing. Typical R6 development usually is between three and twelve stories.	2.0 to 2.4				
R6B		Differs from R6 primarily in lot coverage and height and setback regulations					
R5	General residence district	R5 designation applies to medium density districts containing apartment buildings, and two- and three-family row houses. R5 districts, which allow a variety of housing types, provide another transitional step from low to higher density areas.	1.0 to 1.25	None	Street level	1 to 1 vertical distance for narrow and wide streets	
R4-1	Detached and Semi-Detached Residence District	R4 district permit the same variety of housing type as R3-2 zones, but with a 50 percent increase in building bulk	0.75				
R4	General residence district						
R3-1	Detached and Semi-Detached Residence District	Permits only detached or semi-detached. Generally mapped to follow existing patterns of development.	0.5				
R3-2	General residence district	Allows for a variety of housing types, including garden apartments, row houses and an occasional apartment house surrounded by extensive open space					
R3X	Detached Residence District						

Table 3.4-1 (continued)
Zoning District Characteristics

Special Purpose Districts	
Zone	**Description**
BR	This Special Purpose District is the "Bay Ridge District." It was established to protect the existing scale and character of the Bay Ridge community. It distinguishes the scale of development in the midblock from that on the avenue frontage, encouraging two- and three-family homes in the midblock. Special setbacks, curb cuts, open space, tree planting and ground floor commercial requirements have been included to preserve the character of the existing street wall.
NA-1	This Special Purpose District is "Natural Area District 1." The purpose of a special natural area district is to preserve unique natural characteristics, such as aquatic, biologic, geologic and topographical features having ecological and conservation values. The City Planning Commission must certify that all new development in mapped natural area districts meets applicable preservation standards.
SRD	This Special Purpose District is the "South Richmond Development District." It was established to guide the development of predominately vacant land in the southern half of Staten Island. The special district maintains the densities established by the underlying zones and ensures that new development is compatible with existing communities

Public plans and policies relevant to the sites and study areas were reviewed to determine consistency with the various facilities under consideration. These typically include:

- NYCDCP Plans for the Borough Waterfronts ("Reach Plans");
- Fiscal Year (FY) 2004 Community District Needs Statements (CDNSs);
- NYCEDC Strategic Plan for the Redevelopment of the Ports of New York;
- 197-a Plans;
- Rezoning proposals; and
- Other local NYCDCP studies and plans.

3.5 Socioeconomic Conditions

Demographic characteristics of the sites and study areas are based on the most current, publicly-available data from the United States Census Bureau and data collected from NYCDCP, New York Metropolitan Transportation Council (NYMTC), NYCEDC, and other agencies. To reflect the study area conditions as accurately as possible with existing data, each demographic study area is comprised of all census tracts that meet any of the following criteria: (1) the tract in which the site lies; (2) a tract which lies entirely within ¼-mile of the site; or (3) a tract with at least 50% of its area lying within ¼-mile of the site as long as that portion of the tract contains residential areas that share connectivity with the site (i.e., transportation and pedestrian access).

Data selected to describe the demographic conditions of the site and study area include current estimates and future projections of population (by age, race and sex), as well as household, housing, income, poverty and employment characteristics. Existing and Future No-Build demographics conditions of the study area (including the site) are compared among the City and the borough(s) containing a census tract that is included in the study area. The data for census tracts comprising the study area were summed or averaged, as appropriate, except for median values (such as median incomes), which were reported only for the most populous census tract in the study area. Although discussed in Chapters 4 through 31, only general and brief tables describing socioeconomic conditions are included within the text, while tables containing greater detail are presented in Appendix B and referred to throughout the text.

The economic conditions description and impact assessment was based on a larger area, usually within ½-mile of the site. This entailed the review of available economic information typically retrieved from public policy data sources described in Section 3.4: Land Use, Zoning, and Public Policy. Other specific economic and policy sources include:

- State Empowerment Zone (EZ) Policy;
- City (Economic Development Zone (EDZ) Policy;
- City Industrial Retention Program Policies (e.g., Industrial Development Agency [IDA]); and
- NYCDCP Information on Major Economic Development Projects.

3.6 Community Facilities and Services

Community facilities are public or publicly funded facilities, including schools, hospitals and other medical centers, libraries, day care centers, religious institutions, fire, police and emergency medical services. Adverse effects generally could result when a project either:

- Alters the use or the conditions of a community facility (e.g., disrupts existing traffic patterns within communities near the facility and, thereby, alters the facility's access/egress routes); or
- Causes a change in population that could affect the types and/or levels of service needed by a community.

The analysis of community facilities utilizes the primary and secondary study areas, including any facilities within 250 feet of the outside boundary of the secondary study area and community facilities along truck routes where a significant number of project-generated trucks would converge. An inventory of community facilities and services was based on data available in the Selected Facilities & Program Sites in New York City and CDNSs (FY 1999 and 2004), and the Sanborn Building and Property Atlas. This inventory was used to determine if any community facilities would be displaced by the Proposed Action and Alternatives, as applicable, or would potentially experience other adverse impacts due to proximity to or use on the sites. Information concerning police, fire and emergency medical services, including their capacity to accommodate projected demand, was obtained from the responsible agencies. (Letters from the New York City Fire Department [FDNY] are contained in Appendix A.)

3.7 Open Space

Open space is defined as publicly or privately owned land that is publicly accessible for active and/or passive recreational pursuits. In accordance with CEQR guidelines, an analysis of both direct and indirect impacts to open space was conducted. A direct impact would physically change, diminish or eliminate an open space or reduce its utilization or aesthetic value. (This would include a facility siting that causes increased air or noise emissions, odors or shadows that could adversely affect use of the resource.) An indirect impact could result from a facility siting that would introduce a substantial new user population that would create or exacerbate over-utilization of existing open spaces.

CEQR requirements for a full open-space analysis are related principally to new residential or commercial projects with significant numbers of additional residents or employees who may utilize open spaces. Because the Proposed Plan Facilities and Alternatives, as applicable, would employ fewer than the CEQR screening threshold of 500 employees, no quantitative assessment is required. However, the potential impact the Proposed Plan Facilities and Alternatives, as applicable, would have on traffic, air, odor and noise conditions of nearby open spaces are assessed.

The study area for analysis of potential open space impacts includes the area located within a ½-mile radius of the site boundary (or within 250 feet of it).

The inventory of parks and open spaces is based on information provided through consultation with NYCDPR, including the Parklands Office, Parks' Capital Division, and GreenThumb.[2] Field visits were used to verify the locations of the public parks and to identify passive open spaces and privately owned open spaces that may not have been identified through initial inventory procedures. (A letter from NYCDPR is attached in Appendix A.)

---

[2] Playgrounds were included on the list of publicly accessible open space only if they were operated, at least in part, by NYCDPR. Similarly, only those community gardens listed on the registers of GreenThumb as remaining indefinitely as public access gardens were included in this inventory of public open spaces.

The Future No-Build Conditions of open spaces and parks are assumed to be the same as Existing Conditions except for those parks identified by NYCDPR as currently funded for improvement. Future No-Build Conditions include those planned improvements for which funding has been identified by NYCDPR but not those "wish-listed" improvements for which funding has not been identified.

3.8 Cultural Resources

According to CEQR, cultural resources include:

- Buildings, structures, sites, objects, districts and landscapes of architectural, aesthetic, historic and/or archaeological significance; and
- Properties listed or eligible for listing on the National and/or State Registers of Historic Places or for local landmark designation.

In general, the cultural resources analysis (excluding archaeological resources) is based on the primary and secondary study areas and includes those resources within 250 feet of the outside boundary of the secondary study area. The study area for archaeological sensitivity and potential impact is comprised of only the sites, however, because any facility-related subsurface disturbance would be limited to the site.

Information on cultural resources was obtained through an inspection of the sites and study areas, through research of available archival documentation and data available from the City Landmarks Preservation Commission (LPC) and the State Historic Preservation Office (SHPO). (Agency correspondence is provided in Appendix A.) The assessment of potential impacts on historic and archaeological resources includes:

- Research and documentation of the historic overview of the study areas;
- Identification of historic resources on site and in the study areas and determination of any direct or indirect project-related effects;
- A Stage IA report defining the site's archaeological potential, where required by SHPO, based on review of available literature, historic atlases and state files on areas of archaeological sensitivity; and
- A Stage IB report defining an archaeological testing plan, as necessary, prepared in consultation with the LPC and SHPO.

If mitigation is required, the appropriate measures would be developed in consultation with LPC and SHPO.

3.9 Urban Design, Visual Resources, and Shadows

The urban design and visual quality of an area are defined by both built and natural features. Though manufacturing zones typically do not possess sensitive urban design features or visual resources, a waterfront site or unique setting (even if industrially zoned) may contain a significant viewshed or other visual resource requiring assessment for potential impacts. Study area boundaries generally are coterminous with the boundaries of the neighborhood character study area for each respective site. The study area includes the site and adjacent properties, as well as the area encompassing the broader development pattern, urban design context and view corridors, of which the site may be an integral part.

The following components of the site and site environs were considered in the urban design/visual resources assessment:

- Existing buildings (massing, bulk, materials, orientation), structures and open spaces on the site;
- Existing buildings, structures and open spaces adjacent to the site;
- Existing neighborhood context of the site, with special consideration given to both the built environment (including building types/functions, styles, materials, orientation and massing) and the un-built environment (including the widths of roads, open space, landscaping and borders/buffers);
- Areas that are linked to the site visually (i.e., the area is visible from the site or the site is visible from the area); and
- Existing view corridors, including views through the site to aesthetically important objects and places, and views of the site from public areas such as parks or other important places.

Other issues specific to a site may also be considered in the urban design and visual resources assessment. For example, if there are plans for public parks, access improvements, community facilities or economic development projects within visual proximity of the site, the study area includes these locations for consideration of potential project-related impacts on these planned public developments. Additionally, the aesthetic character of areas traversed by truck routes within the study area is described generally, in accordance with CEQR guidelines. Existing and future views of historic properties in the study area from residential areas and other sensitive locations (e.g., parks) are also described, as applicable. If the facility casts new shadows or

substantially increases existing shadows on a publicly accessible open space or park, historic resource (if the features that make the resource significant depend on sunlight) or important natural feature, shadow studies would be performed (per CEQR guidelines) to illustrate the times and extent of the potential impact. Where a significant impact is identified, mitigation would be proposed, in consultation with the relevant parties/agencies. The impacts of shadows from the Proposed Plan Facilities and Alternatives, as applicable, on the water are addressed in the natural resources sections of Chapters 4 through 31. The analysis of potential urban design and visual quality includes the following:

- An inventory of the site and study area to identify sensitive visual resources;
- Identification of an impact and description of appropriate mitigation if the Proposed Plan Facility or Alternative, as applicable, would eliminate or substantially limit views from an adjacent waterfront neighborhood, public park, landmark structure or district, or natural resource (e.g., vegetation, topography, geologic formations, wetlands, rivers or other water resources) that is deemed to have aesthetic value; and
- Assessment of the effects of increased truck activity at visually sensitive locations along truck routes and description of any significant impacts.

3.10 Neighborhood Character

For each site, a unique set of major contributing factors, including some of the conditions assessed for other environmental categories, creates the integral context and feeling of a neighborhood. Typically, a site's immediate neighborhood is defined in terms of population, urban design and visual characteristics, area history, on-site and proximal land uses, and the transportation network that supports these uses and often defines the physical boundaries of the neighborhood. Other conditions that may characterize the neighborhood of a particular site could include parks, public access to the waterfront, community facilities and/or economic development projects.

Each site-specific neighborhood character study area or "neighborhood" is defined as the area that contains the site, possesses the defining neighborhood character and does not extend beyond physical buffers (e.g., major arterial corridors) that effectively separate the area from its surroundings. Additionally, these neighborhoods were defined to include the truck routes analyzed in the Traffic, Parking, Transit, and Pedestrians sections of Chapters 4 through 31. The dimensions and shape of study areas for analysis of neighborhood character, therefore, vary from site to site.

Assessment of potential effects of the Proposed Plan Facilities and Alternative Facilities, as applicable, on neighborhood character is derived from the other pertinent environmental analyses documented in this SWMP FDEIS and from field reconnaissance of the study area. If the Proposed Plan Facilities and Alternative Facilities, as applicable, would potentially result in significant direct or indirect change(s) to a factor contributing to the study areas' neighborhood character, the degree and type of such change is reported and necessary mitigation measures are identified. The potential for an adverse cumulative effect of individual impacts is examined.

3.11 Natural Resources

3.11.1 Introduction

The sites are located in manufacturing-zoned areas and are, therefore, unlikely to contain significant ecologically sensitive areas or appropriate habitats for threatened and endangered species. However, because many of these sites are on the City's waterfront, potential effects to surface water bodies and habitats were considered. Existing terrestrial and water resources were characterized based on information derived from site visits, data research and coordination with the NYSDEC Natural Heritage Program (NHP). Any significant effects of the facilities (i.e., from the in-water construction of piers or bulkheads) is noted in Chapters 4 through 31 and appropriate mitigation measures identified.

A natural resource is defined by CEQR as "plant and animal species and any area capable of providing habitat for plant and animal species or capable of functioning to support environmental systems and maintain the City's environmental balance." Natural resources consist of water resources; wetland resources; upland resources; built resources; and significant, sensitive or designated resources. The types of natural resources present on each site vary, depending on location, and required evaluation on an individual basis. For the purposes of CEQR assessment, the City's natural resources are categorized as follows:

- Wetlands: freshwater and tidal wetlands;
- Water Resources: surface waters (oceans, rivers, bays, streams, estuaries, ponds, lakes) and groundwater, drainage systems and floodwater systems/floodplains;
- Terrestrial Resources: beaches, dunes, bluffs, thickets, grasslands, old meadows, fields, woodlands and forests, gardens and other ornamental landscaping;
- Built Resources: piers, waterfront structures and ruins that are habitats for marine species and nesting and foraging areas for birds, beach and flood protection structures and other structures offering habitat to various species; and
- Plant and Animal Species and Habitats.

The limits of the study area for the assessment of natural resources of each site were determined by the potential effects of the facility and the resource in question. In all cases, the entire project site was inventoried for these resources based on NYSDEC mapping and information from the NYSDEC NHP. If such resources were identified on the site and were determined likely to be disturbed by the Proposed Plan Facilities and Alternatives, as applicable, additional assessments were made, including the following activities:

- Collection of detailed identification of natural resources that could be impacted directly or indirectly by siting or modifying the Proposed Plan Facility or Alternative Facility, as applicable;
- Field studies and documentary research to determine the value of the affected natural resource, and its relationship to neighboring resources and to the overall area ecosystem;
- Detailed analysis of the construction and operation activities of the Proposed Plan Facility or Alternative Facility, as applicable, and its interaction with, and impacts on, the affected natural resource and the environmental support systems; and
- Development of construction-period and long-term mitigation, which could include techniques to control siltation and erosion during construction, re-vegetation programs, slope and surface protection, water pollution controls, wetlands replacement, etc.

3.11.2 Previous Studies and Literature – Types and Sources of Information Collected

Field investigations of all the sites were conducted during the period January 1999 through July 1999 by a team of terrestrial and aquatic ecologists who observed the extent of the resource, the context of its surrounding and the area where the Proposed Plan Facility and Alternative Facility, as applicable, would be. Field notes and observations were used to characterize the resources in the study area. A literature search was also conducted to identify any potentially valuable or sensitive resources. U.S. Geological Survey Topographic Maps, Federal Emergency Management Agency (FEMA) Flood Plain Maps, National Wetland Inventory, and State Wetland Maps were used to identify and outline potential natural resource areas, wherever appropriate.

Information and data pertaining to the aquatic resources at each site were obtained from the literature and from the results of prior field studies. Over the past 20 years, the Converted MTS sites have had extensive aquatic biology programs conducted either on site, substantially

contiguous to the site or in sufficiently close proximity to warrant inclusion. The existing database covering marine resources of the Converted MTS sites is sufficient to make scientifically sound judgments on the relative project impacts for each of the facilities, given the comparatively modest alterations to the local marine resources.

Each Proposed Plan Facility or Alternative Facility site, as applicable, was examined for the presence or absence of tidal wetlands. The tidal wetlands assessment combined aerial photographic analyses, topography mapping and tidal wetlands mapping. Field investigations were conducted to determine consistency with these data sources.

Additionally, the NYSDEC NHP was contacted to determine whether rare species of plants and wildlife or unique habitats were reported as occurring on or adjacent to each site. NHP provides a database listing that identifies the species and/or habitats with state, heritage and global rankings and other information related to the species. The database list is confidential and cannot be released without written permission from NHP.

The United States Fish and Wildlife Service (USF&WS) was also contacted for any federally listed endangered or threatened species known to be within any of the project areas. Notification of project activity follows the guidelines under Section 7 of the Consultation of the Endangered Species Act (87 Stat. 884, as amended; 16 U.S.C. 531 et. seq.). Response letters from both the USF&WS and NHP typically indicated the presence or absence of rare species and whether further on-site analyses were required. Pertinent species information provided by these agencies is included in each of the site descriptions in this SWMP FDEIS, as are separate narrative descriptions. Essentially, these sections were tailored to the amount of background information available pertaining to each site and to the severity of expected impacts.

3.11.3 Current Ecological Field Studies - Types and Sources of Information Collected

During the fall of 2002, DSNY conducted ecological field studies at the Converted MTS sites. This decision reflected the desire to have sufficient data available to answer any potential regulatory agency questions or concerns. A scope of ecological studies was developed and presented to the relevant review agencies, their comments incorporated, and a final version published. The field studies started in January 2003 and were completed in December 2003.

3.11.4 Screening Methodology

Each Proposed Plan Facility and Alternative Facility site, as applicable, was assessed for Existing and Future No-Build Conditions to determine the value of the natural resource as demonstrated by the variety and density of its species; its use for recreation, open space or commerce; its relationship to neighboring resources and to the overall area ecosystem; or its role in ecosystem cleansing or storm and flood management. Environmental systems that support the natural resources in the study area were examined for each site. A detailed description of the construction and operational activities associated with each Proposed Plan Facility and Alternative Facility site, as applicable, along with an analysis of its interactions with the natural resources and the environmental system that supports it is provided in Chapters 4 through 31.

3.11.5 Impact Analysis Methodology

Both the short-term and long-term impacts of the Proposed Plan Facility and Alternative Facility site, as applicable, on the natural resources were evaluated. Direct impacts are identified as those that intervene or alter the resource immediately by impacting the site conditions, such as filling or draining areas; construction of bulkheads, piers and other structures in the water; or removal of vegetation. Indirect impacts are those that affect a natural system or another resource that supports the resource under study, such as alterations of groundwater flow or quality, and increases in the transport of silt and sediments. The direct or indirect physical effects of the Proposed Plan Facilities and Alternative Facilities, as applicable, were assessed because they modify the functioning of the resource. In addition, the effects were evaluated and expressed in the context of the scarcity or abundance of the resource.

Impacts were predicted by analyzing changes that resulted from similar programs in the past. Where there was no direct comparison to a past project available, the impacts were predicted based upon generalized experience and modeling calculations.

3.11.6 Typical Mitigation Measures

Mitigation techniques can be applied during construction to control erosion and siltation, maintain existing drainage patterns and avoid activities that unnecessarily cause temporary or permanent damage. Such techniques include:

- Using silt fences, hay bales, mulches and other covers to limit areas of soil exposure and to stabilize slopes.
- Installing temporary drainage systems including sediment traps for the duration of the construction.
- Avoiding dredging in contaminated areas. Where this is not practical or feasible, such techniques as silt screens, turbidity curtains and modified dredging methods, such as restricting dredging to the areas of low current velocity, can be used.
- Limiting de-watering wherever possible; disposing of such waters properly so as to maintain the existing drainage system and avoid surface water pollution.
- Limiting construction to periods during which breeding or spawning does not take place.

3.12 Hazardous Materials

3.12.1 Introduction

As part of the CEQR process, this SWMP FDEIS includes a hazardous materials assessment that determines if:

- The Proposed Plan Facility and Alternative Facility site, as applicable, could lead to the increased exposure of people or the environment to hazardous materials;
- There is any presence of existing hazardous materials on the sites (some sites may have hazardous materials from existing uses or residual contamination from past uses when there was less regulation of uses and disposal of such materials);
- Construction activities associated with the Proposed Plan Facility and Alternative Facility site, as applicable, could result in human exposure to hazardous materials or a threat to the environment; and
- The Proposed Plan Facility and Alternative Facility site, as applicable, could introduce an "at-risk population" to exposure to hazardous materials.

Activities that could lead to exposure include:

- Excavation or grading that creates fugitive dust from contaminated soils;
- Demolition of buildings or structures that contain hazardous materials;
- The introduction of new activities or processes that use hazardous materials; and
- The introduction of a new population to an area that contains hazardous materials.

3.12.2 Definition of Study Area

The site is the focus of the study area in the CEQR evaluation of hazardous materials exposure to humans and the environment; however, potential contamination by hazardous materials is not limited by property boundaries. Chapter J (Hazardous Materials), Section 310 of the 2001 CEQR Technical Manual indicates that the study area for hazardous materials includes all other areas that might have affected or that might be affecting the site. This is defined to include at least the adjacent properties and, generally, properties within 400 feet of the site. The study area for record searches of spills and hazardous waste sites is defined as that which is

within a 1,000 foot radius from the site. The study area for record searches of underground storage tanks (USTs) includes the site and adjacent properties. If the facility involves excavation for utilities, the path of those utilities would become part of the study area. Final design plans would determine the need for additional underground utilities.

3.12.3 Types and Sources of Information Collected

In accordance with Chapter J, Section 322 of the 2001 CEQR Technical Manual, federal and state agency database searches were performed for all sites and properties within a minimum of a 1,000-foot radius of the sites. Many of the federal and state records were available on computer databases through commercial service firms. Local records (i.e., FDNY, DSNY, NYCDEP) were obtained as a result of filing Freedom of Information requests. Detailed maps and tables of the record searches were compiled and reviewed.

3.12.4 Screening Methodology

The screening methodology applied for hazardous materials follows the guidelines set forth in Chapter J, Section 320 of the 2001 CEQR Technical Manual, which includes:

- Historical land use review;
- Regulatory agency list review; and
- Site and surrounding area reconnaissance.

3.12.5 Historical Land Use Review

The historical land use review seeks to identify past activities on the sites and adjacent properties that may have involved the use or disposal of hazardous materials. In accordance with Chapter J, Section 321 of the 2001 CEQR Technical Manual, this review extends back for at least 50 years at each site. The Sanborn historical fire insurance atlases are valuable sources for identifying historical land use in the City. Historical atlases for each of the sites were either purchased or reviewed in the City Public Library. These documents (generally available since the early 1900s) indicate the structures present, buried gasoline tanks that exist and the identification of uses (e.g., company name for industrial properties) at the time of preparation.

A search of the City Building Department's records was made to identify new building applications, records of major alterations, demolition records, certificates of occupancy and other records of or plans for additions and changes on file for the subject property. In addition, a search of FDNY records for each site was conducted to identify the presence of underground or above-ground storage tanks.

Where feasible, interviews with individuals knowledgeable of past uses at the subject site were conducted. Based upon the above-mentioned information sources, history of site uses that identifies the potential for the prior usage of hazardous materials was compiled and is presented in Chapter 4 through 31.

3.12.6 Regulatory Agency List Review

The regulatory agency list review involves accessing records of City, state and federal agencies that regulate the storage, handling, emissions and spill cleanup of hazardous materials. These records include:

- United States Environmental Protection Agency's (USEPA's) National Priority List (NPL) and Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS) list, which was reviewed to determine if the property or surrounding properties within the search radius appear on the lists. The NPL contains sites that are targeted for USEPA-mandated cleanup under the federal Comprehensive Environmental Responsibility and Compensation and Liability Act (CERCLA), which authorizes identification and remediation of uncontrolled hazardous waste sites. The CERCLIS list contains potential hazardous waste sites for which there is not enough information to determine if the site should be included on the NPL.
- The Resource Conservation and Recovery Information System (RCRIS) list identifies registered hazardous waste generators, transporters and treatment, and storage and disposal facilities, as defined by the federal Resource Conservation and Recovery Act (RCRA), which regulates management and disposal of hazardous wastes currently generated, treated, stored, disposed or distributed. Inclusion on the RCRIS Notifiers List does not, in and of itself, indicate that the site is a source of contamination. For example, all dry cleaning establishments in the City are on the RCRIS list.

- The Emergency Response Notification System (ERNS), a compilation of hazardous substance spills reported to federal and state authorities.
- NYSDEC databases, which will be reviewed to determine if: (1) the site or nearby sites are on the Inactive Hazardous Disposal Site Registry and are therefore subject to a state consent order for assessment and possible cleanup; (2) there have been any large-scale landfilling operations on or near the site; and (3) there are records of leaking USTs, major oil storage facilities, petroleum bulk storage facilities, chemical bulk storage facilities or solid waste management facilities. Records of spills are listed as Active (under investigation) or Closed (no further action required).

This review is a routine part of the initial assessment that, as defined in the 2001 CEQR Technical Manual, is often referred to as a Phase I Environmental Site Assessment and does not include any testing for contamination. If warranted, Phase II subsurface testing will be recommended to confirm the presence of or to characterize the extent of potential contamination. Phase II is described in more detail in Section 3.12.9.

3.12.7 Site and Surrounding Area Reconnaissance

Following completion of the historical land use review and the review of regulatory agency records, visits were made to the sites to observe and document Existing Conditions and note any signs of the presence of potential hazardous materials, their usage and contamination. A reconnaissance survey of surrounding properties was also taken, though it was less detailed than the site survey. The reconnaissance surveys were performed in accordance with the guidelines of Chapter J, Section 323 of the 2001 CEQR Technical Manual.

3.12.8 Impact Analysis Methodology

The 2001 CEQR Technical Manual indicates that the following two questions be applied in determining if a significant adverse impact would occur from the presence of hazardous materials:

- Is there the potential for human exposure to contaminants? This includes future on-site occupants, off-site occupants and construction workers, and

- Is there potential for environmental exposure to contaminants? This includes contaminants entering on-site or surrounding natural resources or exacerbating existing environmental contamination.

If both questions can be answered "no," it is unlikely that a potential for significant impacts exists. If the answer to either question is "yes," then a significant impact might occur. The site specific radius map indicates only those sites which may create a significant impact to redevelopment or reuse through on-site or off-site pathways. All other sites within the applicable study area radius are shown in the Toxics Targeting Computerized Environmental Report located in the technical backup to this FEIS, which is available upon request.

The potential risk is dependent upon the nature and extent of contamination and the Proposed Actions at the site. The methodology outlined in the 2001 CEQR Technical Manual (Chapter J, Section 400) was used in assessing the significance of impacts. If a potential for contamination was found during this Phase I Assessment, then Phase II surface and subsurface investigations may be recommended as part of the construction phase of project implementation in order to confirm the presence and extent of the contamination and to identify appropriate mitigation measures.

Given that the transfer and export of MSW are not inherently hazardous activities and that Existing Conditions are not likely sources of soil or groundwater contamination, it is anticipated that any potential impact identified during an individual site's Phase I evaluation would rise to a level of significance only if on-site construction was undertaken. In these instances, a process of further detailed analysis, referred to as a Phase II investigation, would be conducted. Phase II investigations would be necessary if soil disturbance from new construction occurs and the Phase I investigation identified the likelihood of hazardous material contamination from previous land uses. Project land parcels that have yet to be acquired would also be properly tested prior to any grading/excavation or construction activities.

The Phase II investigation may include several physical investigations that confirm the presence, type and extent of potential contamination. A Phase II sampling and testing plan is prepared based on findings resulting from the Phase I or Preliminary Assessment (which indicates the

potential presence of contaminants of concern). Subsurface testing may include the following: (1) soil gas sampling with probes to test for volatile compounds; (2) soil borings to sample and test for a full range of potential contaminants; and (3) the installation of groundwater monitoring wells to test for groundwater contamination. Magnetometer or ground penetrating radar may be useful in locating buried storage tanks, underground piping, etc. The Phase II sampling protocol would be submitted to NYCDEP/NYSDEC for review and approval prior to conducting the investigation.

The results of the Phase II investigation would be the basis for determining the necessity to mitigate contamination prior to commencing construction. If elevated levels of contamination exist, the soil would require appropriate remediation to ensure that no significant impacts to on- and off-site occupants would occur. If unexpected contamination is encountered during construction (e.g., discovery of leaking underground tanks, etc.), then mitigation measures would be developed with the concurrence of regulatory agencies that have the appropriate jurisdiction (NYSDEC, NYCDEP, FDNY).

Construction on the site without the proper precautionary measures (e.g., worker Health and Safety Plan) and removal of associated contaminated material and USTs can also result in exposure to hazardous vapors or workers could come into contact with potentially contaminated soils. Therefore, a NYCDEP- and/or NYSDEC-approved site-specific Health and Safety Plan would be prepared on the basis of the site sampling analysis and the expected risk of worker exposure to any identified contaminants prior to any site disturbance (grading/excavation) or construction activities.

If any excavated soil was removed from a site, the soil would be properly tested in accordance with all applicable NYSDEC regulations prior to determining re-use and/or disposal options. Any tanks discovered during excavation would be removed in accordance with all applicable regulations, prior to construction. The contractor would maintain appropriate remediation measures, such as dust suppression, during grading/excavation and construction activities at the site.

Demolition and construction activities may disturb surfaces with lead-based paint and asbestos-contaminated material. Lead and asbestos would be handled in accordance with all applicable rules and regulations of the Occupational Safety and Health Administration (OSHA), and the City, state and federal governments.

3.12.9 Typical Mitigation Measures

Mitigation of potential adverse impacts to eliminate or reduce the sources of impacts to acceptable levels can include reduction or removal of contamination or altering the Proposed Plan Facility and Alternative Facility site, as applicable. Appropriate mitigation measures would be selected on a case-by-case basis. Consultation with the NYCDEP and/or NYSDEC would be advised in selecting appropriate mitigation measures. In the case of a Phase II investigation, such investigation results in recommended mitigation measures that are specific to a project. If contaminated soil exists or is found, it will be removed and disposed of at a regulated disposal facility in a manner that minimizes exposure to workers and the public, in general.

In the City, inactive, underground fuel oil tanks can be closed by first removing any residual fuel oil and tank bottoms, and then by either filling the tank with a concrete slurry or other approved inert material, or excavating and disposing of it off site following applicable standards.

3.13 Water Quality

3.13.1 Introduction

The water quality analysis evaluates the impacts that the Proposed Plan Facilities and Alternative Facilities, as applicable, would have on surface water and identified mitigation, if applicable. For each site, Existing Conditions, No-Build Conditions and potential impacts associated with the Proposed Plan Facilities and Alternative Facilities, as applicable, (Future Build Conditions) were evaluated. Recent water quality data in the vicinity of each site was summarized and compared to local water quality standards. A mathematical model of New York Harbor was used to predict the potential impacts of the Proposed Plan Facilities and Alternative Facilities, as applicable, upon future water quality conditions. The water quality study area includes the receiving water body that is adjacent or as close as possible to each site.

3.13.2 Review of Existing Water Quality Data

As part of the Harbor Survey Program, NYCDEP designated monitoring stations throughout New York Harbor, including the Hudson and East Rivers, which are sampled routinely. Water samples are typically analyzed for conventional pollutants and additional water quality parameters. In addition, ambient metals concentration data are available from sampling conducted during 1991 by Battelle Ocean Sciences for Region 2 of the USEPA. For each of the sites, data from the nearest monitoring stations were compiled and summarized to develop a profile of No-Build water quality conditions. These data were compared to the corresponding NYSDEC water quality standards and guidance values. In addition, NYSDEC information on existing permitted discharges in the vicinity of each site was investigated.

3.13.3 Pollutant Loadings

At each Proposed Plan Facility and Alternative Facility site, as applicable, stormwater runoff would be discharged directly into the adjacent surface waters after passing through an oil/water separator. The volume of stormwater runoff and the associated pollution loading were calculated

using precipitation data and available databases on stormwater pollutant concentrations. The estimated pollutant loading was developed for each site by calculating a runoff flow and assigning an average stormwater concentration for each water quality parameter. The runoff flow was calculated using the following equation:

$$Q_R = CIA;$$

where:

Q_R = Runoff flow (cubic feet per second [cfs]);
C = The runoff coefficient;
I = The average rainfall intensity (inches per hour [in/hr]); and
A = Site area (acres).

The runoff coefficient, C, is directly related to the amount of impervious surface, such as buildings, roads, parking lots or other similar features that water does not infiltrate. To be conservative in the analysis of potential impacts to surface water, it was assumed that all site runoff would discharge to surface waters; therefore, the runoff coefficient is equal to one. The average rainfall intensity, I, is calculated from rainfall data measured at Central Park between 1969 and 2002. These data were analyzed to determine statistics on the duration and intensity of storm events.

For each site, pollutant loading for each water quality parameter was calculated by assigning a pollutant concentration to the runoff flow. Table 3.13-1 presents average concentrations for conventional pollutants and selected metals in urban stormwater runoff. Pollutant concentrations have been determined from the National Urban Runoff Program (NURP) and additional stormwater databases. These additional databases included studies funded by the Washington Council of Governments, the Federal Highway Administration (FHWA), and Santa Clara County, California. Studies in Jamaica Bay (Jamaica Bay Combined Sewer Overflow Facility Planning Project, O'Brien and Gere, 1994), Alley Creek (East River Combined Sewer Overflow Facility Planning Project, URS Consultants and Lawler, Matusky & Skelly, 1996) and the Outer Harbor areas of the City (Outer Harbor CSO Facility Planning Project, Hazen and Sawyer and HydroQual, Inc., 1993) provided additional stormwater runoff data.

Table 3.13-1
Stormwater Runoff Quality for Various Studies

Pollutant	National Stormwater Data				NYC Stormwater Data			Average
	I[1]	II[2]	III[3]	IV[4]	V[5]	VI[6]	VII[7]	
Conventional Pollutants (mg/L) [12]								
BOD [9]	9	5	14	8	12	10	18	11
Total Suspended Solids	100	26	93	66	25	–	55	61
NH_3-N [10]	--	0.26	--	–	–	–	0.41	0.34
(NO_3+NO_2)-N [11]	0.68	0.50	0.66	0.62	–	–	0.79	0.65
Total Phosphorus	0.33	0.26	0.29	0.29	–	–	0.53	0.33
Dissolved Phosphorus	0.12	0.16	--	–	–	–	–	–
Coliform Bacteria (MPN/100 ml) [13]								
Total Coliform	--	--	--	–	175,000	75,000	265,000	172,000
Fecal Coliform	21,000	--	--	2,000	37,000	20,000	92,000	34,000
Heavy Metals (µ/L) [14]								
Copper	34	–	39	31	–	–	–	35
Lead	144	18	234	37	–	–	–	28[8]
Zinc	160	37	217	200	–	–	–	154

(6) Outer Harbor CSO Facility Planning Project. Hazen and Sawyer, P.C. and HydroQual, Inc., 1993.

(7) East River Combined Sewer Overflow Facility Planning Project. URS Consultants, Inc. & Lawler, Matusky, & Skelly Engineers, 1996.

(8) Lead concentrations monitored in the 1970s and early 1980s reflect leaded gasoline use. As a result, stormwater data for II and IV were used to develop average concentrations.

(9) Biochemical oxygen demand

(10) NH_3-N = Ammonia

(11) (NO_3+NO_2)-N = Nitrate plus nitrite nitrogen

(12) = mg/L = milligrams per liter

(13) = MPN/100 ml = most probable number per 100 milliliters

(14) = µ/L = micrograms per liter

The average data from these programs were deemed representative of stormwater from the sites. The three metals analyzed —copper, lead and zinc— are the predominant metals typically found in stormwater.

3.13.4 Modeling Evaluation of Stormwater Impacts

For each site, the impacts of estimated stormwater pollutant loadings were evaluated using the New York Harbor Seasonal Steady State Water Quality 208 Model (208 Model). This model was developed under Section 208 of the Clean Water Act to help state and local water quality management agencies integrate water quality activities and goals into a predictive tool. The 208 Model was used to predict incremental changes in dissolved oxygen levels caused by biochemical oxygen demand (BOD) and incremental increases in the concentrations of other pollutants, such as fecal coliforms, nutrients, total suspended solids and heavy metals. The application of the 208 Model to heavy metals is deemed conservative because only dispersion is considered in determining concentrations. Other reactions that decrease ambient metal concentrations were not included in the analysis. These other chemical and physical reactions may include complexation, oxidation, absorption and settling to sediments.

To evaluate the potential impacts of operations at each site, Future Build water quality conditions were estimated by combining the incremental difference in water quality calculated by the model with the existing data. These estimated water quality conditions were compared with applicable NYSDEC water quality standards and guidance values for the applicable waterways.

3.14 Waterfront Revitalization Program

3.14.1 Introduction

Many of the Proposed Plan Facility and Alternative Facility sites are located within the designated coastal zone boundary established by the New York State Department of State, pursuant to the Federal Coastal Zone Management Act of 1972 and the New York State Waterfront Revitalization and Coastal Resources Act of 1981.

3.14.2 Governing Policy

"The New Waterfront Revitalization Program," prepared by the NYCDCP, identifies ten primary coastal policies that provide for local implementation of the state Coastal Management Program (CMP) in the event that a municipality adopts a local WRP, as is the case with the City.

Developed by the City, the goal of WRP is to foster responsible development of the City's waterfront. The WRP embodies the policies of federal and state coastal management legislation. Its policies cover a comprehensive range of waterfront planning and environmental issues that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

Under the WRP, there are ten primary policies that address: (1) residential and commercial redevelopment; (2) water-dependent and industrial uses; (3) commercial and recreational boating; (4) coastal ecological systems; (5) water quality; (6) flooding and erosion; (7) solid waste and hazardous substances; (8) public access; (9) scenic resources; and (10) historical and cultural resources. These ten policies are further broken down into several subpolicies under each primary policy. The new policies and subpolicies simplify and clarify the consistency review process without eliminating any policy components required by federal and state law.

Each of the sites was evaluated for compliance and consistency with these ten primary waterfront policies and the 32 subpolicies set forth within the WRP. These evaluations include consistency with the WRP and additional discussion or clarification. As necessary and required, appropriate mitigation measures to achieve consistency of a facility with applicable WRP policies were identified and discussed.

In general, each of the WRP policies is either applicable to the Proposed Plan Facilities and Alternative Facilities, not applicable to any of them or applicable on a strictly site-specific basis. A description of all of the policies and subpolicies and their general applicability to the Converted MTSs is provided in Table 3.14-1. In general, under the WRP, the consistency of a Proposed Action needs to be demonstrated with respect to each applicable policy or subpolicy. Policies or subpolicies that are identified as not applicable are those in which the consistency of a Proposed Action does not need to be demonstrated.

In addition, a comprehensive plan for the management of the City's waterfront has been set forth in "The New York City Comprehensive Waterfront Plan – Reclaiming the Water's Edge" prepared by NYCDCP. Likewise, individual waterfront plans for the boroughs have also been developed to address activities and the development of facilities within the coastal zone boundary and provide recommendations for future activities within this zone. These are also considered with regard to solid waste management activities that may occur within the coastal zone boundary area.

Table 3.14-1
Local Waterfront Revitalization Policies and Subpolicies and Their Applicability

Policy Number	Policy Description	Applicability to Proposed Action
Policy 1	Support and facilitate commercial and residential redevelopment in areas well-suited to such development.	
	1.1 Encourage commercial and residential redevelopment in appropriate coastal zone areas.	Never
	1.2 Encourage non-industrial development that enlivens the waterfront and attracts the public.	Never
	1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.	Always
Policy 2	Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.	
	2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.	Site Specific
	2.2 Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.	Site Specific
	2.3 Provide infrastructure improvements necessary to support working waterfront uses.	Always
Policy 3	Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.	
	3.1 Support and encourage recreational and commercial boating in New York City's maritime centers.	Never
	3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.	Always
	3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.	Always

Table 3.14-1 (Continued)
Local Waterfront Revitalization Policies and Subpolicies and Their Applicability

Policy Number	Policy Description	Applicability
Policy 4	Protect and restore the quality and function of ecological systems within the New York City coastal area.	
	4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.	Always
	4.2 Protect and restore tidal and freshwater wetlands.	Always
	4.3 Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.	Always
	4.4 Maintain and protect living aquatic resources.	Never
Policy 5	Protect and improve water quality in the New York City coastal area.	
	5.1 Manage direct or indirect discharges to waterbodies.	Always
	5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.	Always
	5.3 Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.	Site Specific
	5.4 Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.	Always
Policy 6	Minimize loss of life, structures and natural resources caused by flooding and erosion.	
	6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.	Always

Table 3.14-1 (Continued)
Local Waterfront Revitalization Policies and Subpolicies and Their Applicability

Policy Number	Policy Description	Applicability
Policy 6	6.2 Direct public funding for flood prevention or erosion control measures to those locations where the investment will yield significant public benefit.	Never
	6.3 Protect and preserve non-renewable sources for beach nourishment.	Never
Policy 7	Minimize environmental degradation from solid waste and hazardous substances.	
	7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.	Always
	7.2 Prevent and remediate discharge of petroleum products.	Always
	7.3 Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.	Site Specific
Policy 8	Provide public access to and along New York City's coastal waters.	
	8.1 Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.	Always
	8.2 Incorporate public access into new public and private development where compatible with proposed land use and coastal location.	Always
	8.3 Provide visual access to coastal lands, waters and open space where physically practical.	Site Specific
	8.4 Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.	Always

Table 3.14-1 (Continued)
Local Waterfront Revitalization Policies and Subpolicies and Their Applicability

Policy #	Policy Description	Applicability
Policy 8	8.5 Preserve the public interest in and use of lands and waters held in public trust by the state and city.	Site Specific
Policy 9	Protect scenic resources that contribute to the visual quality of the New York City coastal area.	
	9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.	Always
	9.2 Protect scenic values associated with natural resources.	Always
Policy 10	Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.	
	10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.	Always
	10.2 Protect and preserve archaeological resources and artifacts.	Always

3.15 Infrastructure, Solid Waste and Sanitation Services, and Energy

3.15.1 Introduction

The SWMP FDEIS evaluates the potential impacts associated with the development of the Proposed Plan Facilities and Alternative Facilities, as applicable, on existing infrastructure, energy, and solid waste systems for each site in accordance with CEQR guidelines. The analyses include:

- An inventory of existing utility infrastructure (water, sewer, electric and gas) servicing each site;
- A comparison of the estimated Proposed Plan Facilities and Alternative Facilities, as applicable-generated demand on water, sewage, electric, gas and solid waste systems with the infrastructure available to meet these demands;
- A qualitative examination of the need for additional infrastructure and utilities and the generation of solid waste during the construction period; and
- Identification of any significant impacts on the existing infrastructure and energy systems and examination and recommendation of mitigation measures, where appropriate.

3.15.2 Water Supply

The description below of the existing water supply distribution system and its conditions is based upon drawings and information from NYCDEP Bureau of Water and Sewer Operations. For sites currently staffed or in use, the water demand was based upon the current number of on-site employees and a per capita (gallons per day [gpd] per employee) water usage. For the Proposed Plan Facilities and Alternative Facilities, as applicable, water demand was based upon the number of employees and the volume of water to be used for tipping floor washdown and dust control. The employee demand would be 25 gpd per person for all shifts, with an average demand of 2,000 gpd required for tipping floor washdown and dust control. The process water estimates, obtained from the 2001 CEQR Technical Manual for comparable facilities, were compared to the amount of water supplied by the system and their effects on the system's capacity analyzed.

3.15.3 Sanitary Sewage and Stormwater

For each WPCP affected by the Proposed Plan Facility and Alternative Facility, as applicable, the dry weather flow and the average flow, which includes the sanitary and Stormwater flows received by the WPCP during wet weather for the latest 12 months were used. Sewage generation within the applicable WPCP was then projected for the Future No Build scenario through the use of the "New York City Water Demand and Wastewater Flow Projections, August 1998" prepared by NYCDEP.

Sewage generation, due to the facility was based upon all water used on the sites being sent to the WPCP, along with an estimate of process or facility water usage. The incremental generation was estimated with regard to both the average annual and the highest monthly dry weather flows, and the impact on the WPCP's ability to meet the flow limits of its SPDES permit was analyzed. In addition, the additional sewage flows from the proposed facilities were evaluated for their potential to increase combined sewer overflows (CSOs) within the specific WPCP drainage areas.

3.15.4 Solid Waste

The effects of the each Proposed Plan Facility and Alternative Facility, as applicable, on the City's solid waste infrastructure and the conduct of City solid waste management activities were examined. In addition, a review was conducted of the conformance of each Proposed Plan Facility and Alternative Facility (as applicable) with the regulations and permitting of solid waste management facilities by NYSDEC and DSNY.

The future daily volumes of solid waste generated were estimated based on each employee generating 1.3 pounds per day for each shift. This solid waste generation was based on estimates provided within the 2001 CEQR Technical Manual for similar facilities. This volume of waste was compared to the estimated volume of waste, and the impacts analyzed.

3.15.5 Energy

Consolidated Edison's capacity to supply electricity to the Proposed Plan Facilities and Alternative Facilities, as applicable, was determined, and the current on-site demand estimated. Electricity consumption projections for the Proposed Plan Facilities and Alternative Facilities, as applicable, were calculated for the processing equipment (cranes, shuttle cars, etc.), auxiliary equipment and facility lighting. Power consumption projections for the Proposed Plan Facilities and Alternative Facilities, as applicable, was determined from data provided by vendors, consultants and equipment suppliers, based on the 24-hour operation of the process and ancillary equipment. Comparisons were made between this estimated new demand and available capacity for the area network. At Proposed Plan Facilities and Alternative Facilities, as applicable, in which anticipated incremental electrical demands would exceed 1.5% of the network projections, modifications to the network may be required.

Natural gas requirements for the Proposed Plan Facilities and Alternative Facilities, as applicable, were compared with infrastructure capacities projected by Consolidated Edison and Keyspan Energy. The possible impacts of the Proposed Plan Facilities and Alternative Facilities, as applicable, and the policies governing the conduct of solid waste management activities in the City were also assessed.

3.16 Traffic, Parking, Transit, and Pedestrians

3.16.1 Introduction

Traffic, parking, transit, and pedestrians analyses determine if the Proposed Plan Facilities and Alternative Facilities, as applicable, would generate measurable additional traffic in or near the areas surrounding the sites, when additional traffic would be generated and what impacts it would have on intersections and roadways. The results of the analysis are also used in determining impacts on air quality, noise quality, socioeconomic conditions, neighborhood character, community facilities and open space and parklands. The 2001 CEQR Technical Manual guidelines state that if a proposed action generates additional traffic, further analysis may be required. Pursuant to these guidelines, analyses were performed to quantify what impacts, if any, the Proposed Plan Facilities and Alternative Facilities, as applicable, would have upon traffic conditions. The approach taken was to:

- Quantify the level of vehicle trip generation projected for each Proposed Plan Facility and Alternative Facility, as applicable;
- Determine whether detailed traffic analysis is required, based upon the 2001 CEQR Technical Manual guidelines, given the level of trip generation projected;
- Define Existing, Future No-Build Conditions and Future Build Conditions in the study areas of each applicable site;
- Identify and quantify any potentially significant impacts on intersections and approaches to intersections in the study areas of each site;
- Suggest reasonable mitigation measures to alleviate traffic impacts that would be generated by the proposed facilities;
- Identify high accident locations where safety is a concern based upon the 2001 CEQR Technical Manual guidelines; and
- Suggest reasonable mitigation measures to improve safety at high accident locations.

3.16.2 Background

All of the Proposed Plan Facilities and Alternative Facilities, as applicable, would generate an increase in employee vehicle trips, and an increase in DSNY and other agency collection vehicle traffic ~~from~~ compared to Existing Conditions.

New vehicle trips generated by the Proposed Plan Facilities and Alternative Facilities, as applicable, could potentially cause ~~deterioration~~ a decrease in the level of service (LOS) at intersections along the facility access routes in the vicinity of the sites and along local roads near district garages. LOS levels are based upon the average stopped delay calculated for an intersection.

3.16.2.1 CEQR Guidelines

To determine if a detailed traffic analysis is required, the 2001 CEQR Technical Manual guidelines propose comparing the volume of new vehicle trips generated by the proposed action with the analysis thresholds that are specified in the 2001 CEQR Technical Manual. Further analysis may not be required if the proposed action is projected to generate 50 or fewer peak hour vehicular trip ends. Peak hour vehicular trip ends are conservatively considered herein as passenger car equivalents (PCEs).

The 2000 Highway Capacity Manual (HCM 2000) defines a PCE as "the number of passenger cars displaced by a single heavy vehicle of a particular type, under specified roadway, traffic and control conditions." The 2001 CEQR Technical Manual defines waste collection vehicles as a light truck with a PCE factor of 1.5.

3.16.3 Operational Assumptions

Trucks are required by NYCDOT Title 34 to travel on truck routes directly to the facility they are servicing or to the intersection nearest the facility, if streets adjacent to the facility are not designated truck routes. It is assumed that DSNY and other agency collection vehicles currently abide by the rules and regulations set forth in NYCDOT Title 34 and that these vehicles will continue to follow Title 34 in the future. Therefore, collection vehicles are assumed to proceed to the closest designated truck route upon completion of their collection route in order to deliver waste to a Proposed Plan Facility and Alternative Facility, as applicable. DSNY and other agency collection vehicles would also follow truck routes on trips returning from their designated unloading facility, whether returning to the CD to collect additional waste or returning to the district garage at the end of a shift.

3.16.3.1 Existing DSNY Operations

DSNY has designated 59 CDs in the City from which waste is collected and transported by truck to a designated facility. Currently, waste is exported to local commercial waste vendors in and around the City under interim export activities. DSNY schedules its collections and deliveries based upon three operational periods: priority, non-priority and relay.

- Priority loads are assumed for analysis purposes to originate in the center of the CD and are delivered by DSNY collection vehicles to the transfer station. The collection vehicles then return to the CD to collect additional residential waste.
- Non-priority loads are also assumed to originate in the center of the CD and are delivered to the transfer station by DSNY collection vehicles. The collection vehicles then return to the district garage.
- Relay loads return to the district garage and during the relay shift are driven to a disposal facility and unloaded. Relay loads originate at the district garage and DSNY collection vehicles return to the district garage.

Relay loads comprise the bulk of the load deliveries to commercial vendors in Manhattan, Brooklyn and Queens under the Interim Export program. Most commercial waste vendors do not fall within a travel distance that allows priority and non-priority loads from CDs in these three boroughs. Non-priority loads comprise the bulk of the loads delivered to commercial waste vendors in the Bronx.

3.16.3.2 Future No-Build Conditions

Future No-Build Conditions assume that there would be no changes to the existing ~~department~~ DSNY operations in the projected Build year for the project. Traffic volumes are assumed to increase according to growth rates for each section of the City, as designated by CEQR. The Future No-Build Condition also incorporates additional traffic generated by other projects in the area that would be completed by the time the proposed project is completed.

3.16.3.3 Future DSNY Operations

Based upon the capacity and location of the Proposed Plan Facilities and Alternative Facilities, as applicable, DSNY developed allocations of the total number of loads that would be delivered to each facility from each CD, and the tonnage associated with the loads. The number of loads each facility would generate on an average peak day are listed in Table 3.16-1. Where applicable, the number of loads generated by an Alternative Ffacility that was analyzed was based on the increment between the number of DSNY-managed loads currently received by each facility under the Interim Export Program and the number of loads the facility would receive in the future.

Figure 3.16-1 shows the proposed wastesheds for the Proposed Plan Facilities. DSNY would continue to schedule its collections and deliveries based upon the three operational periods described in Section 3.16.3.1. To account for the difference in daylight hours, DSNY's main collection shift would be from 6:00 a.m. to 2:00 p.m. from April 16 through November 14, and from 7:00 a.m. to 3:00 p.m. from November 15 through April 15.

The Proposed Plan Facilities would receive waste 24 hours per day, six days per week (Monday through Saturday) with a peak day each week (typically Monday or Tuesday, depending on the ~~Converted MTSF~~facility) when the tonnage is, on average, approximately 10% to 15% higher than the weekly average. The loads and tons allocated to the Proposed Plan Facilities and Alternative Facilities, as applicable, were based upon this average peak day tonnage, which represents typical worst-case conditions in terms of DSNY collection vehicle deliveries.

3.16.4 Trip Generation

Using DSNY's 1998 MTS scale data for all Converted MTSs (except for the South Bronx Converted MTS, which is based on FY 1997 data), the temporal distribution of waste deliveries to the Converted MTSs was calculated for the average peak day. It was assumed that Proposed Plan Facilities and Alternative Facilities, as applicable, would have a waste delivery temporal distribution similar to the waste delivery temporal distribution of the existing MTSs when they were in operation in 1998.

Table 3.16-1
Average Peak Day Facility Load Allocation

Facility	Total Number of Net Loads of DSNY Collection Vehicles
Hamilton Avenue MTS[1]	267
Southwest Brooklyn MTS[1]	166

Meserole Street Truck to Rail TS	225

Notes:

(1) The total number of loads from DSNY collection vehicles is the same for both the Converted MTSs and the Existing MTSs.

(2) Total number of loads from DSNY collection vehicles includes dray trips to a rail yard.

(3) Future Condition DSNY-managed Waste deliveries to the Scott Avenue TS are less than Existing Condition deliveries to the facility. Therefore, no traffic analysis was performed at this site because Existing Conditions are worse than Future Conditions.

(4) Future Condition DSNY-managed Waste deliveries to out-of-City waste-to-energy facilities would remain the same as Existing Conditions. Therefore, no traffic analysis was performed at this site because there is no change between Existing and Future Conditions.

WTE = waste-to-energy

NA = Not Applicable

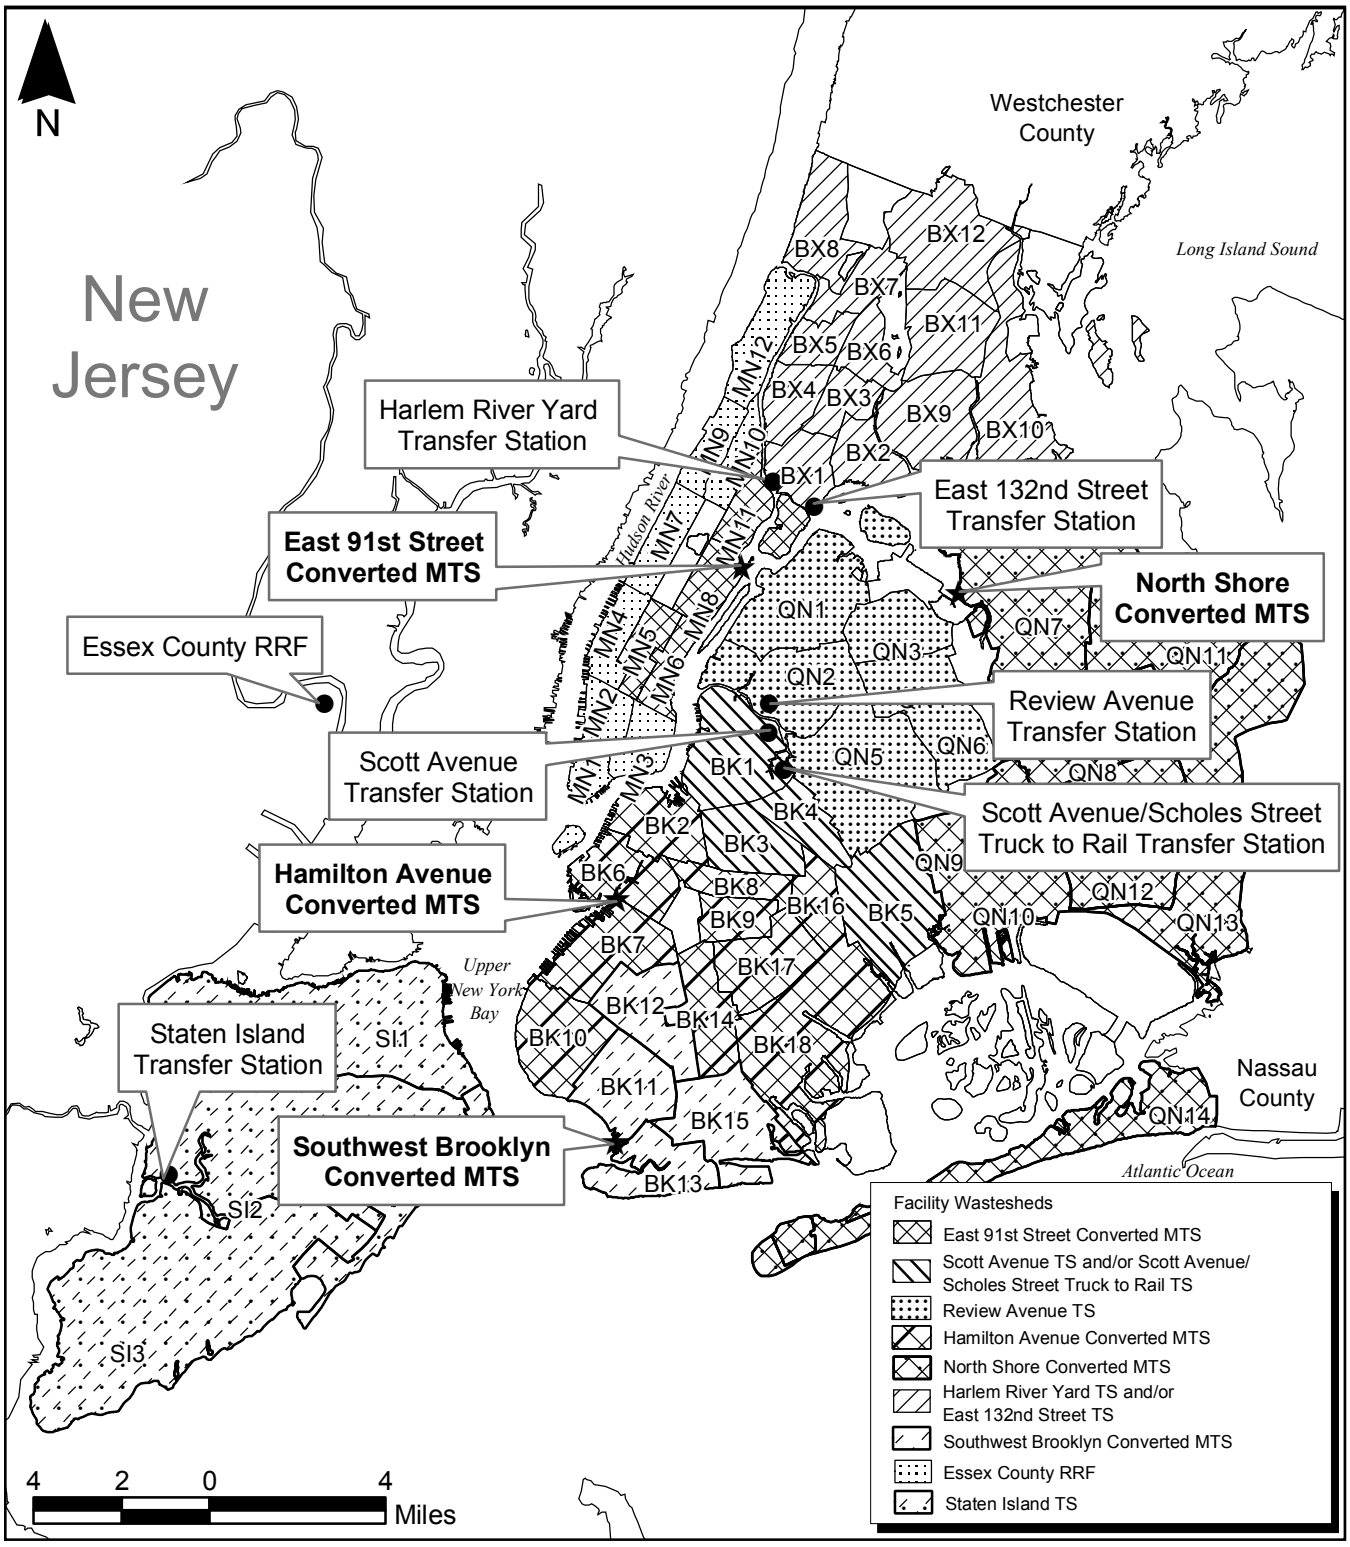

Figure 3.16-1

Long Term Export Facilities and Wastesheds

CITY OF NEW YORK
DEPARTMENT OF SANITATION

FEIS

Using this average temporal distribution and the load allocation for the Converted MTSs, the temporal distribution of waste deliveries to the facilities was calculated in terms of priority, non-priority and relay loads. To be conservative, trip totals were increased by 20% to account for daily and seasonal variations. Following the approach described above, the facility's peak delivery hours and corresponding projected peak hour with the highest number of collection vehicles were identified. Table 3.16-2 illustrates the total number of inbound and outbound DSNY and other City agency collection vehicles generated during the Facility peak hour at each of the Proposed Plan Facilities and Alternative Facilities, as applicable. Table 3.16-2 also illustrates the total PCEs generated by each Proposed Plan Facility and Alternative Facilities, as applicable during the Facility peak hour.

Additionally, Proposed Plan Facilities and Alternative Facilities, as applicable, would generate vehicles trips from employees traveling to and from the facility during a shift change. Converted MTSs are assumed to operate in the future using a three-shift operational structure: 12:00 a.m. to 8:00 a.m.; 8:00 a.m. to 4:00 p.m.; and 4:00 p.m. to 12:00 a.m. Private facility staffing was either provided by the vendor or assumed based on facility design and operations. Employee shift changes are assumed to occur one-half hour before and one-half hour after the start of a shift. For conservative purposes, all arriving employees are assumed to arrive one-half hour before the start of their shift and all exiting employees are assumed to depart within one-half hour after the end of their shift. The number of employee trips was quantified based on the staffing plans of the Proposed Plan Facilities and Alternative Facilities, as applicable. All Converted MTSs were conservatively assumed to generate 40 trips per shift change, one trip per employee, for all employees traveling to and leaving from the Converted MTSs. If a peak hour analyzed for traffic fell partially within the time period of~~during~~ a shift change, only a portion of employee-generated trips were used in the analysis. Employee trips at Alternative ~~facilities~~ Facilities that currently receive DSNY-managed Waste were based on the projected increase in number of employees that would be required to staff the facility to process additional increments of DSNY-managed Waste.

Table 3.16-2
Peak Hour Trips

Facility	Facility Peak Hour	Peak Hour DSNY Collection Vehicles Inbound[1]	Peak Hour DSNY Collection Vehicles Outbound[2]	Total Peak Hour PCEs Generated[3]
Hamilton Avenue[4] MTS	9:00 a.m. – 10:00 a.m.	32	30	93
Southwest Brooklyn MTS[4]	10:00 a.m. – 11:00 a.m.	27	27	81
East 91st Street MTS[4]	9:00 a.m. – 10:00 a.m.	28	28	84
North Shore MTS[4]	10:00 a.m. – 11:00 a.m.	39	38	116
52nd Street Barge Staging Area	NA	0	0	0
65th Street Intermodal Yard	NA	0	0	0
East 132nd Street Site[5]	11:00 a.m. – 12:00 p.m.	45	43	138
Scott Avenue TS[6]	NA	NA	NA	NA
Scott Avenue/Scholes Street Truck to Rail TS	10:00 a.m. – 11:00 a.m.	19	18	56
Review Avenue Truck to Barge TS	10:00 a.m. – 11:00 a.m.	10	10	30

Peak Hour Trips

Facility	Facility Peak Hour	Peak Hour DSNY Collection Vehicles Inbound[1]	Peak Hour DSNY Collection Vehicles Outbound[2]	Total Peak Hour PCEs Generated[3]
West 59th Street MTS[4]	9:00 a.m. – 10:00 a.m.	21	21	63
Meserole Street Truck to Rail TS	10:00 a.m. – 11:00 a.m.	34	33	101

Notes:

(1) Represents the number of collection vehicles the Proposed Action would generate during the peak hour traveling to the Facility.

(2) Represents the number of collection vehicles the Proposed Action would generate during the peak hour leaving the Facility.

(3) DSNY collection vehicles must be multiplied by a factor of 1.5 to convert to PCEs.

(4) The total number of loads from DSNY collection vehicles is the same for both the Converted MTSs and the Existing MTSs.

(5) Vehicles include dray trucks used to transport containers from a facility to an intermodal yard. Dray vehicles must be multiplied by a factor of 2.0 to convert to PCEs.

(6) Future Build Condition DSNY-managed Waste deliveries to the Scott Avenue TS are less than Existing Condition deliveries to the facility. Therefore, no traffic analysis was performed at this site because there is no net increase in truck traffic.

(7) Future Condition DSNY-managed Waste deliveries to out-of-City waste-to-energy facilities would remain the same as Existing Conditions. Therefore, no traffic analysis was performed at this site because there is no change between Existing and Future Conditions.

(8) Indicates a facility at which there are several hours during which the peak hour number of DSNY collection vehicles are predicted to arrive at the facility.

WTE = waste-to-energy
TS = Transfer Station
BCR = Brooklyn Curbside Recyclables

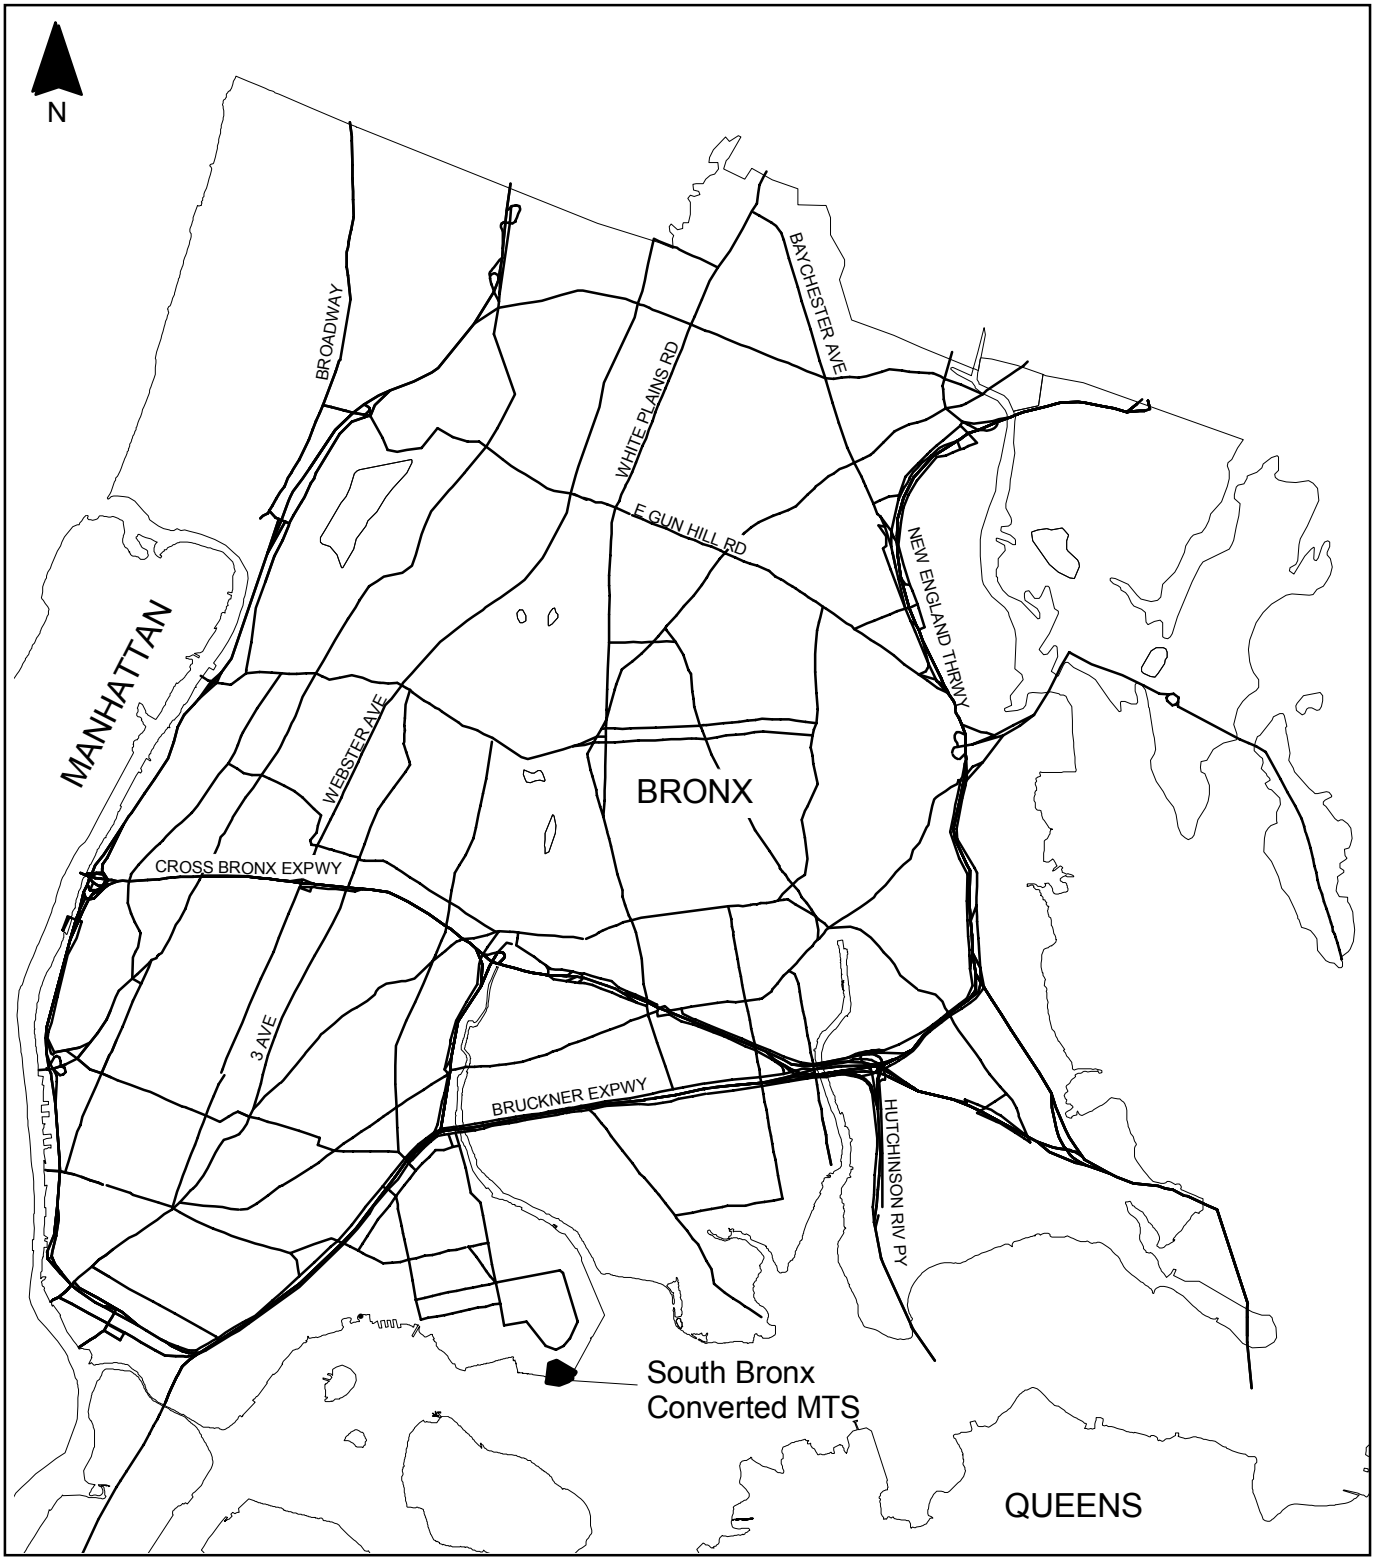
NA = Not Applicable

The number of commercial waste collection vehicles that could potentially make deliveries to the Converted MTSs was based on the available capacity at each facility between 8 p.m. and 8 a.m. It was assumed that commercial waste collection vehicles would carry an average of 11 tons per truck of commercial waste to the Converted MTSs. The number of commercial waste collection vehicles that would make deliveries to each Converted MTS was later adjusted based on constraints from the off-site noise analysis. The revised number of commercial trucks that could potentially make deliveries without causing off-site noise impacts was then analyzed. Truck routes and the origin of commercial waste loads are discussed in Section 3.16.4.2.

3.16.4.1 Traffic Study Area



The study areas include DSNY-assigned collection vehicle routes from each CD and district garage to each facility. The study areas include areas in close proximity to the district garages as well as areas close to the facilities. Figures 3.16-2 through 3.16-5 depict the NYCDOT major and local truck routes for each borough of the City analyzed in the SWMP ~~D~~FEIS. Employee routes were assumed to be along major highways and local roadways.

The traffic study area also included intersections and locations that could be considered high accident locations and problematic from a safety viewpoint. "A high accident location is one where five or more pedestrian accidents occur in any one year in the most recent three-year period for which data is available" as defined by the 2001 CEQR Technical Manual.

3.16.4.2 Traffic Assignment in Study Area

After the initial routes to the facilities were determined, the following steps were taken:

1. The location of the centroid of each CD and the location of each district garage were plotted. The centroid is a location in the center of a CD where all priority and non-priority DSNY collection vehicle trips are assumed to originate.
2. Existing routes to commercial waste vendors under interim export from the centroid of each CD and the district garages were plotted on a site-specific map, as were any CEQR-defined areas of concern or critical intersections.
3. Proposed routes to the facilities from the centroid of each CD and the district garages were plotted on the same site-specific map as the existing truck routes.
4. Existing and future collection vehicle routes were compared to determine the portions of the routes that overlapped.
5. The study area was finalized once the routes were finalized. The study area included an area around the facility where additional collection vehicle traffic would be generated in excess of the CEQR-specified analysis threshold. Intersections within the study area were screened for further analysis using the procedure described in Section 3.16.5.

Site delineations are approximate.

6. NYCDOT reviewed and approved the proposed routes and the site-specific study areas and provided information from prior studies for these areas, if available. NYCDOT suggested additional intersections for inclusion in the study. NYCDOT also provided information on changes to traffic patterns that would be implemented prior to the build year of 2006 due to other projects in the vicinities of the facilities.

DSNY collection vehicles were assigned to a route based on the trip generation data provided by DSNY discussed in Section 3.16.4. The data provided by DSNY included information on the origin of the load by CD and the origin of the load within each CD (either the centroid of the CD or the district garage).

Commercial waste collection vehicles were assumed to use NYCDOT designated truck routes to travel to and from the Converted MTSs. Once close to the Converted MTSs, it was assumed that commercial waste collection vehicles would follow the same paths on local roads as DSNY collection vehicles to access the Converted MTSs.

Origin points of commercial waste were based on information provided by DSNY that identified amounts of commercial waste generated in the City by zip code. Commercial waste was assigned to a Converted MTS by zip code according to the zip codes that were within the CDs assigned to a particular Converted MTS. If a zip code spanned two CDs, the commercial waste was assumed to be from the CD that contained to largest portion of that zip code. It was assumed also that the zip codes with large quantities of commercial waste assigned to a Converted MTS would be most likely to use the Converted MTS in the future, if feasible. Collection vehicle routes from zip codes to a Converted MTS were assumed to be the same as the DSNY collection vehicle routes from the CD in which the zip codes are located. A more detailed discussion of this methodology is included in the Commercial Waste Management Study – Volume III, included in Appendix I to this FEIS.

3.16.5 Screening Methodology

Intersections along truck routes and district garage routes were screened using three different criteria.

- ~~The first criterion identifies intersections through which~~ 50 or more additional PCEs are assigned during peak hours;
- ~~The second criterion identifies intersections in which s~~Significant increases in delay result from less than 50 additional PCEs based on ~~the type of traffic control and characteristics of the intersecting streets.~~field observations of the intersection; and
- The ~~third criterion identifies~~ intersections ~~that~~ are high accident locations, as defined in the 2001 CEQR Technical Manual on page 30-4, based on 2003 accident data provided by NYCDOT.

Because no single CD would generate enough new trips in the Future Build Conditions by itself to warrant a traffic analysis, convergence intersections were screened first. Convergence intersections are those where DSNY collection vehicles traveling to the same facility from different CDs meet or overlap in their routes to and from the facility.

A summary of all critical intersections along CD routes and district garage routes meeting the above screening criteria are presented in each applicable site-specific chapter in this SWMP FD~~D~~EIS. No intersections located near district garages met the above criteria and were not, therefore, considered for further traffic analysis. NYCDOT reviewed and approved the selected intersections. Intersections within the study areas that ~~do~~ did not meet the above criteria ~~will be~~were considered to "screen out" and no further traffic analysis ~~will be~~was performed at these locations.

3.16.6 Data Collection

The following data were obtained for intersections identified for further analysis:

- Data available from prior studies (within a three-year period) conducted for the DSNY or submitted to and/or conducted by the NYCDOT; and

- Signal timing and phasing, and intersection as-built drawings of signalized intersections from the NYCDOT. The timing and phasing of each intersection was then field verified. Geometrics for intersections were field verified.

Where recent data were unavailable or unusable, the following data were obtained in the field:

- Three- or one-day turning movement counts, depending upon the specific study area, schedule and weather constraints. If one-day turning movement counts were obtained, they were adjusted for a three-day average using ATR counts.

- Full turning movement counts for traffic analysis:
  - Time periods: 7:00 a.m. to 7:00 p.m. (data collection times may vary from site to site but are consistent for all intersections studied for a particular site.);
  - Vehicle classifications: autos, trucks, buses (3 or more axles); and
  - Inventories: full physical inventories and intersection operations observation.

- Short-term counts for air quality and noise studies:
  - Time periods: 15- or 20-minute counts per hour during the above hours at each location;
  - Vehicle classifications: six category classification counts by direction; and
  - Inventories: full physical inventories and intersection operations observation.

- Pedestrian sample counts:
  - Sample counts during the above hours at each location.

- Travel time surveys:
  - Time periods: 7:00 a.m. to 7:00 p.m.;
  - Coverage: Six to nine runs per direction per time period; and
  - Procedure: Checkpoints at each signalized intersection, record stopped delay.

- ATR Counts:
  - Duration: Tuesday to Thursday minimum, seven days preferred for 24 hours each day.

- Accident information at intersections
  - Source: Appendix 1; 2001 CEQR Technical Manual; and
  - Source: 2003 NYSDOT Accident Records

3.16.7 Data Compilation

Using data collected in the field, the ~~baseline~~ existing traffic volumes were calculated for the average weekday at each intersection. ~~Automatic traffic recorder (~~ATR~~)~~ data were used to adjust the manual turning movement counts to obtain a more representative measure of the existing hourly traffic volume at each intersection. Future No-Build Conditions were calculated for the Future Build year by applying the CEQR-specified growth rates (Table 3.16-3) to the Existing Conditions. These Future No-Build traffic projections included traffic from any known future developments within or near the study area that have environmental and regulatory approvals in place. Information on future developments was obtained from local community boards and NYCDCP. Finally, the Future Build traffic volumes were calculated by adding the net increase in collection vehicles and employee vehicles to the Future No-Build Condition for each intersection.

3.16.8 Analysis

Three time periods were selected for analysis based upon the vehicle trips to be generated by the operations at each facility:

- The AM peak hour that would experience the greatest impact from the projected net increase in collection vehicles (AM Facility Peak Hour or AM Background Peak Hour) during the Future Build year;
- The PM peak hour that would experience the greatest impact from the projected net increase in collection vehicles (PM Facility Peak Hour or PM Background Peak Hour) during the Future Build year; and
- The Facility Peak Hour, which is the hour during which the most DSNY collection vehicle trips are generated by a given facility. (See Table 3.16-2)

Table 3.16-3
Annual Growth Rates for Studied Areas

Facility	Location	Growth Rate (%)
Hamilton Avenue MTS[1]	Brooklyn	1.0
Southwest Brooklyn MTS[1]	Brooklyn	1.0
East 91st Street MTS[1]	Manhattan	0.5
North Shore MTS[1]	Queens	1.0
52nd Street Barge Staging Area	Brooklyn	1.0
65th Street Intermodal Yard	Brooklyn	1.0
East 132nd Street Site	Bronx	0.5
Scott Avenue TS[2]	Brooklyn	NA
Scott Avenue/Scholes Street Truck to Rail TS	Brooklyn	1.0
Review Avenue Site	Queens	1.0
Collection Vehicle Transport to Out-of-City WTE Facilities[3]	New Jersey	NA
~~MCR~~ BCR to 30th Street Pier at South Brooklyn Marine Terminal	Brooklyn	1.0
MCR to Gansevoort Recyclables Acceptance Facility	Manhattan	0.5
South Bronx MTS[1]	Bronx	0.5
Greenpoint MTS[1]	Brooklyn	1.0
West 135th Street MTS[1]	Manhattan	0.5
West 59th Street MTS[1]	Manhattan	0.5
Meserole Street Truck to Rail TS	Brooklyn	1.0

Notes:

(1) The total number of loads from DSNY collection vehicles is the same for both the Converted MTSs and the Existing MTSs.

(2) Future Condition DSNY-managed Waste deliveries to the Scott Avenue TS are less than Existing Condition deliveries to the facility. Therefore, no traffic analysis was performed because there is no net increase in trucks.

(3) Future Condition DSNY-managed Waste deliveries to out-of-City waste-to-energy facilities would remain the same as Existing Conditions. Therefore, no traffic analysis was performed at this site because there is no change between Existing and Future Conditions.

WTE = waste-to-energy
TS = Transfer Station
BCR = Brooklyn Curbside Recyclables
RRF = Resource Recovery Facility
MCR = Manhattan Curbside Recyclables
NA = Not Applicable

The Facility Peak Hour often occurs closer to the midday peak hour, therefore, no midday peak hour analysis was performed. The peak time periods remained constant for all intersections analyzed in a study area. The time periods may have differed, however, from site to site. Employee vehicles were added to the analysis if such trips occurred during the peak time period analysis hours.

No weekend analyses were conducted because: (1) the facilities would not receive DSNY-managed Waste on Sundays; and (2) the Saturday background traffic and project-induced traffic are lower than the weekday traffic for the Proposed Plan Facilities and Alternative Facilities, as applicable, as presented in this F~~D~~EIS. The following individual facility chapters show the comparison of weekday to weekend traffic for both background volumes and project-generated volumes.

The primary measure of an intersection's general operational state is its LOS. The HCM 2000 defines LOS as "a qualitative measure describing operational conditions within a traffic stream, based on service measures such as speed and travel time, freedom to maneuver, traffic interruptions, comfort and convenience." For all intersections, the HCM 2000 specifies six levels of service: LOS A through LOS F. LOS A generally describes an intersection where there is little or no delay time and progression is extremely favorable. LOS F generally describes poor progression and long delay times and also indicates over-saturation of the intersection. For signalized intersections, LOS is characterized by delay in ~~a~~ each lane group or overall ~~at an~~ intersection delay. The HCM 2000[3] defines delay as "the additional travel time experienced by a driver, passenger or pedestrian." Table 3.16-4 displays the delay for signalized and unsignalized intersections as specified by the HCM 2000 to characterize each of the six levels of service.

---

[3] The methodologies for analyzing signalized and unsignalized intersections have limitations noted for their specific sections. (1) The signalized methodology "does not take into account the potential impact of downstream congestion on intersection operation," nor does the methodology "detect and adjust for the impacts of turn-pocket overflows on through traffic and intersection operation." (2) The unsignalized methodology is "for steady-state conditions . . . the methods are not designed to evaluate how fast or how often the facility transitions from one demand/capacity state to another."

Table 3.16-4
LOS Criteria for Signalized and Unsignalized Intersections

Level of Service	Stopped Delay Per Vehicle (seconds)	
	Signalized Intersection	Unsignalized Intersection
A	≤ 10	≤10
B	> 10 or ≤20	> 10 or ≤ 15
C	> 20 or ≤35	> 15 or ≤25
D	> 35 or ≤ 55	> 25 or ≤ 35
E	> 55 or ≤ 80	> 35 or ≤50
F	> 80	> 50

3.16.9 Impact Analysis Methodology

CEQR states that generally "deterioration in level of service within the clearly acceptable range (LOS A through LOS C) is not considered a significant impact." However, CEQR further states that the level of service must be disclosed and may constitute significant impacts on neighborhood character should they occur on residential streets. Furthermore, "levels of service that deteriorate from clearly acceptable LOS A, B or C in the Future No-Build Condition to marginally unacceptable mid-LOS D (delays great than 45.0 seconds) or unacceptable LOS E or F in the Future Build Condition would be considered significant impacts." It is noted that in cases where a LOS decreased from LOS C to LOS D but the increase in delay was less than five seconds, no mitigation action was taken. All intersections were analyzed by lane group. The same criteria are applied to unsignalized intersections as to signalized intersections. CEQR also states "for the minor street to trigger significant impacts, 90 PCEs must be identified in the Future Build Condition in any peak hour." Table 3.16-5 presents the CEQR-defined significant impacts for signalized and unsignalized intersections that have a Future No-Build Condition of LOS D or worse.

Table 3.16-5
Significant Impacts for Signalized and Unsignalized Intersections

Future ~~Baseline~~ No-Build LOS	Significant Impact Delay Time (seconds)
LOS D	5
LOS E	4
LOS F	3
LOS F with delay > 120 seconds	1

In addition to delay time, CEQR also specifies the use of volume-to-capacity (v/c) ratios as an indicator of intersection LOS, with high v/c ratios (approaching 1.0) indicating the development of problem conditions. CEQR requires the disclosure of both v/c ratios and average vehicle delays for each lane group at an intersection.

All analyses were performed using the Highway Capacity Software Model version 4.1(c/d). Model runs were conducted for the Existing Conditions traffic levels, Future No-Build traffic levels, and the traffic levels in the Future Build year. For both signalized and unsignalized intersection analysis, impacts were calculated by comparing the Future No-Build intersection delay and LOS with the intersection delay and LOS in the Future Build Condition. For both the signalized and unsignalized intersection analysis, the changes were compared with the 2001 CEQR Technical Manual criteria to test whether or not the impacts can be classified as significant. Individual study area findings are presented in the site-specific sections of this SWMP ~~FD~~EIS.

For safety impact analyses, the 2001 CEQR Technical Manual states that "assessment of impacts can generally be made at a qualitative level, but should indicate the nature of the impact, the volumes affected by or affecting such impacts, and the likelihood of its severity, if possible." Increasing pedestrian traffic at high accident locations can lead to increasingly unsafe conditions, and generating measurable pedestrian crossings at non-controlled locations leads to unsafe conditions. If high accident locations were identified, mitigation measures were explored based on the types and frequency of accidents. With the exception of the intersections analyzed for the West 135th Converted MTS and East 132nd Street Truck to Rail Transfer Station, no other intersections evaluated in this FEIS for potential traffic impacts either: (1) were included on the

list of Recent High Pedestrian/Vehicle Accident intersections in the 2001 CEQR Technical Manual or in the 2003 accident data provided by NYCDOT; or (2) were above the minimum screening threshold of five (5) or more pedestrian accidents in any year in the most recent 3-year period that require analysis. For the proposed East 91st Street Converted MTS, one intersection (York Avenue/86th Street) had five (5), three (3) and one(1) pedestrian accident(s) in 1998, 1999 and 2000, respectively. Though the five pedestrian accidents in 1998 just meets the CEQR threshold as a high accident location, there has been a steady and significant improvement in the years since. Therefore, mitigation measures were not explored at this location.

3.16.10 Typical Mitigation Measures

If significant impacts are found under the Future Build year analysis, CEQR requires the identification and evaluation of suitable mitigation measures that would restore traffic to the Future No-Build Conditions or to acceptable levels. For example, if the Future No-Build Conditions are determined to be LOS D, E or F, then a return to the Future No-Build Conditions in the Future Build year is required. If the Future No-Build LOS is A, B or C, and the LOS in the Build year deteriorates to D, E or F, then mitigation to mid-LOS D is required under the 2006 Build Conditions. The mitigation analysis varied by study area and individual intersections based on the severity of the impacts and the existing operation of the intersection. In general, all mitigation measures were evaluated for suitability based upon severity of impact, relative cost of mitigation (defined below as low, moderate or high) and the ease of implementation. Mitigation measures with a high associated cost were considered only to mitigate the most severe impacts when all other alternative mitigation measures were deemed inadequate. Mitigation measures evaluated were:

- Low Cost:
  - Signal phasing and timing modifications;
  - Parking regulation modifications;
  - Lane re-striping and pavement marking changes; and
  - Street direction and other traffic flow related changes (e.g., signage).

- Moderate Cost:
  - Intersection channelization improvements; and

- Traffic signal installation.

- High Cost (where applicable):
  - Street widenings.

Mitigation measures were also considered for locations identified as high accident intersections. Pedestrian safety mitigation measures were considered on the same basis as traffic mitigation measures in terms of Existing Conditions, severity on impact, cost and ease of implementation. Pedestrian safety mitigation measures evaluated were:

- Low Cost:
  - Advanced stop lines;
  - Addition/modification of signs; and
  - High visibility crosswalks.

- Moderate Cost:
  - Traffic signal enhancements; and
  - Addition of pedestrian safety areas (e.g., raised medians and crossing islands).

- High Cost (where applicable):
  - Pedestrian signal upgrade or installation; and
  - Roadway redesigns to benefit pedestrians.

For each study area, a summary of the mitigation measures identified and evaluated for intersections where significant impacts or high accidents were found are presented in the appropriate site-specific chapters of this SWMP FDEIS.

3.16.11 Transit and Pedestrians

The objective of the transit and pedestrian analyses is to determine whether the Proposed Plan Facilities and Alternative Facilities, as applicable, would have a significant impact on public transportation facilities and services and on pedestrian flows. Particularly, the analyses would examine the effects of the Proposed Plan Facilities and Alternative Facilities, as applicable, on rail and subway facilities and services, bus services and pedestrian flow and conditions.

The 2001 CEQR Technical Manual guidelines state that "if the proposed action is projected to result in fewer than 200 peak hour rail or bus transit riders, further transit analyses are not typically required as the proposed action is considered unlikely to create a significant transit impact." Additionally, the 2001 CEQR Technical Manual states that "projected pedestrian volume increases of less than 200 pedestrians per hour at any pedestrian element analyzed would not typically be considered a significant impact, since that level of increase would not generally be noticeable and therefore would not require further analysis."

The Proposed Plan Facilities and Alternative Facilities, as applicable, are expected to generate less than 200 employee trips per day, which is significantly lower than the 200 people per hour threshold stated in the 2001 CEQR Technical Manual. Employees traveling to and from the facilities are the only pedestrian and transit generators that would result from the Proposed Plan Facilities and Alternative Facilities, as applicable. Additionally, many of the employees will travel to and from the new facilities using automobiles, as a number of the facilities are not easily accessible by mass transit. Because pedestrian volumes and transit riders are significantly below the thresholds in the 2001 CEQR Technical Manual, further analysis will not be included. Pedestrian safety at selected intersections will be addressed according to the guidelines stated in the Traffic, Parking, Transit, and Pedestrians section of ~~this DEIS~~the site-specific chapters.

3.17 Air Quality

3.17.1 Introduction

Although located in manufacturing-zoned districts, operations that would occur within the Proposed Plan Facilities and Alternative Facilities, as applicable, would generate some air pollutant emissions within and near each site and potentially alter local air quality conditions. Also, the addition of DSNY and other agency collection vehicles to roadways in the vicinity of the Proposed Plan Facility and Alternative Facility sites would have the potential to affect local traffic conditions and air quality levels near these roadways. The air quality analyses determine whether and to what extent the Proposed Plan Facilities and Alternative Facilities would affect air quality levels at nearby sensitive land uses during construction and operations.

Pursuant to CEQR, the air quality analyses performed for each Proposed Plan Facility and Alternative Facility, as applicable:

- Describe Existing and Future No-Build air quality conditions in the New York Metropolitan Region; and
- Identify and quantify any potentially significant air quality impacts at the ~~Proposed Plan Facility and Alternative Facility~~ sites, as applicable.

Two types of analyses were conducted. ~~to estimate the air quality effect of each Proposed Plan Facility and Alternative Facility, as applicable.~~ The first estimates the impacts associated with emissions generated by on-site operations and the second estimates the potential impacts associated with off-site DSNY and other agency collection vehicle operations.

The following emission sources were considered for the analysis of on-site operations:

- Combustion emissions of diesel engines of operational equipment, including tugboats and moving and queuing collection vehicles, and MSW handling equipment (e.g., wheel loaders) that would operate inside or outside of the processing building;
- Fugitive dust emissions from MSW material handling operations (e.g., loading, unloading, transferring) that would occur inside the processing buildings;
- Re-entrained dust resulting from collection vehicles that would travel on paved roads inside and outside the processing buildings; and
- Heating plant and/or space heater emissions released from stacks on the processing buildings.

For off-site analyses, the effects of the DSNY and other agency collection vehicles traveling to and from each Proposed Plan Facility and Alternative Facility sites, as applicable, were determined by estimating pollutant concentrations at roadway intersections that would be most affected by such vehicles.

Both the on-site and off-site analyses were designed to determine whether Proposed Plan Facility and Alternative Facility operations, as applicable, would cause or exacerbate violations of applicable ambient air quality standards and/or exceed appropriate air quality guideline values or impact thresholds.

3.17.2 Air Quality Standards and Impact Significance Criteria

3.17.2.1 Ambient Air Quality Standards and Guidelines

3.17.2.1.1 National and State Ambient Air Quality Standards

National Ambient Air Quality Standards (NAAQS) have been established by USEPA for six major air pollutants: carbon monoxide (CO), nitrogen dioxide (NO_2), ozone (O_3), particulate matter (PM) (less than 2.5 microns in diameter [$PM_{2.5}$] and less than 10 microns in diameter [PM_{10}]), sulfur dioxide (SO_2) and lead (Pb). The air pollutants identified by USEPA as being of concern nationwide are CO, hydrocarbon (HC), NO_2, O_3, PM, sulfur oxides (SO_X) and Pb. Of these pollutants, those considered in this SWMP FDEIS are:

- **CO.** CO is a colorless and odorless gas that is generated in the urban environment primarily by the incomplete combustion of fossil fuels in motor vehicles. Prolonged exposure to high levels of CO can cause headaches, drowsiness, loss of equilibrium or heart disease. CO concentrations can vary greatly over relatively short distances. Relatively high concentrations of CO are typically found near congested intersections, along heavily used roadways carrying slow-moving traffic and in areas where atmospheric dispersion is inhibited by urban "street canyon" conditions. In the City, more than 80% of CO emissions are from motor vehicles. The addition of collection or other trucks to roadways that are already congested may reduce overall vehicular operating speeds and increase CO emissions.

- **HC.** HC compounds are also referred to as volatile organic compounds (VOCs). While no NAAQS have been established, this class of chemicals can act as a

precursor to the formation of O_3, for which there is a NAAQS. Impacts of the Proposed Plan Facilities and Alternative Facilities, as applicable, on ozone formation are not addressed in this analysis because these impacts occur on a larger, regional scale and any changes in emissions on a regional basis from waste disposal operations would not be significant. However, HC emissions were evaluated for the purpose of assessing human health risks due to the applicable individual toxic air pollutants, for which no NAAQS exist.

- **NO_x.** Nitrogen oxides (NO_X) include nitric oxide (NO) and NO_2. NO_X is emitted by motor vehicles and stationary sources due to the combustion of fuels. While most NO_X emissions leave the stack or exhaust pipe in the form of NO, they gradually convert to NO_2 in the atmosphere, which is the form of NO_X regulated by a NAAQS. NO_X also acts as a precursor to the formation of O_3; however, because such activity occurs on a large, regional scale and Proposed Plan Facility and Alternative Facility emissions would be insignificant on such a scale, the O_3 precursor effects of NO_X were not considered.

- **PM.** Respirable PM with an aerodynamic diameter smaller than 10 microns ~~in diameter~~ (including both PM_{10} and $PM_{2.5}$) is emitted to the atmosphere by sources such as industrial facilities, power plants, construction activity, wind erosion from paved roadways and diesel-powered vehicles, such as collection vehicles and other heavy trucks and buses. The addition of DSNY and other agency collection vehicles to, from and within a Proposed Plan Facility and Alternative Facility site, as applicable, may result in potential impacts from particulates due to tail pipe exhaust and increases in dust particles from truck travel on paved roads (i.e., re-entrained dust). Although there is a state standard for total suspended particulates (TSP), it is no longer enforced and potential impacts of TSP were not considered in this analysis because PM_{10} and $PM_{2.5}$ impacts are more representative of the health-related effects of particulate emissions.

- **SO_2.** Emissions generated from the combustion of sulfur-containing fuels, primarily oil and coal, for power generation, space heating or transportation are associated mainly with stationary sources. Potential SO_2 impacts from the operation of on-site diesel fuel-fired equipment were considered.

Pb impacts were not analyzed in this SWMP FDEIS. Pb emissions, which historically were influenced primarily by motor vehicle activity, have been reduced substantially due to the elimination of lead from gasoline. As a result, a quantitative analysis of Pb is no longer warranted.

The NAAQS specify concentrations of criteria pollutants that are not to be exceeded at ambient air quality receptor sites. NAAQS have been established for various averaging times based on how each pollutant affects human health. The estimated concentrations of criteria pollutants resulting from Proposed Plan Facility and Alternative Facility operations, as applicable, combined with the background concentrations discussed later in this document are compared to the NAAQS. The NAAQS are summarized in Table 3.17-1. The total amount of each applicable criteria pollutant generated by on-site non-fugitive sources was also estimated to determine if the total exceeds major emission source threshold values (as defined in Part 201 of NYCRR). If so, a facility would be subject to major source permitting requirements. ~~The NAAQS are summarized in Table 3.17-1.~~

Table 3.17-1
National and State Ambient Air Quality Standards
($\mu g/m^3$)

Averaging		Federal	
Contaminant	**Period**	**Primary**	**Secondary**
Carbon Monoxide (CO)	8-hour(1)	10,000 (9 ppm)	10,000
	1-hour(1)	40,000 (35 ppm)	40,000
Sulfur Dioxide (SO_2)	Annual	80 (0.03 ppm)	--
	24-hour(1)	365 (0.14 ppm)	--
	3-hour(1)	--	1,300 (0.5 ppm)
Nitrogen Dioxide (NO_2)	Annual	100 (0.05 ppm)	100
Ozone (O_3)(2)(3)	8-hour(1)(4)	0.08 ppm	0.08 ppm
	1-hour(3)	235 (0.12 ppm)	235
PM_{10}	Annual	50	50
	24-hour(2)	150	150
$PM_{2.5}$(4)	Annual(6)	15	15
	24-hour(5)	65	65
Lead (Pb)	Three-month (Calendar quarter)	1.5	--

Notes:
Source: USEPA, *National Primary and Secondary Ambient Air Quality Standards* (40 CFR 50).
(1) Not to exceed more than once per year, per monitor location, over a three-year period.
(2) During any 12 consecutive months, 99% of the values shall not exceed 150 $\mu g/m^3$.
(3) The number of days with hourly levels greater than standard shall not exceed one per year.
(4) Standards for 8-hour O_3 and for $PM_{2.5}$ were promulgated in 1997, but are not yet fully implemented by the USEPA.
(5) During any 12 consecutive months, 98% of the values shall not exceed 65 $\mu g/m^3$.
(6) Spatial average standard, applied by USEPA over a neighborhood scale.

3.17.2.1.2 Significant Impact Thresholds

USEPA is currently implementing procedures for complying with the $PM_{2.5}$ NAAQS.~~, and has not yet made a formal determination on which areas of the United States will be classified as meeting these relatively new standards. Until areas are designated and appropriate background levels established, comparison with the $PM_{2.5}$ NAAQS is not feasible. As an alternative,~~ On December 17, 2004, USEPA designated initial $PM_{2.5}$ attainment and non-attainment areas for the entire United States. All five boroughs of New York City were designated as non-attainment areas. Therefore, the $PM_{2.5}$ impacts were compared with interim significance thresholds of $\mu g/m^3$ for 24-hour impacts and 0.1 $\mu g/m^3$ for annual impacts established by NYSDEC and NYCDEP. The following approach was applied to $PM_{2.5}$:

- Potential incremental 24-hour and annual impacts from Proposed Plan Facility and Alternative Facility operations, as applicable, were estimated using the same modeling methodologies used for other criteria pollutants. For facilities ~~where current operations have little to no effect on air quality~~that are not in operations at a current time, the potential incremental 24-hour and annual impacts are the same as the impacts from the operations from the Proposed Plan Facility and Alternative Facility. Otherwise the incremental impact will be equal to the difference between impacts from existing and future operations.
- Per NYSDEC and NYCDEP policy, r~~R~~esults from the receptor having the highest 24-hour concentration were compared to a screening threshold value (STV) of 5 micrograms per cubic meter ($\mu g/m^3$) to determine if the facility and/or collection vehicle traffic have a significant short-term (24-hour) impact.
- Per NYSDEC policy, i~~I~~f primary PM_{10} emissions from the facility exceeded 15 tons per year, results from the receptor having the highest annual concentration were compared to an STV of 0.3 $\mu g/m^3$ to determine if the facility and/or collection vehicle traffic have a significant annual impact at a single receptor. Otherwise, the highest annual concentration will be included in the technical backup available upon request on compact disk.
- Per NYCDEP policy, ~~T~~the potential incremental impacts from on-site operations on an annual basis were evaluated on a spatial-average basis (neighborhood scale) as follows:
  - A 1 kilometer (km) x 1 km Cartesian receptor grid centered at the receptor having the highest estimated annual $PM_{2.5}$ concentration from the previous analysis (with 25-meter spacing in all directions) was developed. All receptors within the grid but within the Proposed Plan Facility and Alternative Facility property fence line, as applicable, were eliminated from the model input.
  - The results estimated at all receptors within the receptor grid for the on-site emissions were averaged. This value was added to the maximum annual receptor

concentration obtained in the off-site analysis. If there were no intersections within the 1 km x 1 km receptor grid, a receptor was placed at the intersection analyzed for off-site impact. The value was then added to the maximum annual receptor obtained from the off-site analysis.

- The total on-site plus off-site concentration was compared to an annual STV of 0.1 $\mu g/m^3$.
- If the neighborhood averaged impact ~~rounded to the nearest tenth (i.e., 0.15 rounds up, while lower values round down)~~ was greater than or equal to the 0.1 $\mu g/m^3$ STV, the analysis was refined further by combining the emissions from the on-site sources and off-site roadways, including intersections, into a single USEPA Industrial Source Complex Short-term Air Quality Dispersion (ISCST3) model run to determine the neighborhood average using the same methodology as above.

- Per NYCDEP policy, t~~T~~he maximum incremental impact from off-site operations on an annual basis was determined based on concentrations estimated at 15 meters from the edge of affected roadways for selected intersections. However, the off-site contribution was refined by averaging the concentration over the mobile source analysis grid. The on-site impact was then added to the impact from the ~~on~~off-site model receptor and compared to the 0.1 $\mu g/m^3$ spatial average STV as an ~~conservative~~ estimate of a spatial average concentration increment.

In addition to the NAAQS and $PM_{2.5}$ interim significance thresholds, CO incremental impact criteria known as "*de minimis*" criteria have been established under the NYCDEP's CEQR guidelines to estimate the significance of impacts from projects affecting mobile source operations. These are:

- An increase of 0.5 parts per million (ppm) or more for the 8-hour period, when baseline CO concentrations are above 8.0 ppm; and
- An increase of one-half the difference between the baseline and the standard concentration (9 ppm) for the 8-hour period when baseline CO concentrations are below 8 ppm.

3.17.2.1.3 Toxic Air Pollutants

Small quantities of a wide range of the non-criteria air pollutants, known as toxic air pollutants, that are emitted from diesel-fueled vehicles are also of concern. These pollutants can be grouped into two categories: *carcinogenic* air pollutants and *non-carcinogenic* air pollutants. Carcinogenic pollutants in diesel exhaust emissions include formaldehyde; benzene;

benzo(p)pyrene; 1,3 butadiene and acetaldehyde. Non-carcinogenic pollutants include toluene, xylenes, acrolein and various polycyclic aromatic HCs. No federal standards have been promulgated for toxic air pollutants; however, NYSDEC has established acceptable ambient levels for these pollutants based on human exposure criteria in the *Guidelines for the Control of Toxic Ambient Air Contaminants*. In this document, NYSDEC outlines short-term guideline concentrations (SGCs) and annual guideline concentrations (AGCs). Estimated concentrations of toxic pollutants were compared with these values.

USEPA has developed approaches that can be used to assess the potential impacts associated with carcinogenic and non-carcinogenic air pollutant releases. USEPA's "Hazard Index Approach," together with NYSDEC guidelines, ~~was~~ were used to assess the potential impacts associated with chronic and acute risk from the release of non-carcinogenic toxic air pollutants from each Proposed Plan Facility and Alternative Facility, as applicable. The potential impacts of non-carcinogenic air pollutant releases from on-site operating diesel-powered equipment, collection vehicles and tugboats were assessed as follows:

- Ratios of the maximum estimated pollutant concentration, divided by its respective health-related NYSDEC guideline values (SGCs and/or AGCs), were estimated for each applicable non-carcinogenic toxic pollutant;
- Short-term (1-hour) ratios were developed to assess the potential for acute risk exposure, and annual ratios were developed to assess the potential for chronic risk exposures;
- The short-term and annual ratios for each of these pollutants were summed to obtain total short-term and annual ratios of all pollutants combined;
- The total short-term and annual ratios were compared with a hazard index of 1; and
- If the total ratios were found to be less than 1, then no significant air quality impacts would occur due to these non-carcinogenic pollutant releases.

NYSDEC cancer risk thresholds, which are based on USEPA's IRIS database, were used ~~for this analysis~~to analyze the potential impact of carcinogenic air pollutants from each Proposed Plan Facility and Alternative Facility, as applicable. The potential cancer risk associated with each pollutant was estimated, and the total incremental cancer risk associated with the release of all of the carcinogenic toxic pollutants was estimated, by summing the risk associated with each of the carcinogenic pollutants on a receptor-by-receptor basis.

USEPA considers that an overall incremental cancer risk from a proposed action of less than one-in-one million is not significant. If the total combined incremental cancer risk of all of the carcinogenic toxic pollutants at the sensitive receptor locations was less than one-in-one million, cancer-related air quality impacts were determined to be insignificant.

Based on the types of pollutants associated with the Proposed Plan Facilities and Alternative Facilities, as applicable, 16~~5~~ toxic compounds that have been identified as emissions from diesel equipment and that have emission factors developed by USEPA were considered in this analysis, along with their respective NYSDEC guideline values, which were revised in 2000 (Table 3.17-2). The emission factors used for each of the toxic compounds were obtained from USEPA's AP-42 Compilation of Air Pollutant Emission Factors, Table 3.3-2 Speciated Organic Compound Emission Factors for Uncontrolled Diesel Engines, revised in October 1996.

3.17.3.1 Monitored Air Quality and Background Concentrations

Air pollutant levels in the City metropolitan area are monitored by a network of sampling stations operated under the supervision of NYSDEC. Monitored ambient air quality levels for each borough were provided by NYCDEP for use in each Proposed Plan Facility and Alternative Facility site-specific analysis, as applicable. NAAQS attainment status is based on a three-year period of monitoring, so despite the more recent data that shows no violation of NAAQS, the metropolitan area contains NAAQS non-attainment designations for some pollutants, as detailed below.

Background concentrations (i.e., pollutant levels due to emission sources not accounted for in the modeling analysis) of the criteria pollutants for the on-site and off-site air quality impact analyses were obtained primarily from NYCDEP memorandum dated February 18, 2005 received on April 18, 2003 (used in the DEIS) and revised on March 4, 2005 (used in this FEIS). These values are based on ambient monitored values for the last few years of data from NYSDEC's ambient monitoring system. More recent data from the NYSDEC Monitoring Network were used where appropriate. The revised background concentrations were added to the on-site and off-site modeling results to estimate the total pollutant concentrations in this FEIS. The background concentrations presented in Table 3.17-3 and Table 3.17-4, as well as the technical backup submitted to NYCDEP, were used for each site-specific analysis.

Table 3.17-2
Annual and Short-Term Guideline Concentrations

No.	Toxic air Pollutant	Short-Term (1-Hour) Guideline Concentration (SGC) $\mu g/m^3$	Annual Guideline Concentration (AGC) $\mu g/m^3$
Carcinogenic			
1	Benzene	1,300	0.13
2	Formaldehyde	30	0.06
3	1,3 Butadiene	--	0.0036

3.17.3 Regulatory Setting

$PM_{2.5}$ background levels were not used in this analysis because they have not yet been established by NYSDEC or NYCDEP. Instead, facility-related $PM_{2.5}$ impacts were compared to interim "significance impact thresholds" to determine the likelihood of significant impacts. Maximum modeled incremental $PM_{2.5}$ impacts (due to on-site and off-site operations only) for the 24-hour, and annual average neighborhood ~~and annual maximum~~ periods were compared against interim "significance thresholds" of 5 $\mu g/m^3$, and 0.1 $\mu g/m^3$ ~~and 0.3 $\mu g/m^3$~~, respectively.

No background values were considered for the toxic pollutant analysis because toxic pollutant impacts were assessed from a project incremental risk standpoint.

3.17.3.2 Regulatory Status

The federal Clean Air Act Amendment (CAAA) defines non-attainment areas as geographic regions that have been designated as not meeting one or more of the NAAQS. The New York Metropolitan Region is currently designated as being a severe non-attainment area for O_3 and a maintenance area (i.e., a previously designated/ re-designated non-attainment area that has been based on demonstrated compliance with the NAAQS) for CO. ~~In addition,~~ New York County (Manhattan) is designated as being a moderate non-attainment area for PM_{10}. In addition, the Metropolitan Region in now formally designated a non-attainment area for $PM_{2.5}$.

3.17.3.3 Major Stationary Source Requirements

Under federal permitting rule 40 CFR 52.21(b)(1), a new or modified facility within the New York Metropolitan Region is considered a "Major Stationary Source" (i.e., a source subject to major stationary source construction permitting requirements) if the stationary source emissions released from that facility have the potential to emit 25 tons per year or more of NO_X or VOCs, 250 tons per year or more of CO, 100 tons per year or more of PM_{10} in Manhattan and 250 tons per year or more of PM_{10} elsewhere in the City area. NYSDEC is proposing amendments to its permitting regulations (i.e., 6 NYCRR Part 231) that may impose additional permitting requirements. Under the amendments, p~~P~~otential SO_2 emissions of 250 tons or more per year would classify ~~a source as~~ as a "major" under construction permit rules.

Following the guidelines presented in NYCRR Part 201 (Permits and Registrations, Subpart 201-3 Exemptions and Trivial Activities), only emissions released within the Proposed Plan Facility and Alternative Facility (as applicable) processing buildings should be considered in these estimates. Emission estimates would be prepared for each Proposed Plan Facility and Alternative Facility, as applicable, that would be constructed as part of its air permitting process. If a Proposed Plan Facility or Alternative Facility is determined to be a major source for a pollutant, ~~which the area~~ and is located within an area that is designated as non-attainment, emission offsets may need to be obtained.

3.17.4 Methodology Used to Estimate Potential On-site Impacts

3.17.4.1 Analytical Approach

Atmospheric dispersion analyses were conducted to estimate pollutant levels at air quality receptors (i.e., points at or beyond the site fence line, as discussed in Section 3.17.4.5) surrounding each facility. The USEPA's ISCST3 model was used for this analysis. ISCST3 is a versatile model that is often used to predict pollutant concentrations from continuous point, area, volume and open pit sources. This model is often preferred by USEPA because of its many features that enable users to estimate concentrations from nearly any type of source emitting non-reactive pollutants.

The following dispersion modeling options and assumptions were applied:

- Unless the topography surrounding a study area included substantial changes in elevation, flat terrain was assumed;
- As only smaller particulate matter and gaseous pollutants were considered, gravitational settling and deposition of particulate matter was not included;
- Possible wake effects on point source plume dispersion from the Proposed Plan Facility and Alternative Facility, as applicable, and/or other nearby buildings were considered; and
- For each pollutant, an appropriate set of point, area and volume emission source parameters associated with each operation at each Proposed Plan Facility and Alternative Facility, as applicable, was developed.

USEPA's ~~Industrial Source Complex Air Quality Dispersion (~~ISCST3~~)~~ model uses different dispersion coefficients and mixing heights in rural vs. urban settings. The Auer land use technique was applied to each site to determine whether the rural or urban dispersion coefficients and mixing heights should be applied.

Four types of emission sources that were anticipated to operate inside of processing buildings were considered in the analysis. These include emissions from diesel engines for equipment used in waste handling operations, diesel-fueled collection vehicles, heating equipment and particulate emissions from waste handling operations. Emission sources operating outside of the processing building that were considered included collection vehicles and tugboats.

The mechanical ventilation system of each Proposed Plan Facility and Alternative Facility, as applicable, would be designed to force emissions generated in the building into the atmosphere through rooftop vents, which were input into the ISCST3 model as point sources. To negate the effects of plume rise for horizontally-vented emissions, a velocity of 0.001 meters per second (m/s) and a stack diameter of 0 meters (m) was used based on CEQR guidance. If the facility's heating plant had a separate exhaust stack, its emissions were considered as a separate point source.

Moving collection vehicles were considered as emission sources located along the internal roadway system of each Proposed Plan Facility and Alternative Facility, as applicable, and modeled using the volume source, or in some cases area source, algorithms incorporated into the ISCST3 model. Emissions from vehicles operating within 50 meters of each site boundary were modeled together with the emissions from the on-site sources. It was assumed that all vehicles moving on site were traveling at 5 ~~miles per hour (~~mph~~)~~. Tugboats were considered area sources, with emissions distributed evenly over the area of tugboat operations.

The concentrations of each pollutant were estimated by modeling all of the sources of each pollutant from each Proposed Plan Facility and Alternative Facility, as applicable, in one modeling run.

3.17.4.2 Meteorological Data

Detailed dispersion analyses were conducted using a set of meteorological conditions representative of the New York metropolitan area for the latest available five consecutive years of compiled meteorological data. Meteorological data used consisted of LaGuardia Airport surface data and Brookhaven mixing height data for the years 1998~~7 and~~ through 2002~~1~~ for the Proposed Plan Facilities and some Alternative Facilities. For the remaining Alternatives, the 1997 through 2001 meteorological data was used.

3.17.4.3 Emission Sources and Stack Parameters

In general, vendor-supplied information was used to identify site-specific emission source parameters for use in the dispersion analysis. However, in the absence of vendor-supplied data, the following assumptions relating to source (stack) parameters for Proposed Plan Facilities and Alternative Facilities, as applicable, were applied (unless otherwise specified):

- For outdoor moving and idling/queuing collection vehicles, emissions were input as adjacent volume or area sources with a release height of six feet above the elevation of the internal Proposed Plan Facility and Alternative Facility (as applicable) roadway ~~or ramp~~for volume sources, and 12 feet above the elevation of the ramp for area sources. In some cases, however, to refine the analysis, the area source algorithm was used in the event that the source-to-receptor distances ~~are~~were less than three times the initial lateral dimension of the volume sources. For example, if in the case of collection vehicles the lateral dimension of the volume sources were 12 feet, this

distance would be 36 feet. ~~The Rrelease height of the area sources of 12 feet was used. the idling emissions were separated from the volume sources and input as point sources with a release height of 12 feet~~. The dimension of volume sources and area sources were determined on a case-by-case basis considering roadway geometry of each site.

- For tugboats, release heights were assumed to be 10 meters (32.81 feet) above the water level based on exhaust heights above water and a minimum amount of expected plume rise. Area source dimensions were determined for each site based on the size and shape of the operational area anticipated.
- Heating plant exhaust stack emissions and processing building exhaust were modeled as point sources.

Due to the fact that only a small number of employee vehicles are anticipated to operate on site for a small fraction of time during the analysis periods considered, emissions from the vehicles were not considered.

The following assumptions were applied to emission sources at each Proposed Plan Facility and Alternative Facility, as applicable:

- USEPA PART 5 and MOBILE5b were used for the initial analysis of prospective sites performed prior to January 2004~~ for initial analysis for prospective sites~~. To refine the analysis, a~~. A~~ final version of MOBILE6.2, ~~was~~ released in February 2004, ~~and~~ was used for the Proposed Plan Facilities and some Alternative Facility analyses. A supplemental analysis will be performed if any Alternative Facilities are selected as part of the Proposed Plan and were not analyzed using MOBILE 6.2.~~ and in instances where a more refined analysis was warranted.~~
- CO, NO_2 and total HC emission factors for all moving and idling vehicles were estimated using the USEPA ~~MOBILE5b/~~MOBILE6.2 vehicular emission factor model. To estimate the emission rates of CO, NO_X and HC for moving vehicles, emission factors (based on anticipated travel speeds~~ for moving vehicles~~) were multiplied by the distance that an average vehicle will travel and then by the number of moving vehicles.
- Each collection vehicle was considered a heavy, heavy duty diesel vehicle (HHDDV) with a gross vehicle weight of 64,000 pounds when full and 44,000 pounds when empty.
- Exhaust and fugitive dust PM_{10} emission factors for moving vehicles (e.g., re-entrained dust, exhaust, brakes and tires) were estimated using the USEPA Publication AP-42, Section 13.2.1 [12/03], Equation 1:

$$E = k\left(\frac{sL}{2}\right)^{0.65} \times \left(\frac{W}{3}\right)^{1.5} - C$$

where:

E = Particulate emission factor;
~~K~~k = Particle size multiplier (1.8g/veh-mile for $PM_{2.5}$ and 7.3g/veh-mile for PM_{10});
sL = Road surface silt loading (g/m^2);
W = Average weight (tons) of the vehicles traveling the road, and
C = Emission factor for 1980s vehicle fleet exhaust, brake wear and tire wear (0.1617g/veh-mile for $PM_{2.5}$ and 0.2119g/veh-mile for PM_{10}).

- For queuing vehicles (exhaust PM_{10}), the emission factors were estimated using MOBILE6.2. To estimate the emission rate (grams per hour [g/hr]), the emission factor for moving vehicles (grams per vehicle-mile [g/veh-mile]) was multiplied by the distance that an average vehicle would travel, and then by the number of moving vehicles. In some cases, because of low speed (i.e., less than the 10 mph minimum speed for which the AP-42 equation is applicable), emission factors were reduced by a factor of 50% to account for the fact that speeds would be restricted to 5 mph on site.
- A silt loading factor of 0.4 (i.e., factors that are a function of the dust of the roadway that influence resuspended dust emission rates) was used for calculating PM_{10} emissions from collection vehicles.
- Low-sulfur fuel is used in DSNY collection vehicles, so a reduction from 500 ppm to 15 ppm was applied.
- $PM_{2.5}$ emission rates for collection vehicles were estimated using a similar methodology as used for PM_{10} except that re-entrained dust was not considered for $PM_{2.5}$. This is because re-entrained $PM_{2.5}$ emissions from traffic are considered by New York regulatory agencies to be negligible for on-site vehicles at speeds of 5 mph or less. If no $PM_{2.5}$ emission factor was available for a particular type of source, PM_{10} emission factors were conservatively utilized.
- SO_2 emission factors for diesel-fueled equipment and idling collection vehicles were estimated based on the allowable sulfur content in diesel fuel and estimated fuel utilization rates. These factors were calculated using the following equation from USEPA's "Exhaust Emission Factors for Nonroad Engine Modeling – Compression Ignition."

$$SO_2 = BSFC \times 453.6 \times (1 - 0.022) - HC \times sulfur\ \ weight\ \ fraction \times 2$$

~~where~~where:

SO_2 = SO_2 emission factors in grams per horsepower hour (g/hp-hr);

BSFC	=	In-use adjusted Brake-Specific Fuel Consumption in pounds per horsepower-hour (lb/hp-hr) (from Table 1 of the above-mentioned document, for different engine powers and years);
453.6	=	The conversion factor from pounds to grams;
1-0.022	=	An adjustment for sulfur converted to direct PM;
HC	=	The in-use adjusted hydrocarbon emissions in g/hp-hr;
Sulfur weight fraction	=	The weight fraction of sulfur (0.003 for tugboat diesel fuel, 0.000015 for DSNY on-road and nonroad diesel fuel, 0.0004 for non-DSNY on-road diesel fuel and 0.0005 for non-DSNY nonroad diesel fuel); and
2	=	Grams of SO_2 formed from a gram of sulfur.

Regarding the operation of these engines, the following assumptions were made:

- All engines were operating at an average of 70% of maximum engine horsepower during both peak hour and annual average conditions.
- All engines were operating at an average of 20% of maximum engine horsepower while idling.
- Emission factors for space heaters and boilers were obtained from USEPA's AP-42 for natural gas-fired facilities. (Table 1.4-1 for CO and NO_X and Table 1.4-2 for PM, SO_2 and VOC [or HC]).
- The quantity of dust (PM_{10} and $PM_{2.5}$) emissions generated by waste handling (transfer) operations were estimated based on Proposed Plan Facility and Alternative Facility (as applicable) throughput and the following USEPA AP-42 (Section 13.2.4 [~~12/03~~1/95], Equation 1) equation:

$$EF = k \times (0.0032) \times \frac{(u/5)^{1.3}}{(M/2)^{1.4}} - C$$

where:

EF	=	The emission factor in pounds per ton (lb/ton);
k	=	The particle size multiplier (0.35 for PM_{10} and 0.11 for $PM_{2.5}$);
u	=	Mean wind speed (miles per hour), assumed to be 2.2 mph (equivalent to 1.0 m/s); and
M	=	Material moisture content, assumed to be 10% for residential solid waste. This is a conservative estimate based on available data from DSNY's 1992 Solid Waste Management Plan, lower than the moisture content of several low-moisture content categories (i.e., paper, plastics, textiles, wood); ~~and.~~
~~C~~	=	~~Emission factor for 1980 vehicle fleet exhaust, break wear and tire wear.~~

3.17.4.3.1 Emissions from Tugboats

Emissions rates of diesel-fueled tugboats were estimated as follows:

- Values provided in Table 3.5 of the USEPA document, Analysis of Commercial Marine Vessels Emissions and Fuel Consumption Data (February 2000), were used to determine the emission factors for CO, NO_X, HC, PM_{10} and SO_2. A rated horsepower of 1,800 horsepower and a load factor of 0.2 for each tugboat maneuvering at each Proposed Plan Facility and Alternative Facility, as applicable, were assumed. Tugboat emission factors used in this analysis are provided in Table 3.17-5.
- It was assumed that emissions from tugboats were released as area sources located within a tugboat operating area. This area was determined on a site-by-site basis depending on the layout of each facility.

Following CEQR guidance, a diesel fuel sulfur content of 0.3% was assumed for tugboats.

Table 3.17-5
Tugboat Emission Factors

Contaminant	Emission Factor (g/kw-hr)
CO	4.344
NO_X	17.634
$PM_{10}/PM_{2.5}$	0.321
HC	1.132
SO_2	1.968

Based on design assumptions, tugboats were assumed to operate for five hours per day. Peak hour emission rates were estimated by assuming that one tugboat would be operating for the entire hour. Annual average rates were estimated by assuming that one tugboat was operating at the Proposed Plan Facility and Alternative Facility, as applicable, for four hours per day, 302 days per year.

3.17.4.4 Coordinate System and Receptors

A Universal Transverse Mercator (UTM) coordinate system was used to establish geographic coordinates of buildings, sources and receptors for each Proposed Plan Facility and Alternative Facility, as applicable. These coordinates were input into ~~to~~ the modeling analysis for each Proposed Plan Facility and Alternative Facility (as applicable) location.

Locations of ambient air receptors (i.e., sensitive land uses where air quality concentrations are estimated) surrounding each Proposed Plan Facility and Alternative Facility, as applicable, were developed. These included locations outside of property and fence line boundaries where the general public has access. Areas over water that were within either the tugboat operating areas or the bulkhead lines were excluded. The following sets of receptors were developed around each Proposed Plan Facility and Alternative Facility, as applicable:

- A Cartesian ground-level (i.e., at 1.8 meters above the ground) receptor grid out to a distance of approximately 500 meters from the site property line in all directions, in 50-meter increments, including over water;
- Discrete elevated receptors (e.g., windows, balconies or air intakes), if any;
- Discrete sensitive land uses, such as playgrounds, schools and residential areas; and
- Property line or boundary receptors that were located in 15-meter increments around each site.

3.17.4.5 Operating Scenarios

Emission rates of each pollutant from all sources of that pollutant were estimated for each operation that would occur at each Proposed Plan Facility and Alternative Facility, as applicable. Separate analyses were conducted to estimate short-term (1-hour, 3-hour, 8-hour and 24-hour) pollutant levels and long-term (annual average) pollutant levels. Short-term emission estimates were based on peak 1-hour activity levels at each site; long-term estimates were based on annual average activity levels at each site. It was possible that some of the short-term emission rates, especially for the 24-hour estimates as determined in this manner, would significantly overestimate maximum values. If 24-hour impacts based on the peak 1-hour emission rates exceeded the thresholds of concern, more realistic hourly distributions or period average estimates of emissions were developed to refine the analysis on a case-by-case basis.

Based on anticipated operating scenarios from DSNY, it was assumed that each Proposed Plan Facility and Alternative Facility, as applicable, would operate an average of two shifts per day, 302 days per year. Evaluations were made for a 2006 analysis year using appropriate emission factors, background values and traffic estimates. Because vehicular emission factors are projected to decrease in future years as a result of increasingly stringent emission control requirements, concentrations were anticipated to decrease in future years.

The assumptions made regarding the operation of each piece of equipment at each Proposed Plan Facility and Alternative Facility, as applicable, are presented in the air quality technical backup documentation submitted to NYCDEP.

3.17.5 Methodology Used to Estimate Potential Off-Site Impacts

3.17.5.1 Analytical Approach

Mobile source analyses were conducted to estimate concentrations of CO, PM_{10} and $PM_{2.5}$ at locations (e.g., congested intersections) near each Proposed Plan Facility and Alternative Facility, as applicable, that might be affected by the addition of DSNY and other agency collection vehicles. Analyses were conducted for roadways in the vicinity of each Proposed Plan Facility and Alternative Facility, as applicable, to estimate whether changes in the number, routing and/or scheduling of the collection vehicles would cause or exacerbate violations of applicable NAAQS and/or exceed applicable CEQR impact thresholds.

Maximum 1-hour and 8-hour CO concentrations and maximum 24-hour and annual PM_{10} and $PM_{2.5}$ concentrations were estimated as appropriate at analysis sites near each Proposed Plan Facility and Alternative Facility, as applicable, using procedures provided by the 2001 CEQR Technical Manual and by NYCDEP. While pollutant levels were estimated at multiple receptor locations near each analysis site, only the highest levels predicted at any of these locations were reported as an indication of the maximum levels for the analysis site as a whole.

3.17.5.2 Selection of CO Analysis Sites

The selection of analysis sites for detailed microscale modeling of CO impacts was completed based on the number of facility-generated collection vehicles that would be added to signalized intersection locations during peak 1-hour traffic conditions, and a comparison of these values to CEQR screening impact thresholds. These thresholds were established to identify locations where air quality levels might be potentially affected by the addition of such vehicles. These impact thresholds, which are region-specific, are provided in Table 3.17-6.

Table 3.17-6
CEQR CO Screening Thresholds

Location	Incremental 1-hour Vehicular Trips (Per Intersection)
Manhattan between 30th and 61st Streets	75 or more new auto trips
Downtown Brooklyn	50 or more new auto trips
Long Island City	50 or more new auto trips
All Other Areas	100 or more new auto trips

These thresholds were established for facility-generated passenger cars. An appropriate factor of 1.5 was applied to account for the difference in traffic operations (e.g., ~~affect~~ effect on approach capacity, queuing and operating speed from larger vehicles). This factor is based on the information provided in the HCM 2000, which states that a heavy-duty vehicle is equivalent to approximately 1.5 passenger cars.

Locations exceeding the traffic impact thresholds were identified, and for each Proposed Plan Facility and Alternative Facility, as applicable, up to four sites were selected for a detailed microscale analysis using the following criteria:

1. Locations with high traffic volumes under the ~~future~~Future No-Build Condition that would experience the largest increases in incremental, facility-generated traffic volumes. Changes in traffic volumes are the major factor in the selection of PM_{10} and $PM_{2.5}$ analysis sites.

2. Locations with a Future No-Build LOS of C or worse that would experience a change in LOS between the Future No-Build and Future Build Conditions.
3. Locations with a change in delay of any approach link of 10 seconds or more between ~~future~~Future No-Build and Future Build Conditions, where the v/c ratios are greater than 0.85 and surveyed travel speeds ~~are~~ were less than 10 mph.

If the microscale analysis had indicated potential violations of the NAAQS at any of the analysis sites selected, then additional representative locations in the vicinity would have been analyzed based on the site selection criteria described above. This, however, was not the case.

The analysis sites considered near each Proposed Plan Facility and Alternative Facility, as applicable, are presented in the site-specific analysis sections of this ~~SWMP~~ FDEIS.

3.17.5.3 Selection of PM_{10} Analysis Sites

PM_{10} analyses were conducted at up to five intersections near each Proposed Plan Facility and Alternative Facility with the highest volumes of facility-generated collection vehicles. Where appropriate, these locations were the same as those for the CO analysis.

3.17.5.4 Selection of $PM_{2.5}$ Analysis Sites

Detailed mobile source $PM_{2.5}$ analyses were performed for intersections near each Proposed Plan Facility and Alternative Facility that would experience a facility-related increase of 21 trucks per hour or ~~greater~~ more for the peak project traffic demand hour. Prior sensitivity studies by NYCDEP have found insignificant $PM_{2.5}$ impacts with a facility-generated increase of less than 21 trucks per hour.

3.17.5.5 Analysis Years

Analyses were conducted for the following years:

- ~~2002/~~2003 (based on when traffic data were collected) to estimate air quality concentrations under Existing Conditions; and

- 2006 to estimate air quality concentrations under Future No-Build and Future Build Conditions.

3.17.5.6 Traffic Data

Traffic data were developed for peak analysis periods for each set of analysis conditions. The HCM 2000 methodology and field monitoring data were used to develop the following traffic data necessary for the air quality analysis for all the roadway links within 1,000 feet of each of the selected analysis sites:

- Peak hour traffic volumes (traffic volumes for the daily 1-hour period with the highest morning [AM] and afternoon [PM] background volumes) obtained from traffic analysis;
- Traffic volumes during periods with the highest number of facility-generated vehicles (facility peak);
- Average peak hour free flow travel speeds for signalized approaches and average travel speeds for unsignalized roadway approaches;
- Vehicle classifications (percent autos, sport-utility vehicles [SUVs], medallion taxis [where applicable], light-duty and heavy-duty trucks and buses);
- Width of traveled roadways (the effective width of the roadway);
- Signal timing data (cycle length, red time length);
- Number of effective moving lanes and exclusive turn lanes;
- Saturation flow rates (i.e., the maximum amount of vehicular throughput) per lane; and
- Arrival rate at signalized approaches.

The CO ~~and~~, PM_{10} and $PM_{2.5}$ analyses were conducted for up to three traffic periods (AM peak, facility [or midday] peak and PM peak). ~~The $PM_{2.5}$ analysis was conducted for facility peak periods.~~ It was generally assumed for these analyses that the traffic volumes during these traffic periods would occur for every hour of the 8-hour, 24-hour and annual average analysis periods. At these locations where exceedances of either the NAAQS or significance thresholds were estimated using this conservative assumption, refined Tier II analyses were conducted using hour-by-hour traffic conditions for the 8-hour, 24-hour and annual average analysis periods for Proposed Plan Facilities and some Alternatives. For Alternatives that show an exceedance of NAAQS or significance thresholds that did not undergo a Tier II analysis in this FEIS, a supplemental environmental review will be conducted if that Alternative is selected as a Proposed Plan Facility.

3.17.5.7 Vehicular Emissions

3.17.5.7.1 Carbon Monoxide

Mobile source CO emissions for the Proposed Plan Facilities and some Alternative Facilities were estimated using the USEPA MOBILE 6.2 emission factor program, and for the remaining Alternative Facility sites were estimated using the USEPA MOBILE 5b (EPA-AA-AQAB-94-01) emission factor program. A supplemental analysis will be performed if any Alternative Facilities are selected as part of the Proposed Plan and were not analyzed using MOBILE 6.2. The most current state- and City-approved input parameters were used to estimate existing and future emission factors. Input files for the 2003 and 2006 analysis years, showing parameters recommended by NYCDEP, including local vehicular age-distribution rates, inspection/maintenance and anti-tampering program credits, and low emission vehicle (LEV) program credits, are presented in the air quality technical backup submitted to NYCDEP.

Taxi emissions for 2002/2003 and 2007 were modeled where appropriate (i.e., near the East 91st Street and West 59th Street Converted MTSs) by using the latest version of MOBILE5b/MOBILE6.2 obtained from NYCDEP for new medallion taxis. Specific vehicle age and mileage accumulation distribution for taxis were also incorporated, and the inspection and maintenance, anti-tampering and LEV program credits that are applicable to light-duty medallion taxis were applied.

3.17.5.7.2 Particulates

Mobile source PM_{10} and $PM_{2.5}$ emissions for the Proposed Plan Facilities and some Alternative Facilities were estimated using the USEPA MOBILE 6.2 emission factor program for idling plus moving vehicles emissions, and AP-42 for moving vehicle emissions. For the remaining Alternative Facility sites, PM_{10} and $PM_{2.5}$ mobile source emissions were estimated using USEPA's PART 5 for idling plus moving vehicle emissions and AP-42 for moving vehicle emissions. A supplemental analysis will be performed if any Alternative Facilities are selected as part of the Proposed Plan and were not analyzed using MOBILE 6.2. The most current state- and City-approved input parameters at the time of the analysis were used to estimate existing and future emission factors. Parameters recommended by NYCDEP included local

vehicular age-distribution rates. Emissions from moving and idling vehicles were estimated for all vehicle types; idle exhaust PM_{10} and $PM_{2.5}$ emissions were estimated only for heavy-duty diesel trucks and buses because emissions from idling vehicles could not be calculated for non-heavy duty diesel vehicles. ~~using USEPA's PART 5~~ Idle PM_{10} and $PM_{2.5}$ emissions from non-heavy duty diesel vehicles (HDDVs) are considered to be negligible in comparison to the other idling and moving vehicle emissions estimated for this analysis.

Emissions of fugitive dust (i.e. emissions caused by the re-entrainment of dust into the air by moving vehicles) are primarily dependent on vehicle weight and on the surface silt loading. At the direction of the NYCDEP, the following silt loading factors were used for estimating PM_{10} and $PM_{2.5}$ emissions:

- 0.16 for roadways with more than 5,000 vehicles per day (NYSIP, 1995);
- 0.10 for principle and minor arterials with more than 5,000 vehicles per day (NYSDEC & NYCDEP, 2002);
- 0.015 for expressways (NYSDEC); and
- 0.4 for roadways with fewer than 5,000 vehicles per day (AP-42, 1997).

An average vehicle fleet weight of 6,000 pounds was used for all analyses (NYSIP, 1995), where the area (or Borough) specific average fleet weight was not available (see Table 3.17-7).

Table 3.17-7
Average Fleet Weight by Borough[1]

County	Average Fleet Weight (pounds)
Bronx	5,149
Kings	5,055
Manhattan	5,085
Queens	5,119
Richmond	5,085

(1) Source: NYCDEP, 2005.

Re-entrained dust was considered for the 24-hour $PM_{2.5}$ analysis (incremental contribution at receptors three meters away from the edge of the roadway). However, re-entrained dust was not included in the $PM_{2.5}$ annual neighborhood analysis due to the fact that existing neighborhood-scale ambient air monitoring data indicates that on a long-term (annual) average very little paved road dust is collected by $PM_{2.5}$ monitors. Most $PM_{2.5}$ samples collected in the City have been found to consist primarily of combustion-related emissions; although, on a short-term (24-hour) basis, especially near road fugitive sources, this may not always be the case.

3.17.5.7.3 Ambient Temperature

Following CEQR guidance, CO mobile emission rates were computed for Proposed Plan Facilities and some Alternatives with the MOBILE6.2 model, and for the remaining Alternatives with the MOBILE 5b model, using ambient temperatures for winter conditions of 50°F for Manhattan and 43°F for the rest of the City. Ambient temperatures are not a required input for PM analyses.

3.17.5.7.4 Vehicle Classification

Vehicle classification data required to determine composite emission factors were based on traffic survey data and included percentages of light duty gasoline vehicles (LDGVs), SUVs, medallion taxis, light-duty trucks, heavy-duty trucks and buses. [Based upon current CEQR guidance, SUVs were classified as light-duty gasoline trucks (LDGT). ~~with 75% of SUV emissions modeled as LDGT1, while the remaining 25% were LDGT2. The two groups (LDGT1 and LDGT2) are based on local registration data. The registered split between LDGT1 and LDGT2 used in the analysis was 73% to 27%, respectively.~~ The split between heavy duty gasoline vehicles (HDGVs) and HDDVs was based on local registration data.] ~~values presented in NYCDEP's Report #34 for each borough during a particular time period.~~ All Metropolitan Transportation Authority (MTA) and private commuter buses and DSNY and other agency collection vehicles were considered as HDDV. Traffic-related data used in this analysis ~~are~~ were presented in the air quality technical backup submitted to NYCDEP and traffic technical backup submitted to NYCDOT.

3.17.5.7.5 Thermal State Data

Hot and cold vehicle thermal state conditions for background automobile traffic were obtained from NYCDEP's Report #34 (see Table 3.17-~~7~~8), where applicable. Based upon current CEQR guidance, SUVs are assumed to have the same thermal states as automobiles. These data were input into the ~~MOBILE 5b/MOBILE6.2~~ model for each borough for each applicable time period and roadway type. Light duty truck operating conditions (excluding SUVs) were based on data supplied by the NYMTC, as presented below. All taxis and heavy-duty trucks were assumed to be operating in a hot-stabilized mode.

Table 3.17-~~7~~8
Thermal State Conditions for Light Duty Gasoline Trucks

Location	% Cold Non Catalytic	% Hot Start	% Cold Catalytic
Manhattan	3.2	45.3	4.1
Rest of City	5.4	50.5	5.1

3.17.5.8 Dispersion Modeling

The CO dispersion analysis was conducted using USEPA's dispersion model, CAL3QHC, which uses worst-case meteorological data to estimate 1-hour CO concentrations. Eight-hour maximum CO concentrations were estimated by multiplying the 1-hour maximum concentrations by a "persistence factor" (see ~~below~~Section 3.17.5.10). The CAL3QHCR dispersion model was used to estimate peak 24-hour and annual average PM_{10} and $PM_{2.5}$ concentrations. The CO, PM_{10} and 24-hour $PM_{2.5}$ analyses followed USEPA's Intersection Modeling Guidelines (EPA-454/R-92-005) for modeling methodology and receptor placement. These air quality dispersion analyses for CO, PM_{10} and 24-hour $PM_{2.5}$ were conducted as follows:

- All major roadway segments (links) within approximately 1,000 feet of each intersection were considered. Elevated sources were included where appropriate.
- Receptors were placed: (1) near the midpoint of the adjacent sidewalks (generally 6- to 7½-feet from the curb line) and set back from the corner of the intersection in accordance with USEPA's modeling guidelines; (2) adjacent to queued approaches at

the corner of each intersection and set back at 25, 50 and 75 meters from the corner, as well as at the mid-block location, if appropriate; and (3) near sensitive land uses (schools, hospitals, etc).

- Receptor heights were 1.8 meters (6.0 feet) above ground level.

In addition to the above receptors, for the annual neighborhood average $PM_{2.5}$ analysis, receptors were placed at a distance of 15 meters (49 feet) from the curb line and set back from the corner of the intersection in accordance with USEPA's modeling guidelines (i.e., at the corner of each intersection and set back at 25, 50 and 75 meters from the corner, as well as at the mid-block location, as appropriate).

3.17.5.9 Meteorological Conditions

Reasonable worst-case meteorological conditions shown in Table 3.17-98 were used to estimate peak 1-hour CO concentrations.

Table 3.17-98
Reasonable Worst-Case Meteorological Conditions[1]

Condition	Worst Case
Wind Speed	1 m/s (2.25 mph)
Stability Class	D (neutral stability, meaning moderate mixing)
Temperature	50°F for Manhattan, 43°F for the rest of NYC
Mixing Height	1,000 meters (0.6 mile)
Wind Angles	5 degree increments from 0 degrees to 360 degrees
Surface Roughness Factor[1]	▪ 321 centimeters (cm) for Manhattan CBD; ▪ 370 cm for Hunts Point, Bronx and Southwest Brooklyn; and ▪ 175 cm for Greenpoint, Hamilton Avenue, Brooklyn, North Shore and Queens

Note:
[1] Source: EPA-454/R-92-006, User's Guide to CAL3QHC version 2.0, Table 1.

Peak 24-hour and annual average PM_{10} and $PM_{2.5}$ concentrations were estimated using five consecutive years of meteorological data from LaGuardia Airport (19987 to 20021).

3.17.5.10 Persistence Factors

Peak 8-hour concentrations of CO were obtained by multiplying the highest peak hour CO estimates by persistence factor values presented in Table 3.17-~~9~~10 for each affected area. These factors, obtained from NYCDEP, account for the fact that over the 8-hour periods, vehicle volumes will fluctuate downwards from the peak, vehicle speeds may vary and meteorological conditions including wind speed and wind direction will vary as compared to the very conservative assumptions used for the single hour.

Table 3.17-10~~9~~
Eight-Hour Persistence Factors

Location	Factor
Midtown Manhattan	0.77
Rest of the City	0.70

Maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced traffic only) for the 24-hour and annual periods were compared against interim "significance thresholds" of 5 $\mu g/m^3$ and 0.3 $\mu g/m^3$, respectively.

3.17.6 Combined Impact Analysis

For those locations where detailed on-site and off-site air quality analyses were performed, a combined source analysis was conducted for $PM_{2.5}$ by adding the predicted on-site results to the predicted off-site results at the off-site receptor location with the highest reported off-site 24-hour and maximum annual neighborhood average $PM_{2.5}$ concentrations. The combined air quality results are reported in Chapters 4 through 31 of this FEIS, as applicable.

Since publication of: (1) the EIS-level air quality analysis for Converted MTSs presented in Appendix D to this FEIS - the Commercial Waste Management Study, Converted MTSs Commercial Waste Processing and Analysis of Potential Impacts -Volume III; and (2) the DEIS, the air quality analyses were revised using the USEPA MOBILE 6.2 emission factor program

(for Proposed Plan Facilities and some Alternatives), the updated background pollutant concentrations, and based on final facility designs. For processing only DSNY-managed Waste at the proposed Converted MTSs, the combined air quality results are reported in Chapters 4 through 7 and Chapters 19 through 22 of this FEIS. The combined air quality results of processing DSNY-managed Waste plus Commercial Waste at the Converted MTSs are reported in revised Tables A.4-1 through A.4-16 in Appendix D of this FEIS.

3.17.7~~6~~ Mitigation Measures

3.17.6.1 On-Site Air Quality

Mitigation measures could include changes: (1) to the number and/or types of operating pieces of equipment to lower emissions; (2) in operations to limit the length of time a piece of equipment is operating; or (3) to the Proposed Plan Facility and Alternative Facility (as applicable) design to modify the location of a source or sources with respect to off-site receptors. If required, site-specific mitigation is addressed in Chapters 4 through 31 of this SWMP F~~D~~EIS.

3.17.6.2 Off-Site Air Quality

Mitigation measures could include changes to DSNY and other agency collection vehicle routes and/or temporal distribution. If required, site-specific mitigation is addressed in Chapters 4 through 31 of this SWMP F~~D~~EIS.

3.18 Odor

3.18.1 Introduction

Design of a modern solid waste transfer facility includes environmental controls within the processing building to minimize odors emitted from on-site waste transfer operations. Effective odor control is implemented through a variety of facility design features, such as maintaining negative air pressure in the tipping floor area of the processing building to prevent untreated odors from escaping to the outdoors, and operational procedures. NYSDEC Part 360 Solid Waste Facility Regulations require that odors be controlled effectively so that they do not constitute a nuisance or hazard to health, safety or property. City Zoning Regulations require that odors not be detectable at any point along or beyond lot lines.

An odor analysis was conducted to estimate the potential impacts of the odor sources in the vicinity of each Proposed Plan Facility and Alternative Facility, as applicable, and to determine if additional design or operational measures would be required for odor mitigation.

3.18.2 Overview

Typically, odors, such as those generated from wastewater treatment plants, composting operations and landfills, can be evaluated by obtaining air samples and analyzing them to identify the odorous compounds, such as ammonia, sulfides, mercaptans and others. Concentrations of these compounds can be compared to published odor detection thresholds to determine if the compounds would be detected. Many odor studies have been conducted at wastewater treatment plants, composting facilities and landfills to identify the types and concentrations of compounds present from these operations. For example, the *Final Generic Environmental Impact Statement for the New York City Sludge Management Plan* dated May 1992 (Sludge Composting EIS) characterized odors and non-criteria air pollutants from the City Sludge Composting Facilities using indicator compounds (such as sulfides, ammonia and hydrogen sulfide), and the June 2003 FEIS for the Newtown Creek WPCP Track 3 Upgrade characterized odors using hydrogen sulfide (H_2S) as an indicator compound.

In ~~the current~~this ~~current~~ study, odors have not been characterized by measuring just a particular compound or group of compounds, but rather~~,~~ by applying a "whole air" odor analysis approach. This approach considers the odor level of the whole sample, based on evaluation in the laboratory by a representative group of individuals referred to as an "odor panel."

Odors generated from residential MSW are dependent upon the composition of the waste disposed, which can vary widely from day to day and from household to household (as opposed to odors from decomposed MSW in landfills that are attributed to specific chemical compounds, such as hydrogen sulfide, as the waste undergoes decomposition). The odors are also affected by factors such as the residence time of the waste before it is disposed, the moisture content of the waste, and ambient temperature. In addition to the residential MSW, waste from other City and state agencies (e.g., office waste, brush and furniture) would be transported to the Proposed Plan ~~Facility~~ Facilities and Alternative ~~Facility~~Facilities, as applicable and mixed in with the MSW.

The current odor study is based on odor panel analysis of several types of odor emissions sources connected with solid waste handling and processing, including:

- Full barges (containing uncovered, loose, solid waste) moored outdoors;
- Empty barges (with solid waste debris) moored outdoors;
- Process building vents/stacks;
- Shipping container (containing compacted waste) vent openings; and
- Waste collection vehicles.

The 2001 FEIS odor study included odor sampling from the first four categories of sources listed above. The ~~current~~ FEIS study included sampling of DSNY waste collection vehicles, and also makes use of separate processing building vent sampling that was conducted in the summer of 2003 for several commercial waste processing facilities.

The first two types of sources listed above are relevant to the alternative for re-use of the City's Existing MTSs. The last three types of sources are relevant to the Proposed Plan ~~Facility~~ Facilities and Alternative Facilities~~y~~, as applicable. For the Proposed Plan Facilities and

Alternative Facilities, as applicable, only sealed containers would be loaded on barges and shipped to out-of-City disposal sites. Sampling of the MTS vents in the prior study yielded detectable odors, while sampling of the shipping container vents found no significant odor emissions. Therefore, the modeling analysis for this FDEIS considers odor emissions from each of the above source types except for shipping containers, for which odor generation is expected to be insignificant.

Table 3.18-1 presents several odor classes, chemical types and examples of the odors from these chemical types, many of which relate to odors that may emanate from the Proposed Plan Facilities and Alternative Facilities (as applicable) exhaust vents.

Table 3.18-1
Odor Classes and Examples[1]

Odor Class	Chemical Types	Examples
Acidic	Acid anhydrides Organic acids Sulfur dioxides	Vinegar, perspiration, rancid oils, resins, body odor, garbage
Sulfury	Selenium compounds Arsenicals Mercaptans Sulfides	Rotting fish and meat, cabbage, onion, sewage
Basic	Vinyl monomers Amines Alkaloid Ammonia	Feces, manure, fish and shellfish

Note:
(1) Source: ASTM D 1292 – 86 (Re-approved 1995): Standard Test Method for Odor in Water.

Odor levels are typically measured or analyzed in relation to the minimum detectable level or detection threshold (DT), which is the level of odor that can just be detected by 50% of the individuals in an odor panel. Some time odor levels in contaminated air are reported in units of dilutions-to-threshold (D/T), which is the number of volumes of pure air that must be added to a volume of contaminated air before the diluted sample becomes undetectable to 50% of the odor panelists. Thus, the DT value is equal to the D/T value plus one. For the purpose of evaluating

and presenting dispersion modeling results in this study, results will be presented as multiples of DT. In other words, an odor concentration of 10 DT in an air sample or in the ambient air means that the odor level is 10 times the average laboratory detection threshold.

3.18.3 Odor Impact Criteria

There are no federal standards that establish acceptable ambient odor levels. New York State does not set quantitative odor limits for solid waste handling facilities or any other facilities. Title 6 NYCRR Part 360-1.14(m) specifies: "Odors must be effectively controlled so that they do not constitute nuisances or hazards to health, safety or property." The Zoning Resolution Performance Standards Article IV 42-24 requires that the emissions of odorous matter in M1 or M2 districts be in such quantities as to not be readily detectable at any point along lot lines or to produce a public nuisance or hazard beyond lot lines. Therefore, a comparison of odor results to quantitative regulatory standards cannot be made. Levels of one particular odorous and toxic compound, hydrogen sulfide (H_2S), can be compared to the NYSDEC Air Quality Standards Part 257-10.3 hourly 0.01 ppm standard. Meeting this standard will minimize H_2S odors, but not necessarily eliminate them. Also, because there are many other odorous compounds, it is necessary to apply a "whole air" odor approach as described above.

Given a lack of applicable odor standards, it is necessary to make a judgment on what levels of odor in the ambient air are likely to represent an impact that is great enough to be recognizable and a nuisance to the public. Two factors were evaluated in establishing an appropriate odor impact control level, above which mitigation should be considered, for this study. First, a review was made of other state and local regulations for controlling odor in the United States. Most state and local agencies have some odor control requirements, but most do not have quantitative odor limits that can be used for comparison with the current study results. Table 3.18-2 lists odor limits established by other state and local jurisdictions, as found through a search ~~on~~ of on-line (Internet) regulations databases. These are presented here in (converted to) units of the detection threshold (DT), even though many limits are stated in terms of D/T.

Table 3.18-2
Odor Limits of State and Local Agency Jurisdictions[1]

State/Jurisdiction	Odor Limit (as multiple of DT)
California, Bay Area AQMD[2]	5 DT at property line or beyond
Colorado	8 DT for residential & commercial areas 16 DT for all other areas
Connecticut	8 DT in ambient air
Illinois	9 DT in residential and commercial areas 25 DT on/adjacent to industrial areas 17 DT in all other areas
Missouri	8 DT
Nevada	9 DT in places of occupancy
North Dakota	8 DT outside facility property boundary
Wyoming	8 DT at property line

Notes:
(1) Source: On-line regulations available on Internet as of August 2004.
(2) AQMD = Air Quality Management District

A second factor considered in establishing an appropriate odor impact threshold is the odor level of the background air. Pristine background air will make it easier to detect odorous emissions, while more contaminated air, such as may exist in urban areas, will tend to mask additional odorous emissions. As part of the current study, background air odor samples were taken in the vicinity of the proposed Converted MTS sites. Also, background air odor samples were taken upwind of four commercial waste facilities, which were analyzed in the preparation of the March 2004 Commercial Waste Management Study (CWMS). These background odor data are summarized in Table 3.18-3 and show that measured background odor levels are typically in the 5-7 DT range in New York City.

Table 3.18-3
Background Sampling Results

Date	Sample Location	DT
July 18, 2003	Queens	5
July 25, 2003	Bronx	5
August 13, 2003	Brooklyn	5
August 11, 2004	Manhattan	5 to 7
	Brooklyn	6 to 7
August 17, 2004	Manhattan	6 to 7
	Brooklyn	6 to 7
August 18, 2004	Queens	5 to 6
	Brooklyn	7
	Bronx	5 to 6

Based on the odor standards established by other jurisdictions and on the analyzed background odor levels as summarized above, an odor mitigation threshold of 5 DT has been established for this study. This level is equal to the lowest background odor level listed above and the lowest quantitative odor standard established for other jurisdictions. Predicted (modeled) odor impacts above 5 DT at a sensitive receptor (i.e. residence, adjacent business, ~~park~~and park) are assumed to represent a potentially unacceptable impact and would be grounds for considering mitigation to reduce the predicted impacts.

3.18.4 Odor Analysis

In accordance with procedures recommended by USEPA and the Air and Waste Management Association (AWMA), a scientific organization involved in reviewing and reporting on quantitative procedures for testing and evaluating odors, several methods can be used to collect odor samples from each source. All methods involve capturing odorous source air in a sealed Tedlar® sample bag. The evaluation of air samples for odor is conducted by ~~a trained panel of individuals, referred to as~~ an "odor panel," w~~ho~~hich quantifies~~y~~ odor concentration, odor intensity and odor persistence and determines equivalent butanol concentrations. H_2S concentrations are measured on site using a portable H_2S analyzer.

Odor panel members are selected and odor analyses conducted by a laboratory in accordance with the following established protocols and standards set by the American Society for Testing and Materials (ASTM):

- Selection and Training of Sensory Panel Members (Standard Practice 758);
- Determination of Odor and Taste Thresholds by a Forced-Choice Ascending Concentration Series Method of Limits (Standard Practice E679-91); and
- Referencing Suprathreshold Odor Intensity (Standard Practice E544).

The analysis was conducted to:

- Determine concentrations, emission rates and persistence of odors from identified odor sources for facilities subject to this study;
- Evaluate the effect of these odor sources at off-site sensitive receptors (e.g., residences, schools, churches, parks), if any, through atmospheric dispersion modeling; and
- Based on dispersion modeling, determine whether the facility designs need to include mitigating measures to minimize the escape of odors to the ambient air.

3.18.5 Sampling Program

Conditions were evaluated in 1999 at three existing MTSs in Brooklyn (Southwest Brooklyn, Hamilton Avenue and Greenpoint), one in Queens (North Shore) and a private facility in the City~~,~~ to identify those facilities most suitable for sampling odors from residential MSW. Sampling data from the selected facilities were then used to estimate odor emission rates from facilities.

Details of the sampling program are described in the Sampling Protocol for the Department Barge Odor Study prepared by DSNY's consultant, finalized based upon comments received from DSNY on October 2, 1998, and updated on June 18, 1999 (Sampling Protocol). The City Department of Environmental Protection (NYCDEP) was provided with a copy of the Sampling Protocol on July 29, 2003. The measurement methodology allows samples to be taken in a manner that isolates source air from ambient air. Results from the samples obtained from the exhaust points at the MTS before and after a neutralizing agent was applied and with and without barge slip doors closed were used in this F~~D~~EIS analysis.

Fall sampling was conducted at the Greenpoint MTS, North Shore MTS and the Fresh Kills Landfill during the week of October 5, 1998, with follow-up sampling conducted at the Southwest Brooklyn MTS on October 26, 1998. Summer sampling was conducted at the Greenpoint MTS and the Fresh Kills Landfill during the week of June 21, 1999, with follow-up and sampling of full containers of compacted waste from a private transfer station in the City during the week of July 12, 1999. After collection, samples were sent to an off-site laboratory for odor panel evaluation as described below. H_2S readings were taken during the summer sampling event during the week of July 12, 1999. Additional samples could not be collected for this ~~SWMP~~ F~~D~~EIS because the MTSs were subsequently closed and no one facility in or near the City currently accepts and processes only residential MSW from DSNY.

In addition to the sampling of odors from barge and MTS facility exhaust vents as described above, this study utilized odor sampling results from commercial waste facilities, completed in the summer of 2003 as part of the CWMS, and odor sampling of full DSNY waste collection vehicles parked in a DSNY garage, completed in the summer of 2004.

3.18.5.1 Sample Collection

In accordance with guidance documents published by USEPA and AWMA and procedures described in the Sampling Protocol, a total of 32 odor samples and 15 H_2S samples were obtained from area sources using an equilibrium chamber and from point sources from exhaust fans. A point source is a single localized source, such as a stack, vent or exhaust fan. An area source is typically a low-level or ground-level emission from a two-dimensional area, such as the surface of loose garbage in a loaded barge. The 15 H_2S samples were composites of several readings taken at 15 different times and/or locations.

For all sources sampled for odor panel evaluation, tygon vinyl tubing was used to connect the air sampling location to the sample pump inlet and the sample pump outlet to the sample bag. The tygon vinyl tubing was replaced between samples or the line was flushed with ambient air at a rate of five liters per minute (liters/min) for several minutes between samples. Tygon vinyl tubing was used because it is tasteless and odorless and is formulated specifically for use in peristaltic pumps (pumps used for sampling a media that does not come in contact with the pump itself). Air samples were drawn through the tubing into 25-liter Tedlar® sample bags. Tedlar® bags are recommended for use by the AWMA Subcommittee on the Standardization of Odor Measurement (AWMA Odor Subcommittee) because they have a low permeability that results in minimal sample loss or outside infiltration (thus maintaining sample integrity), and they have the lowest background odor. For sources analyzed for H_2S, tygon vinyl tubing was used to connect the air sampling location directly to the Jerome analyzer.

In keeping with practices recommended by the AWMA Odor Subcommittee, the sampling line and sample bags were pre-conditioned with a sample of the odorous air being evaluated, and then the air was evacuated from the bag prior to collecting the actual sample. Bags were filled to approximately 75% to 80% of capacity to prevent decompression during shipping. All samples were presented to the odor panel for evaluation within 24 hours of collection. Due to restrictions at the laboratory on the time it takes to analyze the odor sample, a maximum of six samples were collected each day.

Exhaust (point sources) air samples were obtained by using a funnel attached to the tip of the tubing and held up to the face of the exhaust point. The flow rate of the sampling pump for these sources was set at 5 liters/min, which is low enough, given the exhaust vent flow rate, to prevent ambient air from being pulled into the sample bag.

3.18.5.2 Sample Analysis

As described in the ASTM Standard Practice E679-91 (see Section 3.18.4), the odor panel evaluation uses a dynamic dilution binary scale butanol olfactometer. Air is passed through a vessel containing n-butanol (1-butanol) liquid, which allows the air stream to become saturated with n-butanol. Specific measured amounts of fresh air are also added to the odor-saturated air samples to vary the dilutions in each of eight sniffing ports of the olfactometer. When analyzing an odor sample, a member of the odor panel is asked to match the intensity of the odor in the air sample with the diluted odor level in a given port on the olfactometer. The odor panel's results are reported as multiples of the detection threshold (DT) and odor intensity (provided as a butanol equivalent concentration, not used for the current study). H_2S samples were analyzed on site using the hand-held Jerome analyzer.

3.18.5.3 Sampling Results

Tables 3.18-3 through Table 3.18-5 contains a summary of the odor samples (types and source/locations) obtained and the analytical results (in multiples of DT) for each of the samples. After all sampling was completed, the maximum concentration of the values from summer samples was used to calculate emission rates of odors from the sources at each facility. Table 3.18-6 contains a summary of the H_2S results obtained on site using a portable analyzer.

As noted previously in Section 3.18.2, odors from certain operations can be evaluated by analyzing air samples for specific odorous compounds. H_2S is commonly used as a surrogate for odors at wastewater treatment plants. While not necessarily the primary odorous compound present from solid waste transfer stations, measurements were obtained at the request of NYCDEP. The average H_2S concentration of samples collected from fan exhausts with~~out~~ the addition of neutralizing agent are below the New York Ambient Air Quality Standard for H_2S of 0.01 ppm.

NA= Not Applicable

The average H_2S concentration of samples obtained from four containers of waste stored for four to six days are above the New York Ambient Air Quality Standard for H_2S of 0.01 ppm. However, the container samples were taken by inserting the sample tubing directly into the container vents after sealing all vents on the container. To obtain a sample of the air from the sealed containers, a pump was used to draw air out of the containers at a rate of 0.5 to 1.0 liters per minute, which is much higher than the natural airflow from the containers. Airflow measurement from the same vents on a full container indicated that over the course of a day, ~~there was~~ an extremely small amount of air ~~that~~ was forced out of the vent (presumably due to diurnal heating), ~~which~~ but, again, this amount was~~is~~ much lower than the sampling rate of the pump. In addition, the age of waste in the containers sampled was greater than would be expected for normal operations at the Converted MTSs. The very low resulting H_2S emission rate means that the rapid dilution by atmospheric turbulence would quickly reduce the concentration of H_2S to below the 0.01 ppm standard by the time the emissions are a few feet from the container.

The result from the fan exhaust without the addition of neutralizing agent was 0.0117 ppm H_2S, slightly above the standard. The very low H_2S emission rate that results from the barges means that the rapid dilution by atmospheric turbulence will rapidly reduce the concentration of H_2S to below the 0.01 ppm standard by the time the emissions are only a few feet from the barge. Therefore, no dispersion modeling was performed for H_2S because concentrations would be below 0.01 ppm at off-site locations.

The NYCDEP measures H_2S from its WPCPs and compares modeled concentrations at off-site residential receptors to a 1 part per billion (ppb) guideline. Because emission rates are so low, containers are stored on site and facilities are located in industrial areas with the nearest residential receptors located several hundred feet away, it is expected that H_2S concentrations would be below the 1 ppb guideline at any residential receptor.

3.18.6 Odor Modeling Methodology

Potential impacts of odors on nearby receptors were estimated by:

- Conservatively calculating the emission rates based on the highest DT value for each source type;
- Entering the emission rate for each point (exhaust vent) source into USEPA's ISCST3 (version 97363) dispersion model;
- Inputting the coordinates of buildings for the Proposed Plan Facilities and Alternative Facilities, as applicable;
- Inputting coordinates of receptors at 50-meter (150-foot) intervals around the site boundary; and
- Conducting air dispersion modeling using historical meteorological data to determine whether odors, if any, would be detected by off-site receptors.

3.18.6.1 Mass Emission Rate Calculation

Sensory data alone cannot be used to conclude whether a specific odor source can become an odor problem. Although a specific release point may have a high odor concentration and/or intensity, it may not be the primary cause of the odor if that source has a low air release rate.

Also, depending upon the downwind distance from the source to a receptor, odor emissions may be diluted through atmospheric dispersion to levels that are not a concern.

Sources are characterized as either point, volume or area. A point source is a single localized source, such as a stack, vent or exhaust fan. A volume source is typically a ground-level emission source with no plume rise that originates in a three-dimensional space. For example, queued waste collection vehicles on a facility ramp are best characterized as volume sources because emissions could emanate from various locations around the sides of the waste collection vehicles. An area source is typically used to characterize a low-level or ground-level emission from a two-dimensional area, such as the surface of loose garbage in a loaded barge. In some cases, however, to refine the analysis, an area source is used to model collection vehicles on the ramp. ~~In~~ in the event that the source-to-receptor distances are less than three times the initial lateral dimension of the volume sources.

The results of the sampling and laboratory analyses described in the section above were reviewed and used together with source characterization information to estimate odor emission rates for model input, as described in the following sections.

3.18.6.1.1 Exhaust Vent (Point) Source Emission Rate

The exhaust vents of the facilities were considered point sources. Calculation of the point source emission rate (expressed in odor units per second [OU/sec]) of the facility exhaust vents was based upon the volumetric flow rate (cubic meters per second [m^3/sec]) of the exhaust system and the DT value (expressed as odor units per cubic meter [OU/m^3]) of the collected samples. The odor emission factors used for the analysis are expressed as "odor units" (OU) per second, where 1 OU is defined as the amount of mass of odor needed to generate a concentration at the detection threshold (where 50% of the odor panel can detect the odor) in a volume of one cubic meter of air. The laboratory analysis by an odor panel, as described above, provided the concentration of odor for each sample in multiples of DT, also referred to as odor units. The DT value for a sample was then multiplied by the air exhaust flow rate from the vent sampled to estimate the OU/sec emission rate for that vent.

Table 3.18-7 provides a summary of the estimated odor emission factors based on all odor samples analyzed for this FDEIS. These data show that the emission factors ranged from 136 OU/sec to 6,904 OU/sec.

Table 3.18-7
Summary of Emission Rates

Sample Date	Location/Facility	Sample ID	Operating Rate (tons/hour)	Odor Panel DT	All Fans Total Exhaust Flow (m^3/sec)	Calculated Emission Rate (OU/sec)	Calculated Emission Factor (OU/sec) (ton/hour)
DSNY-managed Waste

August 20, 2003	Private TS4	RR082003	7	16	94	14.2
			7	16	188	28.4
			7	16	471	71.1

It is assumed that odor generation (and the resulting emission rate) is proportional to the amount of waste processed. Therefore, based on the sample data for exhaust vents and the solid waste processing rates for the sampled facilities, the calculated odor emission rate for each exhaust vent sample was divided by the facility's measured solid waste processing rate to estimate an emission factor in units of OU/sec/ton of solid waste processed per hour. This emission factor was then multiplied by the peak design processing capacity (tons/hour) of each facility to obtain an estimated odor emission rate that is scaled to each facility's capacity.

The summer 1999 exhaust vent (point) sample data generated the highest emission factor. The maximum emission factor, used as the basis for exhaust vent emissions from all facilities that would accept DSNY-managed Waste only, is 16.2 OU/sec/(ton of solid waste processed per hour).

For the CWMS, air samples were obtained from private transfer stations that accepted only commercial waste. The maximum emission factor for the commercial waste is 414.2 OU/sec/(ton of solid waste processed per hour). For a facility that will potentially accept commercial waste, a ratio of commercial and DSNY-managed Waste to total waste received is applied as a weighted average to the commercial and residential waste emission factor. Since the commercial waste deliveries would only occur from 8:00 p.m. to 8:00 a.m., the potential commercial waste tonnage~~,~~ with the off-site noise constraints~~,~~ and the DSNY-managed Waste delivered during those hours were used. The emission rate is calculated based on this ratio for each site.

The air release height for the point source is based on the height of the exhaust fans on the roofs of the facilities. Because the vertical momentum of the exhaust air is assumed to be obstructed by the design of the exhaust vents, the vents were modeled using very small input diameters and velocities~~,~~ in order to simulate no plume rise for these point source emissions.

3.18.6.1.2 Barge (Area) Source Emission Rate

Barge odor air samples obtained (for the 2000 SWMP FEIS) from full and empty barges at MTSs and the Fresh Kills Landfill were analyzed as area sources because the sides of the barges are enclosed. Area source odor emission factors (mass/time/unit area) were estimated by calculating the OU using the D/T provided by the laboratory for each sample, divided by the area covered by the enclosure where the sample was collected, and ~~divided~~ dividing that result by the duration of sampling. The peak-to-mean adjustment and decimal place adjustment were applied to obtain emission rates for the ISCST3 input.

For the 2000 SWMP FEIS, samples were collected by extracting 20 to 25 liters of air within an approximate one cubic meter enclosure with an open bottom that is approximately one square meter (1,000 liters) placed over the odor source. The chamber was placed over the waste for a period of time before the sampling pump was turned on, thereby allowing some accumulation of odors before sampling. Since the sample volume was 2% to 3% of the enclosure volume, any dilution effect caused by ambient air pulled into the enclosure was ignored. Each sample was collected over an average of approximately 20 to 25 minutes. This sampling was conducted for both full barges, and for "empty" barges, in which case the sampling apparatus was placed on the barge bottom, over waste residue.

The highest emission factor for either full or empty barges was conservatively used as the basis to develop model inputs for all facility scenarios involving the use of open-top barges (non-containerized waste). For facilities that accept commercial waste, emission factor was assumed using the weighted ratio between the emission factor of the point source of commercial waste and DSNY-managed Waste combined. The emission rate is then calculated using the same methodology as that for emission factor for the DSNY-managed Waste. The emission rates for barges were calculated to be 0.00000057 odor units per second per squared meter (OU/sec-m^2) for residential waste and 0.000008 OU/sec-m^2 to 0.000015 OU/sec-m^2 for facilities that accept commercial waste. The odor emission release height of the barges was assumed to be 12 feet (3.66 meters), based on the approximate height of the barge side above the water line.

3.18.6.1.3 Container (Volume) Source Emission Rate

Estimated odor emission rates from shipping containers were based on the sampling of odors from inside vent openings on the sides and/or rear of the containers. The D/T for these samples was generally higher than those obtained for exhaust vents. Due to the tightly compacted waste inside a shipping container, however, there is little air space within these containers. Winds cannot force air through the containers and, consequently, there is very little airflow out of these vents. Whatever airflow does exit the vents is probably due to diurnal heating of the small vapor space left after the compacted waste is placed in the container.

As a test of potential airflow out of a container due to diurnal heating effects, all openings on a container were sealed with tape and an empty one-liter sample bag was attached to an orifice installed in the taped opening. The bag was set in place early in the morning on a sunny day during the summer 1999 odor sampling program. Observation of the bag at intervals over the daytime period revealed that only a very small portion of the bag was filled due to the diurnal heating or other potential off-gassing effects of the waste. The conclusion, based on this test, is that much less than a liter of airflow is emitted from diurnal heating of a shipping container with tightly compacted waste. Based on the very low air flow sampled from filled shipping containers (as part of the 2000 SWMP FEIS), and the very low estimated emission rates, the containers were not included as an emissions source in the dispersion model. Filled container odor emissions are expected to be negligible in comparison to other odor sources analyzed for the ~~proposed~~ Proposed Plan F~~f~~acilities and Alternative Facilities.

An empty container has a much ~~bigger~~ greater volume of space within ~~the container~~it. Although, based on calculation, a higher air flow is emitted from diurnal heating of empty containers when compared to a full container, the estimated emission rates are still very low in comparison to other odor sources from the ~~proposed~~ Proposed Plan ~~facility~~Facilities or Alternative Facilities. Therefore, empty container odor emissions are also expected to be negligible.

3.18.6.1.4 Collection Vehicles (Volume or Area) Source Emission Rate

Estimated odor emission rates from collection vehicles were based on the sampling of odors from a DSNY garage where full collection vehicles were parked. See Appendix J to this FEIS for a more detailed discussion of DSNY collection vehicle odor sampling and analysis. The DT values and garage ventilation exhaust air flow rate for these samples were used to calculate the emission factors and rates on a per collection vehicle basis. The maximum emission rate based on highest DT value of any sample was applied in the ISCST3 model, using the volume or area source algorithm to simulate odor emissions from collection vehicles queued on facility inbound ramps.

3.18.6.1.5 Emission Rate Summary

Table 3.18-8 contains a summary of the emission rates or factors used for each type of sampled source. Note that the shipping container emission rate is so low that container emissions were not included in the dispersion modeling analyses.

Table 3.18-8
Modeled Odor Emission Rates/Factors

Source Type	Unit Emissions	ISCST3 Emissions
Facility Exhaust Vents	16.2 OU/sec/(ton of solid waste processed/hr) for residential waste 414.2 OU/sec/(ton of solid waste processed/hr) for Commercial Waste	0.00072 OU/sec [(1)] (residential waste) 0.008 OU/sec – 0.015 OU/sec (Residential + Commercial Waste) [(1)(2)]
Barges	5.7×10^{-7} OU/sec-m^2 for residential waste 1.5×10^{-5} OU/sec-m^2 for Commercial Waste	5.7×10^{-7} OU/sec-m^2 (residential waste) 8.0×10^{-6} OU/sec-m^2 – 1.4×10^{-5} OU/sec-m^2 (Residential + Commercial Waste)[(2)]
Collection Vehicles[(3)]	3.2 OU/sec/collection vehicle	Varies for each site based on number of collection vehicles.

Notes:
OU/sec = odor units per second.
OU/sec-m^2 = odor unit per second per squared meter
(1) Based on a 4,290 tpd facility for typical facility.
(2) Based on potential residential waste and commercial waste to be delivered during the hours of 8:00 p.m. to 8:00 a.m.
(3) Based on DSNY collection vehicles.

3.18.6.2 Dispersion Modeling

Based upon emission rates, exhaust parameters, building design and site characteristics for each Proposed Plan Facility~~ies~~ and Alternative Facility~~ies~~, as applicable, atmospheric dispersion modeling was used to assess the distance at which the odor would not be detected and the odor unit level at the property line and off-site receptors. For this FEIS, additional off-site odor sensitive receptor results are reported in Chapters 4 through 7 and 22 for consistency with additional noise-sensitive receptors analyzed in the DEIS. While dispersion models are used typically by regulatory agencies to determine compliance with air quality regulations, odor modeling techniques have been developed using these same air quality dispersion models. Using the emission characteristics of the facility, USEPA's ISCST3 model was used to assess worst-case estimates of maximum short-term concentrations from a single point, area or volume source, and from combinations of multiple point, area and volume sources. The odor dispersion modeling followed the same basic approach as that for criteria and toxic pollutants of on-site sources.

The purpose of using dispersion modeling for the odorous emissions was to determine the distance from the Proposed Plan Facilities and Alternative Facilities, as applicable, at which the modeled emission rates had resulting concentrations that were equal to or less than 5 OU. For assessing whether there are adverse or objectionable odors, there is no specified odor limit that has been established by the City. Thus, this study considered the odor levels in background samples taken at various locations in the City~~,~~ as well as precedents established by other state and local agencies nationwide in regulating odor levels~~,~~ to develop an odor level considered protective of the general public's sensibilities.

The shortest averaging period accommodated by the ISCST3 model is one hour. Because odor can be detected on an instantaneous basis by the human nose, it was necessary to apply a multiplication factor – referred to as a "peak-to-mean" factor – to the ISCST3 one-hour concentration predictions. This peak-to-mean factor was set at 2.5, based on data contained in the publication *Meteorology and Atomic Energy* (Slade, et. al., 1968). However, because the ISCST3 concentration predictions are proportional to the emission rate for a single source, the emission rates were simply multiplied by 2.5 for input to the ISCST3 model so that ISCST3 output concentrations would be adjusted for peak – rather than one-hour average – odor impacts.

Because the modeled emission rates are actually input in units of "grams/second" and the output concentrations are in units of "micrograms/cubic meter," one can simply move the decimal point six places to the left in the modeled emission rates, so that output concentrations are effectively in units of grams/cubic meter. It does not matter to the model whether one is modeling "grams" or "odor units" or any other measure of mass. Therefore, if one defines the input as "odor units/second" the output, after making the decimal place adjustment, will effectively be in units of "odor units/cubic meter" or equivalently, multiples of DT.

Together, the peak-to-mean adjustment and decimal place adjustment in emission rates make it possible to have the model output show directly the predicted number of odor units (multiples of the DT) at each receptor location. As an example, a facility processing 4,290 tons per day (tpd) of waste would have an stack/vent estimated emission rate of 7,195 OU/sec ([4,290 tons of solid waste processed per day x 16.1 OU/sec/(ton of solid waste processed/hr)/(24 hrs/day)] x 2.5). This value would then be divided by 10^6 to give a model input emission rate of 0.007195, which would then produce output concentrations in OU/m3, or effectively, multiples of the detection threshold (DT).

3.18.6.3 Modeling Procedures

The following procedures were followed for modeling the odor sources:

1) BPIP. The USEPA Building Profile Input Program (BPIP) was used to determine dimensions for simulating building downwash effects on the plume of the stack/vent located on the roof of the processing building. The ISCST3 model takes the output generated by the BPIP program and simulates downwash effects by limiting any plume rise and by increasing the rate of vertical and horizontal plume spread. The BPIP program calculates 36 projected building widths and heights (one set for every 10° of arc, 360° total, with respect to a point source).

2) ISCST3 Model. The source emission rates in OU/sec were input into ISCST3 along with all other necessary input data. Model inputs were set to calculate and output the peak value that was representative of how odors are detected by humans.

Several modeling assumptions were used for the analysis of each Proposed Plan Facility site and Alternative Facility site, as applicable:

- Stack heights were set at 3 feet or 0.91 meters above the process building roofline with an exit velocity of 0.001 m/s, to simulate horizontally-directed exhaust.
- Calm wind conditions were not represented in the ISCST3 results since the USEPA regulatory default option was used. Calm wind conditions are a worst-case dispersion condition and tend to keep odors closer to the source and show higher impacts at or near the facility property line. However, calm wind conditions only occur at a maximum of 3% of the time on an annual basis for the 1997 through 2001 LaGuardia Airport meteorological data set.
- A Cartesian coordinate system was developed to encompass all emissions at the process building stack as well as the receptor points, which are the locations where the model calculates odor concentrations. The receptor grid was developed out to a distance of 500 meters (approximately 1,640 feet) from the property boundary in all directions over land in 50-meter (approximately 164-foot) increments. This allowed creation of contour plots to help define any areas of predicted detectable odors and to determine whether these areas overlapped any sensitive receptors.
- The building ventilation exhaust stack(s) were modeled as a point source(s) located at the top of the process building, unless otherwise specified. The emission rate for the point sources was modified for facility capacity and number of emission points, if applicable. The ISCST3 model is the same as that used to determine compliance with applicable air quality standards and guidelines. The emission rates from each source were determined by converting the sampled concentrations into odor emission rates calculated in units of OU/sec. In addition, physical parameters of the sources and surrounding structures, such as exhaust fan height, were incorporated into the model.
- The barges were modeled as area sources located outside of the processing building.
- The collection vehicles were modeled as volume or area sources located on the ramp of the facility where the collection vehicles could potentially queue.

Since publication of: (1) the EIS-level odor analysis of Converted MTSs presented in Appendix D to this FEIS - the Commercial Waste Management Study, Converted MTSs Commercial Waste Processing and Analysis of Potential Impacts -Volume III; and (2) the DEIS, the odor analyses were revised based on the proposed Converted MTS final designs, and several additional sensitive receptor location results were reported for the proposed East 91st Street Converted MTS. For processing only DSNY-managed Waste at the proposed Converted MTSs, the revised odor results are reported in Chapters 4 through 7 and 19 through 22 of this FEIS. The revised odor results of processing DSNY-managed Waste plus Commercial Waste at the proposed Converted MTSs are reported in revised Tables 1 through 8 in Appendix D of this FEIS.

3.18.7 Mitigation Measures

Examples of design features that may be associated with facilities to mitigate odor problems include:

- Installation of building exhaust fans and filter systems (e.g., bag houses and cyclones) to create negative air pressure that would minimize the escape of fugitive odors from the Proposed Plan Facilities and Alternative Facilities, as applicable; and
- Installation of an automatic spray system that would disperse odor neutralizing agents within the building and into the ducts of the exhaust air system.

Operational procedures that have been shown to be effective at reducing odors include:

- Requiring all waste handling operations to be conducted within the enclosed facility and limit the length of time solid waste can be retained on site;
- The requirement that the doors in the waste receiving area be closed except during waste deliveries;
- The use of covered or enclosed trucks for all waste delivery and transfer operations; and
- The use of neutralizing agents on the loose waste in the barge.

3.19 Noise

3.19.1 Introduction

This section briefly outlines the methodology that will determine the extent to which Proposed Plan Facility and Alternative Facility (as applicable) operations could affect noise levels. Each site is located in manufacturing-zoned districts but has the potential to generate noise that could affect nearby noise-sensitive receptors, such as residential land uses and outdoor areas (e.g., parks). Noise sources evaluated include both mobile and stationary sources operating within the site boundary and DSNY and other agency collection and employee vehicles traveling on roads leading to and from the facility. The analysis, which is based upon guidance found in the 2001 CEQR Technical Manual, includes:

- A screening step to determine if further analysis is warranted; and
- If warranted, a detailed analysis including a monitoring task to determine existing noise levels near the site and at noise-sensitive receptors, ~~based upon guidance found in the 2001 CEQR Technical Manual~~ and modeling techniques to predict ~~for~~ on- and off-site noise levels.

The on-site noise analysis used a spreadsheet model with standard noise calculations that accounts for multiple indoor noise sources, ~~attenuation~~ transmission loss provided by building walls, multiple outdoor sources, attenuation due to propagation (geometric spreading) toward off-site receptors, equipment utilization factors and shielding provided by intervening buildings.

The FHWA Traffic Noise Model Version 2.1 (TNM 2.1) or field simulations of DSNY or other agency collection vehicles along routes near sensitive receptors were used to predict potential off-site noise impacts.

3.19.2 Background

Noise is often described as unwanted sound. Factors affecting the physical characteristics of sound when it is perceived subjectively as noise by the human ear are:

- Actual level of the sound (perceived loudness);

- Distribution of sound energy among individual frequency bands in the audible range;
- Period of exposure to the noise; and
- Changes or fluctuations in the noise levels during the period of exposure.

The human ear does not perceive all sound frequencies equally well, so measured sound levels are adjusted or weighted to correspond closely to human hearing. The adjusted basic measurement unit is known as the A-weighted decibel (dBA). Community noise levels in urban areas usually range between 45 dBA and 85 dBA, 45 dBA being the daytime noise level in a typical quiet living room, and 85 dBA being the approximate noise level near ~~the~~ a sidewalk adjacent to heavy traffic. Figure 3.19-1 illustrates noise levels from typical fluctuating and non-fluctuating (steady) noise sources, based on the A-weighted decibel measure of noise.

Because ~~dBA describes a noise level at just one moment and~~ very few noises are constant, ~~other~~ methods of describing noise over extended periods are used. One way of describing fluctuating sound is to describe the fluctuating noise heard over a specific time period as if it has been a steady, unchanging sound. For this condition, a descriptor called the equivalent sound level, L_{eq}, is computed. An L_{eq} is the constant sound level that conveys the same sound energy as the actual time-varying sound in a given situation and time period, for example, 1 hour.

The 1-hour L_{eq}, as recommended by CEQR, and the New York City Noise Code, ~~and the DSNY Transfer Station Operational Requirement Rules,~~ is used as the noise descriptor in this analysis. The 1-hour L_{eq} sound level allows for comparison with federal and local noise standards and indicates to what extent local residents will be affected by changes in facility-related noise levels. Maximum 1-hour L_{eq} sound levels are used to provide an indication of expected sound levels during the loudest hour of facility operations. Minimum 1-hour L_{eq} sound levels provide a basis for impact assessment during the quietest hour of operations. ~~The 1-hour L_{eq} sound level allows for comparison with federal and local noise standards and indicates to what extent local residents will be affected by changes in facility-related noise levels.~~ In addition to the L_{eq}, statistical descriptors of L_5, L_{10}, L_{50} and L_{90} are also used in this analysis. These descriptors represent noise levels that are exceeded 5%, 10%, 50% and 90% of the time. Therefore, an L_{10} of 60 dBA means that during 10% of the measurement period, the noise levels will be higher than 60 dBA. Similarly, an L_{50} of 60 dBA means that during 50% of the measurement period, the noise levels will be higher than 60 dBA.

The average person's ability to perceive changes in noise levels is well documented. Generally, changes in noise levels of less then 3 dBA will barely be perceived by most people, whereas a 10 dBA change is perceived as a doubling (or halving) of noise levels. The general principle on which most noise acceptability criteria are based is that a change in noise is likely to cause annoyance whenever it intrudes upon the existing noise from all other sources. Essentially, annoyance depends upon the noise that exists before the start of a new noise-generating project or an expansion of an existing project.

Ways for expressing noise emission levels for equipment are sound power level (SWL) and sound pressure level (SPL). A ~~decibel~~ sound power level is defined as:

$$Lw = 10 \times \log(W/Wref)$$

where:
- W = Watts, a unit of power;
- Wref = a reference power (usually 1 x 10-12 W); and
- Lw = sound power level.

Sound power can be thought of as the amount of energy generated and propagated per unit of time. Sound pressure level is a variation in pressure above and below atmospheric pressure and is proportional to sound power level. For example, two piston cylinders of different diameters can be driven so that they put out the same amount of sound power. The sound power per unit area, or sound intensity, in the smaller tube will be greater than that in the larger tube because the same amount of energy is distributed over a smaller area. This means that the sound pressure disturbances in the smaller tube are larger because the sound intensity is higher.

A sound pressure level is defined as:

$$Lp = 20 \times \log(P/Pref)$$

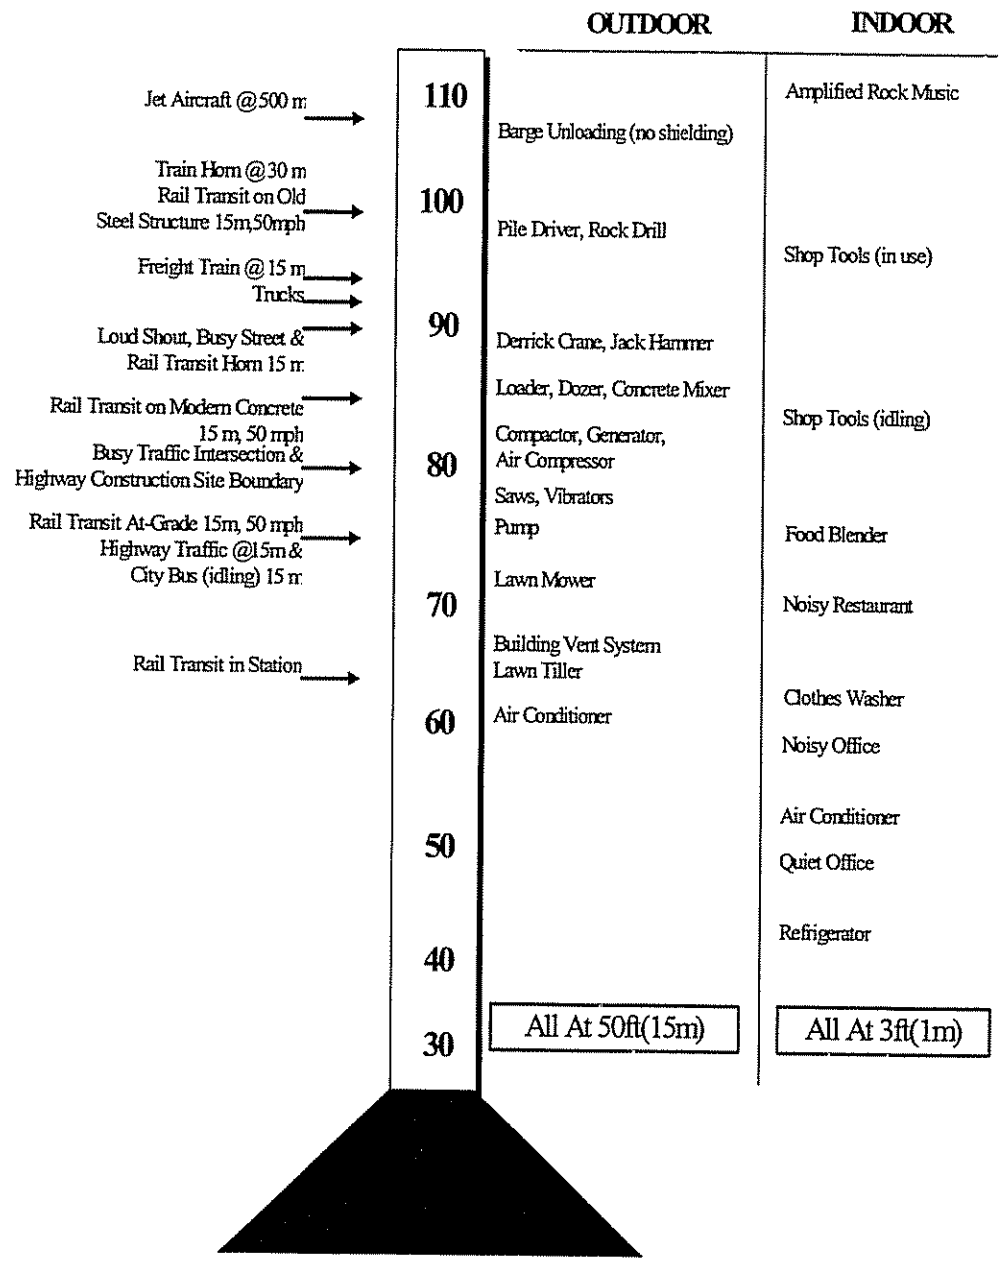
where:
- P = Micropascals (μPa), a unit of pressure
- Pref = a reference pressure (usually 20 μPa)
- Lp = sound pressure level.

3.19.3 Criteria

The noise analyses are based upon CEQR standards, the Current New York City Noise Code and Performance Standards of the New York City Zoning Code for Manufacturing Districts that set limits on facility-generated noise levels at the property boundary and the nearby residential areas. However, for private transfer station sites, only a CEQR analysis was performed. The criteria used include a determination of the following:

- ~~If~~ For the ~~existence of the~~ Proposed Plan Facilities~~y~~ and Alternative ~~Facility~~Facilities, as applicable, ~~and related activities would raise the existing hourly minimum plant noise levels by 3 dBA or more at the nearest noise sensitive receptor~~ adherence to the CEQR Noise Standards;
- For the MTSs, adherence to the Current New York City Noise Code requirements in all facilities; and
- For the MTSs, adherence to the Performance Standards of the New York City Zoning Code for Manufacturing Districts.

3.19.3.1 Current New York City Noise Code



The Current New York City Noise Code 24-243 (Ambient Noise Quality Zone), which specifies a ~~24~~1-hour $L_{eq(1)}$ level less than or equal to 70 dBA for noise emitted from land uses zoned for manufacturing at the property line of the Proposed Plan Facility and Alternative Facility site, as applicable, was applied.

3.19.3.2 CEPO-CEQR Noise Standards

The noise analysis is based on Section R of the 2001 CEQR Technical Manual, which includes definitions of environmental acoustics concepts, guidance for determining if a noise analysis is appropriate, assessment methods, impact thresholds and mitigation guidance. The noise requirements of the 2001 CEQR Technical Manual are as follows:

- On-Site Noise
  - If the Future No-Build Condition ~~traffic~~ noise level is less than 60 dBA $L_{eq(1)}$ and the analysis period is during the day, the threshold for significant impact from the proposed project will be an increase of 5 dBA ~~$L_{eq(1)}$~~.

Figure 3.19-1
Common Indoor and Outdoor Noise Levels

Sources: Parsons Brinckerhoff Quade & Douglas, Inc., July 1998
FTA Report DOT-T-95-16. "Transit Noise and Vibration Impact Assessment: Final Report", April 1995
Hudson River Waterfront Transportation Corridor DEIS, November 1992

- If the Future No-Build Condition ~~traffic~~ noise level is equal to or greater than 62 dBA $L_{eq(1)}$ or if the analysis period is during the nighttime, the threshold for significant impacts from the proposed project will be an increase of 3 dBA.

- Off-Site Noise
  - The threshold for significant impacts is an increase of 3 dBA or more, over the existing minimum noise at the nearest sensitive receptor, when impacts are analyzed for cumulative noise effects from proposed facility-related truck traffic and noise.

A screening analysis was performed for on-site and off-site noise sources to evaluate the potential for noise impacts and to determine if additional refined noise analyses were required. Refer to Section 3.19.5 for a discussion of the screening analyses, Section 3.19.7 for a discussion of the detailed noise analyses and impact thresholds, and Section 3.19.8 for a discussion of typical mitigation measures for impacted locations.

3.19.3.3 City Zoning Regulations

City Zoning Regulations also address noise emissions. The following section of the City Zoning Regulation was applied: City Zoning Regulations 42-213, which specifies maximum permissible octave band sound pressure levels for manufacturing districts M1 and M3 from plant equipment operations, including the operation of rooftop ventilators and air circulation devices (see Table 3.19-1).

The octave bands provided above are "old" and can no longer be measured with the noise monitoring equipment available. The American National Standards Institute (ANSI) has promulgated a standard for the conversion of the old octave bands to the current octave bands. (See Table 3.19-2.)

If the facility boundary is located adjacent to a residential zone, these sound pressure levels must be reduced by 6 dB.

Table 3.19-1

3.19.4 Noise Sources

3.19.4.1 On-Site Noise Sources

Solid waste management facilities may include a variety of on-site noise sources, such as gantry cranes and ventilation equipment. For practical purposes, certain mobile sources were modeled as on-site sources, including collection vehicles loading/unloading at the Proposed Plan Facilities and Alternative Facilities, as applicable, front-end loaders moving waste on site, barge loading/unloading equipment and street sweepers. To be conservative and identify the period with the highest incremental effect, it was assumed that typical daytime facility operations occur 24 hours per day.

3.19.4.2 Off-Site Noise Sources

For the purposes of this analysis, collection and employee vehicles were considered as off-site mobile sources.

3.19.5 Screening Methodology

3.19.5.1 On-Site Source Screening Analysis

Both stationary and mobile equipment operate indoors and outdoors. The operations within the facility boundary were treated as stationary sources for the purpose of the screening analysis. The locations of equipment and activities at each site at each facility's peak capacity were drawn on a scaled layout map. A reference noise level for each piece of equipment, both indoor and outdoor, was obtained and added together. The combined noise levels were used to identify the 55 dBA noise contour line (i.e., the point at which on-site noise would attenuate to 55 dBA). As 55 dBA is a generally acceptable nighttime noise level, it was used as a threshold for screening purposes. Noise-sensitive receptors located between the facilities and the 55 dBA contour, if any, were identified.

To calculate the 55 dBA contour line, a -6 dBA drop-off rate (i.e., level of attenuation per doubling of distance from the source) was assumed. The shielding effects of intervening buildings was accounted for by applying 5 decibels of shielding for each row of buildings that provides 70% to 90% coverage (of the line of sight), with a 10-decibel limit (FHWA-RD-77-108, page 33). A 10-decibel attenuation was used for buildings providing more complete coverage.

If noise-sensitive receptors were not located within the 55 dBA contour line, the facilities were screened from further CEQR analysis and a qualitative discussion is provided. If noise-sensitive receptors exist within the 55 dBA contour line, a detailed stationary noise source analysis was performed. If the nearest noise-sensitive receptor was located outside of the 55 dBA contour line, background noise levels were measured at that noise-sensitive receptor to determine if they were below 55 dBA. If the noise level was below 55 dBA, a contour line for that noise level was determined and a detailed stationary noise source analysis was performed.

The following were considered to be noise-sensitive receptors:

- Parks/playgrounds;
- Schools and educational facilities;
- Residences;
- Churches and other places of worship;
- Outdoor performance facilities;
- Indoor performance facilities with windows;
- Healthcare facilities; and
- Libraries and community centers.

Noise analyses were also conducted at noise-sensitive receptors that were non-conforming uses in particular zoning districts.

3.19.5.2 Off-Site Source Screening Analysis

CEQR includes guidelines for a screening-level analysis of off-site sources to determine if additional refined analyses are required. The only off-site sources for the Proposed Plan Facilities and Alternative Facilities, as applicable, are DSNY and other agency collection and employee vehicles on local roads traveling to and from the sites.

Noise screening was performed in a two-level process. The first level consisted of converting the Future No-Build traffic volume and the DSNY and other agency collection vehicle and employee traffic volume to PCEs. The Future No-Build traffic volume was determined by escalating the existing traffic volume obtained by automatic traffic recorders (ATRs) using the CEQR traffic escalation formula. The Future No-Build traffic volume was converted to PCEs using New York State Department of Transportation (NYSDOT) site-specific axle factors. These categorize the traffic volume into two classes: (1) Automobile/Light Truck/Medium Truck/Bus; and (2) Heavy Trucks. The CEQR PCE factors for the vehicles in Class 1 range from 1 to 18, per Section R 332.1 of the 2001 CEQR Technical Manual. A conservative PCE factor of 1 was used for Class 1, therefore resulting in a lower Future No-Build traffic PCE volume. ~~that~~This volume cannot be doubled, per the CEQR screening threshold. The CEQR PCE factor for the vehicles in Class 2 is 47, which was also used to convert the collection vehicle traffic volume to PCEs. Employee vehicles were converted to PCEs using the CEQR PCE factor of 1 for cars. The two PCE values (Future No-Build and Future Build) were then compared. If the Future Build PCEs (Future No-Build PCEs plus collection vehicle PCEs ~~plus~~ and employee vehicle PCEs) were double the Future No-Build PCEs, the collection vehicles and employee vehicles would cause a possible impact. A second-level screening process was then required.

For the second-level screening, the hour for which the greatest ratio of Future Build PCEs to Future No-Build PCEs was analyzed for each roadway that resulted in a doubling of PCEs based on the first-level screening. If the first-level screening resulted in possible impacts during the daytime (7:00 a.m. to 10:00 p.m.), as well as the nighttime (10:00 p.m. to 7:00 a.m.), both the hour with the greatest ratio from the daytime and the hour with the greatest ratio in the nighttime were further analyzed in the second-level screening.

Similar to the first-level screening, the collection vehicle traffic volume and employee vehicle traffic volume was converted to PCEs using a PCE factor of 47 for Heavy Trucks and 1 for cars, respectively, for this level. However, for this level, Future No-Build PCEs were calculated using: (1) the field-obtained vehicle classification count for the hour(s) being screened or a vehicle classification count representative of the vehicle distribution expected during that time of the day; and (2) the following conversion factors from 2001 CEQR Technical Manual Section R 332.1:

- Each Automobile or Light Truck: 1 PCE;
- Each Medium Truck (gross vehicle weight from 9,900 pounds to 26,400 pounds): 13 PCEs;
- Each Bus: 18 PCEs; and
- Each Heavy Truck (gross vehicle weight more than 26,400 pounds): 47 PCEs.

As a result of the second-level screening process, if the Future No-Build PCEs were either doubled or nearly doubled along a roadway due to an increase in traffic volume from the addition of DSNY and other agency collection and employee vehicles at any time there is a possible impact, then a detailed noise analysis was required per the 2001 CEQR Technical Manual, Section R 311.1.

3.19.6 Noise Monitoring

3.19.6.1 On-Site Monitoring

Noise-sensitive receptors near each site were identified using a combination of land use and zoning maps, aerial photography and field visits to each site. Noise monitoring was conducted continuously for 24 hours to establish Future No-Build noise levels at the facility property line closest to the nearest sensitive receptor. Monitoring results were expressed as L_{eq}, L_{min} (the minimum sound level), L_{max} (the maximum sound level) and the statistical descriptors of L_5, L_{10}, L_{50} and L_{90}. For sites located near highways or airports, Future No-Build noise levels might

include noise generated by these existing sources. Because many of the Proposed Plan Facilities and Alternative Facilities, as applicable, are on waterfront sites, Future No-Build noise levels might include noise generated by marine activities, such as pleasure boats and tugboats, etc. If the screening process identified the need for a detailed on-site analysis, then short-term, 20-minute readings were taken at the closest noise-sensitive receptor during the hour in which the greatest difference between facility-related noise and background noise levels occurred in order to estimate the maximum potential impacts on that receptor.

3.19.6.2 Off-Site Monitoring

If the screening analysis task for off-site sources determined that PCEs either doubled or nearly doubled along a roadway due to an increase in traffic volume resulting from the addition of DSNY and other agency collection and employee vehicles, a detailed off-site noise source analysis was performed. The detailed off-site noise source analysis consisted of noise monitoring and modeling to predict noise levels during the hours expected to receive the largest change in noise levels (when the difference between traffic noise and background noise levels is greatest). For each location in which PCEs doubled, noise monitoring was performed to determine the existing background noise level at the representative nearest sensitive receptors along the study area. ~~The Future No-Build Condition noise level and the Future Build Condition noise level predicted by the FHWA's TNM 2.1 was calibrated using the background noise level (measured).~~ The FHWA's TNM 2.1 was used to predict the Future No-Build Condition noise level and the Future Build Condition noise level. The difference between~~of~~ the ~~calibrated~~ Future No-Build Condition noise level and the ~~calibrated~~ Future Build Condition noise level was compared with 2001 CEQR Technical Manual noise impact thresholds and reported in a tabular format. If ~~the Traffic Noise Model (TNM)~~ predicted an impact at a site, noise simulations were performed that included noise monitoring of the existing background noise level and simulation of DSNY collection vehicles passing through the site during all hours that the screening resulted in a possible impact.

3.19.7 Impact Analysis

3.19.7.1 On-Site Impact Analysis

On-site noise impacts were evaluated during the hour in which the greatest difference between project-related noise and background noise levels would occur (on-site noise analysis hour). If the greatest incremental difference would occur at night, activities at the on-site sources would be largely, but not entirely, indoor operations, with occasional collection vehicles delivering waste to the facility. However, to be conservative, typical daytime operations were also assumed to occur at nighttime. Indoor activities include collection vehicles dumping waste on the tipping floor, loaders moving waste toward the hoppers, the tamping down of waste into containers, container lidding operations and housekeeping. Boilers would be located within the processing buildings, but are not a significant noise source. The outdoor analysis accounts for trucks queuing on site, container-handling activities, and barge loading by gantry cranes. ~~and housekeeping activities by street sweepers.~~

For the Proposed Plan Facilities, a refined analysis was performed including refining utilization factors for equipment noise from facility fans and more accurately, defining the interior building conditions and shielding.

3.19.7.1.1 CEQR and Part 360 Noise Code Analysis

Because operations were conservatively assumed to occur 24 hours per day, the quietest background hour was the hour during which the greatest difference between facility noise levels and background noise levels occurred (the hour during which the greatest impact would occur). To determine this hour, the 24-hour background noise levels measured at the site boundary nearest to the closest noise-sensitive receptor were reviewed for the lowest $L_{eq(1)}$. Short-term 20-minute readings were taken at the closest noise-sensitive receptor during this hour to estimate the maximum potential impacts upon that receptor.

Noise levels from indoor and outdoor on-site activities were predicted at the nearest noise-sensitive receptor and combined logarithmically.

The source noise level at 50 feet from the source, for each piece of equipment, was obtained from manufacturers. However, if this data were not available, monitoring of the equipment was performed to determine the source noise level. When possible, the equipment noise level was monitored at 50 feet from the equipment for the time period necessary to monitor one full cycle of the equipment in operation. If monitoring was performed for the equipment performing various operations at different times, for example idling vs. moving, the highest noise level was used.

The noise level included in the DEIS from trucks queuing on the facility ramp was based on trucks queuing the entire length of the inbound portion of the ramp and one DSNY truck queuing on the outbound scale. For Proposed Plan Facilities, if a higher noise level was predicted from the expected mixture of DSNY and Commercial Waste Trucks, then the mixture of DSNY and Commercial Waste trucks was analyzed. Corrected utilization factors were applied to these on site queuing vehicles between the DEIS and this FEIS.

~~Boilers would be located within the processing buildings, but are not a significant noise source.~~is FEIS. ~~Roof exhaust fans are located on top of the processing buildings; however, manufacturers' data for a typical roof exhaust fan has a sound pressure level of 45 dBA at 50 feet. Even with 10 roof exhaust fans, the Lp for these fans without enclosures would be 55 dBA at 50 feet, which would not change the overall noise level calculated for each Proposed Plan Facility and Alternative Facility, as applicable. The exhaust fans for the Converted MTSs are located within the processing buildings on an enclosed heating, ventilation and air conditioning (HVAC) platform located above the tipping and loading levels. This enclosure and the fact that the fans are located within the building will further attenuate the noise levels. Therefore, noise contributions from roof exhaust fans were not included in the analysis for each Converted MTS.~~

The steps involved in performing a CEQR detailed on-site analysis were as follows:

- **Step 1**: Calculate the cumulative boundary noise levels from equipment located inside the plant building during the on-site noise analysis hour. For each piece of equipment:

  a) Establish the sound power level (SWL).

  b) Calculate the sound pressure level (SPL) at the inside of the building wall.

c) Determine the SPL ~~in the~~ outside ~~areas~~ of the building by applying a ~~20~~ 15 decibel (dB) reduction to the SPL at the inside of the building wall due to transmission through the wall.

d) Use the outside SPL and area of the wall to calculate the SWL of the wall.

e) Convert the wall SWL to an SPL at selected distances to the plant boundary taking into account multiple pieces of equipment of the same type and the equipment utilization factor (when equipment utilization is 100% during 1-hour, the SPL is equivalent to $L_{eq(1)}$.

- Repeat steps (a) through (e) for all plant equipment operating indoors during the on-site noise analysis hour.

- **Step 2**: Calculate the noise level contributions from all of the outside equipment in operation during the on-site noise analysis hour at the closest noise-sensitive receptor. For each piece of outside equipment, including on-site DSNY and other agency collection vehicles:

a) Establish the SPL at 50 feet from the noise source, the reference distance. ~~(A reference noise level at a reference distance is required to predict noise levels at certain distances from a source.)~~

b) Convert the SPL at 50 feet to the SPL at the distance to the closest noise-sensitive receptor, taking into account multiple pieces of equipment of the same type and the equipment utilization factor. For all equipment except DSNY collection vehicles, this calculation utilizes a -6 dB/distance doubled drop-off rate to express noise propagation on-site. This drop-off rate is generally assumed to occur close to (in the near field of) a point source. For DSNY collection vehicles, this calculation utilizes a -4.5 dB/distance double drop-off rate to express noise propagation on site. This drop-off rate is generally assumed to be a line source.

c) Make appropriate corrections for factors such as shielding.

- Repeat steps (a) through (c) for all outside equipment.

- **Step 3:** Calculate the overall facility-predicted noise level at the closest sensitive receptor by logarithmically adding the L_{eq} contributions from plant equipment operating indoor and outdoors at that location.

The overall facility-predicted noise level was logarithmically combined to the background (measured) noise levels (to determine an overall predicted combined noise level (Future Build noise level). The difference between the overall predicted combined noise level (Future Build

noise level) at the receptor and the background (measured) noise level (Existing noise level) was compared with noise impact CEQR Threshold defined in Sections 3.19.3.2 and 3.19.3.4. ~~If a noise impact is predicted, a more refined analysis, including refining utilization factors for equipment, will be performed.~~

3.19.7.1.2 Current Noise Code

Noise levels from indoor and outdoor on-site activities were combined ~~logarithmically~~ at selected locations around the site boundary. The steps involved in performing a Current Noise Code analysis were as follows:

- **Step 1**: Calculate the cumulative boundary noise levels from equipment located inside the plant building during the on-site noise analysis hour. For each piece of equipment:

  a) Establish the SWL.

  b) Calculate the SPL at the inside of the building wall.

  c) Determine the SPL ~~in the~~ outside ~~areas~~ of the building by applying a ~~20~~ 15 dB reduction to the SPL at the inside of the building wall due to transmission through the wall.

  d) Use the outside SPL and area of the wall to calculate the SWL of the wall.

  e) Convert the wall SWL to an SPL at selected distances to the plant boundary taking into account multiple pieces of equipment of the same type and the equipment utilization factor (when equipment utilization is 100% during 1-hour, the SPL is equivalent to $L_{eq\ (1)}$.

  - Repeat steps (a) through (e) for all plant equipment operating indoors during the on-site noise analysis hour. To determine the total projected plant boundary noise levels from all indoor plant equipment at the selected locations, logarithmically add the L_{eq} contributions from each piece of indoor equipment.

- **Step 2**: Calculate the cumulative plant boundary noise level contributions from all of the outside equipment in operation during the on-site noise analysis hour. For each piece of outside equipment, including on-site DSNY and other agency collection vehicles:

a) Establish the SPL at 50 feet from the noise source, the reference distance. ~~(A reference noise level at a reference distance is required to predict noise levels at certain distances from a source.)~~

b) Convert the SPL at 50 feet to the SPL at distances to selected plant boundary locations, taking into account multiple pieces of equipment of the same type and the equipment utilization factor. For all equipment except DSNY collection vehicles, this calculation utilizes a -6 dB/distance doubled drop-off rate to express noise propagation on site. This drop-off rate is generally assumed to occur close to (in the near field of) a point source. For DSNY collection vehicles, this calculation utilizes a -4.5 dB/distance double drop-off rate to express noise propagation on site. This drop-off rate is generally assumed to be a line source.

c) Make appropriate corrections for factors such as shielding.

- Repeat steps (a) through (c) for all outside equipment. To determine the total projected plant boundary noise levels from the outside equipment at the selected locations, logarithmically add the L_{eq} contributions from each piece of outside equipment.

- **Step 3**: Calculate the total L_{eq} at selected locations around the property line by logarithmically adding the L_{eq} contributions from plant equipment operating indoors.

These total L_{eq} at selected boundary locations around the property lines were compared to the Current Noise Code criteria defined in Sections 3.19.3.1 and 3.19.3.5. ~~If a noise impact is predicted, a more refined analysis, including refining utilization factors for equipment, will be performed.~~ The noise level at boundary locations above water was not included in the analysis because noise sensitive receptors are not expected to be in this area. In addition, if receptors are in the area, they would most likely be in motorized boats that would emit a louder noise level than that emitted by the facility. Since the DEIS, additional property boundary points were added and analyzed in this FEIS at each Proposed Plan Facility and Alternative, as indicated in the revised Noise Code Analysis results tables in Chapters 4.0 through 31.0, as applicable.

3.19.7.1.3 Performance Standards for Zoning Code

Spectral noise levels from indoor and outdoor on-site activities were combined logarithmically at selected locations around the site boundary. Outdoor DSNY collection vehicles~~,~~ or ~~other agency~~commercial waste hauling ~~collection~~ vehicles, ~~as well as~~and tug boats, are ~~which were~~

considered as transportation facilities, and were not included in the Performance Standards for Zoning Code analysis, in accordance with the City Zoning Code Performance Standards for Manufacturing Districts. The steps involved in performing a Zoning Code analysis were similar to those performed for the Current Noise Code analysis but on a spectral noise L_{max} basis. The spectral noise levels predicted at selected boundary locations around the property lines were compared to the Performance Standards for the Zoning Code analysis defined in Section 3.19.3.3. Since the DEIS, additional property boundary points were added and analyzed in this FEIS at each Proposed Plan Facility and Alternative, as indicated in the revised Zoning Code Analysis results tables in Chapters 4.0 through 31.0, as applicable.

3.19.7.2 Off-Site Impact Analysis

As mentioned previously, the off-site analysis used the FHWA TNM 2.1 or field simulations of DSNY and other agency collection vehicles along routes near sensitive receptors to predict traffic noise levels for the Future Build Condition. At study areas where TNM was used, sensitive receptors within 200 feet and with an unobstructed view of the roadway were identified and modeled to determine the predicted traffic noise levels for the Existing, Future No-Build and Future Build Condition. In most cases, this limited the analysis to the first row of buildings along a roadway. If necessary, the FHWA shielding methodology was applied if buildings obstructed the line of site between a roadway and a sensitive receptor.

If the TNM analysis predicted an impact at a site, noise measurements were performed at the same site that included simulation of DSNY and other agency collection vehicles passing through the site during all hours that the ~~second~~ first level screening resulted in a possible impact. For this procedure, two sets of noise measurements were taken, with and without DSNY collection vehicles, by routing a set number of such trucks during the affected nighttime hours past the sensitive receptor. The difference between the noise levels with and without DSNY collection vehicles were compared to the CEQR standards. In addition, TNM was used to determine the existing and the existing plus DSNY collection vehicle (project-related traffic) noise level for comparison purposes.

From these two sets of measurements obtained during the simulations, it was possible to calculate the average acoustic energy from each individual truck movement in terms of $L_{eq(1)}$. The individual truck noise energy which was calculated for each site was used to estimate number of trucks that could be allowed on a street without causing noise impact, per CEQR guidelines. Appendix K provides a more detailed description of the truck simulations.

The existing noise level predicted by TNM and the existing noise level estimated from simulation tests (as described above) did not always agree. In cases where such differences were less than 3 dBA, the TNM-predicted noise levels were adjusted so that it agreed with the estimated existing noise level. However, for purposes of CEQR analysis, it is the difference between the Future Build and Future No-Build that matters, and this difference will not change following the adjustment to the Future Build and Future No-Build noise levels.

In cases where the disagreement between the TNM-predicted existing noise level and the estimated or measured existing noise level was more than 3 dBA, such disagreements were attributed to the fact that the existing noise level in some areas of the City during the quietest hours of the night is not entirely from road traffic but is dominated by other noise sources which include sirens, window air conditioners, and activities in bus garages and in the general community. Under these circumstances, the TNM modeling may not strictly be applicable though it was performed for comparison purposes.

3.19.8 Combined Impact Analysis

For those locations in which detailed on-site and off-site noise analyses were performed, a combined source analysis may also be conducted if the potential impacts affected the same noise-sensitive receptor. The combined analysis study area was defined by the 55 dBA isopleth contours from the on-site source and the bottom driveway entrance to the site. The other limits for the combined analysis study area were defined by the first row of buildings along the roadway between the 55 dBA contour and the driveway entrance to the site.

If noise-sensitive receptors were not located in the study area, a combined analysis was not performed. If noise-sensitive receptors exist in the study area, then the TNM was used to predict mobile traffic noise levels at that receptor. Noise levels from the on-site source were estimated at each receptor using the spreadsheet model employed in the on-site analysis. The combined noise level was calculated using a spreadsheet. The combined analysis was performed during the off-site noise analysis hour(s).

3.19.9 Typical Mitigation Measures

Mitigation measures available were limited to those that affect the source, the propagation path or the receiver. The typical mitigation measure for the path of noise between source and receiver is a noise wall. Noise walls can be designed to provide noise attenuation for noise-sensitive areas located relatively close to the wall. Noise attenuation provided by the wall decreases as distance from the wall increases. Receiver treatments may include the construction of noise walls at residential property lines or the installation of replacement windows and air conditioning. The latter two mitigation measures are suggested in the 2001 CEQR Technical Manual. Typical mitigation measures at the source include: (1) changes in operations schedules to reduce noise emissions; (2) reduction in DSNY collection vehicles; (3) using noise mufflers for the exhaust pipes of material handling equipment (e.g., side loaders, yard tractors, etc.) or other source noise reduction methods; and (4) maintaining the equipment through regularly scheduled maintenance and repairs. If significant impacts were identified, noise attenuation measures were explored and either included in the Proposed Plan Facility and Alternative Facility (as applicable) design or operations plans, if feasible, or evaluated to identify if the mitigation measures would avoid, lessen or mitigate the impacts. ~~If significant impacts were identified, noise attenuation measures were explored and either included in the Proposed Plan Facility and Alternative Facility (as applicable) design or operations plans, if feasible, or evaluated to identify if the mitigation measures would avoid, lessen or mitigate the impacts.~~ However, mitigation measures that were developed for a specific code or regulation may no longer be required and therefore not implemented if the code or regulation is no longer applicable to the Proposed Plan Facility or Alternative Facility, or if the code or regulation no longer exists at the time of construction.

Since publication of the: (1) EIS-level noise analysis for Converted MTSs presented in Appendix D to this FEIS - the Commercial Waste Management Study, Converted MTSs Commercial Waste Processing and Analysis of Potential Impacts -Volume III; and (2) the DEIS, the noise analyses were revised based on the proposed Converted MTS final designs, inclusion of the fans in the analyses, and corrected utilization factors for the on-site queuing waste hauling vehicles. For the four Proposed Plan Converted MTSs, the revised noise analysis results are reported in Chapters 4 through 7 of this FEIS. As a result of these revisions, additional restrictions on the deliveries of commercial waste to the proposed North Shore Converted MTS are required to mitigate potential predicted on-site noise impacts. Therefore, the revised "Summary of Commercial Waste Trucks Allowed for the 8:00 p.m. to 8:00 a.m. Period" table is included in Appendix D of this FEIS, and hourly summaries presented in Chapter 7 of this FEIS.

CHAPTER 4 ENVIRONMENTAL REVIEW: HAMILTON AVENUE CONVERTED MTS

4.1 Introduction

The results of the environmental analyses of the Hamilton Avenue Converted MTS are presented in the following sections:

4.2 Land Use, Zoning, and Public Policy
4.3 Socioeconomic Conditions
4.4 Community Facilities and Services
4.5 Open Space
4.6 Cultural Resources
4.7 Urban Design, Visual Resources, and Shadows
4.8 Neighborhood Character
4.9 Natural Resources
4.10 Hazardous Materials
4.11 Water Quality
4.12 Waterfront Revitalization Program
4.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
4.14 Traffic, Parking, Transit, and Pedestrians
4.15 Air Quality
4.16 Odor
4.17 Noise
4.18 Commercial Waste to the Hamilton Avenue Converted MTS

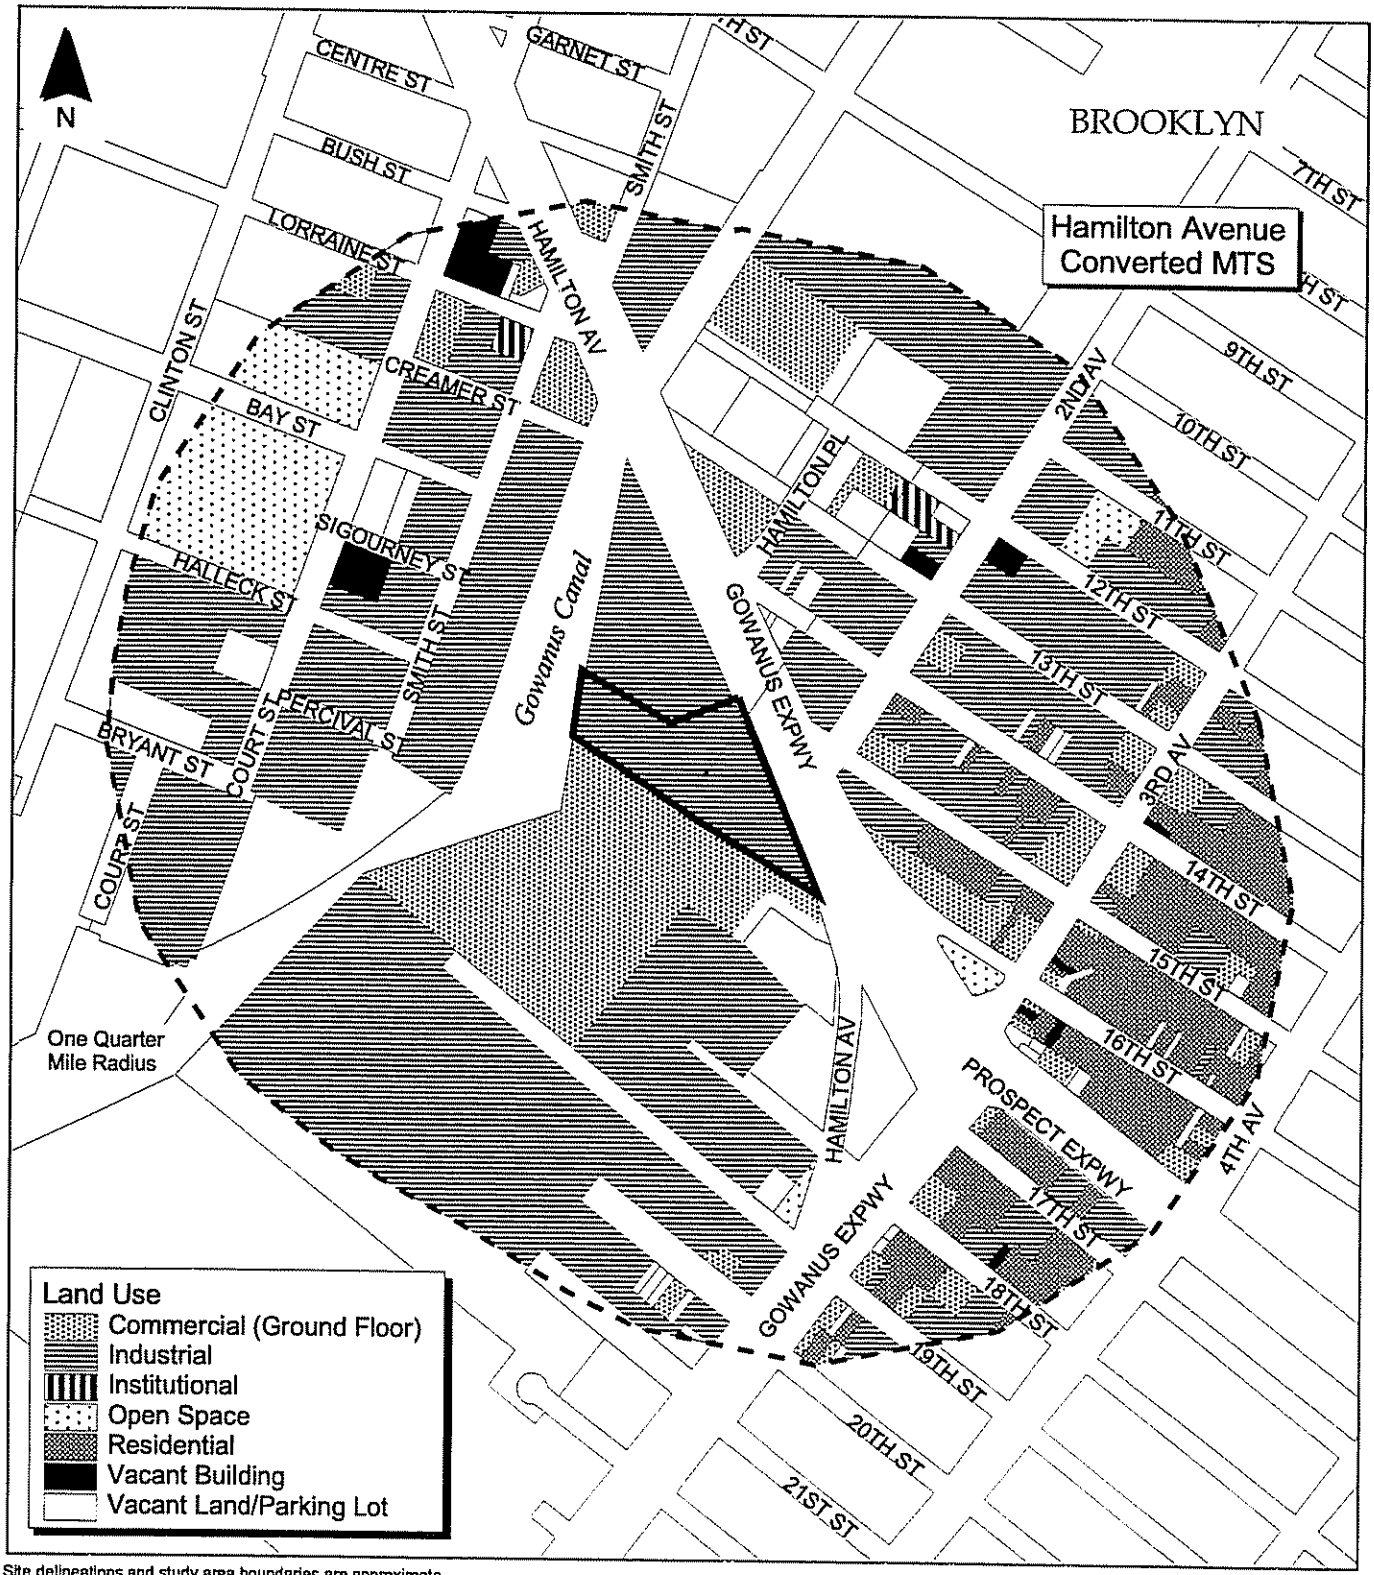
Section 2.2.1 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

4.2 Land Use, Zoning, and Public Policy

4.2.1 Existing Conditions

4.2.1.1 Definition of the Study Areas

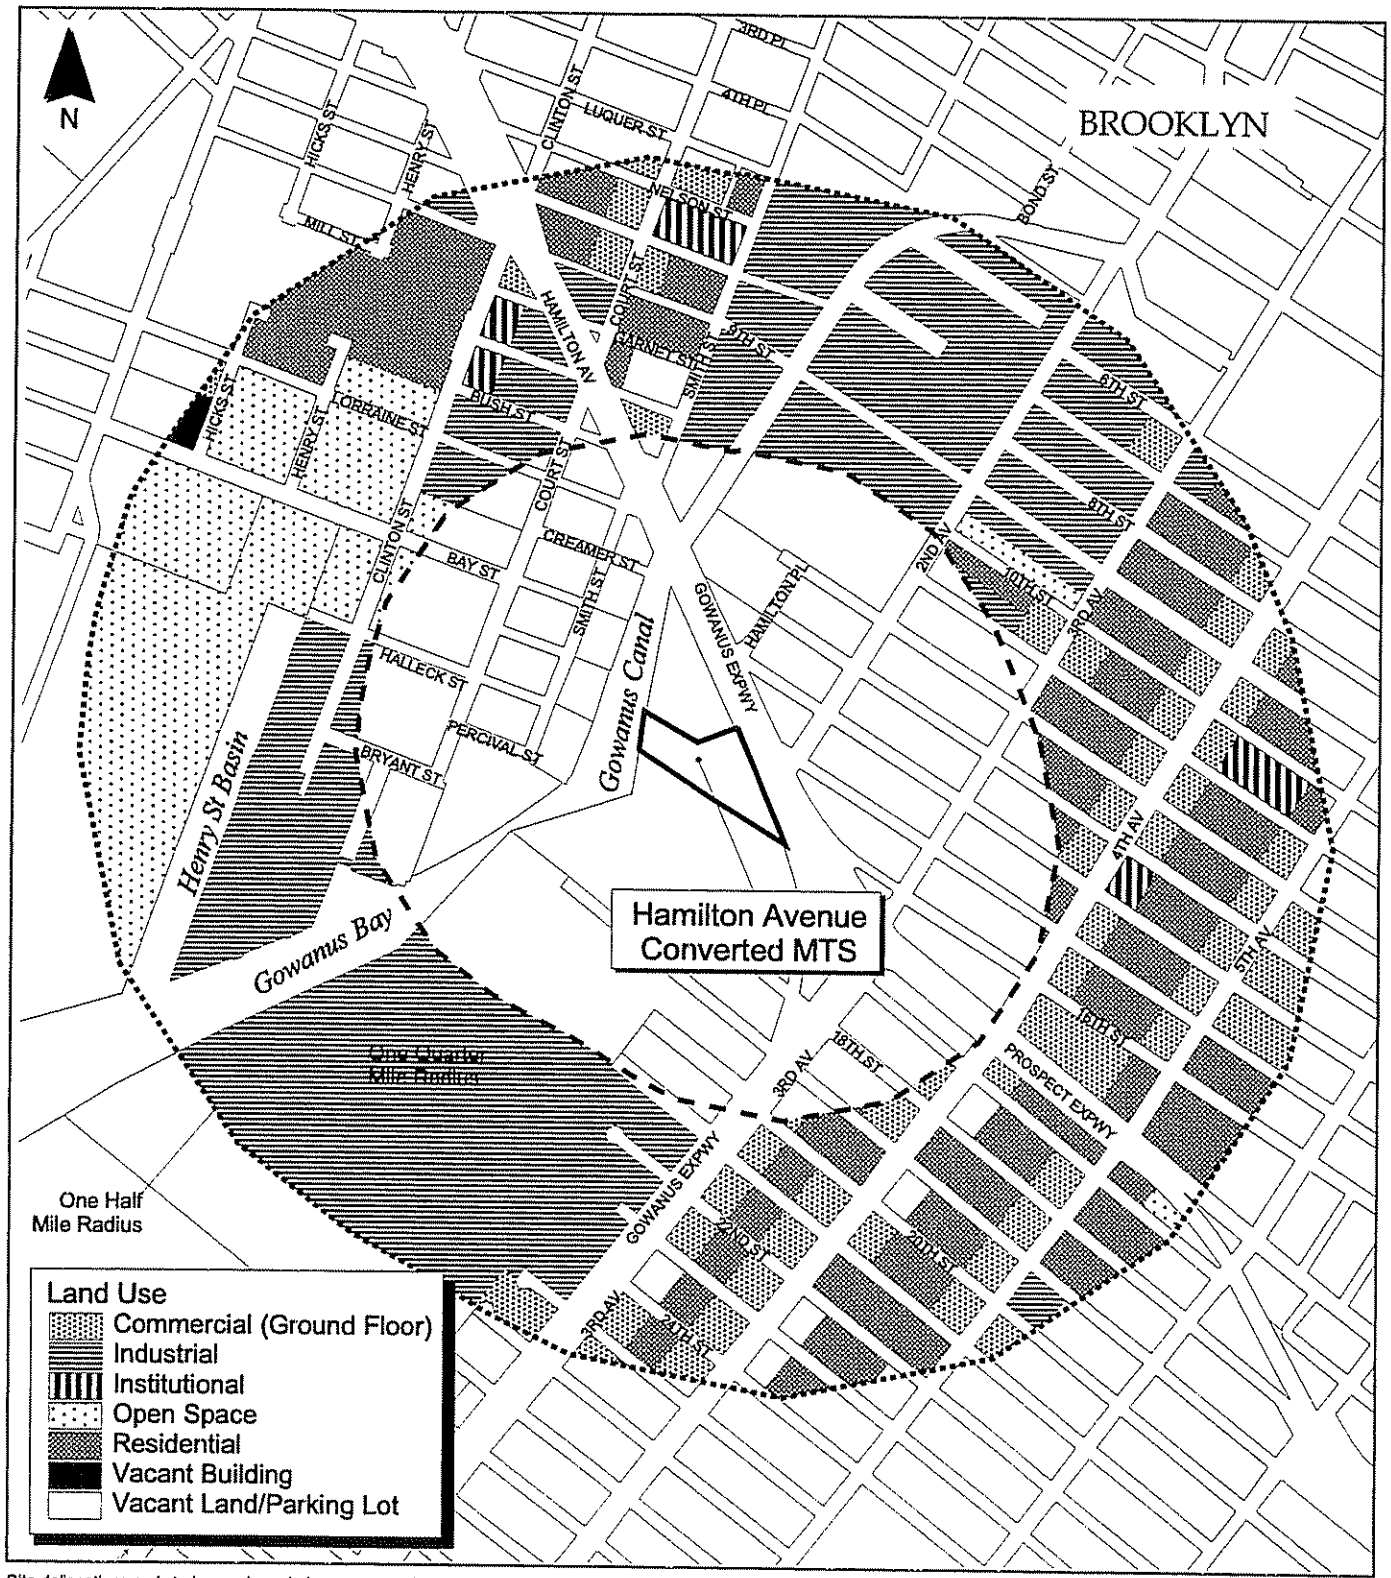
The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 4.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 4.2-2). Section 3.4 describes the methodology used in these analyses and Section 2.2.1 provides information on existing land uses and operations on the site.



4.2.1.2 Land Uses Patterns

4.2.1.2.1 General Context

The site is in a predominantly industrial area on the southeastern side of Gowanus Canal in Brooklyn at the mouth of the Gowanus Bay. It is surrounded by industrial uses, primarily warehousing and transportation infrastructure, and is separated physically from residential areas located further inland.



4.2.1.2.2 Land Uses in the Primary Study Area

The site is bordered on the west by the Gowanus Canal and on the northeast by an NYCDOT asphalt plant and storage yard. Hamilton Avenue, which is a busy arterial, and the elevated Gowanus Expressway define the eastern boundary of the site, separating it from various automotive service uses and warehouses beyond. The large, two-story parking lot/garage associated with a Home Depot on 19th Street borders the site on the south.

Site delineations and study area boundaries are approximate

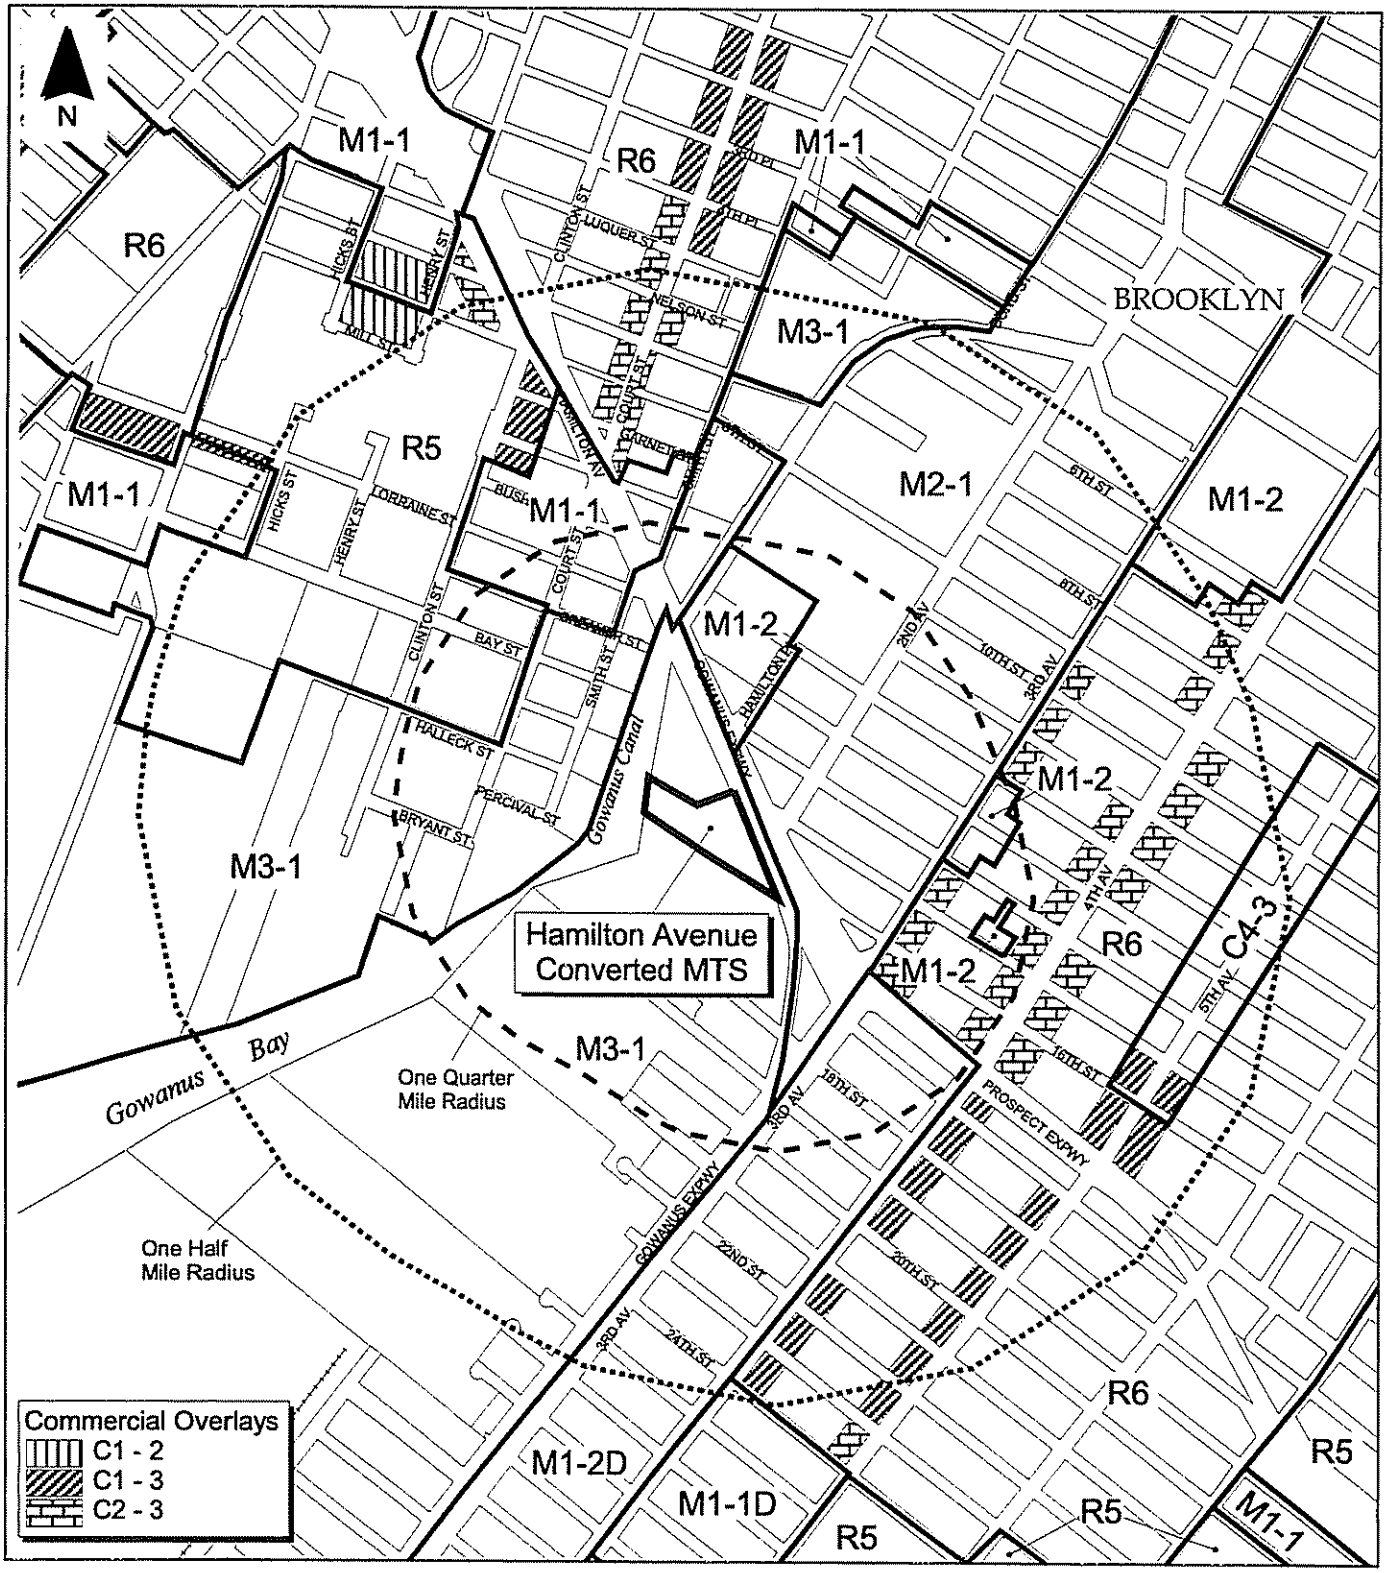
Figure 4.2-2 Land Use in the Secondary Study Area

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Large lots in the northeastern portion of the primary study area contain industrial and warehouse uses. Automotive services are located along Hamilton Avenue just east of the site, including DSNY's Brooklyn 2 garage.

Warehouses, automotive services and industrial uses, including Hess Industries oil tanks, are located in the northern portion of the primary study area, west of the canal. Further west is the Red Hook Houses Recreational Area (between Halleck Street, Court Street, Bay Street and Clinton Street). Southwest of the site, just beyond the Home Depot, are the Sunset Industrial Park and surrounding large-lot warehouses. Smaller-lot warehouses line the northwestern side of Third Avenue/Gowanus Expressway. There is a mix of warehousing, vacant buildings, residences and commercial uses southeast of Second Avenue, with more residences located southeast of Third Avenue.



4.2.1.2.3 Land Uses in the Secondary Study Area

Large-lot industrial uses line both sides of Gowanus Bay and Canal throughout the secondary study area southwest and northeast of the site. The area southeast of Third Avenue, in Park Slope, is almost exclusively residential with ground-floor commercial uses located on the avenues. The large Red Hook Houses complex is located west of Clinton Street, between Lorraine Street and West 9th Street, where it dominates the northwestern portion of the secondary study area. Vacant lots and large parkland areas surround the complex. A small portion of the large Carroll Gardens/South Brooklyn (Gowanus) neighborhood is included in the secondary study area northwest of the canal.

4.2.1.3 Zoning On and Near the Site

4.2.1.3.1 Zoning Within the Primary Study Area

The primary study area is zoned primarily for manufacturing: M3-1, M1-2 and M2-1 zoning districts are southeast of Gowanus Bay and Gowanus Canal and M3-1 and M1-1 districts are to the west. A small portion of the larger R5 residential zoning district in Red Hook is just beyond these manufacturing districts. (See Figure 4.2-3 and Table 3.4-1: Zoning District Characteristics.) A small portion of a larger R6 district lies east of Third Avenue.

Site delineations and study area boundaries are approximate.

Figure 4.2-3 Zoning

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

4.2.1.3.2 Zoning Within the Secondary Study Area

The majority of the secondary study area is zoned for manufacturing, although it includes portions of the residential zoning districts east of Third Avenue and west of the canal in Red Hook.

4.2.1.4 Plans and Policies

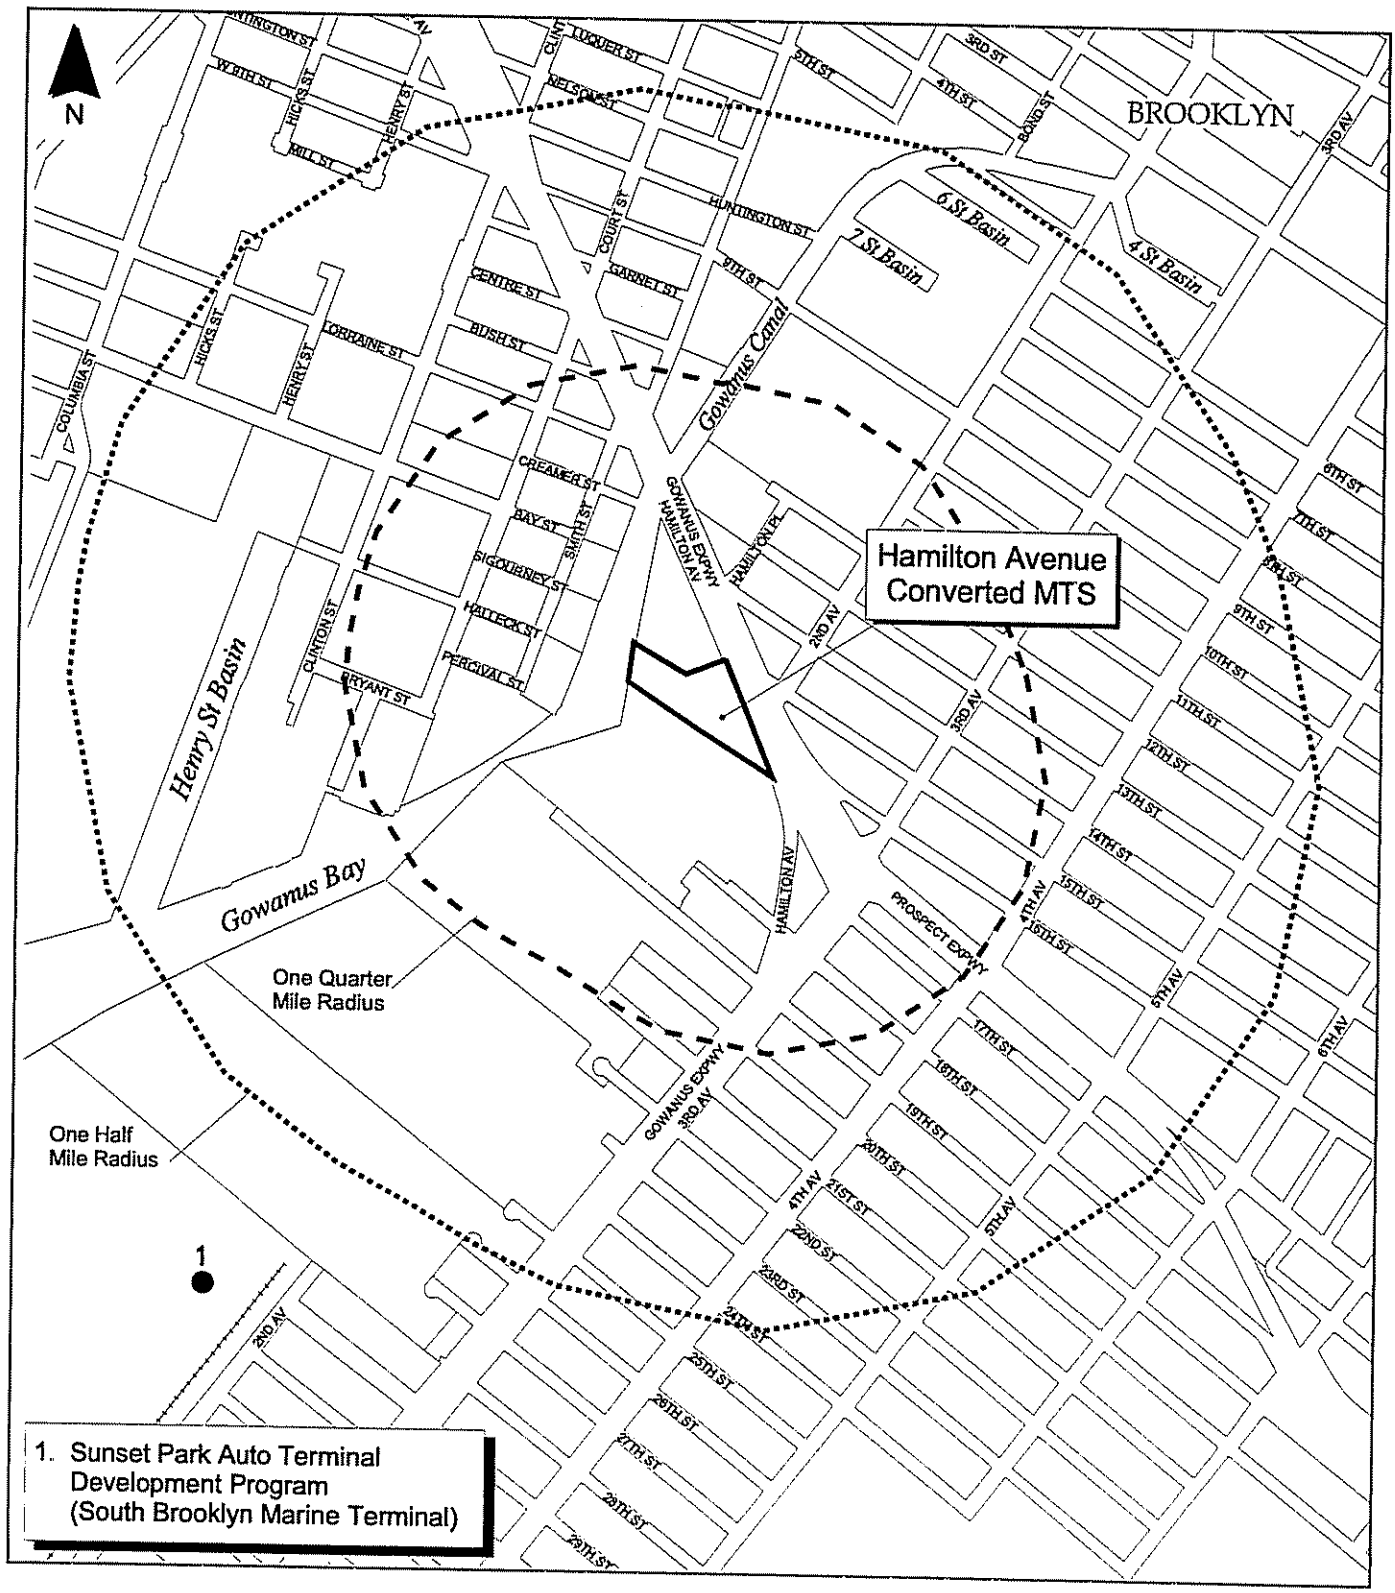
CD 6 covers most of the primary and secondary study areas east and north of Gowanus Bay and north of the Prospect Expressway, but not the site. The Fiscal Year (FY) 2004 CDNS for CD 6 reports the community's desire to study the economic development potential of the Gowanus Canal, such as through the development of maritime light manufacturing. The community overall also notes the need to expand enforcement of truck traffic regulations, especially in the Red Hook neighborhood.

CD 7 covers the site and the remainder of the study area. The FY 2004 CDNS for CD 7 does not make specific reference to recommended or anticipated physical development affecting the site or study area. Specifically regarding the site, the community mentions its desire for long-term export by barge or rail to replace the current truck-dependent waste handling. The CD Board also requests that comprehensive air quality studies be undertaken. The CDNS reports that 197-a planning efforts have been initiated to ensure intelligent community-based economic development planning for the waterfront.

The Red Hook 197-a Plan, which is relevant to the portion of the study area northwest of the bay, contains no recommendations for land immediately across the canal from the site or for land within view of the site. It does, however, recommend the general preservation and expansion of industrial and maritime uses present in the southeast section of Red Hook. Specifically, the plan suggests that the Red Hook Marine Terminal and the waterfront between Erie Basin and Gowanus Bay be preserved and strengthened.

The site is located within the northernmost portion of the Sunset Park sub-area according to the Plan for the Brooklyn Waterfront, within Reach 14, which stretches from Brooklyn's northernmost East River shoreline to about 65th Street on the southern end. The plan notes that

there is no natural waterfront of significance and, although it does recommend development of public access, such public access is not recommended for the industrial waterfront within the study area. The plan recommends that Erie Basin and Sunset Park be designated as Significant Maritime and Industrial Areas (SMIAs) to form the hub of Red Hook's working waterfront. Likewise, the plan specifically recommends investment in the infrastructure associated with the publicly owned land along the Gowanus Canal. (See Section 4.12 for a review of consistency with the Waterfront Revitalization Program [WRP].)



NYCEDC plans for development of the Sunset Park waterfront (29th Street to about 65th Street) south of the secondary study area are described in its Strategic Plan. This development would potentially include a new auto terminal at the South Brooklyn Marine Terminal (SBMT) and a 90-acre container port.

4.2.2 Future No-Build Conditions

The existing incinerators on the site will be demolished, though the existing MTS will remain, and the associated DSNY salt storage and parking area will continue to be fully utilized. It is reasonable to anticipate that the Future No-Build Conditions in the primary and secondary study areas will generally resemble Existing Conditions; although new development may be realized, it would not alter the land use of the study areas overall.

On April 30, 2003, the City Planning Commission adopted the Park Slope Rezoning Proposal that would increase the permitted density for residential development on Fourth Avenue to 6.02 (R8A) from 3.0 (R6 with Quality Housing on a wide street). In its environmental review, NYCDCP identified a number of development sites along the Fourth Avenue corridor, but its analysis showed that the most likely sites to be developed in the next 10 years would be north of the site, outside the secondary study area.

Additionally, an IKEA warehouse is proposed for a site at Columbia Street and Halleck Street, outside the secondary study area, north of Gowanus Canal in Red Hook. It would be 300,000 square feet with 1,400 parking spaces. This development would require a rezoning action, as well as various special permits and certifications through the ULURP process. Although IKEA has not yet filed for the ULURP action, NYCDCP reports that the proposed Build year is 2005 or 2006. Figure 4.2-4 shows the planned development sites.

Site delineations and study area boundaries are approximate.

Figure 4.2-4 Planned Development Sites

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

4.2.3 Potential Impacts with the Hamilton Avenue Converted MTS

4.2.3.1 Land Use and Zoning

The Hamilton Avenue Converted MTS would entail replacing the existing deactivated MTS with a similar new one that would feature containerization functions. The new facility would be situated further inland, partly within the eastern portion of the site where the incinerator, which will have been demolished, now stands. Delivered waste would be containerized for transport on barges to disposal sites out of the City – a change from the previous practice of loading loose waste onto larger barges for intra-harbor transport to the now-closed Fresh Kills Landfill. The reactivation of garbage handling at the site would not be likely to affect the surrounding land use or zoning patterns.

4.2.3.2 Consistency with Public Plans and Policies

There are no recommendations stated in relevant plans and policies that specifically relate to the site, study areas or proposed development, but the Hamilton Avenue Converted MTS would be consistent with the Red Hook 197-a Plan and the Plan for the Brooklyn Waterfront insofar as it would enhance existing public infrastructure and maritime industrial uses on the Gowanus Canal and Gowanus Bay.

4.3 Socioeconomic Conditions

4.3.1 Existing Conditions

4.3.1.1 Definition of the Study Areas

Two study areas were used for analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (See Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area is comprised of Census Tracts 18 and 117 (see Figure 4.3-1). Census Tract 18 covers industrial waterfront areas between Gowanus Bay and approximately 65th Street, approximately to the west of Second Avenue. Census Tract 117 covers an area of approximately one dozen blocks northeast of the Gowanus Expressway and south of 10th Street, between Second Avenue and Fourth Avenue. For comparison purposes, both 1990 and 2000 Census data were also gathered at the borough and City levels.

Detailed socioeconomic information referred to in the text but not presented in table format may be found in Appendix B.

4.3.1.2 Demographic Characteristics

4.3.1.2.1 Population

The total 2000 study area population was 4,328 persons (see Table 4.3-1). In terms of total population growth from 1990 to 2000, the study area experienced a considerably greater percentage increase (88%) than did the borough (7%) or the City (9%) during the same period.

4.3.1.2.3 Families and Households

There were 591 families in the study area in 2000 and the percentage of these families that had children under the age of 18 (58%) was larger than those families in Brooklyn with children under 18 (51%) and in the City (49%). There was a slightly smaller percentage of married-couple families in the study area (55%) than in the borough (59%) or the City (62%), and 56% of these families had children, greater than Brooklyn (50%) and the City (48%).

The proportion of families headed by a female householder was roughly the same in the three areas: 32% in the study area, 33% in the borough and 30% in the City. Of these, 60% had children under the age of 18, compared to 55% in the borough and the City.

There were 1,050 households in the study area in 2000, with an average household size of 2.8 persons, equivalent to Brooklyn and slightly greater than the City (2.6 persons).

From 1990 to 2000, the number of households in the study area increased by 32%, compared with a 6% increase in the borough and a 7% increase in the City.

4.3.1.2.4 Employment

Within the study area, 40% of people aged 16 and older participated in the labor force in 2000, compared to 55% in Brooklyn and 58% in the City. The majority of these people in all three areas were employed as private wage and salary workers.

There were proportionally fewer government workers in the study area – 12% of employed persons 16 years and over compared to Brooklyn (19%) and the City (16%). There were also fewer self-employed workers in the study area – 3% of the study area's working population as compared to 5% for the borough and 6% for the City.

From 1990 to 2000, the number of employed persons increased by 37% in the study area, while it decreased by 41% in the borough and remained the same in the City. Among employed persons, those engaged in government jobs decreased by 4% compared to a 14% decrease in the borough and a 10% decrease in the City.

Current forecasts indicate that about 88,754 employees worked in Brooklyn CDs 6 and 7 in 2005.[1]

4.3.1.2.5 Housing

Most of the housing units in the three areas were constructed before 1960. As of 2000, there were 1,129 housing units in the study area with a vacancy rate of about 8%, greater than either the borough (5%) or the City (6%). Most of the housing units were renter-occupied (71%), slightly more than the borough (69%) or the City (66%). Median monthly rent ($755) was higher than in the borough ($672) and the City ($705). The 2000 median value of housing units in the study area ($173,300) was lower than in Brooklyn ($224,100) or the City ($211,900). In the study area, housing values increased by 23%, compared to increases of 15% and 13% in Brooklyn and the City.

The turnover in the study area (52%) from 1995 until 2000 was greater than that of the borough and the City (both 43%).

From 1990 to 2000, a total of 180 housing units were added in the study area, representing a 19% increase, markedly greater than the borough and the City (both 7%).

4.3.1.2.6 Education

Consistent with the lower number of children in the area, there was a lower rate of school enrollment (22%) than in either the borough (31%) or the City (29%). Of those enrolled in school within the study area in 2000, 60% were enrolled in elementary school or high school and

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

31% were enrolled in college or beyond. In Brooklyn, 64% were enrolled in elementary school or high school and 24% in college or beyond, while 62% of the City's enrolled population was in elementary or high school and 27% in college or beyond.

The study area witnessed a 14% increase in the number of persons enrolled in school from 1990 to 2000, equal to the borough and close to the City's (18%) growth.

The study area had a far lower educational attainment level than either the borough or the City. A smaller proportion (34%) of the study area population aged 25 and over had a college degree or some college education, compared to Brooklyn (42%) and the City (48%). The study area had a similar percentage of people with only high school diplomas (27%) compared to the borough (27%), but slightly greater than that of the City (24%).

The study area witnessed rising numbers of educational attainment from years 1990 to 2000. The number of college graduates increased 95%, and the same trend was evident in the borough and the City, which experienced increases of 41% and 29%, respectively.

4.3.1.2.7 Income and Poverty

In 2000, the median household income ($30,833) and median family income ($33,233) were lower than in Brooklyn ($32,135 and $36,188, respectively) and the City ($38,293 and $41,887, respectively). Compared to the larger two areas, a greater percentage of study area households were concentrated at the lowest income levels, with the majority of annual household incomes (57%) below $35,000. Thirty percent of households in the study area had incomes of $50,000 and above, compared with 33% in the borough and 40% in the City.

Within the study area, the percentage of families living below the poverty level (24%) was slightly more than that of Brooklyn (22%) and the City (19%). The percentage of families that have children under 18 living below the poverty level (34%) was greater than the percentages in Brooklyn (29%) or the City (26%).

The same percentage of persons in the study area and Brooklyn under the age of 18 were living below the poverty level in 2000 (34%), which was slightly more than the City (30%). The 2000 Census also reported that 33% of persons 65 and older were living below the poverty level in the study area, compared to 22% in the borough and 18% in the City.

Between 1990 and 2000, the percentage of people living below the poverty level grew 53% in the study area, far higher than in the borough (19%) or the City (20%).

4.3.1.3 Economic Conditions

The study area contains a number of industrial and municipal activities on the southeastern side of Gowanus Bay in Brooklyn. The site is bordered by an NYCDOT asphalt plant and storage yard, a Home Depot store and parking lot/garage and major transportation infrastructure elements. Southwest of the site, just beyond the Home Depot store on 19th Street, is the Sunset Industrial Park, surrounded by large-lot loft factory buildings, with smaller warehouses lining the northwestern side of Third Avenue/Gowanus Expressway. Automotive services and warehouses are located north and east of the site. Hess Industries tanks are on the west side of the bay in Red Hook.

Portions of the study area fall within the City's Southwest Brooklyn Economic Development Zone (EDZ). The EDZ program was created to stimulate economic activity in distressed areas. It encourages business development through targeted incentives and benefits to new and expanding commercial and industrial firms.

State benefits are available through wage tax credits, investment tax credits, sales tax refunds (building/construction costs) and financial assistance. Utility discounts and free security surveys are also provided to relocating or expanding businesses.

4.3.2 Future No-Build Conditions

4.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Brooklyn CDs 6 and 7 will remain about the same as current conditions.[2]

4.3.2.2 Economic Conditions

Improvements are planned for industrial and port facilities in Sunset Park and other City ports as part of the NYCEDC's Strategic Plan. In the near term, and potentially before 2006, an auto terminal is proposed at the South Brooklyn Marine Terminal about ½-mile from the site, at its closest. A subsequent phase of development at that property would include a 90-acre container terminal as part of the overall NYCEDC Sunset Park Development Program. The terminal would increase the area's job base and bring additional economic activity to the area. Other transportation and infrastructure improvements in the Sunset Park environs that are expected to occur within the next several years, such as increased rail access and float bridge improvements, will make the area more viable for industrial- and distribution-related firms.

Regional projections indicate that employment in Brooklyn CDs 6 and 7 will remain about the same as current conditions.[3]

The near-term economic health of industrial areas such as the study area may be supported by established City programs that are available through the Industrial Development Agency (IDA). These programs, such as the Industrial Incentive Program and the Small Industry Incentive Program, provide business tax incentives for capital renovation and expansion projects.

---

[2] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.
[3] Ibid.

4.3.3 Potential Impacts with the Hamilton Avenue Converted MTS

The Hamilton Avenue Converted MTS represents reactivation of solid waste transfer operations on the site with added containerization functions. Therefore, it would not result in socioeconomic changes in the study area. No significant direct or indirect impacts are anticipated related to socioeconomic conditions.

4.3.3.1 Residential Impacts

No direct or indirect displacement of residential uses would occur as a result of the Hamilton Avenue Converted MTS and land use and neighborhood character analyses predict no adverse impacts.

4.3.3.2 Direct Business and Institutional Impacts

No direct displacement of businesses or institutional uses is expected to occur as a result of the Hamilton Avenue Converted MTS.

4.3.3.3 Indirect Business and Institutional Impacts

The Hamilton Avenue Converted MTS would not affect the adjacent and nearby businesses, which are industrial uses congruent with MTS operations and added containerization activities.

4.3.3.4 Employment Impacts

The Hamilton Avenue Converted MTS is expected to generate approximately 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

4.4 Community Facilities and Services

4.4.1 Existing Conditions

4.4.1.1 Definition of the Study Areas

The primary study area is defined as that area within ¼-mile of the site. The secondary study area is defined as the area between ¼- and ½-mile from the site.

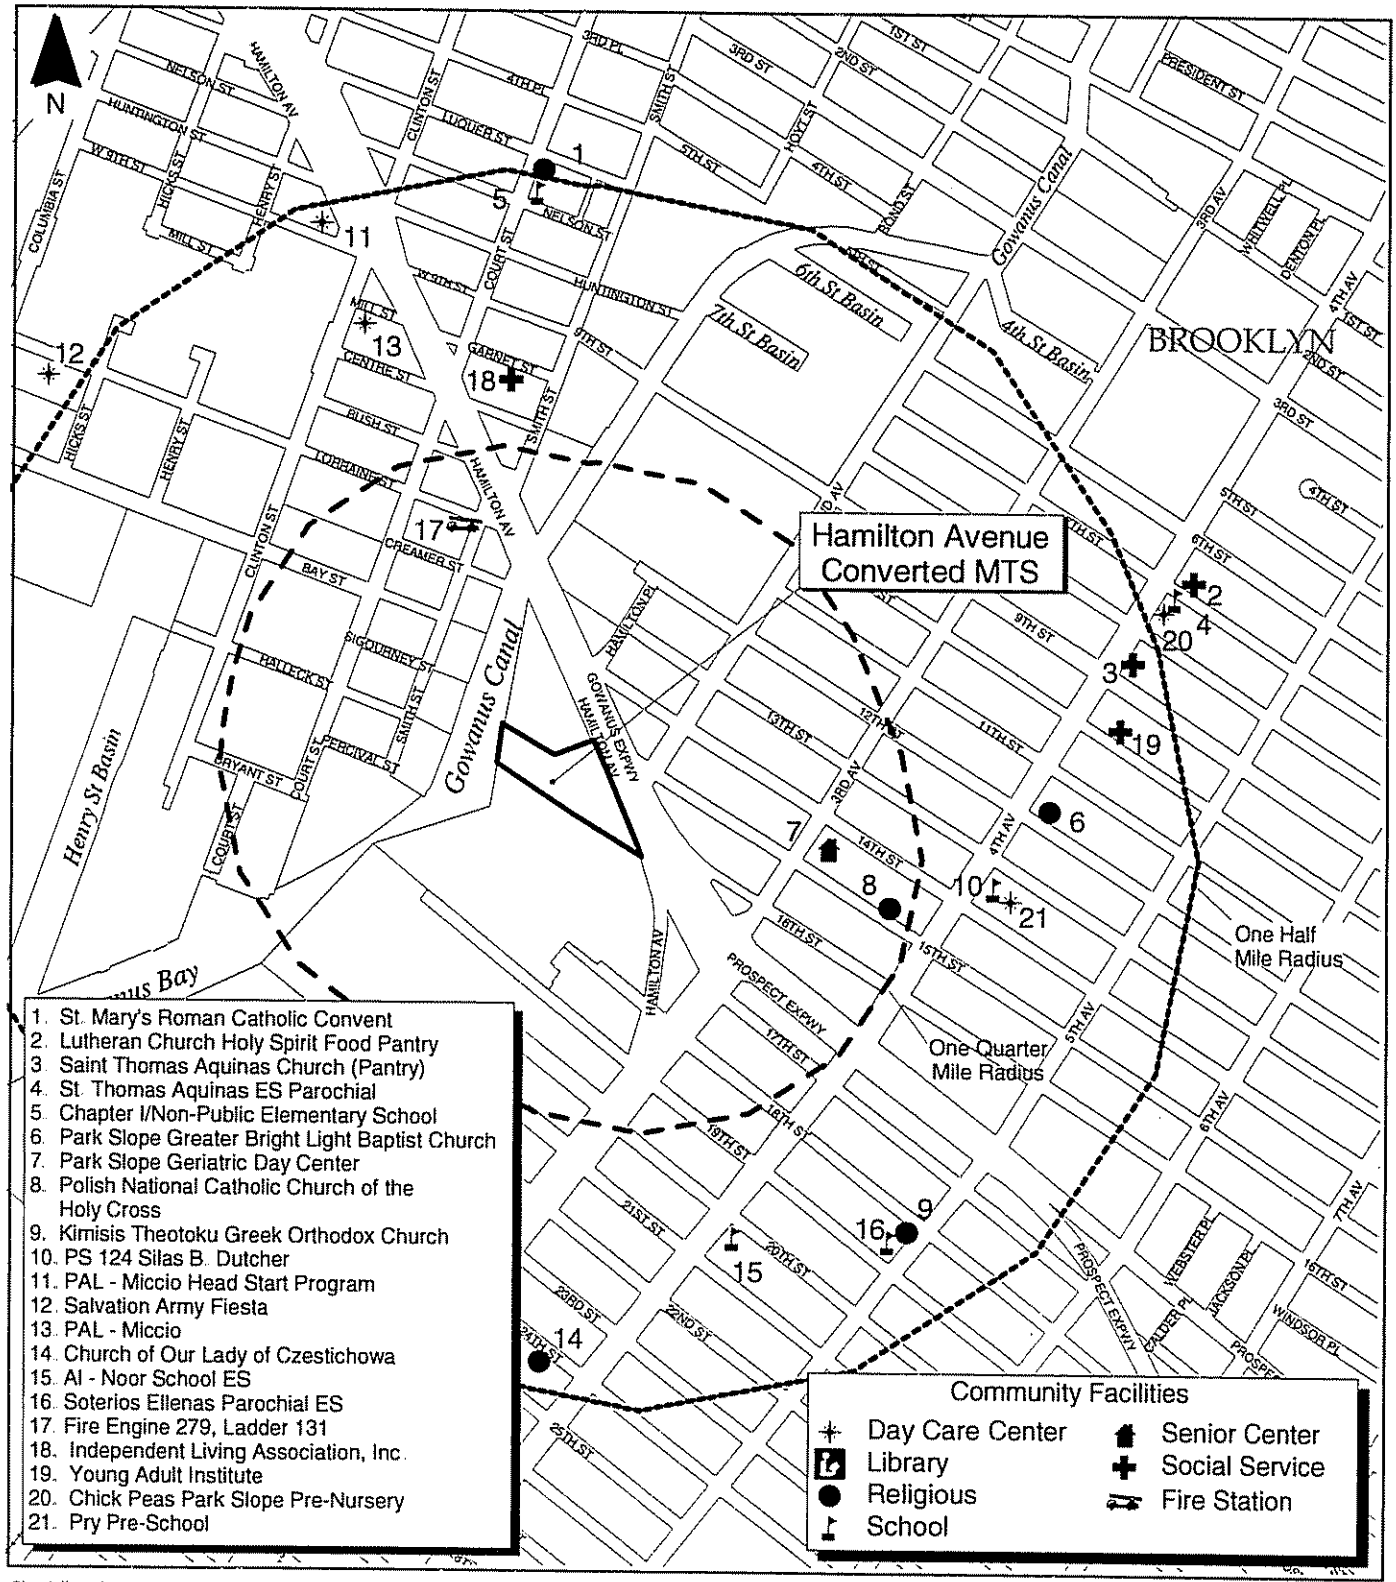
4.4.1.2 Summary of Community Facilities and Services

Three community facilities are located within the primary study area and 13 within the secondary study area, which includes portions of the Red Hook, Carroll Gardens and Park Slope neighborhoods. Community facilities serving the area are listed in Table 4.4-1 and shown on Figure 4.4-1.

4.4.2 Future No-Build Conditions

There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity and adequacy of delivery.

4.4.3 Potential Impacts with the Hamilton Avenue Converted MTS



The Hamilton Avenue Converted MTS would not create any significant new demand on services and community facilities and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the Hamilton Avenue Converted MTS (see Appendix A).

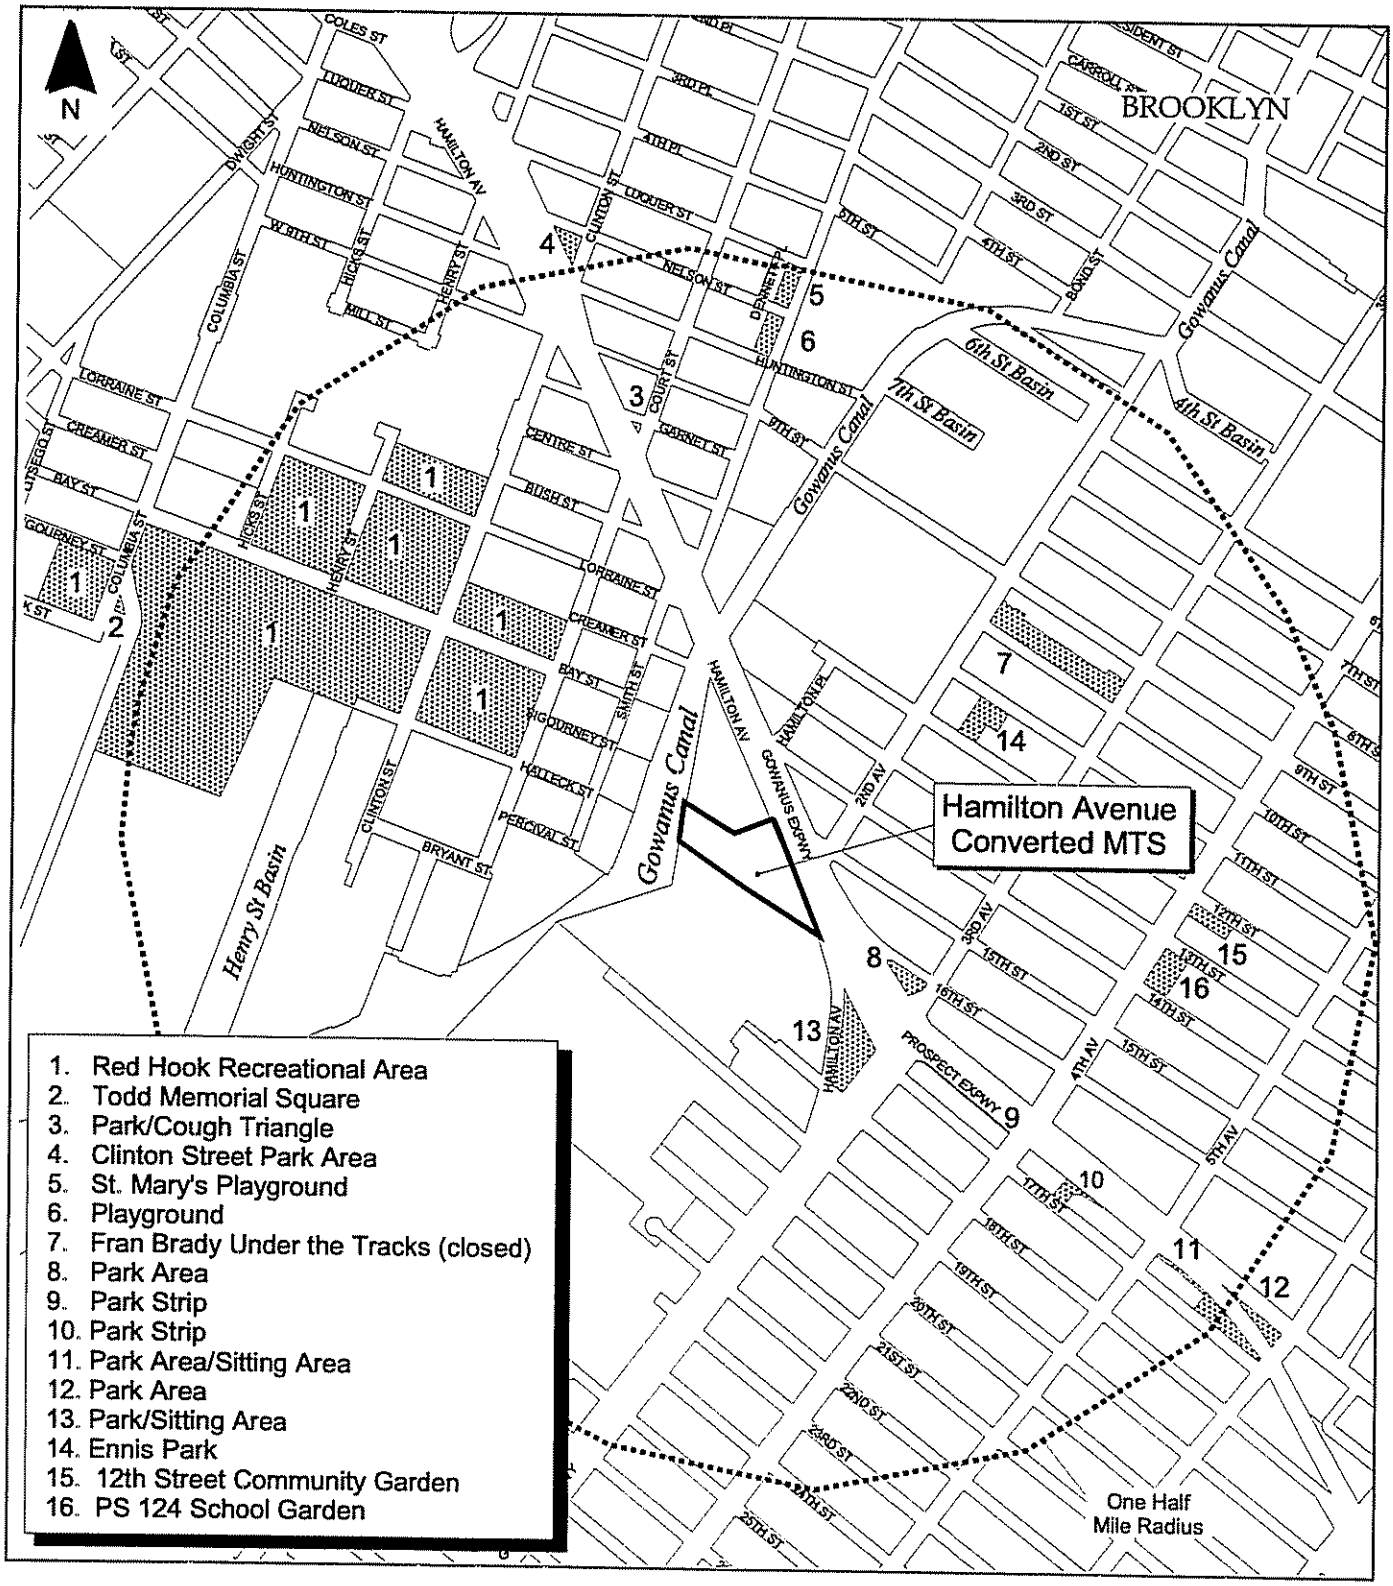
4.5 Open Space

4.5.1 Existing Conditions

4.5.1.1 Definition of the Study Area



The study area for open space is the area within ½-mile of the site.

4.5.1.2 Summary of Open Space in the Study Area

There are 14 public parks and open spaces within the study area, including one large regional facility. They are listed below in Table 4.5-1 and shown on Figure 4.5-1.

4.5.2 Future No-Build Conditions

NYCDPR has no long-term development plans or notable development projects associated with the open spaces in the study area. Currently, there is no ongoing work at these facilities nor capital funding allocated to them.

Since the publication of the DEIS, the Brooklyn Greenway Initiative (BGI) and the Regional Plan Association (RPA) have published the "Brooklyn Waterfront Greenway: A Plan for Community Boards 2 and 6 (DRAFT)," February 2005. In addition to proposing planning principles and guidelines, the draft plan also delineates a route for the greenway extending along the waterfront of the two Community Districts. West of the Hamilton Avenue site, the proposed route runs along the Red Hook waterfront northwest of the Gowanus Canal. A primary access point is designated at Smith Street and Hamilton Avenue, which is 1,000 feet north of the site on the opposite side of the canal. East of the site, the route would run inland to the south along Hamilton Avenue.

The report does not identify when the greenway might be in place; however, an interim greenway may be implemented in 2005 at the discretion of NYCODT and NYCDPR. As noted in the draft plan , the Brooklyn Waterfront has historically been a place of maritime and industrial uses, and the greenway would provide New Yorkers an opportunity to gain access to the working waterfront.

4.5.3 Potential Impacts with the Hamilton Avenue Converted MTS

The Hamilton Avenue Converted MTS would have no effect on any open space resources within the study area, nor would it physically change, diminish or eliminate any open space or reduce its use or aesthetic value, nor would it introduce a substantial new user population that might create or exacerbate over-utilization of open space resources.

Adverse environmental impacts to the interim greenway as a result of the Hamilton Avenue Converted MTS (analyzed in this FEIS) are unlikely, since traffic, air, odor, and noise studies predicted no significant adverse impacts associated at the site boundary or on the streets surrounding the proposed facility.

4.6 Cultural Resources

4.6.1 Existing Conditions

4.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site.

4.6.1.2 Development History of the Area

The Gowanus Canal is an artificial waterway that lies to the northeast of the site and extends from Hamilton Avenue to Douglass Street. In the 1840s, the natural canal was enlarged by Edwin C. Litchfield, a prominent Brooklyn landowner, who transformed it into an industrial watercourse 5,700 feet long, 100 feet wide and up to 15 feet deep.

The land along the Gowanus Canal soon developed with heavy industries such as coal, lumber, brick and stone yards; paint and ink factories; foundries; electroplating shops; flour, plaster and paper mills; and an early purveyor of household heating and cooking gas. As a result of these noxious industries and disposal practices, the canal became one of the City's most polluted waterways, and earned the moniker "Lavender Lake."

By the late 1800s, the immediate neighborhood had earned a reputation for rowdiness and was nicknamed the Gashouse District. One 12-block section of Smith Street had 23 taverns and many rooming houses that catered to seamen and laborers.

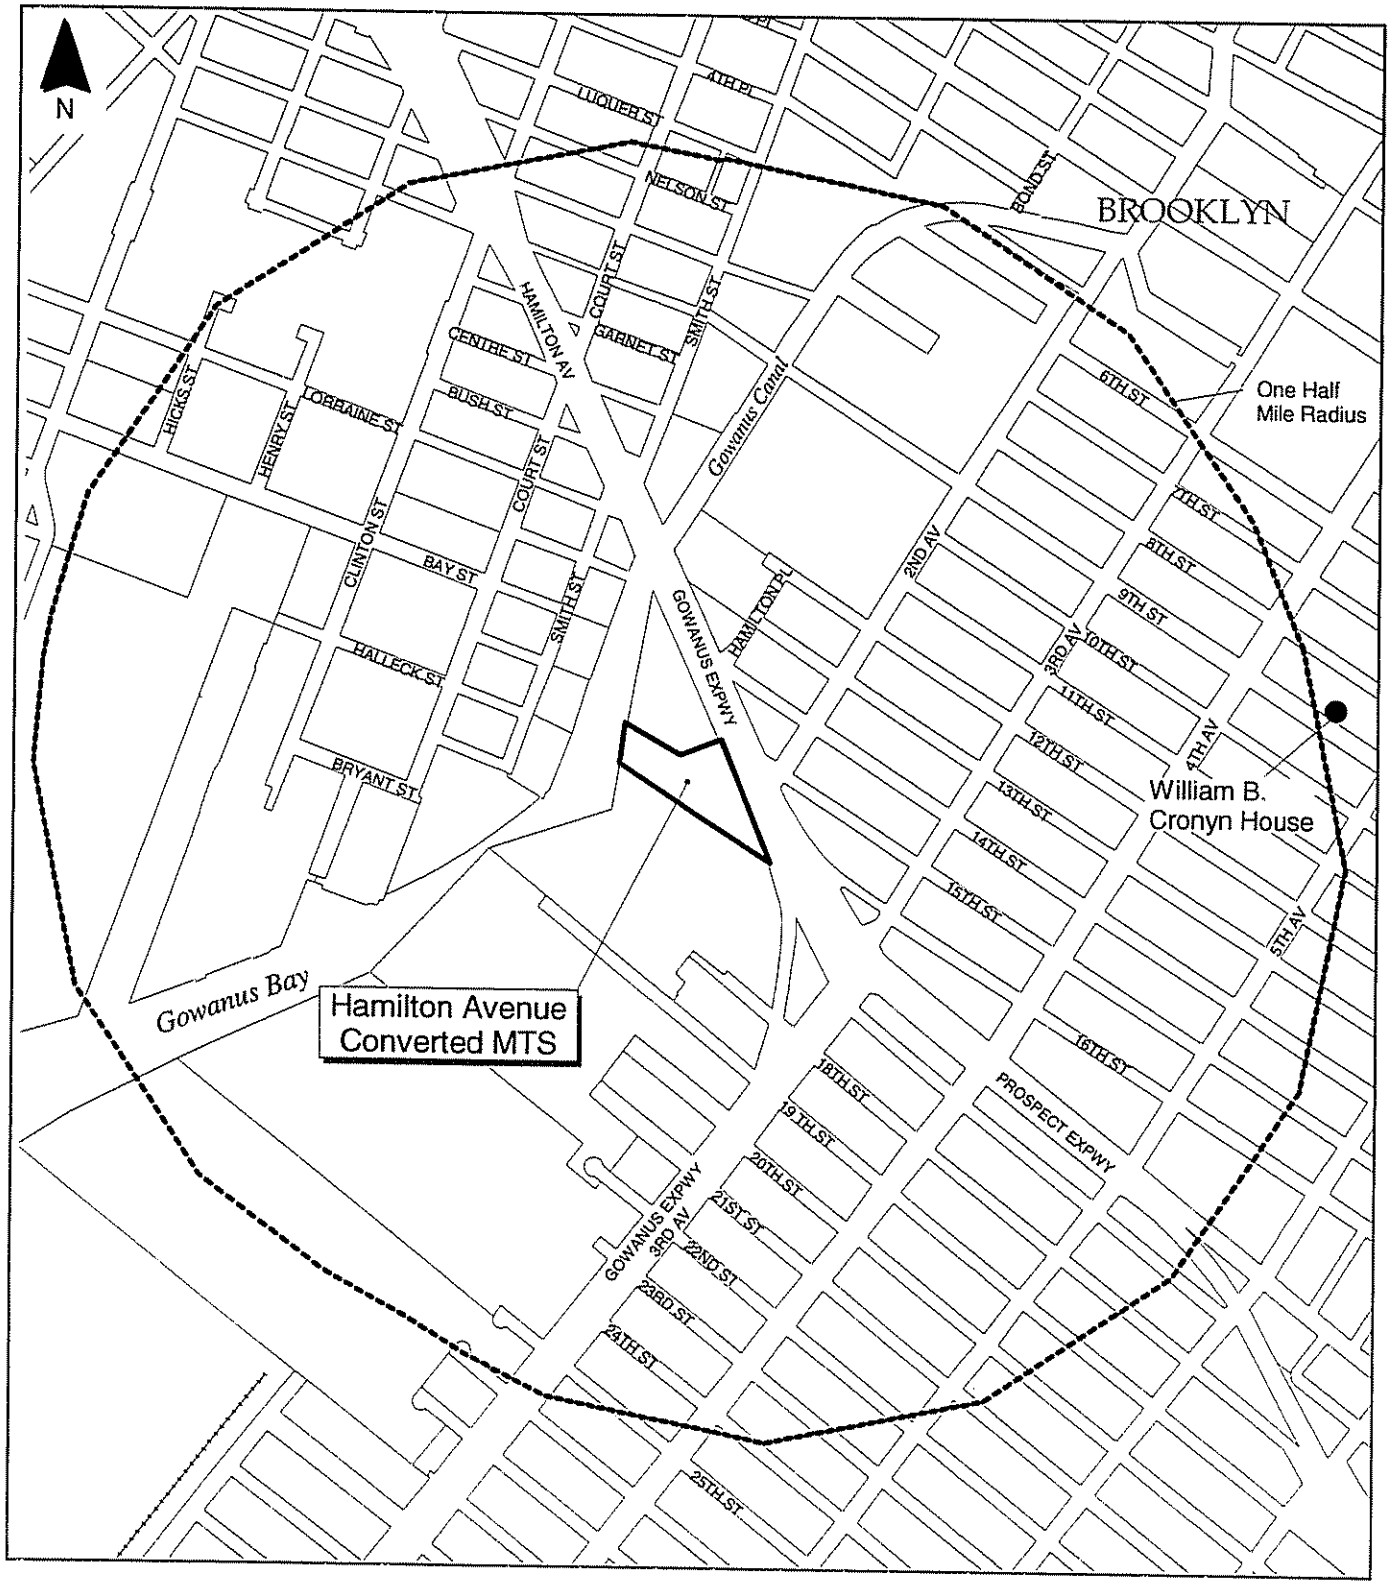
Industrial activity along the canal declined in the early 1960s with the move toward containerized shipping elsewhere in the New York Harbor. The canal continues to be an industrial venue lined with stone, gravel and concrete yards, some foundries, and outdoor-loading petroleum facilities.

The elevated Gowanus Expressway and Prospect Expressway, built in the 1950s, serve to physically separate the site from its surrounding inland context of Red Hook to the northwest, Carroll Gardens to the north and Park Slope to the southeast.

4.6.1.3 Cultural Resources on the Site

There are no elements of architectural or archaeological significance within the site.

4.6.1.4 Historic Resources Within the Study Area



There are no state-, national- or City-designated landmarks or historic districts within ½-mile of the site, although the City-landmarked William B. Cronyn House at 271 9th Street is just outside the study area (see Figure 4.6-1).

4.6.2 Future No-Build Conditions

There are no additional elements of potential architectural or archaeological significance slated for review. Therefore, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

4.6.3 Potential Impacts with the Hamilton Avenue Converted MTS

As there are no existing or eligible resources on the site or in the study area, the Hamilton Avenue Converted MTS would have no effect on any cultural resources. Based upon its review, SHPO has confirmed that the Hamilton Avenue Converted MTS would have no impact upon cultural resources in, or eligible for inclusion in, the SRHP and NR. The LPC has stated that the site contains no architectural or archaeological significance (see Appendix A).

4.7 Urban Design, Visual Resources, and Shadows

4.7.1 Existing Conditions

4.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (see Figure 4.8-1). The site has been developed in a manner consistent with adjacent properties and the overall study area. It is a non-sensitive industrial area in terms of urban design and visual quality assessment. There are no sensitive view corridors or publicly accessible open areas or points of waterfront access that would likely experience visual quality impacts from the Hamilton Avenue Converted MTS.

4.7.1.2 Description of the Site

The existing MTS and associated DSNY structures dominate the site (see Figure 4.7-1). The permanently closed incinerator, which stands on the site between Hamilton Avenue and the curved existing MTS ramp at Prospect Avenue, is the most visible on-site structure (see Figure 4.7-2). It largely blocks the existing MTS from inland views. The incinerator is comprised of a five-story square building and two cylindrical incinerator stacks that rise to approximately 200 feet, more than twice the height of the main building, and taper toward the top. There is an outdoor salt storage area adjacent to the incinerator on Hamilton Avenue (see Figure 4.7-3), and the area between the incinerator and the existing MTS is used for employee parking and DSNY truck storage. The site, like its surroundings, which include elevated highway infrastructure, is paved and has no on-site landscaping or vegetation other than minimal growth of opportunistic plant species (see Figure 4.7-4). Also visible from the interior of the site is the NYCDOT asphalt production plant, north of the site along Hamilton Avenue (see Figure 4.7-5).

Figure 4.7-1 : View of the site interior, facing east from the Home Depot parking lot.

(Photo 2000)

Figure 4.7-5 Urban Design and Visual Quality

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

4.7.1.3 Urban Design and Visual Resources of the Study Area

There are no publicly accessible views through the site to the Gowanus Bay. Views from around the intersection of Hamilton and Prospect Avenues terminate at the incinerator, which blocks from sight the existing MTS, the fuel storage tanks west of the site along the shore and the hulking Port Authority Grain Terminal (also to the northwest of the site).

The only publicly accessible views of the bay or into the site are from the two-story Home Depot parking lot.

4.7.2 Future No-Build Conditions

Although the on-site incinerator will be demolished, there are no plans for the site or surrounding environs that would lead to changes in urban design or visual quality conditions. The site will remain DSNY property, the existing MTS will remain and the associated DSNY salt storage and garage facilities will continue to operate. The anticipated Future No-Build Conditions are fundamentally the same as Existing Conditions.

4.7.3 Potential Impacts with the Hamilton Avenue Converted MTS

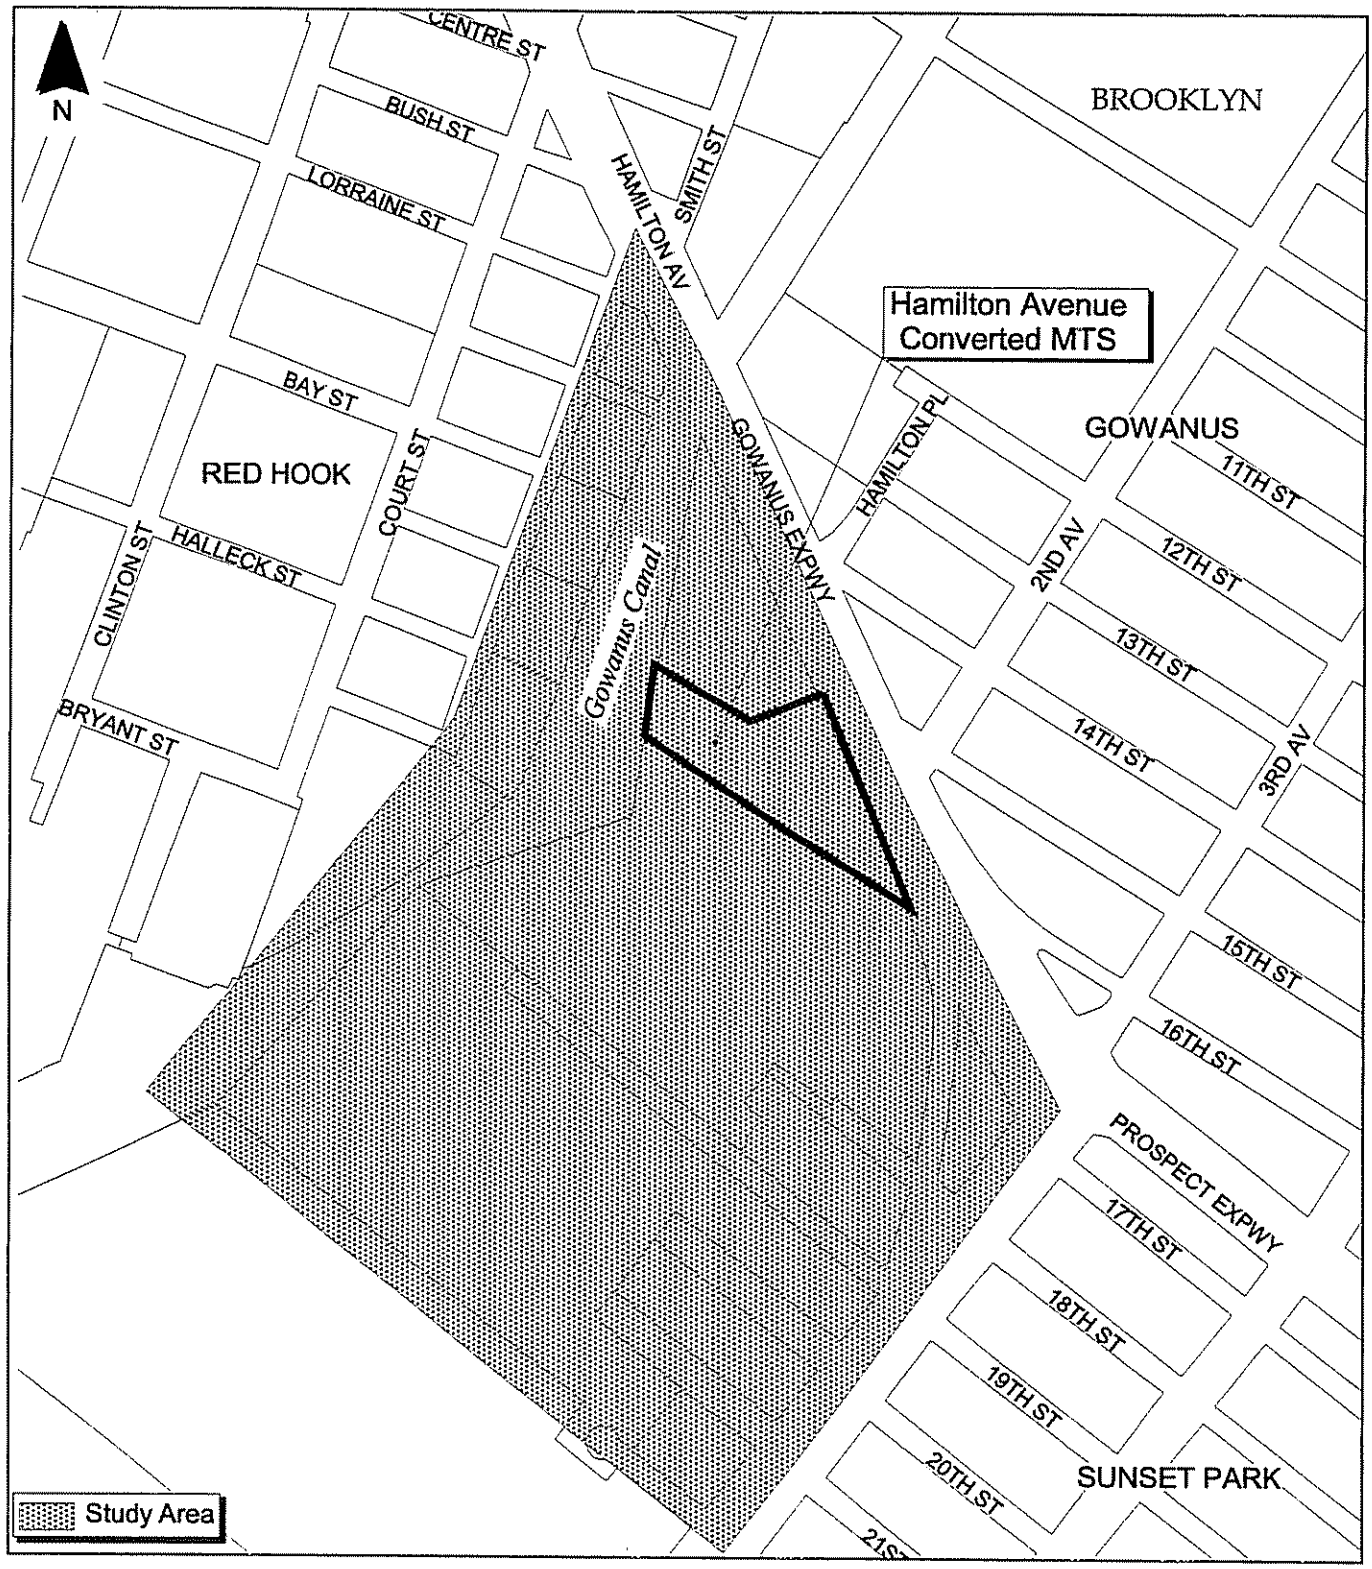
The Hamilton Avenue Converted MTS would be compatible with the existing urban design context and visual conditions of this portion of the industrial Gowanus Bay waterfront. It would entail removing the existing MTS and replacing it with a similar, though larger, facility further upland that would include containerization functions. The Hamilton Avenue Converted MTS, therefore, would not result in significant adverse impacts on the urban design and visual quality of the study area.

According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.)

A survey was conducted within this 430-foot area and found that there were no parks, publicly accessible open spaces, historic resources or important natural features; therefore, no assessment of shadows was deemed necessary and no shadow impact is expected as a result of the proposed project.

4.8 Neighborhood Character

4.8.1 Existing Conditions



4.8.1.1 Definition of the Study Area

The neighborhood character study area is defined by the predominance of industrial land uses and associated visual quality of the Gowanus Bay. The study area is defined by physical landscape elements that distinctly mark the edge of a specific neighborhood character, visually insulate the site and study area or physically obstruct pedestrian and vehicular access to it from outlying areas.

The study area is bounded by the Gowanus Expressway (and Hamilton Avenue) and Third Avenue to the north, east and southeast; 22nd Street (extended west across Gowanus Bay) to the south and southwest; and Smith Street to the west on the opposite side of the canal. Although the bay clearly is a physical barrier limiting access to the site from the west, this portion of the Gowanus Bay waterfront is included in the study area because it mirrors the industrial character of the study area east of the bay and is connected with it visually. While the land uses and visual quality along most of Gowanus Bay and Gowanus Canal extending beyond the study area are similar to those within the study area, Hamilton Avenue – the first major arterial roadway that crosses the canal north of the site – effectively defines the northern end of the study area (see Figure 4.8-1).

4.8.1.2 Description of Neighborhood Character

The study area is characterized by warehouses, large-scale, industrial uses on large lots and noisy, truck-dominated streets in a neighborhood named for the canal – Gowanus or South Brooklyn. The site, the adjacent NYCDOT asphalt plant and the adjacent Home Depot store are of a larger scale than any of the uses located east of the expressway. Hamilton Avenue and the elevated Gowanus Expressway separate the industrial and commercial uses along the Gowanus Bay from the mixed industrial, commercial and residential uses to the east, outside the study area.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

300 0 300 Feet

HDR URBITRAN EEA Cambridge Environmental Inc Hydroqual PB

Figure 4.8-1 Neighborhood Location

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The streets are not well suited to pedestrians, although there are sidewalks along Hamilton Avenue near the site. Except for the Gowanus Expressway and major streets such as Hamilton and Prospect Avenues, local roads are used almost exclusively by trucks and area employees accessing the warehouses along the avenues or other industries that line the waterfront.

4.8.2 Future No-Build Conditions

While the on-site incinerator will be demolished by 2006, there are no known plans for development on the site or in the study area that would potentially lead to changes in neighborhood character. The site will remain DSNY property, the existing MTS will remain and the associated DSNY salt storage and parking facilities will continue to be fully utilized. The Future No-Build Conditions are expected, therefore, to be the same as Existing Conditions.

4.8.3 Potential Impacts with the Hamilton Avenue Converted MTS

No change to industrial neighborhood character would be expected, though the Hamilton Avenue Converted MTS would reactivate MTS activities formerly accommodated on the site and add containerization functions. Since the character of the neighborhood will not have changed substantially under Future No-Build Conditions, it is reasonable to conclude that the reactivation of a similar facility on this site but with containerization would result in no significant adverse effect to neighborhood character.

4.9 Natural Resources

4.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from the Hamilton Avenue Converted MTS.

4.9.1.1 Definition of Study Area

The study area includes the site and the waterfront section that is bounded by the Gowanus Canal to the north (see Figure 2.2.1-1). The upland portions of the site and the surrounding neighborhood parcels are fully developed and contain very limited terrestrial natural resources. Such resources that do exist are discussed in following sections. Because Future Build Conditions would include dredging of bottom sediments and construction of a new MTS, a description of aquatic communities is included.

4.9.1.2 Geology

According to borings performed for the MTS Conversion Conceptual Design Report (2003), multiple strata of sediment are located beneath the Hamilton Avenue MTS. The first layer, the surficial stratum, ranged in thickness from 10 to 25 feet and consisted of loose fill material comprised of concrete, brick, glass, asphalt mixed with sand and gravel, and materials such as cinders, wood and vegetation.

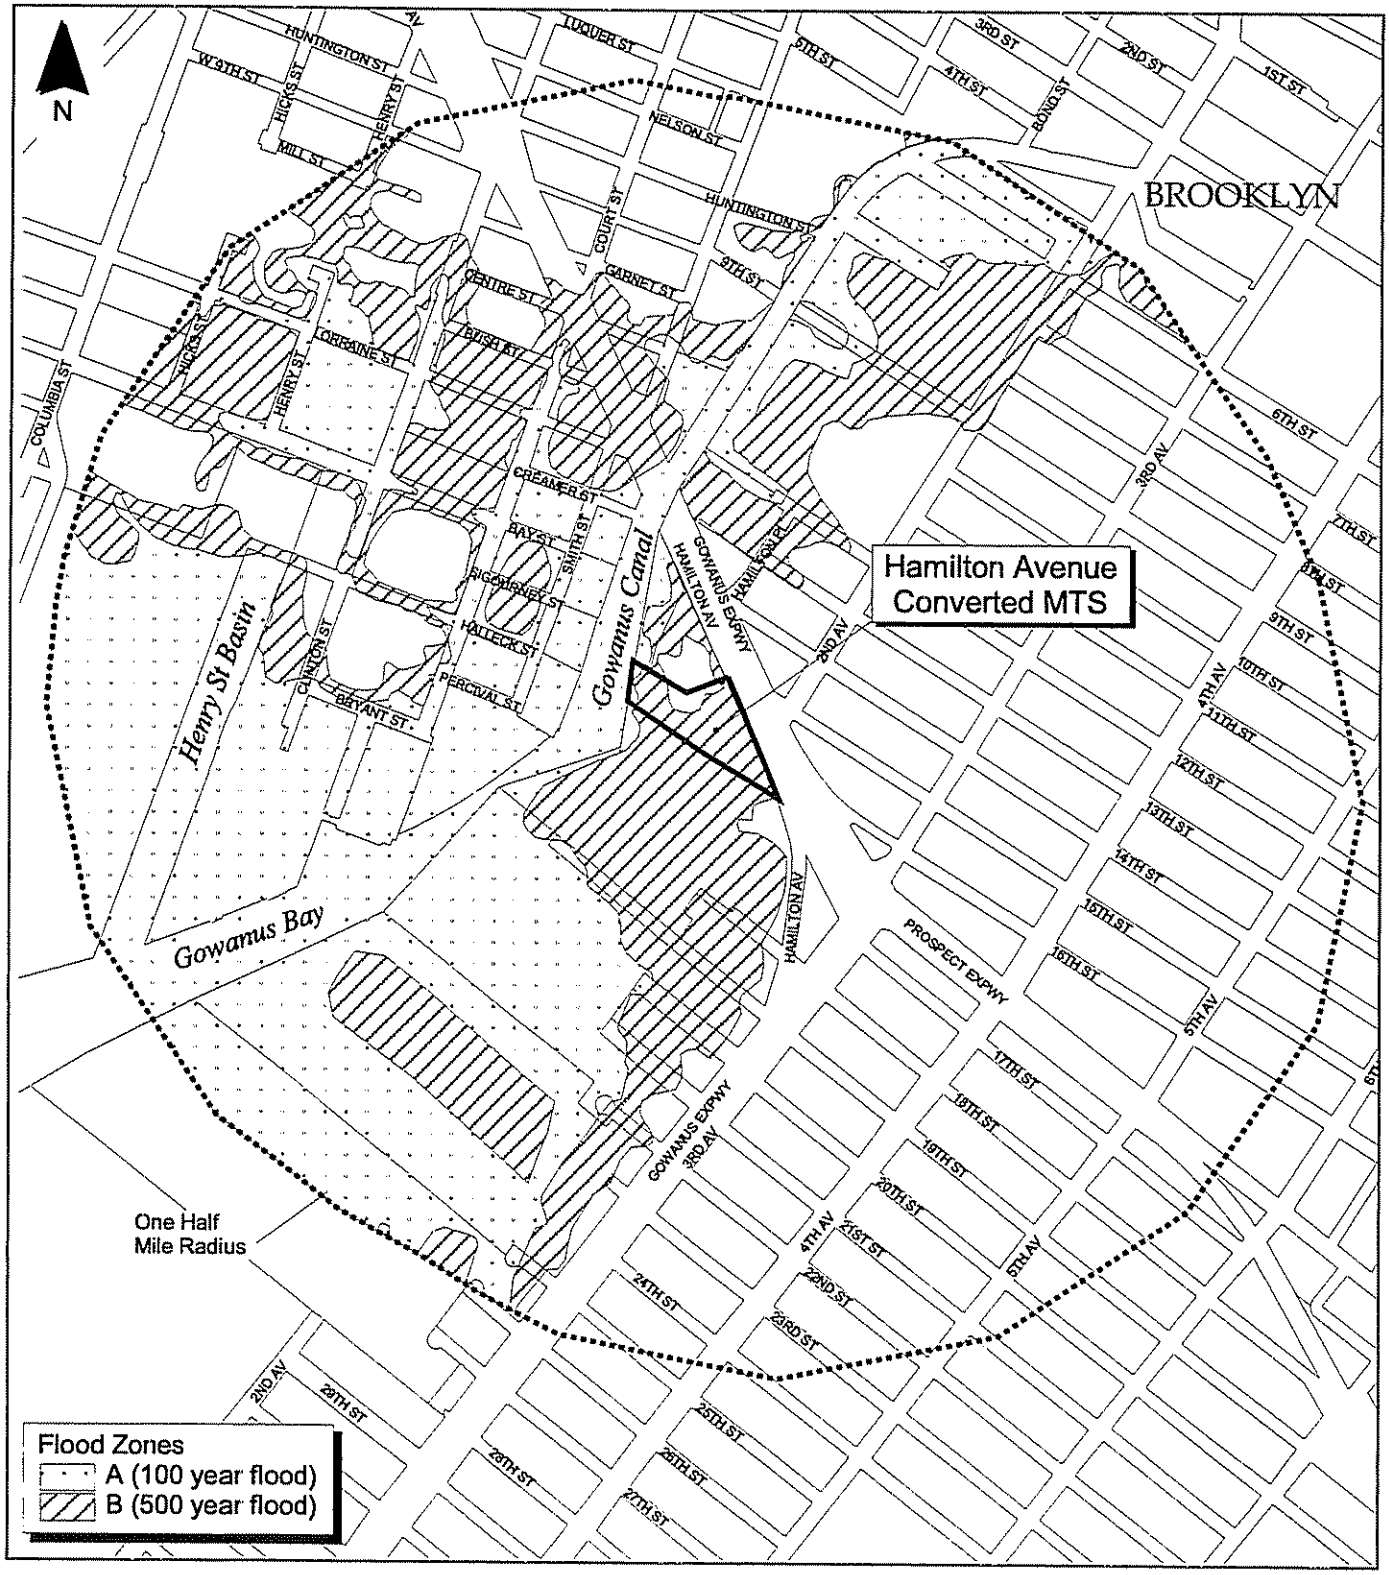
A 10- to 20-foot-thick stratum of soft, black to gray organic soil with loose, gray silty sand and loose gray, poorly graded sand with silt underlaid the fill. Shells and vegetation were also encountered in this layer. In addition, a one- to four-foot-thick layer of dark brown to black peat was located in this layer.

A stratum of stiff, gray silt with sand approximately 2 to 14 feet thick was located beneath most of the organic soil. A dense, red brown poorly to well-graded sand with silt stratum 20 to 30 feet thick with occasional gravel layers was located beneath the silt with sand stratum.

A second stratum of silt was located beneath the sand with silt stratum. This silt stratum consisted of stiff to very stiff gray silt sand layered with stiff, gray lean clay. It ranged in thickness from 4 to 20 feet.

The deepest stratum encountered was a very dense, red brown poorly to well-graded sand with silt layer with occasional layers of gravel. The thickness of the stratum was undetermined.

Results of the sediment samples collected for analysis in 2003 show that surficial sediment is characterized as 73.5% silt and clay, 16.6% sand and 10% gravel.[4] The sediment has 103,769 milligrams per kilogram (mg/kg) of total organic carbon (TOC) and is somewhat degraded by contaminants. The metals with the highest concentrations in the sediment were lead (161.85 mg/kg), barium (102.46 mg/kg) and chromium (63.77 mg/kg).



4.9.1.3 Floodplains

The site is constructed within the 100 to 500 year coastal floodplain (see Figure 4.9-1). No intertidal wetlands exist on the site. Gowanus Canal, which is a NYSDEC-designated littoral zone, is a part of the study area (see Figure 4.9-2).

4.9.1.4 Ecosystems

Vegetative cover on the site was confined to the outer edges of the upland portions between the existing MTS and the fence, and around the outer edges of the incinerator building. The vegetative cover was too sparse in these areas to be mapped. Various opportunistic plant species are present on the site, including mugwort (*Artemesia vulgaris*), Queen Anne's lace (*Daucus carota*), poor-man's pepper (*Lepidium virginicum*), seaside goldenrod (*Solidago semper virens*),

green foxtail (*Setaria viridis*), common reed (*Phragmites australis*), pokeweed (*Phytolacca americana*) and poison ivy (*Rhus radicans*). Saplings of tree-of-heaven (*Ailanthus altissima*) were observed in the vicinity of the ramp to the existing MTS and along the outside of the incinerator building. The NYSDEC NHP does not list any rare or endangered plant species as being present in the study area.

A field program conducted in 2003 was designed to fully characterize the marine biological resources of the study area. The program included monthly sampling for finfish eggs and larvae and water quality, and quarterly sampling for benthic organisms and sessile colonizing organisms. Results of the program are discussed in the following paragraphs.

Water and sediment quality were poor at the Hamilton Avenue Converted MTS. There were visible oil slicks and floating debris, and dissolved oxygen concentrations were very low in the summer. The densities of finfish eggs and larvae were lowest at the Hamilton Avenue Converted MTS compared to all other MTS sampled, presumably due to decreased survival as a result of the poor water quality. The benthic communities were also indicative of a stressed environment.[5]

Dominant finfish eggs collected at the Hamilton Avenue Converted MTS were cunner (*Tautogolabrus adspersus*), bay anchovy (*Anchoa mitchilli*), tautog (*Tautoga onitis*) and Atlantic menhaden (*Brevoortia tyrannus*). Dominant finfish larvae were winter flounder (*Pleuronectes americanus*), anchovy spp., Atlantic menhaden and goby spp. (*Gobiosoma* spp.). Three species identified as having Essential Fish Habitat (EFH) in the region were collected from the Hamilton Avenue Converted MTS. Eggs of windowpane (*Scophthalmus aquosus*) and larvae of winter flounder, windowpane and Atlantic herring (*Clupea harengus*) were found in the water surrounding this MTS.

The dominant benthic invertebrates collected at the Hamilton Avenue Converted MTS were pollution tolerant worms. The most abundant species collected was *Capitella capitata*, followed by *Streblospio benedicti* and oligochaetes. A Jaccard's Index[6] indicates that this MTS has fewer

---

[5] Ibid.

[6] A Jaccard's Index is a statistical test that shows the similarity of organisms present at compared MTSs. It shows the proportion of the number of species observed in either of two MTSs that occurred in both MTSs. The index

benthic organisms in common with the other MTSs and the population may be more distinct. The most abundant epibenthic colonizers present at the Hamilton Avenue Converted MTS were *Polydora* sp. (polychaete worms), *Molgula manhattensis* (sea grapes), *Balanus* sp. (barnacles), and hydrozoans, mud and algal film. The organisms are also pollution tolerant.

The peregrine falcon (*Falco peregrinus*), a federally listed endangered species, was not listed as present for this site in the recent response from the USF&WS.

4.9.2 Future No-Build Conditions

If the Hamilton Avenue Converted MTS were not constructed, the study area would remain as it is at present, except for removal of the incinerator. The limited aquatic and terrestrial natural resources would remain, and the study area would continue to be an impacted urban area dominated by opportunistic species of vegetation and marine organisms.

4.9.3 Potential Impacts with the Hamilton Avenue Converted MTS

The Hamilton Avenue Converted MTS would involve removal of the existing MTS and construction of a new facility on the incinerator site. The facility would be completely upland and the existing platform would be removed. Dredging may also be necessary to accommodate the barges. The Hamilton Avenue Converted MTS would result in an increase of ecologically productive open water space and pose no adverse ecological impacts, other than the temporary loss of benthic organisms from dredging activities, and no loss of habitat to rare or endangered species.

4.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of

---

ranges from zero to one. An index of zero means that the MTSs are completely dissimilar and have no species in common. An index of one means the MTSs have all the same species.

sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

4.9.3.2 Floodplains

Implementation of the Hamilton Avenue Converted MTS would have no effect on the elevation of the site. The facility would be constructed within the 100 to 500 year floodplain, and would not include any provisions for raising any portions of the site over this level.

4.9.3.3 Ecosystems

Existing on-site buildings and paved parking areas have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Therefore, no impacts on the terrestrial natural resources are anticipated.

Dredging activities would result in an immediate, short-term destruction of the benthic invertebrates in the area, and the removal of the existing pilings and MTS would result in loss of habitat for attached organisms. Recolonization of the area by benthic invertebrates can be expected to occur within 6 to 12 months after cessation of dredging activities.[7] Given the relatively small size of the project, minimal impact is expected from the removal of the existing MTS. The only negative impact would be the reduced area for epibenthic growth. However, this is only a small overall loss of surface area and organisms will still be able to grow on the bulkheading surrounding the MTS. In addition, the increase in open water area may create a more ecologically productive habitat for finfish as more sunlight will pass through the water column increasing primary production.

[7] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

Operational impacts will last the entire lifespan of the facility. The major impact is the removal of the existing platform. The proposed plan for the Hamilton Avenue Converted MTS is for a complete removal of the existing platform, resulting in an increase of ~~34,905~~29,450 square feet of unshaded water. The removal of the platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[8] Epibenthic communities, however, will lose some surface area for growth, but the decrease should not be significant, and finfish should return to the area with the return of food sources.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by Energy and Environmental Analysts, Inc. (EEA) in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[9] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as they provide shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. However, because the decrease in shading over water is very small, there are not expected to be significant community changes. There is a possibility of a slight shift in the finfish community with the decrease in over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

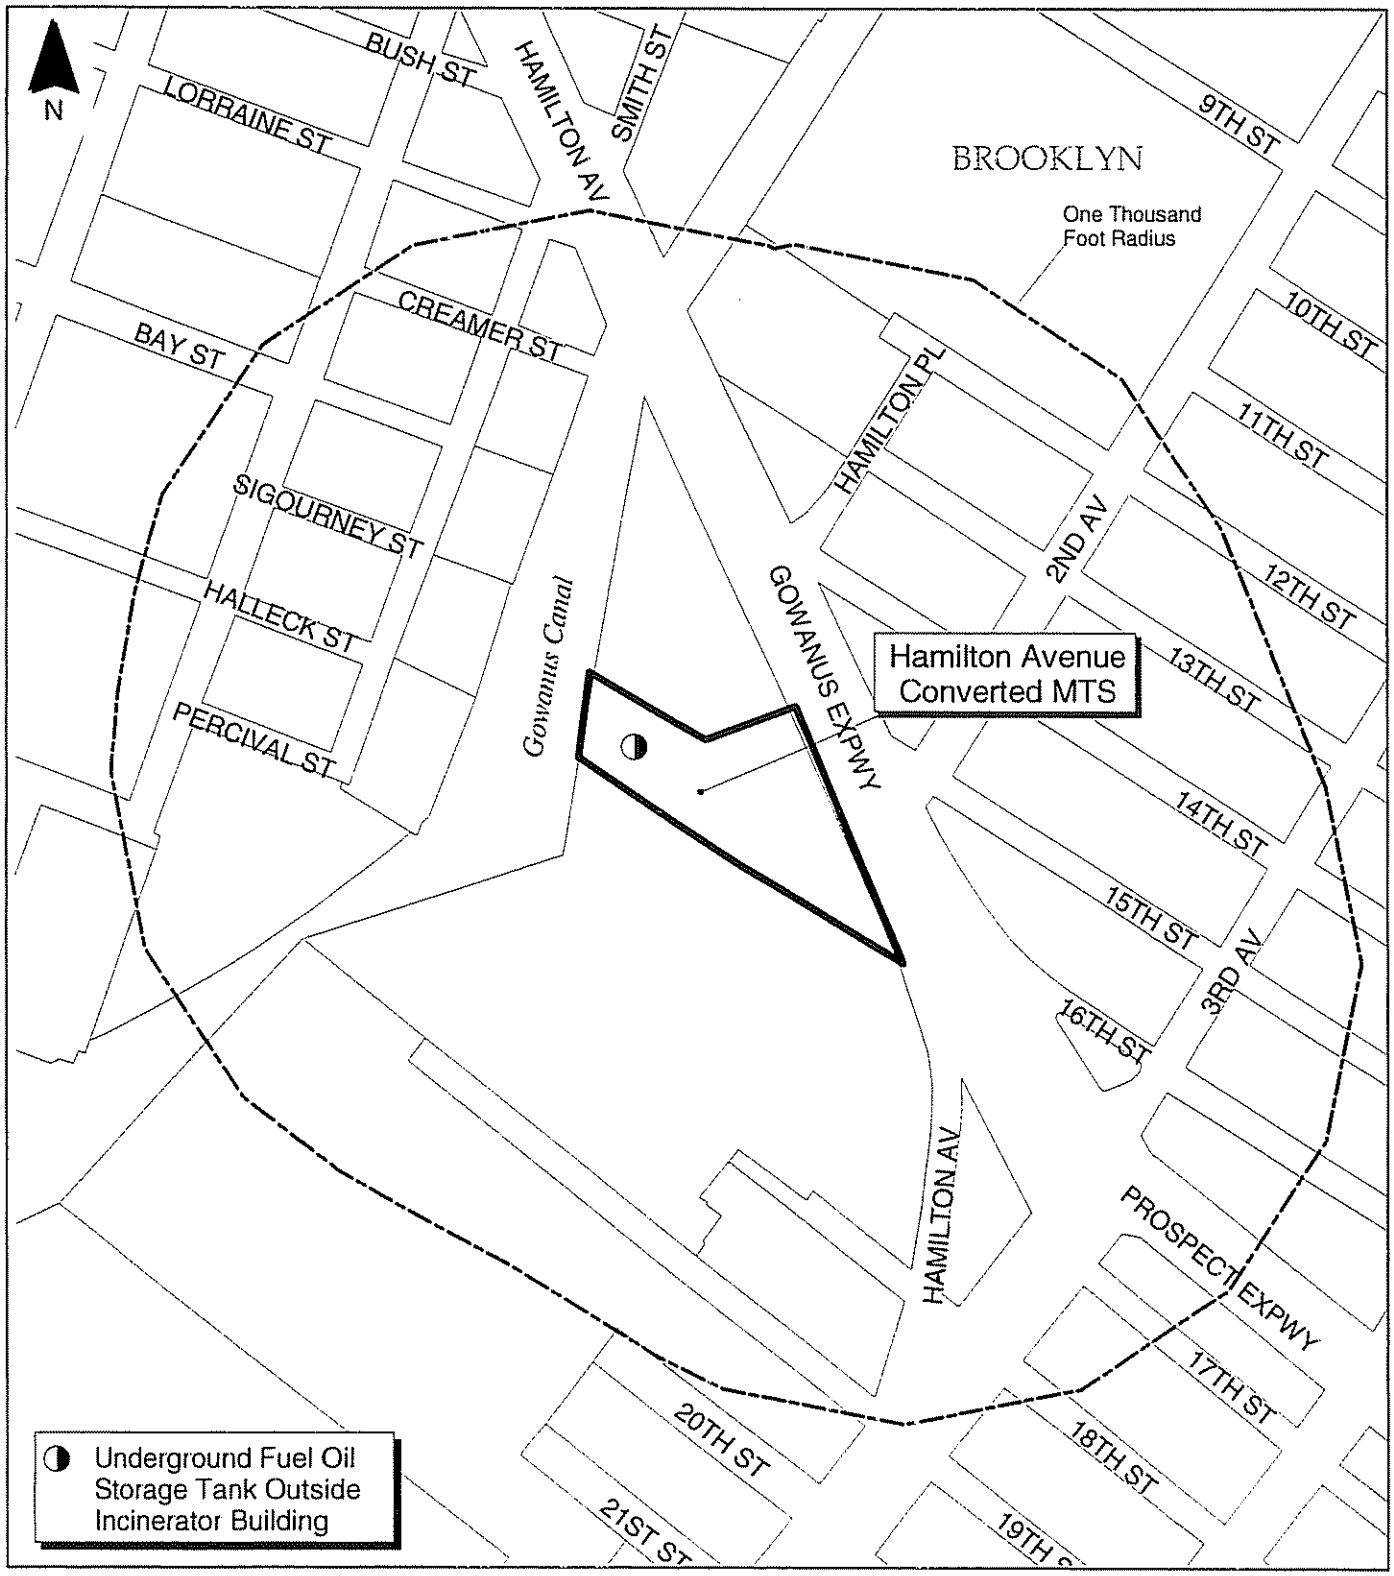
Construction of the new upland facility would not have any significant impact on the few areas of vegetation present on the site. Existing on-site buildings and paved parking areas have

[8] Hudson River Center Site Aquatic Environmental Study Final Report, 1988. Prepared for New York City Public Development Corp. by EEA, Inc.

[9] Duffy-Anderson, J.T. & Able, K.W., 2001. "An Assessment of the Feeding Success of Young-of-the-Year Winter Flounder (*Pseudopleuronectes americanus*) Near a Municipal Pier in the Hudson River Estuary, U.S.A." Estuaries, Vol. 24, No. 3, p. 430-440.

precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Vegetation observed on the site was opportunistic weeds and plants, none of which were rare, endangered or particularly important from an ecological perspective. No significant terrestrial impacts would result from the Hamilton Avenue Converted MTS because the site is already fully developed and the creek is heavily contaminated. Removal of the above-water section of the existing MTS eliminates shading of the marine environment in this area. The only shading that would take place under the Future Build Condition would be temporary due to temporary barge dockage and, therefore, any impacts of shading would also be temporary.

4.10 Hazardous Materials



4.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I Environmental Site Assessment (ESA) established by the American Society for Testing and Materials (ASTM) (ASTM E-1527). The assessment was performed in April 1999 and updated in February 2003. It included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the City Fire Department (FDNY) for underground storage tank (UST) records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors. Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

4.10.1.1 Definition of Study Area

The study area encompasses the site and neighboring properties within a 1,000-foot radius (see Figure 4.10-1).

Site delineations and study area boundaries are approximate.

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

4.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater and building components/equipment within the study area where the presence or likely presence of hazardous materials exists and for which the Hamilton Avenue Converted MTS could lead to an increased exposure of people or the environment to those materials. The areas of concern at the subject site are as follows:

- Probability of asbestos-containing materials (ACMs) in the incinerator building.
- Probability of underlying layers of lead-based paint in the incinerator building.
- The incinerator's listing as a CERCLIS site.
- An "active" spill report, Number 9711052, of 200 gallons of possibly transformer oil spilled into the water in early 1998. Also, a stain of oil was noticed during the February 2003 reconnaissance near the fill port of the existing MTS's 5,000-gallon fuel oil tank.

A field program to investigate the potential impacts to the soil and groundwater from the historic use of the property as an incinerator and MTS was completed in November 2003 in accordance with a ~~NYSDEC approved work plan~~ work plan reviewed by the NYSDEC.[10] The site investigation included:

- Performing a ground-penetrating radar and magnetometer survey over accessible areas of the site.
- Collecting one subsurface soil sample from nine boring locations.
- Collecting one surface soil sample from six boring locations.
- Collecting one groundwater sample from three permanent monitoring wells.
- Collecting one groundwater sample from two boring locations.
- Laboratory analysis of all soil samples for asbestos, volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides/polychlorinated biphenyls (PCBs) and Resource Conservation and Recovery Act (RCRA) metals.
- Laboratory analysis of all water samples for VOCs, SVOCs, pesticides/PCBs and RCRA metals.

[10] New York City Department of Sanitation, October 2003. Final phase II Site Investigation Work Plan, Hamilton Avenue Marine Transfer Station, Brooklyn, New York.

- Resampling and analysis of soils for total and Toxicity Characteristic Leaching Procedure (TCLP) lead in all areas where total lead concentrations exceeded NYSDEC Technical and Administrative Guidance Memorandum (TAGM) guidelines.
- Determination of the direction of the groundwater gradient by land survey measurements and measurement to the top of the groundwater surface.
- Comparison of the analytical results obtained from the soil and groundwater sampling program with the NYSDEC TAGM guidelines.
- Preparation and submittal of a detailed site investigation report.[11]

Low concentrations of VOCs were detected in the soil and groundwater samples collected from this site. Elevated concentrations of SVOCs (above TAGM Guidelines) were detected in some of the soil and groundwater samples collected. Elevated concentrations of several RCRA metals were detected in all soil samples collected, indicative of typical ash fill materials used in this area. Resampling and analysis of the soil samples for total and TCLP lead was completed in all five borings where total lead was found to be above TAGM guidelines. Analytical results from three soil samples showed TCLP concentrations of lead in excess of the maximum concentration for the toxicity characteristic.

4.10.2 Future No-Build Conditions

The property would remain in its present state except for the demolition and removal of the incinerator. Any asbestos-containing building materials found in the incinerator would be removed prior to demolition in a manner that is consistent with City building codes and practices. Any contamination present at the site would remain.

4.10.3 Potential Impacts with the Hamilton Avenue Converted MTS

Historical soil and groundwater contamination is present at the existing MTS; however, this contamination should not prevent development of the site. If the Hamilton Avenue Converted MTS was implemented, any residual contaminated soil would require disposal in a manner that is consistent with the level of contamination found during the demolition/construction phase. The necessary and appropriate health and safety measures would be used to mitigate and minimize any exposure risk to workers and the general public.

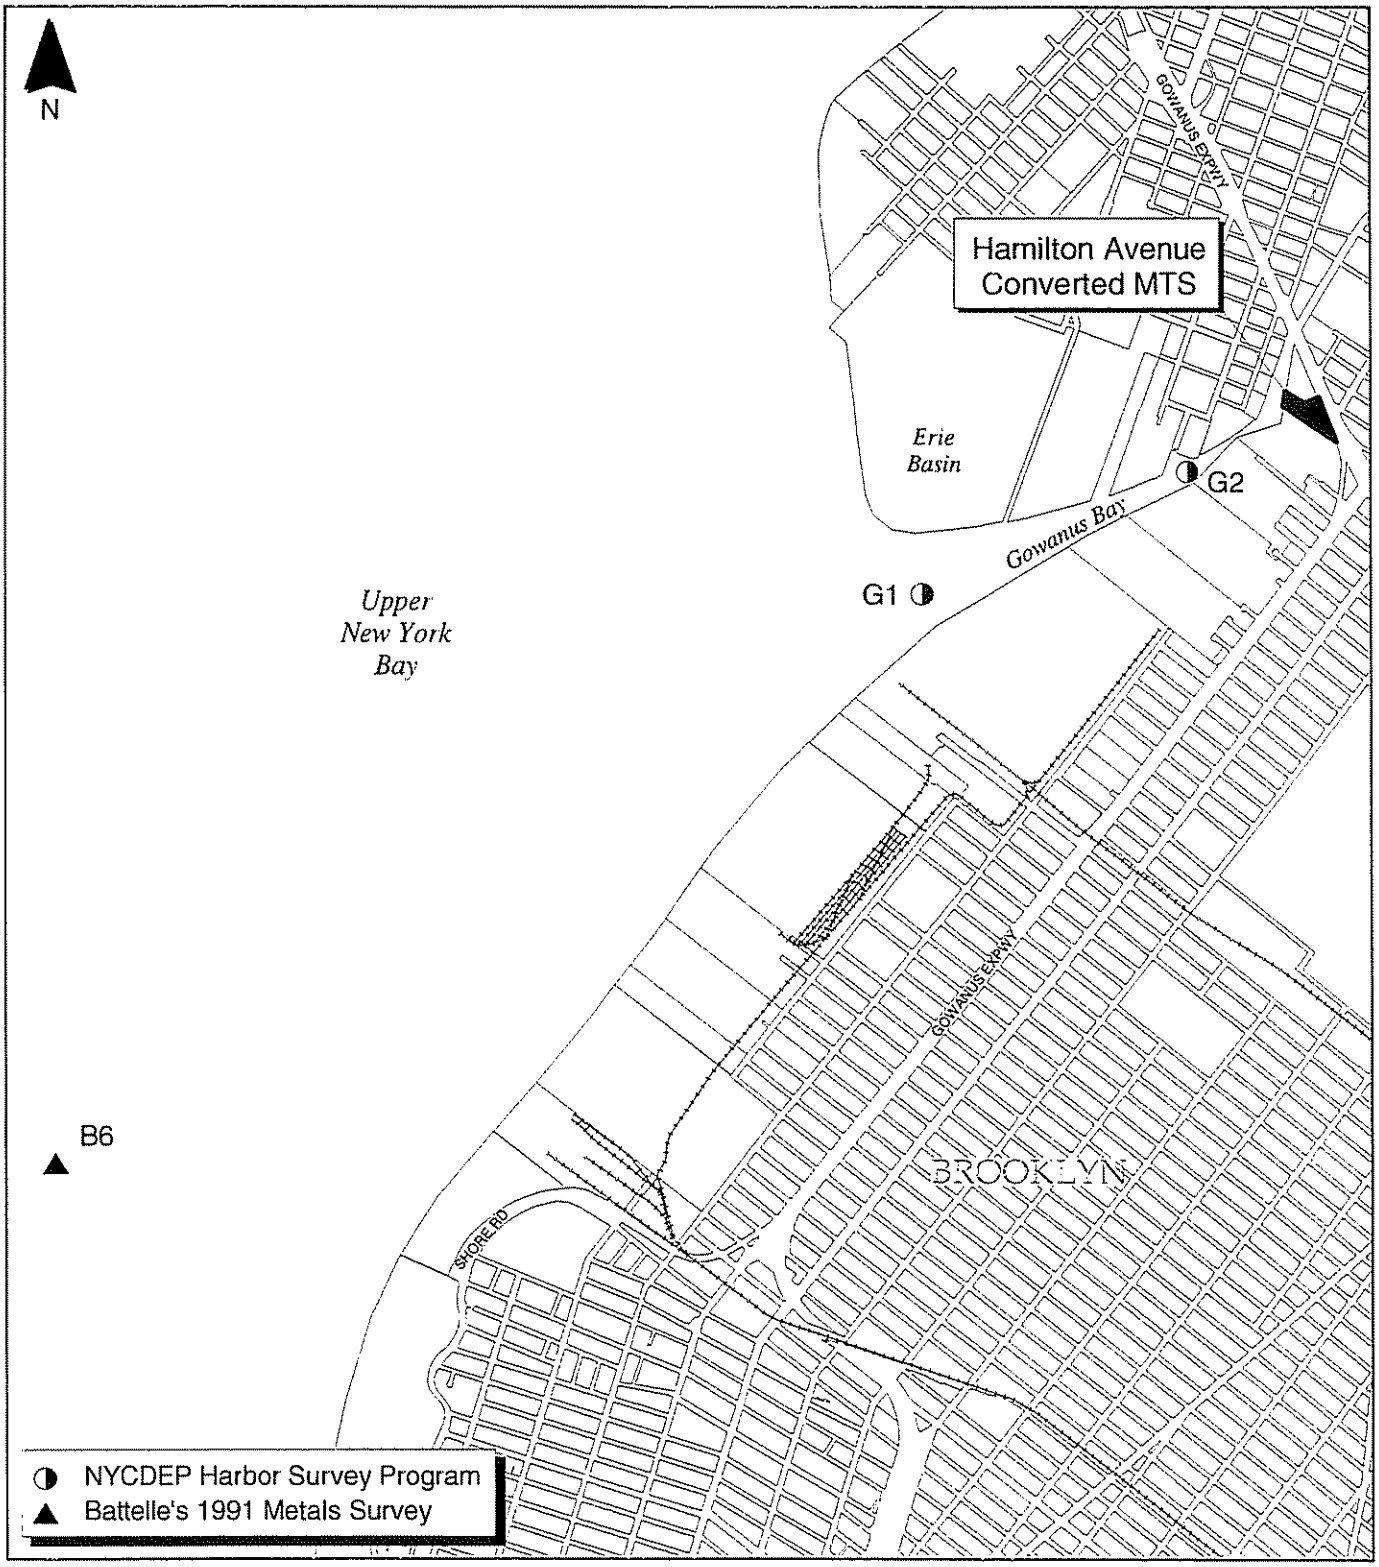
4.11 Water Quality

4.11.1 Existing Conditions

4.11.1.1 Definition of Study Area

The water quality study area encompasses Gowanus Bay, Gowanus Channel and Upper New York Bay, and includes discharges from point sources and combined sewer overflows (CSOs) located within ½-mile of the site.



4.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 4.11-1, are generally representative of conditions in the study area:

- NYCDEP Harbor Survey Program – Stations G-1 at Gowanus Bay and G-2 at Gowanus Channel; and
- Battelle's 1991 Metals Survey – Station B-6 in Upper New York Bay.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 4.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class SD," which indicates fish survival only.

As shown in Table 4.11-1, on average, NYSDEC standards and guidance values are met. The mercury concentration for Battelle Station B-6 did not conform to the water quality standard for mercury.

Site delineations are approximate

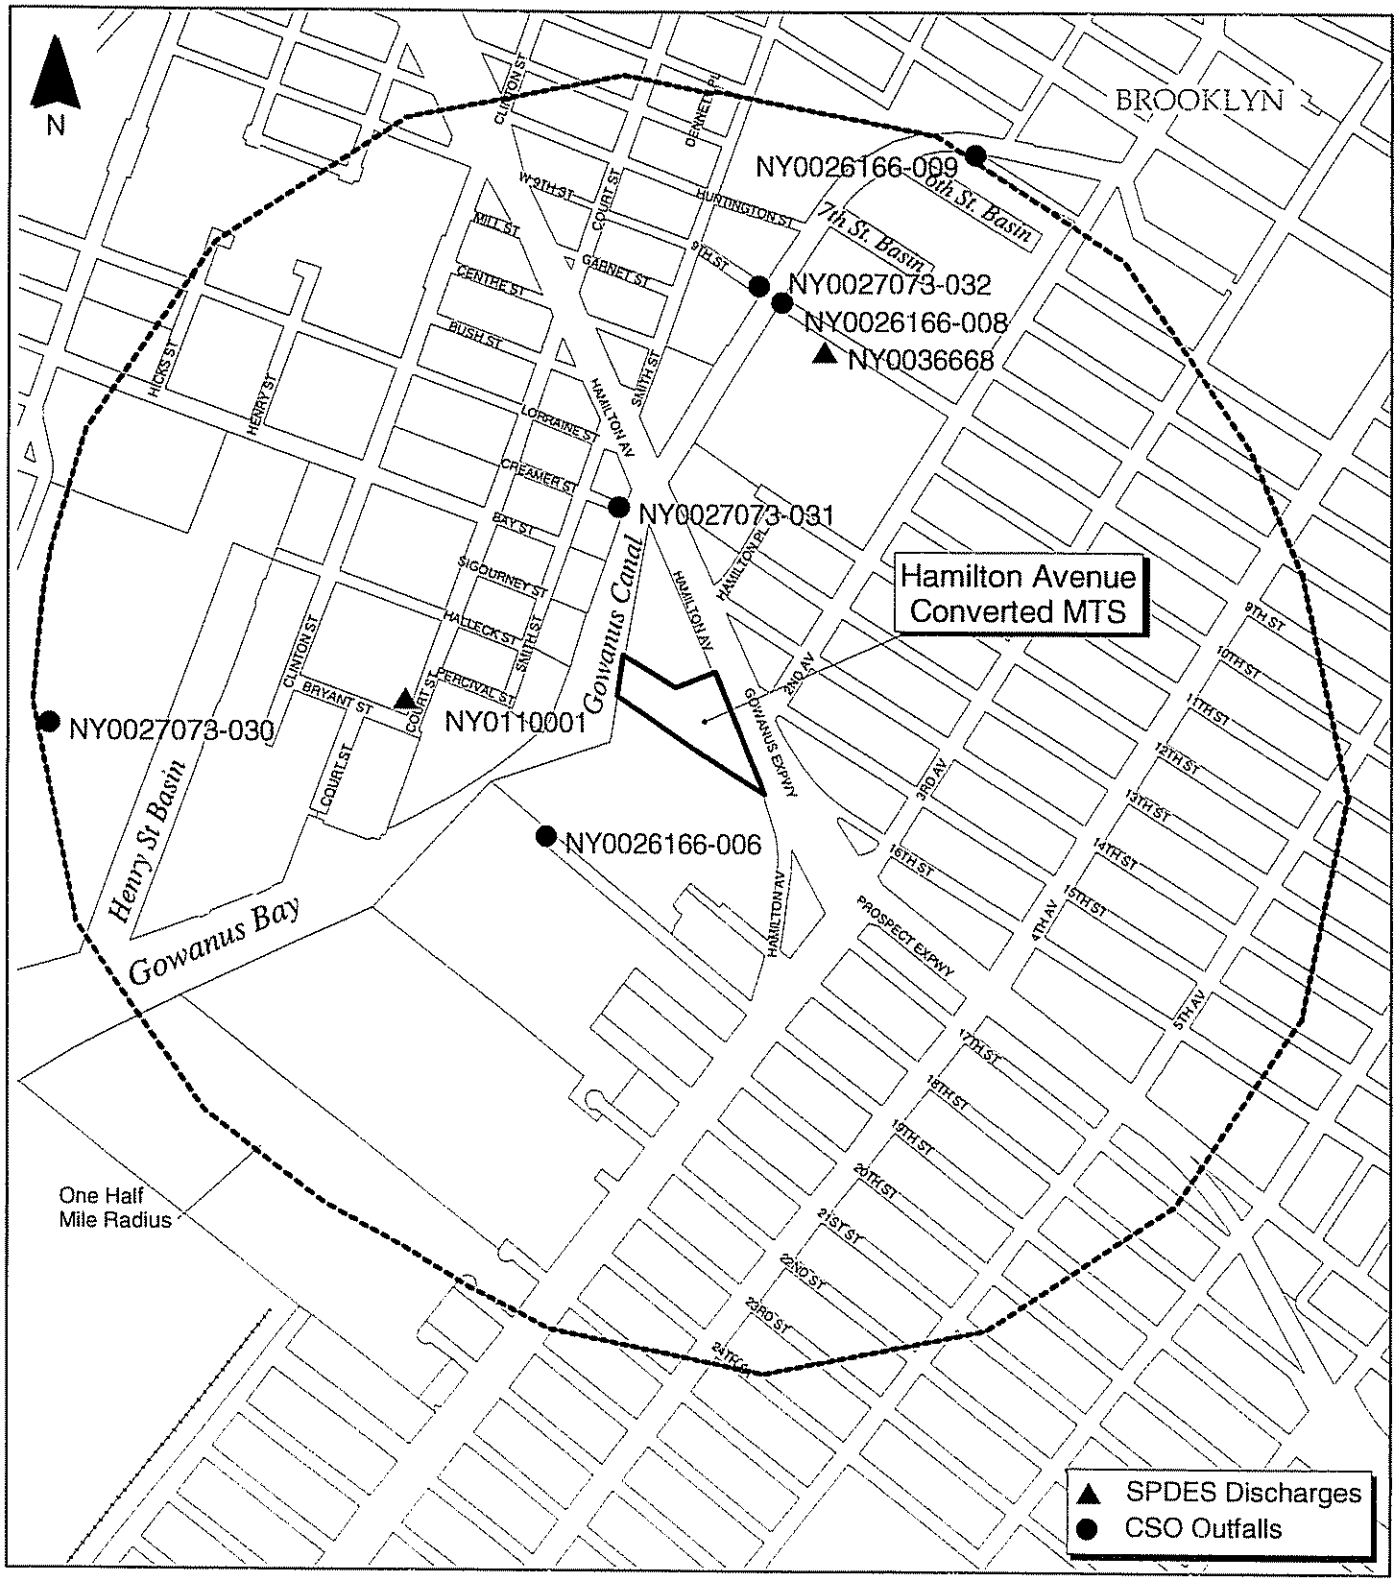
MF = membrane filter
µg/L = micrograms per liter

4.11.1.3 Permitted Discharges



A review of the most recently available NYSDEC and USEPA databases indicated that there are several permitted discharges in the vicinity of the site. Those within a ½-mile radius of the Hamilton Avenue Converted MTS site are shown in Figure 4.11-2 and listed in Table 4.11-2. These discharges consist of six CSOs and two industrial sites, all of which are permitted by the NYSDEC.

4.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, estimates of stormwater pollutant loadings were calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and infiltration. A runoff flow of 0.255 cfs was calculated using the impervious site area (4.24 acres), an average rainfall intensity per storm of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 4.11-3, represent the existing loads at the site.

4.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to ongoing water improvement programs, such as the NYCDEP CSO Abatement Program, which will reduce untreated discharges to the receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from the City WPCPs; and other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

Site delineations and study area boundaries are approximate

Notes:
[1] Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
[2] Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

4.11.3 Potential Impacts with the Hamilton Avenue Converted MTS

With the development and operation of the Hamilton Avenue Converted MTS, the overall area of the site would decrease. This would effectively decrease the impervious area and therefore the stormwater loadings at the site. Table 4.11-4 shows the existing impervious area, the change in impervious area and pollutant loads. With the development of the Hamilton Avenue Converted MTS, conditions would not be significantly different from Future No-Build Conditions.

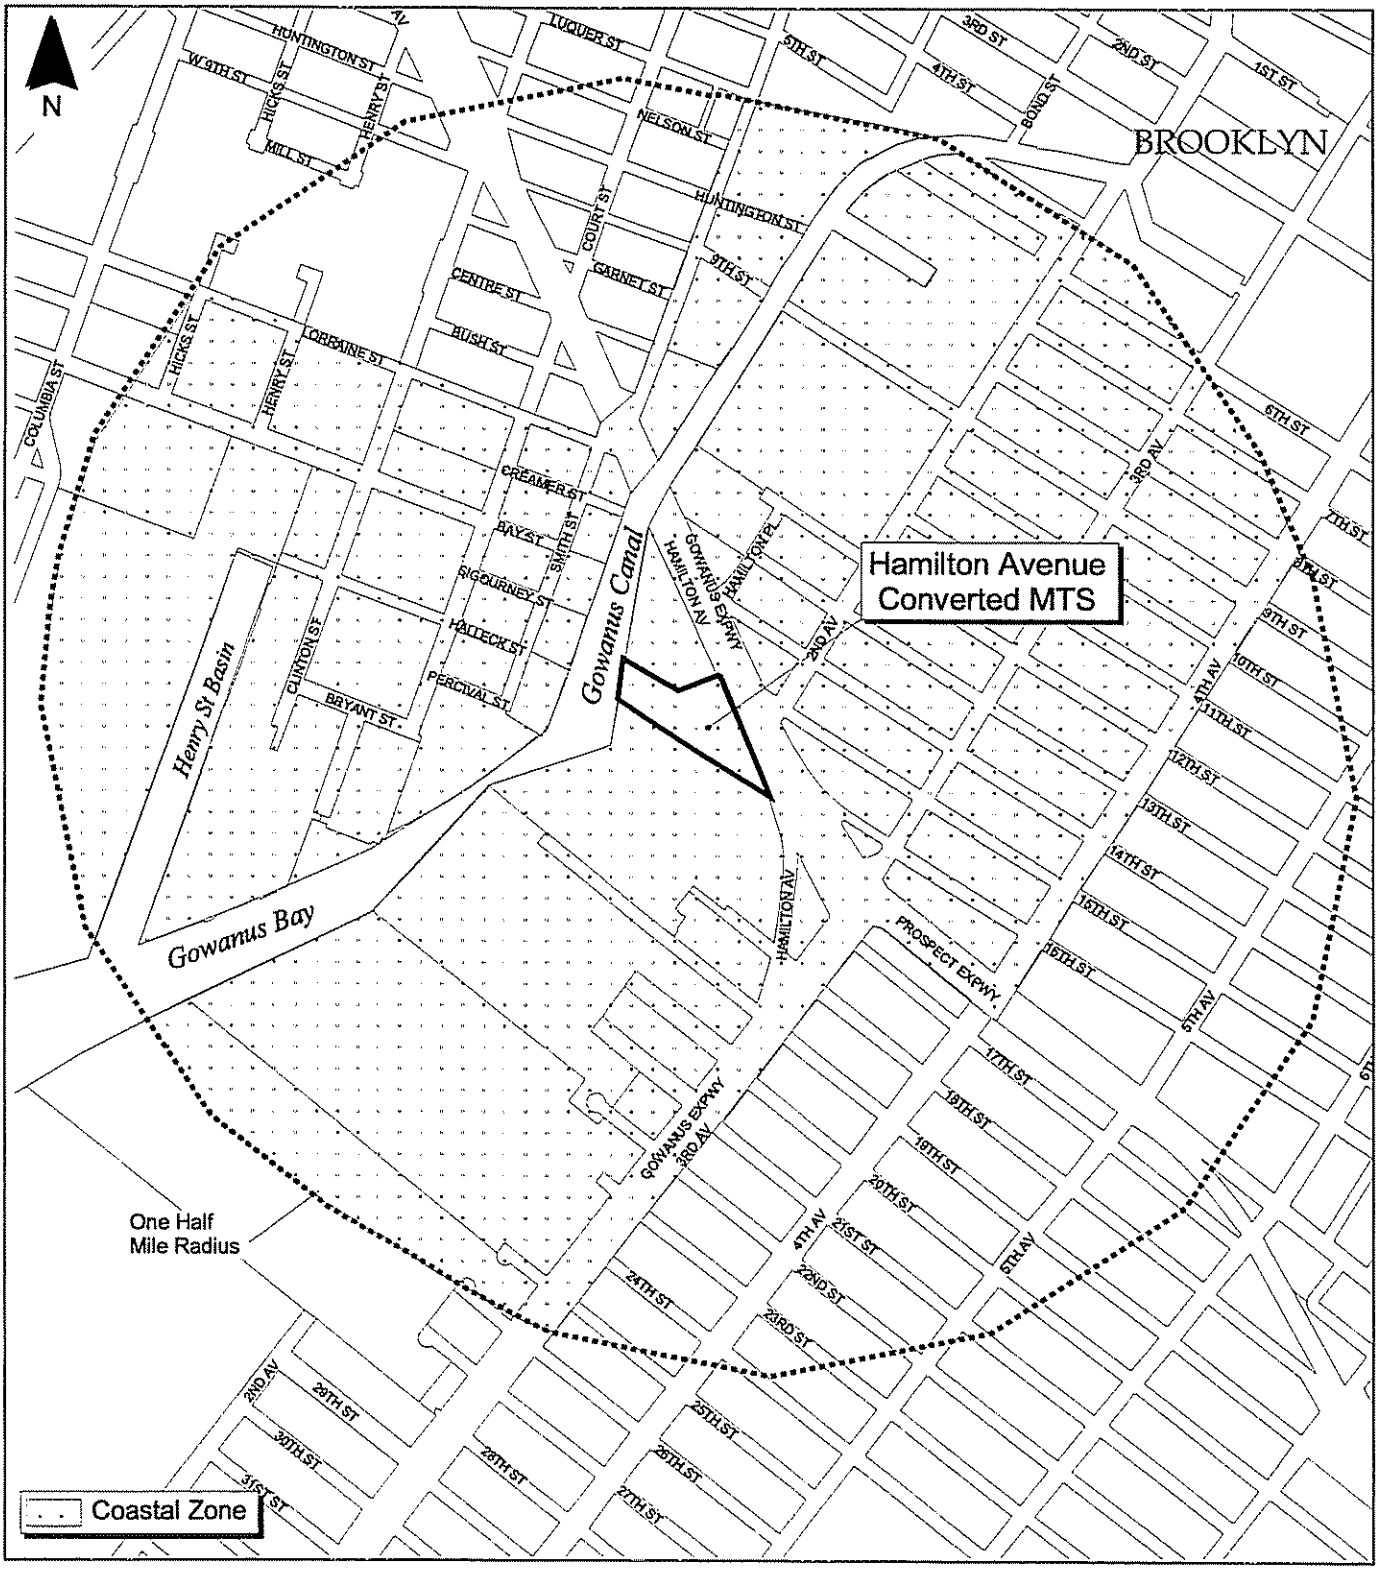
All solid waste processing at the Hamilton Avenue Converted MTS would occur within the structures on the site. All process wastewater from waste handling operations at the facility, such as washdown water, would be routed to an on-site pretreatment system (e.g., oil/water separation). After pretreatment, the process water would be discharged to the municipal sewer system and, ultimately, to the Owl's Head WPCP, where it would be treated prior to discharge to New York Bay. Therefore, the Hamilton Avenue Converted MTS would not affect water quality.

Table 4.11-4
Impervious Area and Estimated Pollutant Loads
Hamilton Avenue Converted MTS

			Estimated Pollutant Loadings/Incremental Change [1]				
Conditions	Total Impervious Area (acres)	Change in Impervious Area (acres)	Fecal Coliform[2]	BOD (lbs/day)	Copper (lbs/day)	Lead (lbs/day)	Zinc (lbs/day)
Existing Conditions	4.24	0.0	46,659/NA	15/NA	0.048/NA	0.038/NA	0.211//NA
Future Build Conditions	3.87	-0.37	42,513/-4,146	14/-1	0.044/-0.004	0.035/-0.003	0.193/-0.018

Notes:
(1) Incremental change refers to the difference in pollutant loading between the Existing Conditions and Future Build Conditions.
(2) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable

Unimpeded operation of the Hamilton Avenue Converted MTS may also require dredging activities to construct the waterfront structures and to improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with



applicable federal, state and local regulations and required permits would be acquired before any such activities commenced. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not be expected to result in any significant adverse long-term impacts.

4.12 Waterfront Revitalization Program

4.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of Gowanus Canal and Gowanus Bay, the Hamilton Avenue Converted MTS would be within the City's coastal zone boundary (see Figure 4.12-1). According to the "New Waterfront Revitalization Program," the Hamilton Avenue Converted MTS would be classified as a water-dependent, industrial use. It would be located within the NYCDCP-designated Sunset Park SMIA, within Reach 14 East River/Upper Bay as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Brooklyn Waterfront." It is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The Hamilton Avenue Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3, 8.1, 8.5 and 10.2. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. In instances where a component of the Hamilton Avenue Converted MTS required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below. A description of waste handling operations is provided in Section 2.2.1.

Site delineations and study area boundaries are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

4.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the Hamilton Avenue Converted MTS. As part of the Hamilton Avenue Converted MTS, connections from the new facility to existing utilities in the vicinity (e.g., sewer and electrical connections, etc.) would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

According to the "The New Waterfront Revitalization Program," the Hamilton Avenue Converted MTS would be located within the Sunset Park SMIA. Its development would involve the demolition of the existing over-water truck-to-barge MTS and construction of a new truck-to-container-to-barge (TCB) MTS located primarily within the upland portions of the site for marine transport of DSNY-managed Waste to remote out-of-City disposal facilities.

The demolition and site redevelopment, as described in Section 2.2.1, would help to restore and revitalize industrial waterfront property and would be compatible with existing and neighboring heavy industrial uses. The majority of reconstruction activity would occur within the upland portions of the site, and

would consist of four primary components: (1) an enclosed processing building which would include a tipping floor, loading floor and pier level; (2) an elevated access ramp, with accompanying retaining walls, to the truck gallery; (3) a gantry crane, outside of the processing building and at the waterfront; and (4) a new bulkhead and fendering systems ~~for barge slips.~~. A gantry crane would be used in the loading and unloading of DSNY barges at the site. The Hamilton Avenue Converted MTS would be consistent with existing land uses in the vicinity of its site and with the "Plan for the Brooklyn Waterfront," which recommends the continued industrial use of the area. Although it would not encourage or facilitate the siting of any additional water-dependent uses, the Hamilton Avenue Converted MTS would represent an upland expansion and reactivation of an existing water-dependent use and would be compatible with surrounding uses. The Hamilton Avenue Converted MTS would, therefore, be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The Hamilton Avenue Converted MTS would involve the demolition of the existing MTS and the development of a new and expanded facility within the upland portions of the site. It would allow for marine transport of solid waste to licensed out-of-City disposal facilities. The development would consist of four major components: (1) an enclosed processing building which would include a tipping floor, loading floor and pier level; (2) an elevated access ramp; (3) a gantry crane located at the waterfront and adjacent to the processing building; and (4) bulkhead and fendering systems. In addition, a 21-inch and an 18-inch stormwater outfall would be constructed within the south bulkhead. These outfalls would drain stormwater runoff from the facility into Gowanus Canal. Before Stormwater is discharged into Gowanus Canal it will pass through a stormwater treatment system. The pilings that support the existing MTS would be removed as part of the demolition of the existing MTS.

In addition, the Hamilton Avenue Converted MTS would require dredging to improve existing water depths at and in the immediate vicinity of the site and to allow for the unimpeded operations of barges and tugboats once it became operational. All required dredging would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any proposed dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The development of the Hamilton Avenue Converted MTS would involve the revitalization of an existing waterfront use and would not interfere with any maritime industrial, commercial or recreational vessel activities in the vicinity of the proposed site. Activities within Gowanus Canal and Gowanus Bay resulting from the Hamilton Avenue Converted MTS would be limited to barge loading along the pier level and the periodic swapping of loaded barges at the ~~slips~~mooring berths. Approximately four ~~or five~~ barges would be loaded on a daily basis at the Hamilton Avenue Converted MTS. Barge swapping activities would be conducted in close proximity to the Hamilton Avenue Converted MTS and be comparable in nature to previous barge activities at the existing MTS. Therefore, no adverse impacts upon other uses within the water body would be anticipated. The Hamilton Avenue Converted MTS would, therefore, be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The Hamilton Avenue Converted MTS would involve the conversion of an existing over-water facility from a truck-to-barge waste transfer station where loose waste was placed in open barges, into an upland TCB transfer station where waste would be transferred into containers that would be sealed and placed into flat deck barges for marine transport to out-of-City disposal locations and, therefore, would be protective of the aquatic environment and surrounding land and water uses. All solid waste handling would occur within an enclosed processing building. All waste would be placed in sealed containers before leaving the building for loading on barges.

Building ventilation would be maintained under negative pressure, which would maintain dust inside the enclosed processing building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environment. Litter control methods, such as routine sweeping and washing of the tipping floor, would be implemented to minimize or eliminate the potential for litter entering surface waters. All process wastewaters generated on site (e.g., washdown waters, etc.) would be properly treated prior to their discharge to the municipal sewer system. In addition, on-site storage of petroleum products and hazardous materials related to the operation of the Hamilton Avenue Converted MTS would be done in accordance with applicable federal, state and local regulations. Therefore, the Hamilton Avenue Converted MTS would be consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of Special Natural Waterfront Areas (SNWAs), as described in "The New Waterfront Revitalization Program," as well as Recognized Ecological Complexes and Significant Coastal Fish and Wildlife Habitat (SCFWH) information, the Hamilton Avenue Converted MTS would not be located within a designated area. The Hamilton Avenue Converted MTS would represent an upland expansion in size of a previous over-water use and would not be anticipated to result in any long-term impacts to natural resources in the vicinity of the site. The Hamilton Avenue Converted MTS would, therefore, be consistent with this subpolicy.

4.2 *Protect and restore tidal and freshwater wetlands.*

A review of NYSDEC tidal and freshwater wetland maps was conducted to determine the presence of wetlands within the site. The Hamilton Avenue Converted MTS would be located adjacent to the Gowanus Canal, a NYSDEC-designated littoral ~~zone.~~ zone, however, due to the existing water depths at the site being deeper than six feet, no effects to wetlands would occur. No freshwater wetlands exist on the site. The Hamilton Avenue Converted MTS would involve the demolition of the existing over-water MTS and development of a new MTS within the upland portions of the site. These activities and anticipated dredging would not result in ~~limited, short-term impacts~~effects to ~~these tidal~~ wetlands.

Dredging activities associated with the development of the Hamilton Avenue Converted MTS are not anticipated to have significant ~~impacts~~ effects on wetlands in the vicinity of the site, primarily due to previous and ongoing activities and previous dredging that has historically occurred at the existing MTS and adjacent ~~staging area~~mooring rack. ~~Mitigation for potential~~Potential ~~impacts~~ effects upon wetlands would be ~~proposed~~ addressed during the environmental review and permitting of the Hamilton Avenue Converted MTS. ~~This mitigation, if required, would address potential impacts that may occur due to the construction of the Hamilton Avenue Converted MTS.~~ DSNY in coordination

with the NYSDEC and other involved agencies would determine the appropriate measure to address potential effects that may occur due to the Hamilton Avenue Converted MTS and would effectively restore these wetlands and their associated value. The Hamilton Avenue Converted MTS would, therefore, be consistent with this subpolicy.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

A review of the NYSDEC NHP database indicates that there are no known species of special concern in the vicinity of the site. As part of the Hamilton Avenue Converted MTS development, the existing MTS and its support pilings would be removed. In addition, dredging would be required to improve existing water depths in the vicinity of the site for barge and tugboat operations. Modifications to the site would pose little, if any, adverse ecological impacts or loss of habitat for rare or endangered species.

Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer system. Stormwater runoff from the Hamilton Avenue Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. Further, the Hamilton Avenue Converted MTS would not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 *Manage direct or indirect discharges to waterbodies.*

The Hamilton Avenue Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site treatment system, which would consist of oil/water separators, etc., discharging eventually to the municipal sewer system. In addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. Development of the proposed MTS would involve the installation of two stormwater outfalls that would drain stormwater runoff from the facility into Gowanus Canal. Prior to discharging, stormwater runoff would travel through a stormwater treatment system. Stormwater runoff from the Hamilton Avenue Converted MTS would be managed in accordance with all applicable federal, state and local regulations.

In addition, the majority of activity associated with the Hamilton Avenue Converted MTS would be conducted within an enclosed processing building. Only sealed, air- and watertight containers would be transferred to barges outside of the processing building by gantry cranes installed at the pier level. Inside the facility, several measures would be taken to minimize the potential for environmental degradation as a result of the facility. Building ventilation would be maintained under negative pressure, which would keep dust inside the enclosed processing building. Litter control methods, such as routine sweeping and washing of the tipping floor, would be implemented to minimize or eliminate the potential for litter entering surface waters. The Hamilton Avenue Converted MTS would be consistent with this subpolicy.

5.2 *Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.*

Best management practices (BMPs) would be used to the extent possible during all phases of construction, including demolition of the existing MTS, and during operation of the Hamilton Avenue Converted MTS, in order to minimize any

nonpoint discharges. The Hamilton Avenue Converted MTS would comply with federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be conducted within an enclosed processing building. During construction, non-structural and, if necessary, structural, measures would be used to minimize nonpoint source pollution.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

The pilings that support the existing MTS would be removed and dredging would be necessary to provide sufficient water depths for unimpeded operations once the Hamilton Avenue Converted MTS is operational. ~~Any dredging~~Dredging undertaken as part of development of the Hamilton Avenue Converted MTS would result in temporary impacts and would be conducted in a manner to minimize siltation and erosion and other short-term impacts to water quality. All possible non-structural and, if necessary, structural, measures would be used to minimize siltation and potential adverse impacts to tidal wetlands in the vicinity. All dredged materials would be disposed of at a permitted upland facility in accordance with applicable federal, state and local regulations. Therefore, the Hamilton Avenue Converted MTS would be consistent with this subpolicy.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The Hamilton Avenue Converted MTS would have no impact on the quality or quantity of surface or ground waters. Process wastewaters (e.g., washdown waters, etc.) would be conveyed to an on-site treatment system and would then discharge to the municipal sewer system. Stormwater runoff from the Hamilton Avenue Converted MTS would be managed in accordance with all applicable federal, state and local regulations. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer of water supply. The Hamilton Avenue Converted MTS would be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to a review of FEMA National Flood Insurance Program maps, the Hamilton Avenue Converted MTS would be situated within portions of both the 100-year (Zone A) and 500-year (Zone B) floodplain boundaries. As part of its development, the existing over-water MTS would be demolished and a new MTS would be constructed within the upland portions of the project site. The pilings that support the existing MTS would also be removed and dredging would be necessary to provide sufficient water depths for unimpeded operations once the Hamilton Avenue Converted MTS is operational. To the extent practicable, non-structural and, if necessary, structural, measures would be used to minimize impacts due to flooding and erosion during the demolition and subsequent construction of the Hamilton Avenue Converted MTS. Construction of the Hamilton Avenue Converted MTS within the upland portions of the site would not affect the potential for flooding or erosion. All structures would comply with applicable building code requirements.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The Hamilton Avenue Converted MTS would not involve the storage, treatment or disposal of hazardous waste, but would facilitate the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Unless emergencies close the facility, solid waste

would generally be containerized within 24 hours of tipping. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the Hamilton Avenue Converted MTS. The majority of proposed activities would occur within an enclosed processing building. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility. Only sealed, air- and watertight containers would be utilized outside the facility.

On-site storage of petroleum or hazardous materials related to the operation of the Hamilton Avenue Converted MTS would be minimal. All storage would be done in accordance with applicable federal, state and local regulations. The Hamilton Avenue Converted MTS would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 *Prevent and remediate discharge of petroleum products.*

Soil and groundwater contamination is present at the existing site and is discussed in further detail within section 4.10. Existing contamination of the site would be addressed as part of the proposed development of the site, if required. This contamination would not be expected to prevent the proposed development of the Hamilton Avenue Converted MTS. Removal and disposal of contaminated materials, if required, would be done in accordance with applicable regulatory guidelines. In addition, as appropriate, health and safety measures would be used to mitigate and minimize any exposure risk to workers or the general public. Also see response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1 and 7.2.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

Due to the existing, heavy industrial uses at and in the immediate vicinity of the Hamilton Avenue Converted MTS, public access would not be compatible with the principal use of the site. Therefore, this subpolicy is not applicable.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The Hamilton Avenue Converted MTS would be a stand-alone, water-dependent, industrial facility fronting Gowanus Canal. Public access would not be compatible with the Hamilton Avenue Converted MTS; however, its development would not preclude any future development of public access at other locations along the Gowanus Canal or Gowanus Bay waterfront.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

Development of the Hamilton Avenue Converted MTS site would represent an upland expansion in size of an existing waterfront use and would not impair visual access to coastal lands, waters or existing open space. The existing MTS would be removed and a new MTS would be constructed within the upland

portions of the site. The Hamilton Avenue Converted MTS is not anticipated to significantly impact visual access within the area. See also response to Subpolicy 9.1.

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

A cluster of several small parks and open spaces collectively known as the Red Hook Recreational Area is located west of the Hamilton Avenue Converted MTS. In addition, various playgrounds and other parks and open space areas are scattered within the study area. There would be no impacts to these areas because the facilities are located across either Gowanus Canal or the Gowanus Expressway and are generally screened by existing, industrial buildings. In addition, the reactivation of an existing MTS use within an established and existing industrial area, located approximately ¼-mile from these park areas, would not result in any impacts to mapped parklands or open space resources. Therefore, the Hamilton Avenue Converted MTS would be consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 *Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.*

The Hamilton Avenue Converted MTS would be an upland expansion in size and rehabilitation of an existing waterfront use and, therefore, would be compatible with the existing urban design context and visual conditions of this portion of the industrialized Gowanus Canal and Bay waterfront, as noted in Section 4.7.3. Based on the information presented in that section, the Hamilton Avenue Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The Hamilton Avenue Converted MTS would pose no impact to scenic values associated with natural resources. It would be compatible with existing uses in the vicinity of the site, which do not allow for scenic views. Therefore, this subpolicy is not applicable.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

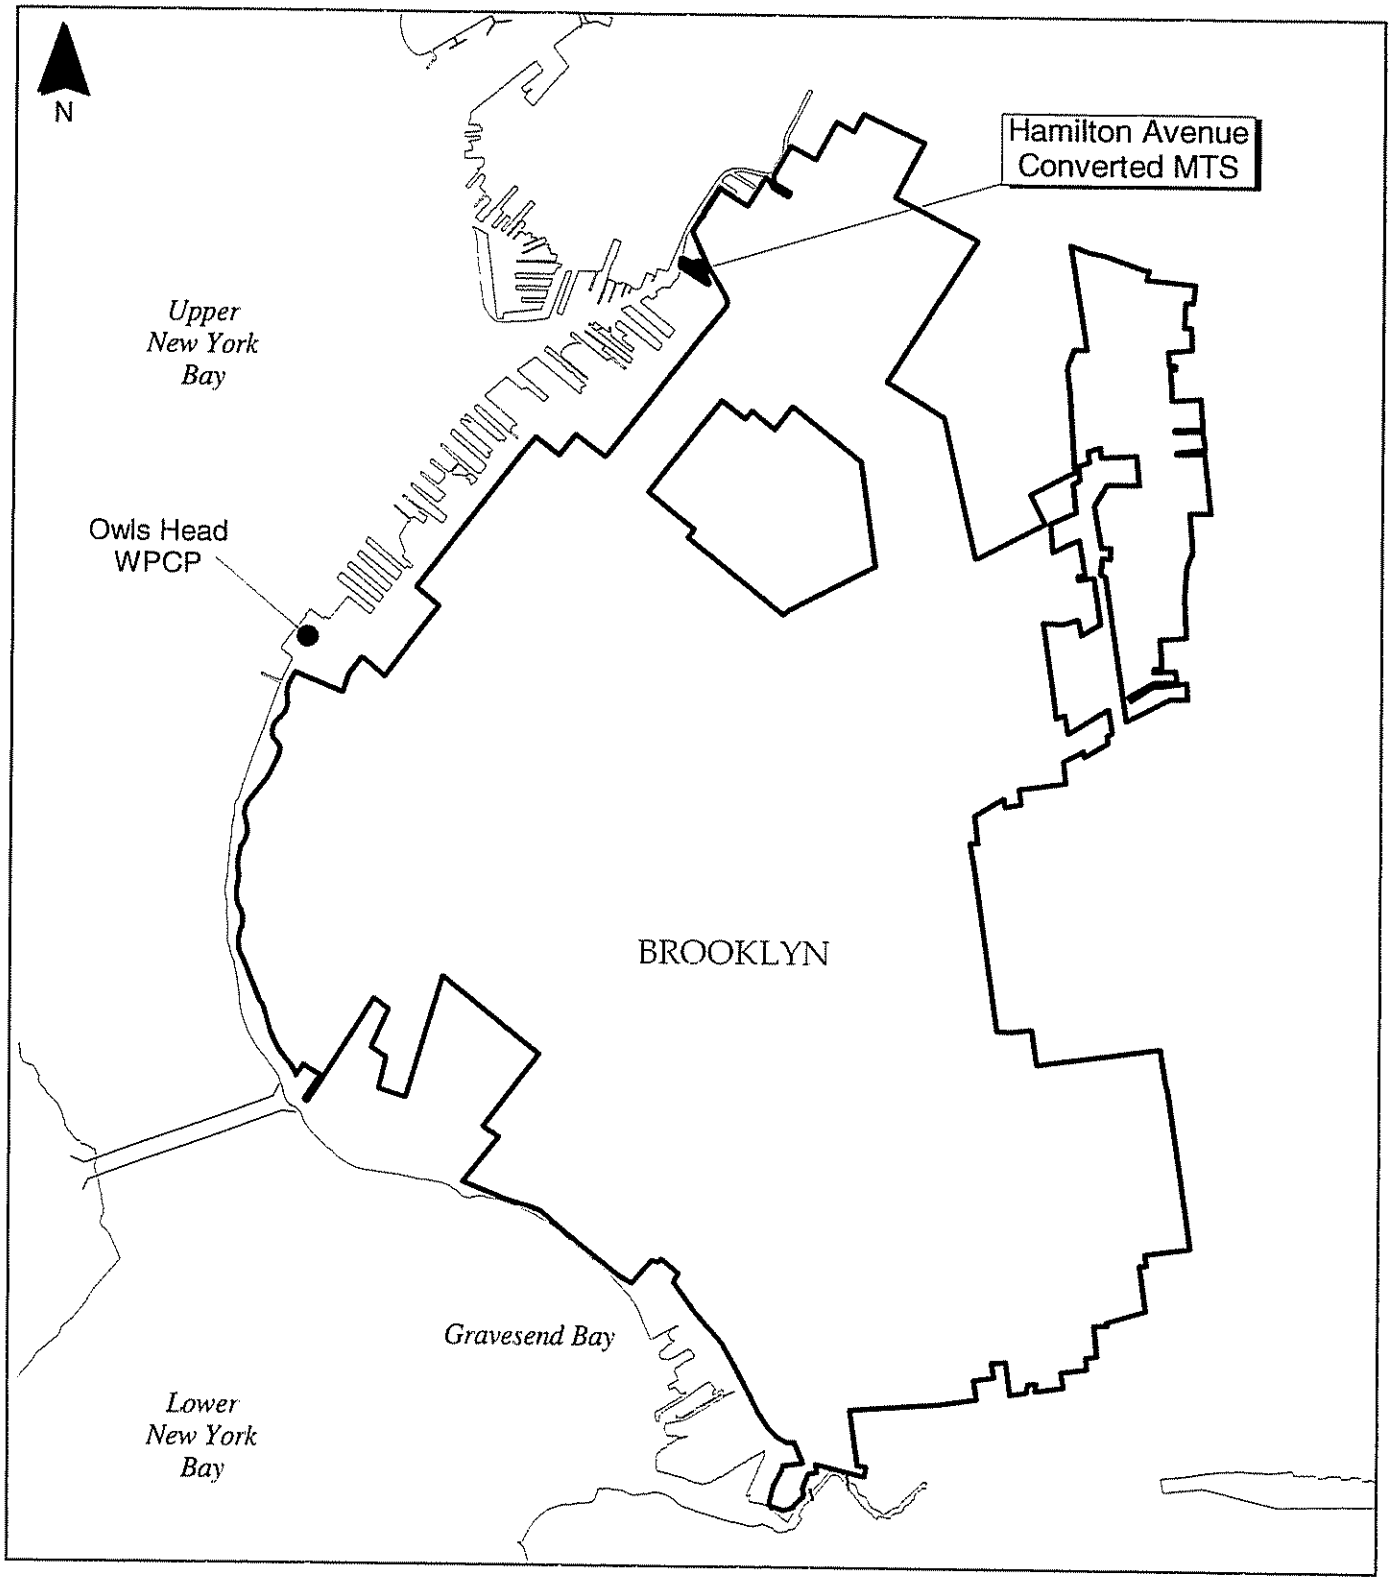
10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

The Hamilton Avenue Converted MTS would have no effect on any cultural resources on or near the site, as noted in Section 4.6.3. Based on the information presented in that section, the Hamilton Avenue Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site or in the study area. This subpolicy is, therefore, not applicable.

4.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



4.13.1 Existing Conditions

4.13.1.1 Water Supply

Water is supplied to the existing Hamilton Avenue MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. An 8-inch-diameter pipe that runs along Hamilton Avenue provides potable water for both potable and sanitary requirements. There is a 20-inch high-pressure fire system water main that flows south under the Gowanus Expressway along 3rd Avenue. Water pressure throughout the City system is generally about 20 pounds per square inch (psi), which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

4.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP infiltration and inflow (I&I) maps shows that the site is served by the Owls Head WPCP, which serves a large portion of Brooklyn. The WPCP drainage area is illustrated in Figure 4.13-1. From July 2002 through June 2003, the WPCP treated an average of 95 million gallons per day (mgd) of wastewater under dry weather flow conditions and an average flow of 104 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 4.13-1). The maximum dry weather flow during this period was 99 mgd during October 2002 and the maximum average flow was 114 mgd during June 2003. Effluent from the plant is discharged to Upper New York Bay and is regulated by NYSDEC under the State Pollutant Discharge Elimination System (SPDES). The current SPDES permit limit for flow to the Owls Head WPCP is 120 mgd. It is estimated that current on-site employee water usage at the existing Hamilton Avenue MTS is about 75 gallons per day (gpd). This estimate is based on three security employees (one employee per shift, three shifts per day) using 25 gallons per person per day (2001 CEQR Technical Manual). As the facility is not currently accepting waste, no additional potable water is used and no operational personnel are assigned to the site.

Site delineations are approximate

July 2002	90	93
August	94	99
September	97	107
October	99	113
November	96	111
December	96	104
January 2003	93	99
February	91	101
March	94	103
April	95	105
May	94	102
June	98	114
Average Effluent	**95**	**104**

Note:
(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

Based on a review of the I&I maps and information provided by the NYCDEP, Brooklyn Water and Sewer Permits, wastewater from the MTS is conveyed to a 12-inch municipal combined sewer running to the southeast along Hamilton Avenue, the northern boundary of the site. Near the corner of 2nd Avenue and Hamilton Avenue, the 12-inch line intersects a 30-inch combined sewer, which conveys flow to the southeast to a 78-inch combined line at the intersection of 3rd Avenue and Hamilton Avenue. From this intersection, the sewer system conveys wastewater generally to the south through a series of combined sewer lines and interceptors along 3rd and 1st Avenues to the Owls Head WPCP. CSOs connected to the lines on 3rd and 1st Avenues en route to the WPCP include one at 19th Street and Gowanus Bay associated with the pump station near the corner of 19th Street and 3rd Avenue, and another at 49th Street and the Upper Bay.

Municipal storm sewers in the vicinity of the MTS include a 12-inch line which conveys flow to the northwest along Hamilton Avenue from near the intersection of 2nd Avenue and Hamilton Avenue to Gowanus Canal.

4.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each of the three security employees at the existing MTS produces approximately nine pounds of solid waste per week for a facility total of 27 pounds per week (approximately 4 pounds per day). The solid waste is collected by DSNY personnel and transported by truck to an appropriately licensed solid waste management facility.

~~Based on a review of the I&I maps and information provided by the NYCDEP, Brooklyn Water and Sewer Permits, wastewater from the MTS is conveyed to a 12-inch municipal combined sewer running to the southeast along Hamilton Avenue, the northern boundary of the site. Near the corner of 2nd Avenue and Hamilton Avenue, the 12-inch line intersects a 30-inch combined sewer, which conveys flow to the southeast to a 78-inch combined line at the intersection of 3rd Avenue and Hamilton Avenue. From this intersection, the sewer system conveys wastewater generally to the south through a series of combined sewer lines and interceptors along 3rd and 1st Avenues to the Owls Head WPCP. CSOsombined sewer overflows connected to the lines on 3rd and 1st Avenues en route to the WPCP include one at 19th Street and Gowanus Bay associated with the pump station near the corner of 19th Street and 3rd Avenue. Another combined sewer overflow is located at 49th Street and the Upper Bay.~~

~~Municipal storm sewers in the vicinity of the MTS include a 12-inch line which conveys flow to the northwest along Hamilton Avenue from near the intersection of 2nd Avenue and Hamilton Avenue to Gowanus Canal.~~

4.13.1.4 Energy

Consolidated Edison supplies electricity to the facility through electric lines running along Hamilton Avenue. The existing Hamilton Avenue MTS currently utilizes a negligible amount of electricity due to the low staffing levels (for security purposes only). No gas is currently supplied to the facility, but utility maps from KeySpan show that there is a 1.5-inch gas main that runs southbound along Hamilton Avenue.

4.13.2 Future No-Build Conditions

The existing Hamilton Avenue MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near the Existing Conditions levels for security employees. Wastewater flows to the Owls Head WPCP would continue to increase and would be projected to be 104.6 mgd by 2006.

4.13.3 Potential Impacts with the Hamilton Avenue Converted MTS

4.13.3.1 Water Supply

The Hamilton Avenue Converted MTS would have up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The Hamilton Avenue Converted MTS would have no impact on the existing system's ability to supply water reliably. According to NYCDEP, the water pressure in the area is about 45 psi. Under worst-case conditions, this usage would not have significant impacts on water pressure in the system

4.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,300 gpd for the Hamilton Avenue Converted MTS, the small quantities of wastewater sent to the Owl's Head WPCP would not significantly impact the sewage flow rate or the ability of the Owl's Head WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 104.6 mgd in 2006, which would be well below the permitted capacity of 120 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in ~~combined sewer overflows~~ (CSOs).

4.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 pounds per day [lbs/day] per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees per day, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the Hamilton Avenue Converted MTS and would not significantly impact the system.

4.13.3.4 Energy

The Hamilton Avenue Converted MTS would require approximately 5.51E+10 British thermal units per year (BTU/year) of electricity. Natural gas facility heating would be used with an estimated demand of 1.34E+07 BTU/year.

Consolidated Edison has been notified of the power requirements of the Hamilton Avenue Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

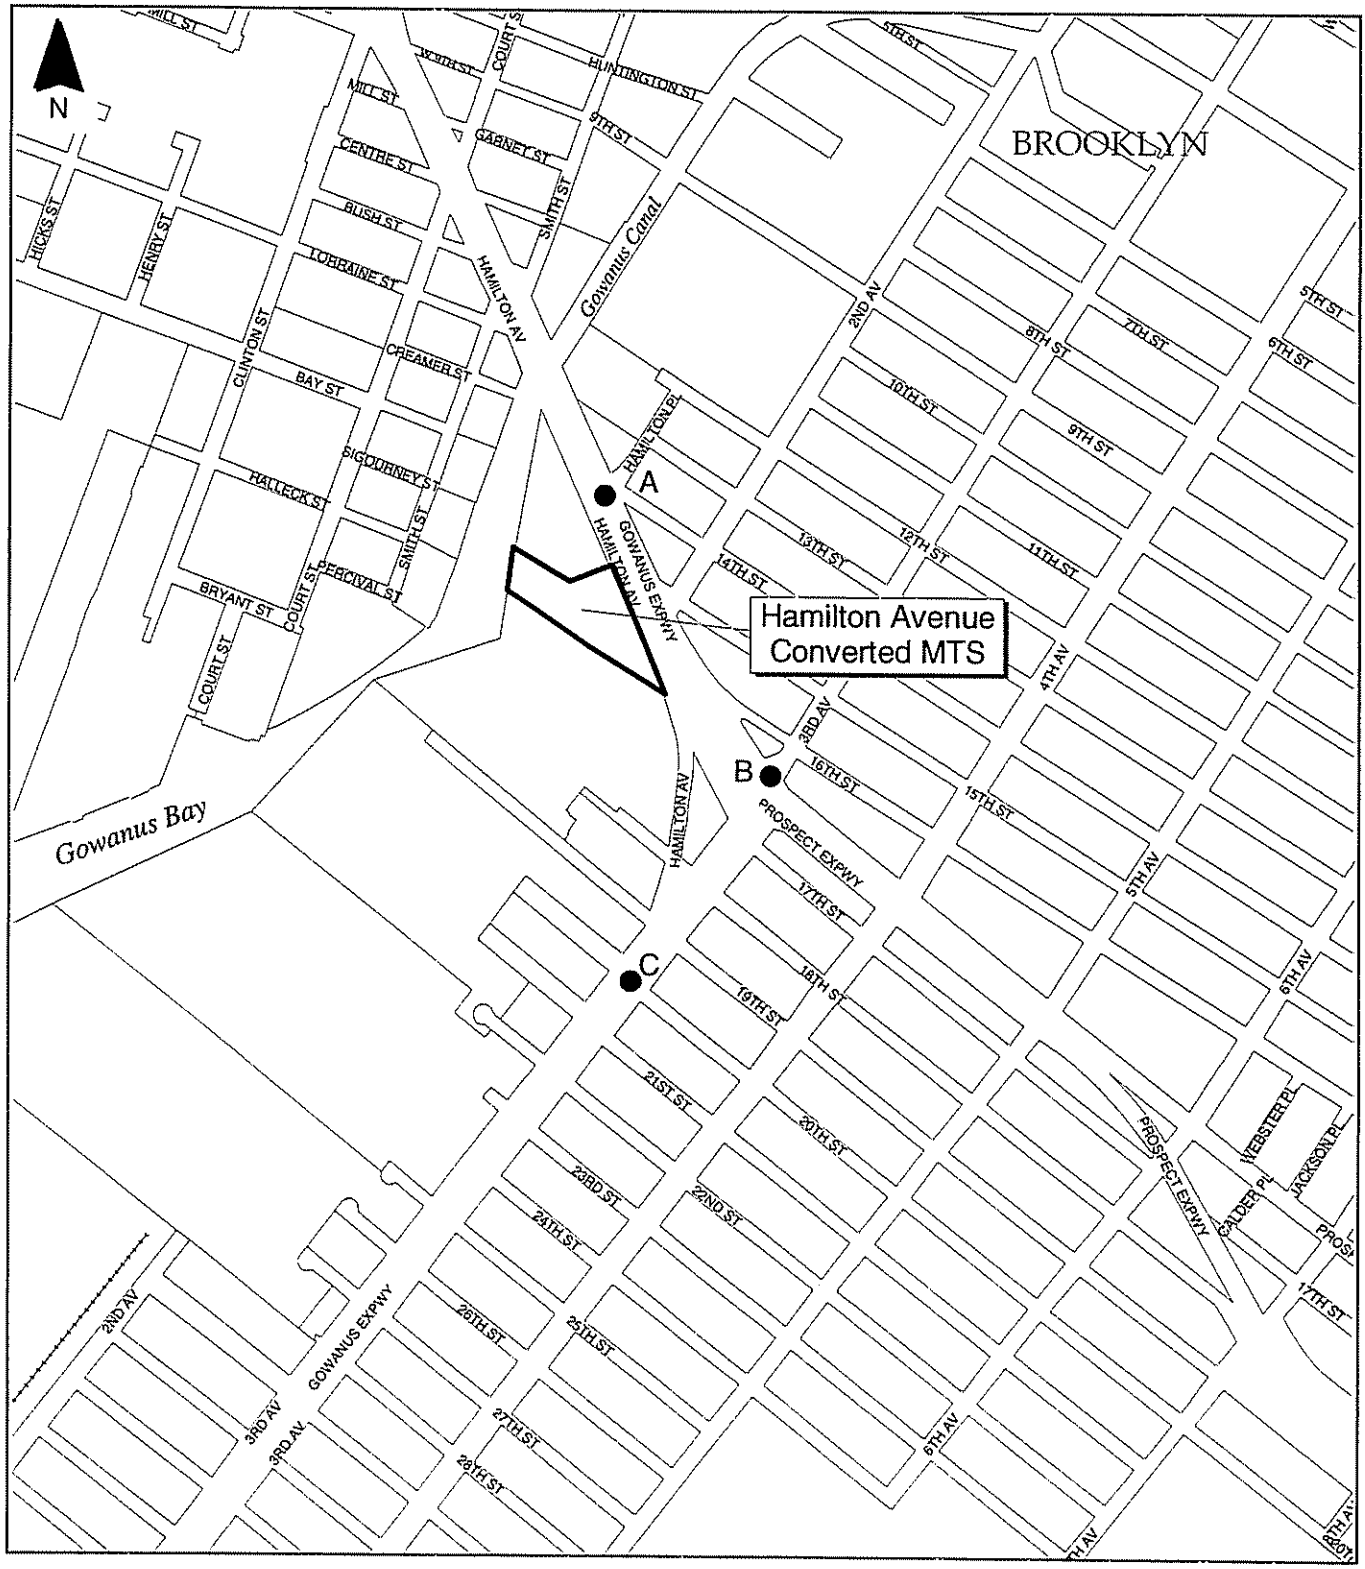
Consolidated Edison was also notified of the natural gas requirements of the Hamilton Avenue Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts on the utility.

4.14 Traffic, Parking, Transit, and Pedestrians

4.14.1 Introduction

The Hamilton Avenue Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

4.14.2 Existing Conditions



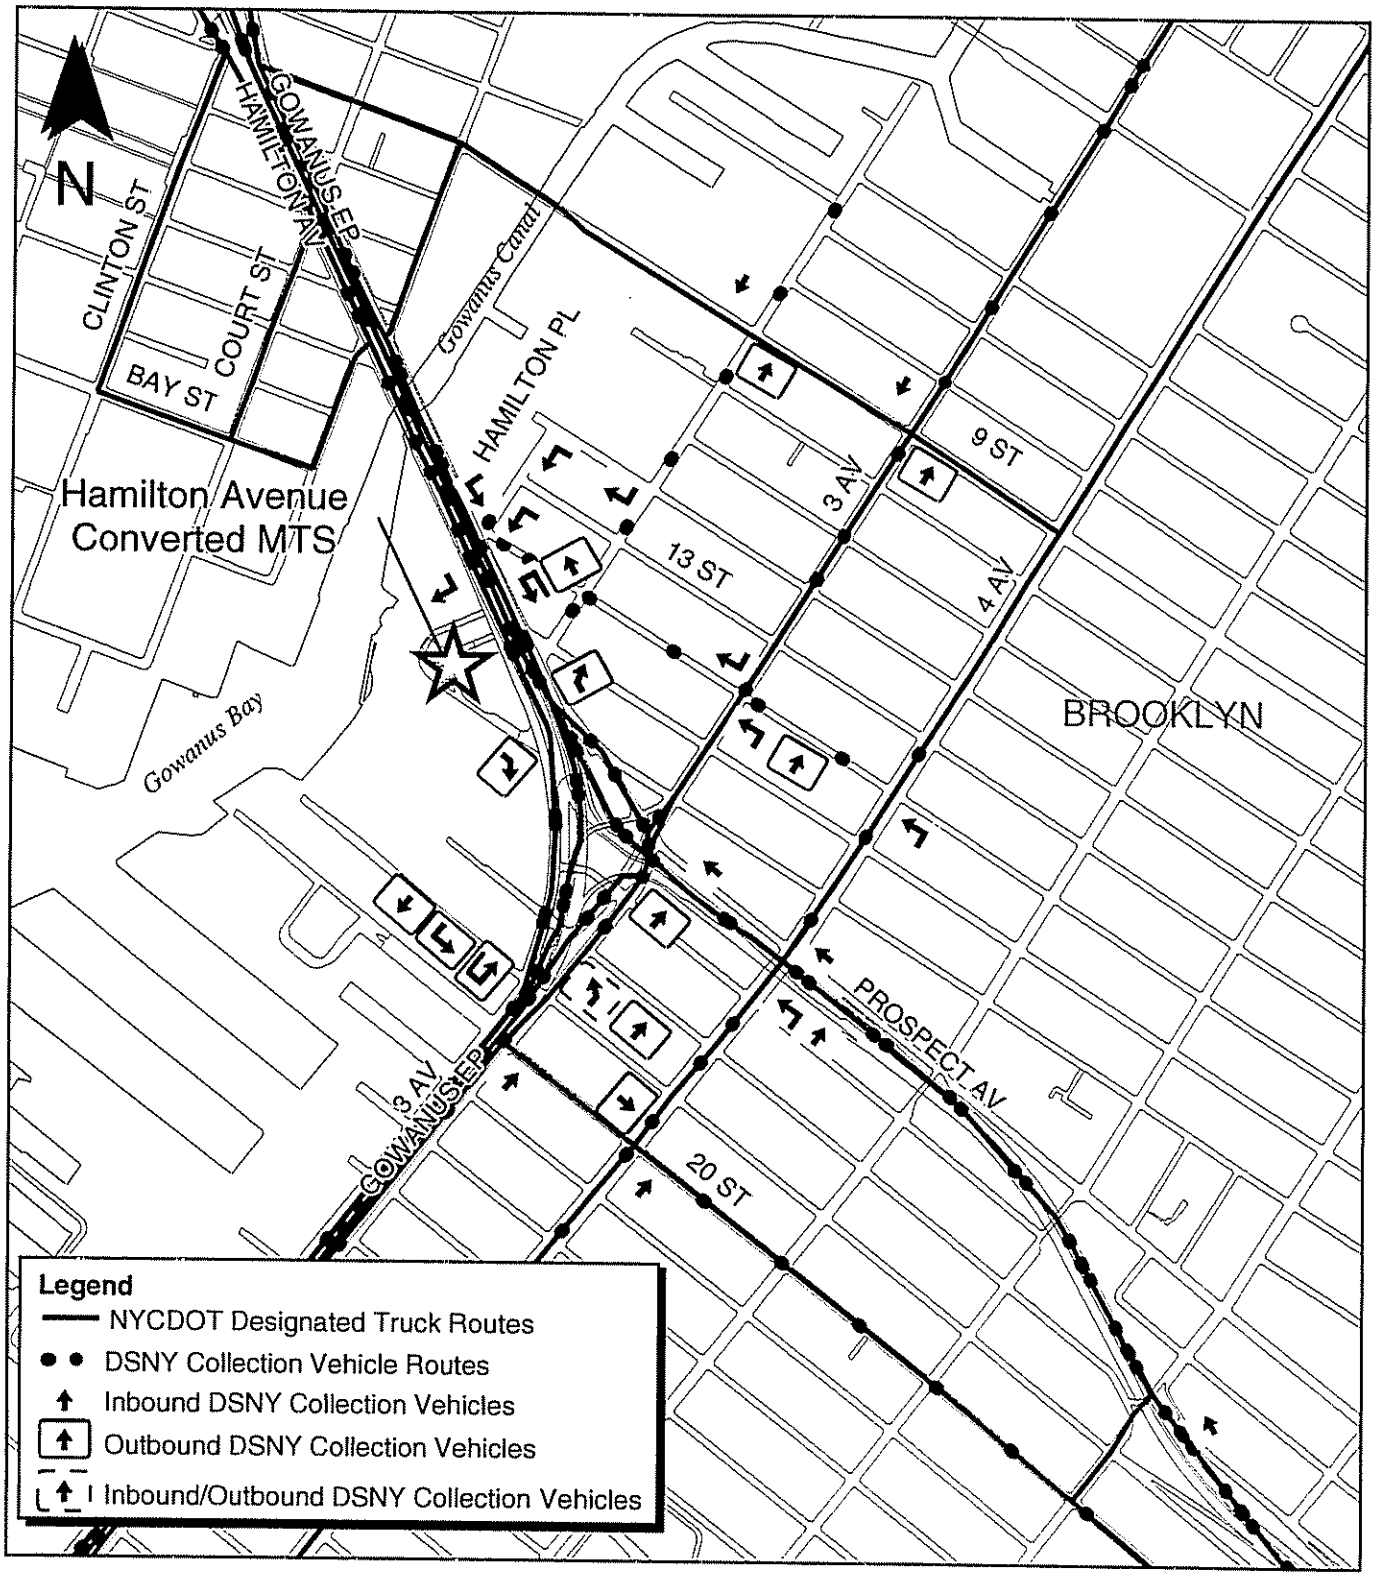
4.14.2.1 Definition of Study Area

The traffic analysis study area is relatively limited, existing entirely within the Gowanus area of Brooklyn. It includes the major corridors along the Gowanus Expressway, including Hamilton Avenue and Third Avenue. This study area is predominantly industrial in nature. There are no CEQR-defined areas of concern located within it. Figure 4.14-1 shows the locations of the intersections selected for analysis (locations A through C). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points in conjunction with local truck routes. Section 4.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the Hamilton Avenue Converted MTS.

4.14.2.2 Surface Network

Two major highways, the Gowanus Expressway and Prospect Expressway, service the traffic analysis study area. Second Avenue, Third Avenue, Hamilton Avenue, Prospect Avenue and 20th Street are local truck routes that provide access to and from the site. A map showing all major truck routes and local truck routes in Brooklyn is provided in Section 3.16 (see Figure 3.16-3).



Site delineations are approximate
Base Map Source: New York City Department of City Planning

Figure 4.14-1 Traffic Analysis Study Area
Hamilton Avenue Converted MTS
CITY OF NEW YORK
DEPARTMENT OF SANITATION

Hamilton Avenue is a principal arterial that provides north-south access from Prospect Expressway to the industrial areas in Red Hook, Brooklyn. Hamilton Avenue is a divided road with northbound traffic on the east side of the Gowanus Expressway and southbound traffic on the west side of the Gowanus Expressway. The Gowanus Expressway is an elevated roadway in the area that runs above 3rd Avenue and Hamilton Avenue. Third Avenue is a minor arterial that provides north-south access from Sunset Park and Bay Ridge to downtown Brooklyn. Fourth Avenue is a principal arterial that provide north-south access to the area. Prospect Avenue and 20th Street are minor arterials that provide east-west access for local and commercial traffic on either side of the Prospect Expressway. Both Hamilton Place and 14th Street are local streets that are not designated truck routes.

DSNY and other agency collection vehicles traveling south to the Hamilton Avenue Converted MTS could use either 3rd Avenue or the Gowanus Expressway. Vehicles traveling on the Gowanus Expressway would use Exit 26, the Hamilton Avenue exit, and travel to the Converted MTS on Hamilton Avenue (southbound). Vehicles traveling south on 3rd Avenue would turn west on 14th Street, then south on Hamilton Place. All vehicles traveling to the Hamilton Avenue Converted MTS converge at the intersection of Hamilton Avenue and Hamilton Place. All vehicles traveling north on Hamilton Avenue (northbound) must turn west on Hamilton Place and then south onto Hamilton Avenue (southbound) to access the Converted MTS. DSNY and other agency collection vehicles traveling north to the facility would use either 3rd Avenue or 4th Avenue. Vehicles traveling along 3rd Avenue would turn north onto Hamilton Avenue and then proceed to Hamilton Place. Vehicles using 4th Avenue would turn west on 14th Avenue and proceed to Hamilton Place. DSNY and other agency collection vehicles originating east of the Hamilton Avenue Converted MTS would travel west on the Prospect Expressway and exit onto Prospect Avenue. Prospect Avenue turns into Hamilton Avenue (northbound) and the vehicles would continue to Hamilton Place. Figure 4.14-2 depicts NYCDOT-designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

All DSNY and other agency collection vehicles exiting the Hamilton Avenue Converted MTS must turn south onto Hamilton Avenue (southbound). DSNY and other agency collection vehicles returning to points south of the Converted MTS continue on Hamilton Avenue

Site delineations are approximate

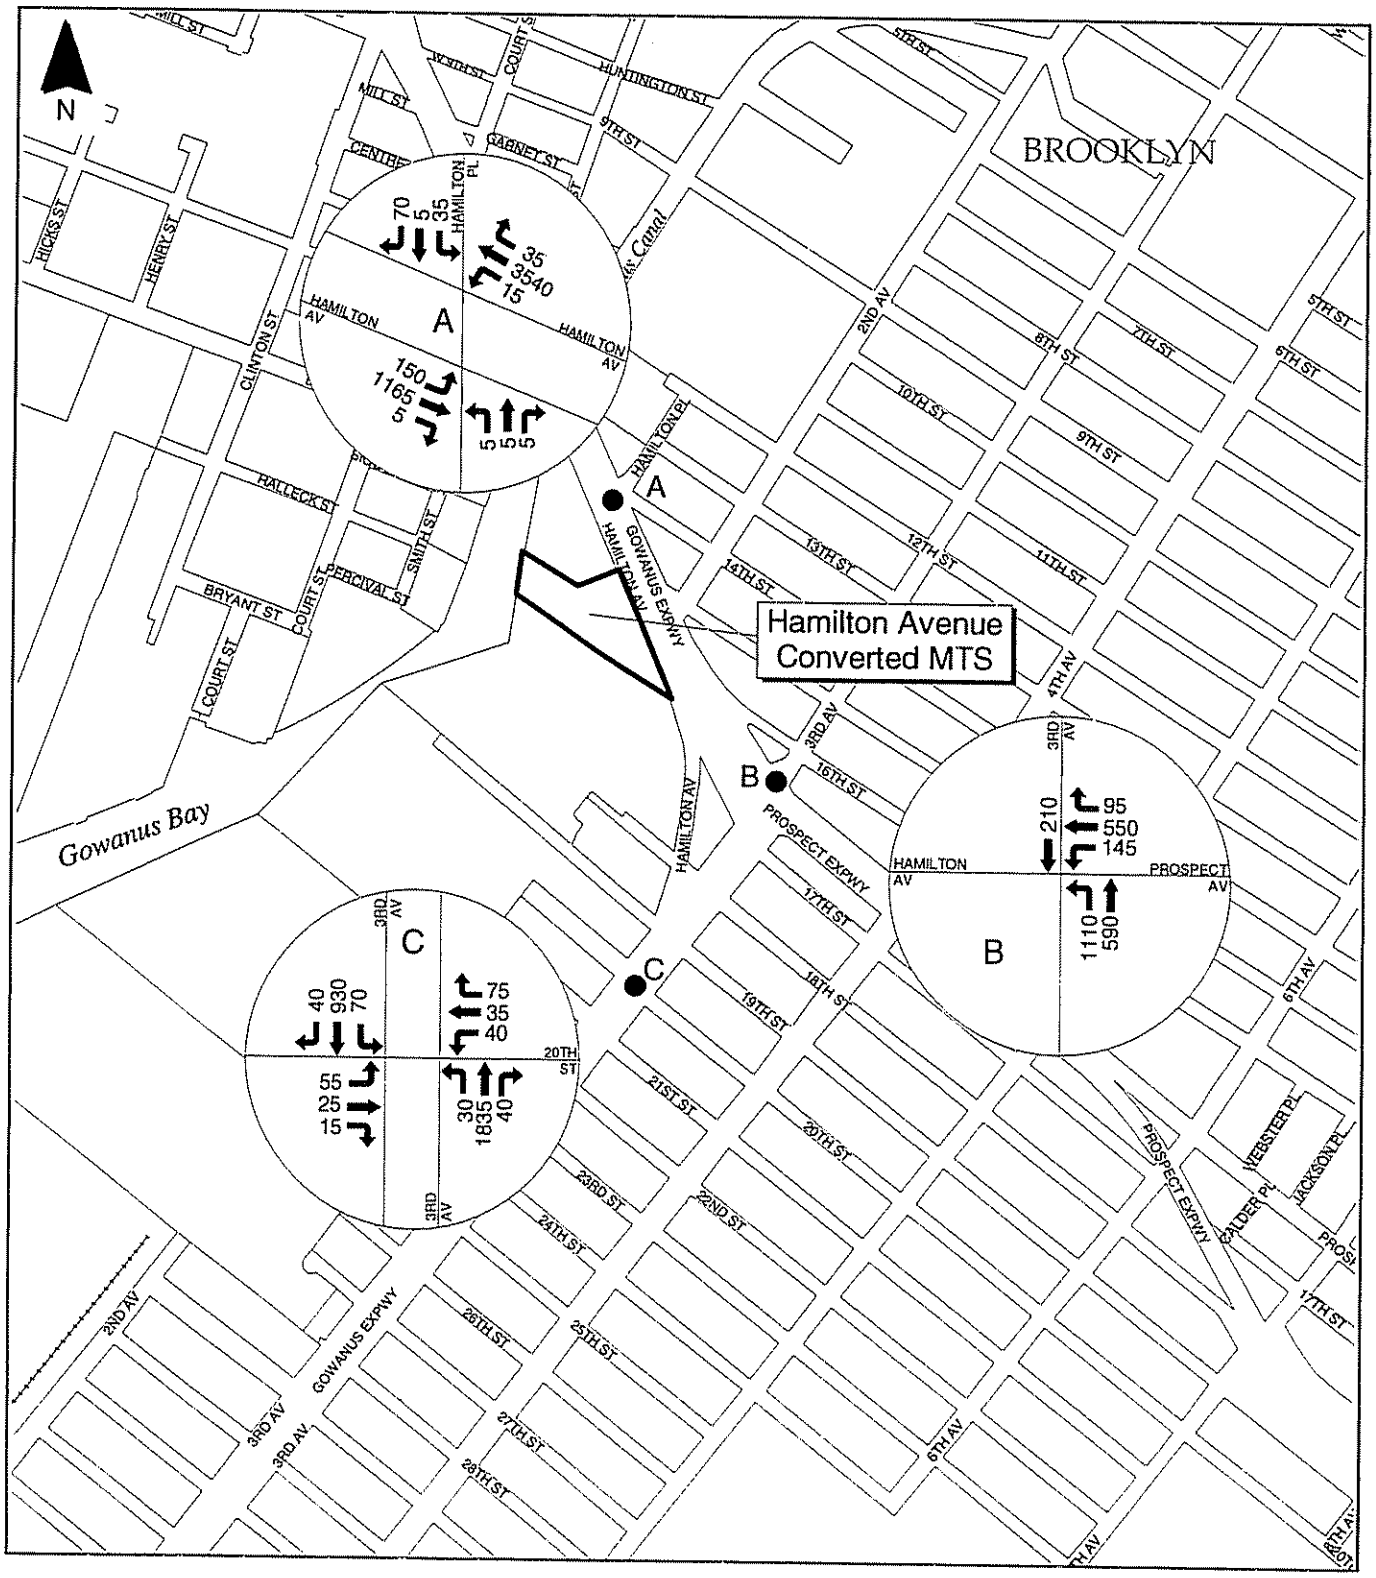
DEPARTMENT OF SANITATION

(southbound) and merge onto 3rd Avenue. Vehicles that return to points east of the Converted MTS turn east on 20th Street. Vehicles that return to points north of the facility also turn east onto 20th Street and then north onto 3rd Avenue. Vehicles that traveled south on the Gowanus Expressway turn onto Hamilton Avenue (northbound) from 3rd Avenue and then proceed to the Gowanus Expressway.



4.14.2.3 Existing Traffic Operations

The three intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the Hamilton Avenue Converted MTS. All of them are on major arterials and/or collection vehicle routes. Diagrams of these intersections are included in the technical backup submitted to NYCDOT.

- Hamilton Avenue and Hamilton Place and 14th Street – Signalized Intersection (see Figure 4.14-1 – location A)
- Prospect Avenue and Third Avenue – Signalized Intersection (see Figure 4.14-1 – location B)
- Third Avenue and 20th Street – Signalized Intersection (see Figure 4.14-1 – location C)

Hamilton Avenue is a principal arterial that provides north-south access from Prospect Expressway to the industrial areas in Red Hook, Brooklyn. Third Avenue is a minor arterial that provides north-south access from Sunset Park and Bay Ridge to downtown Brooklyn. Prospect Avenue and 20th Street are minor arterials that provide access for local and commercial traffic on either side of the Prospect Expressway. Both Hamilton Place and 14th Street are local streets.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between February 4 and February 6, 2003 and ATR counts were conducted between February 3 and February 7, 2003. Figures 4.14-3, 4.14-4 and 4.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally

occurred between 8:15 a.m. and 9:15 a.m., the Facility peak between 9:00 a.m. and 10:00 a.m., and the PM peak between 4:45 p.m. and 5:45 p.m. Table 4.14-1 presents the volume-to-capacity (v/c) ratio, delay and LOS for the three intersections during the AM, Facility, and PM peaks.

Existing truck traffic through most of the intersections was moderate. The percentages of trucks increases steadily during the morning hours, remaining at between 13% and 16% during midday hours, then decreasing to 7% or lower during the PM peak hours.

4.14.2.3.1 LOS at Signalized Intersections

Table 4.14-1 shows that the signalized intersections generally operated at an overall LOS of C or D, with some exceptions. The lane group with the least favorable LOS was the westbound through and right movements at the intersection of Prospect Avenue and Third Avenue. During the PM peak hour, this approach operated at LOS F with a delay of 82.7 seconds. Several other lane groups at various intersections operated at an LOS of D during various peak hours.

4.14.2.3.2 LOS at Unsignalized Intersections

No unsignalized intersections were analyzed.

4.14.2.4 Existing DSNY-Related Traffic

The privately-owned IESI-Court transfer facility located at 577 Court Street in the nearby Red Hook section of Brooklyn accepts waste from Brooklyn CD 6, the AFF and EZ-Pack Operations (from CDs 10, 13 and 16). The existing DSNY-related traffic in the vicinity of the Hamilton Avenue Converted MTS is generated by DSNY and related facilities in the immediate study area, including the DSNY Brooklyn Districts CDs 2 (465 Hamilton Avenue) and 6 (Second Avenue and 12th Street) garages, and the Brooklyn CD 6 Center at Second Avenue and 5th Street. Within the study area, DSNY-related traffic is primarily routed along Hamilton Avenue, Prospect Avenue, Second Avenue, Third Avenue, 20th Street, Gowanus Expressway and Prospect Expressway.

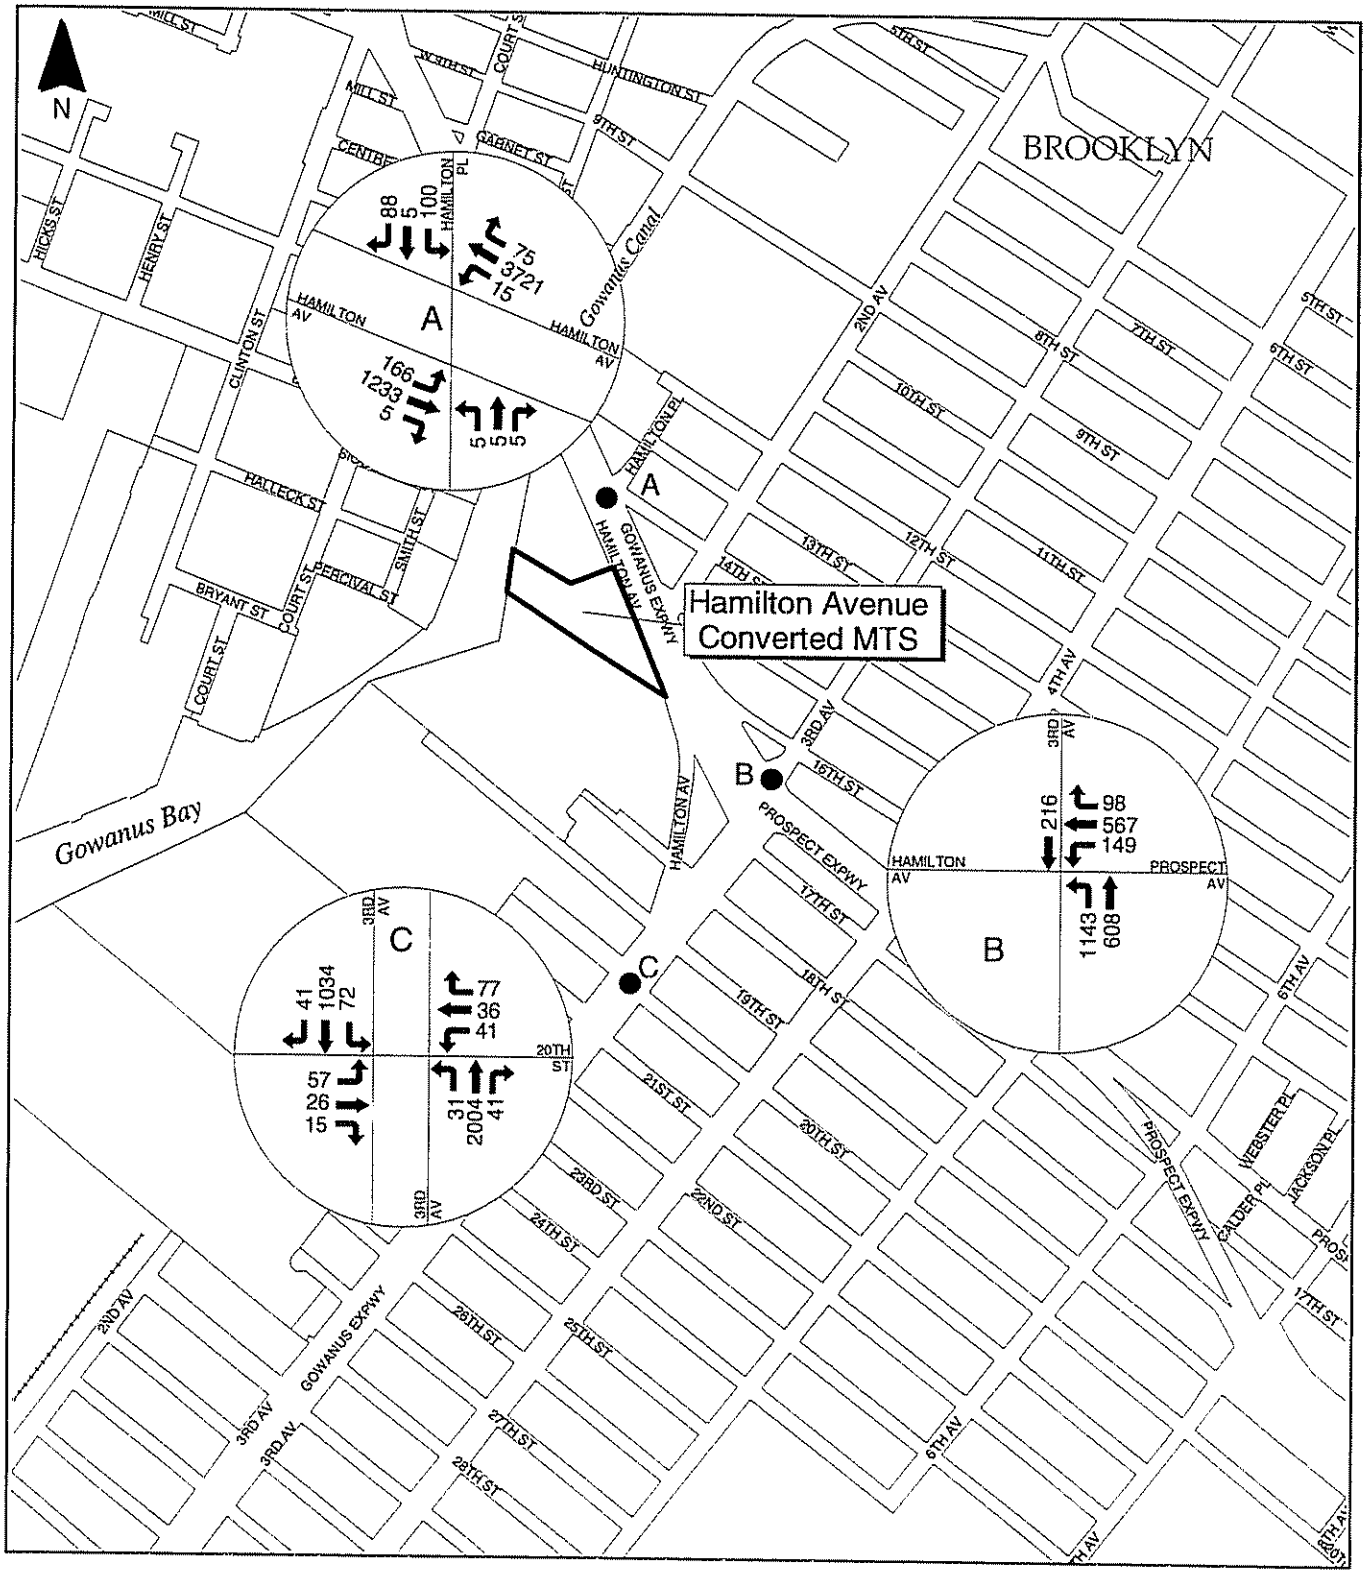
4.14.2.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The Prospect Avenue stop on MTA's "M," "N" and "R" subway lines is located approximately ¼-mile east of the site at the Prospect Avenue/Fourth Avenue intersection. MTA operates one local bus line, B37, through the study area, operating along Third Avenue. Bus stops are located at the Third Avenue/20th Street intersection and scheduled stops occur at various times during the day.

4.14.2.6 Pedestrian Activity

Pedestrian activity is generally low within the study area. Striped crosswalks and pedestrian signals are provided at all signalized study intersections. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.



4.14.3 Future No-Build Conditions

4.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1.0% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. In addition, additional traffic generated by proposed developments in the study expected to be completed by the Future No-Build year (2006) was also included. The following is a listing of the approved or in-process developments that are expected to generate significant volumes of traffic through the study area, and thus were specifically accounted for as part of this analysis:

- Lowe's (home improvement retail);
- Red Hook Stores (residential and retail); and
- Ikea Furniture (Retail)

Figures 4.14-6, 4.14-7 and 4.14-8 depict the Future No-Build traffic volumes for the AM, Facility, and PM peak hours at the intersections analyzed. Table 4.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delays and LOS for the study intersections. Overall, unsignalized intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their existing condition LOS, with the following exceptions:

WB = westbound

LT = left through movement

L = left movement

TR = through right movement

- During the AM peak hour, the delay of the westbound approach at the intersection of Hamilton Avenue and Hamilton Place and 14th Street increased from 54.6 seconds to 178.3 seconds (LOS D to LOS F).
- During the Facility peak hour, the delay of the westbound approach at the intersection of Hamilton Avenue and Hamilton Place and 14th Street increased from 50.8 seconds to 87.6 seconds (LOS D to LOS F).
- During the PM peak hour, the delay of the westbound approach at the intersection of Hamilton Avenue and Hamilton Place and 14th Street increased from 49.1 seconds to 99.0 seconds (LOS D to LOS F).
- During the PM peak hour, the delay of the westbound through and right movements at the intersection of Prospect Avenue and Third Avenue increased from 82.7 seconds to 92.5 seconds (LOS F in both cases).
- During the AM peak hour, the delay of the eastbound approach at the intersection of Third Avenue and 20th Street increased from 34.8 seconds to 35.4 seconds (LOS C to LOS D).

4.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

4.14.3.3 Pedestrian Activity

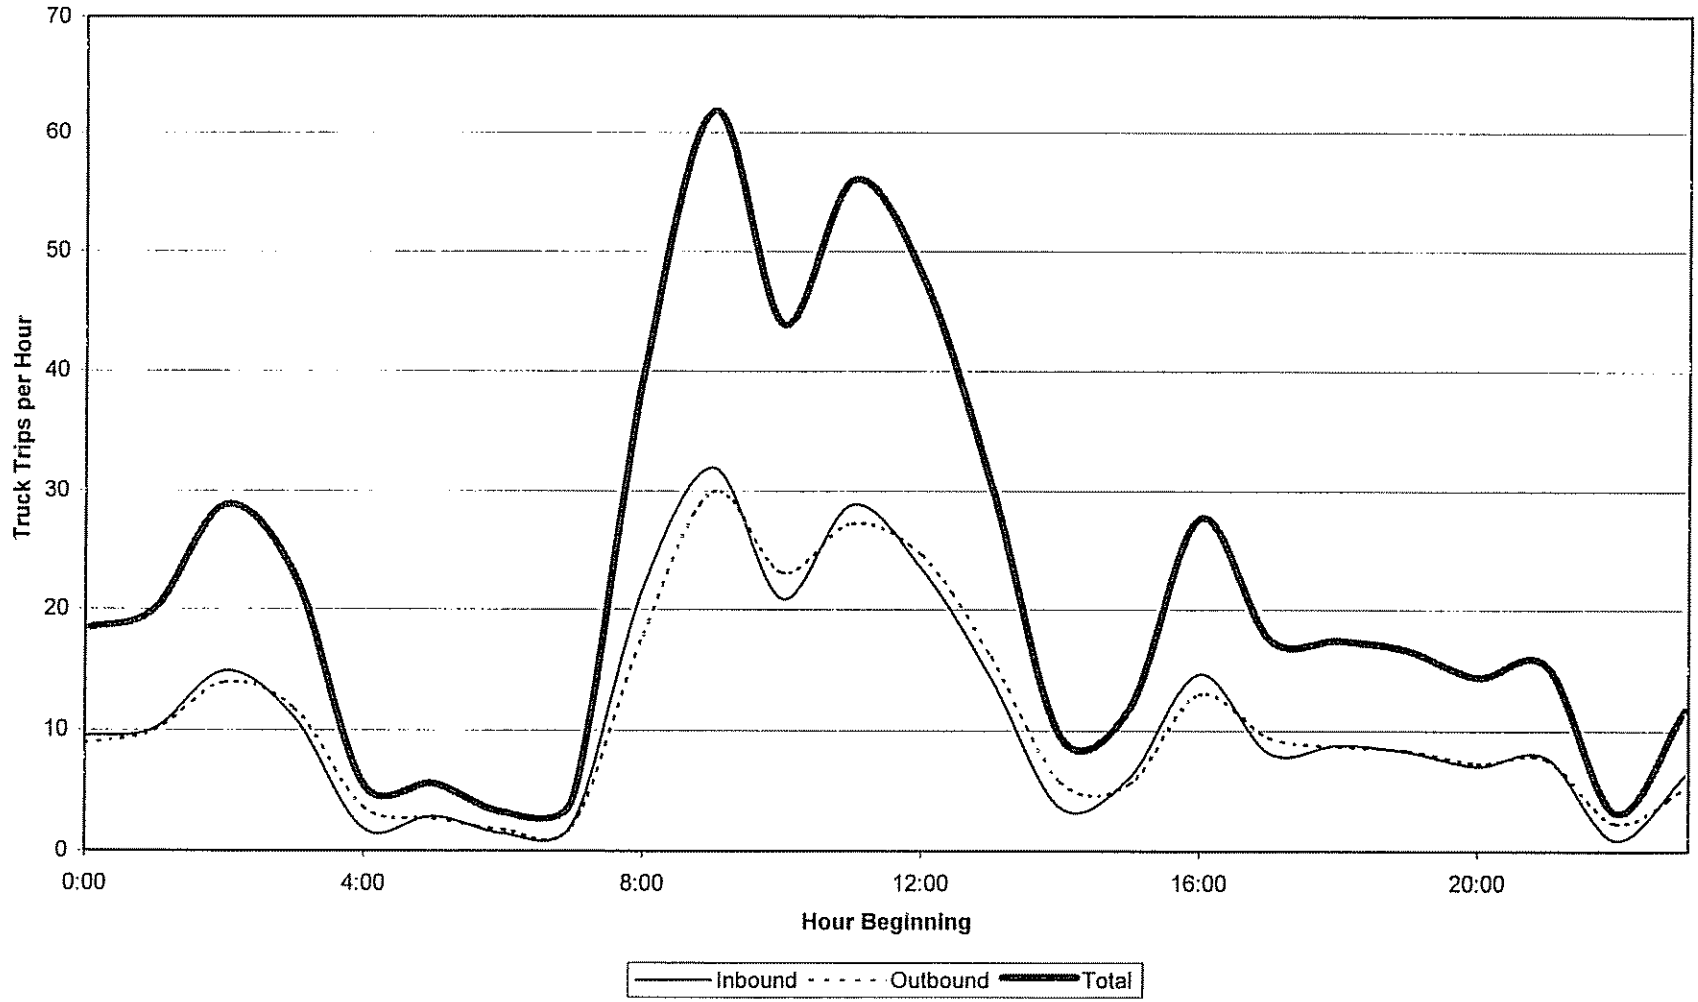
Future No-Build Conditions are expected to remain the same as Existing Conditions.

4.14.4 Potential Impacts with the Hamilton Avenue Converted MTS

The Hamilton Avenue Converted MTS would receive waste from 10 CDs in Brooklyn — Brooklyn CDs BKS02, BKS06, BKS07, BKN08, BKS09, BKS10, BKS14, BKS16, BKS17 and BKS18. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours.

4.14.4.1 2006 Future Build Traffic Conditions

2006 Future Build Traffic Conditions assume that the Hamilton Avenue Converted MTS would generate 267 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site



or the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the Hamilton Avenue Converted MTS are shown in Figure 4.14-2.

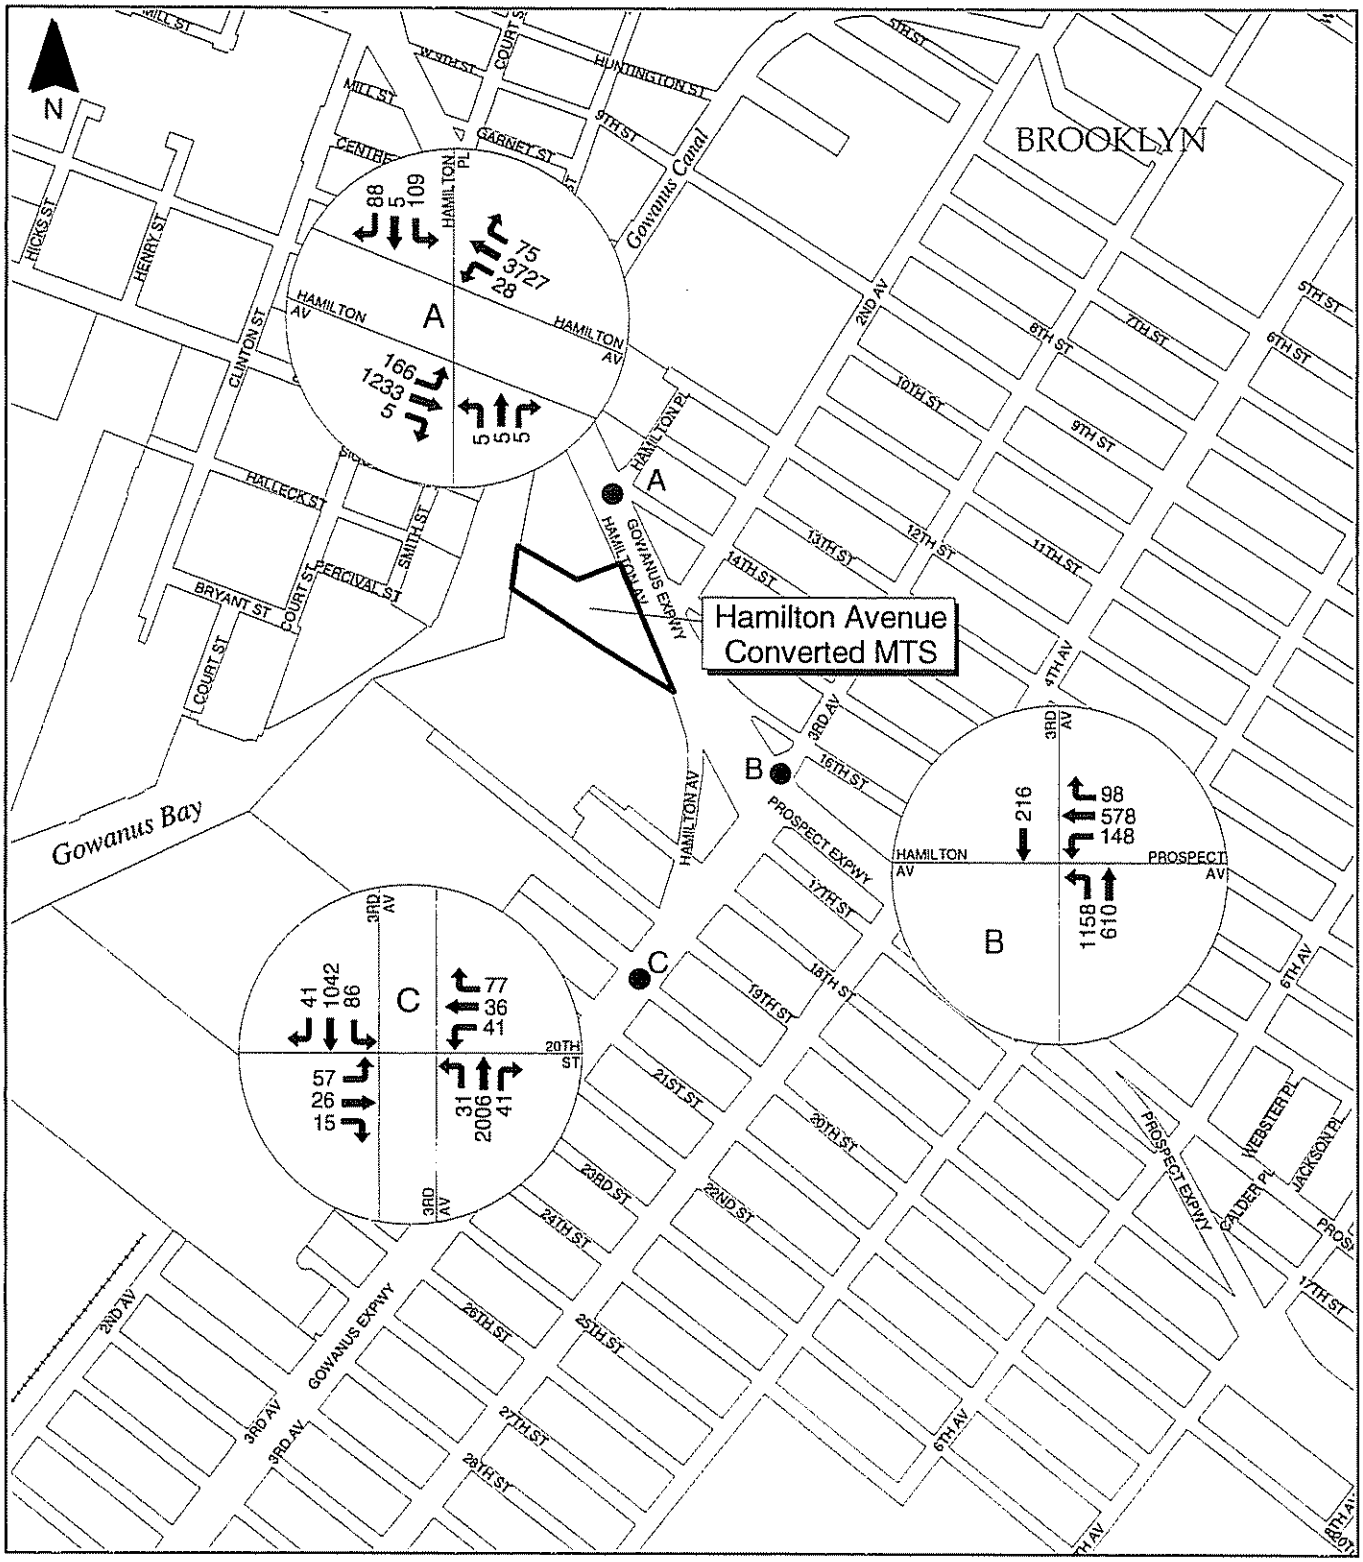


Figure 4.14-9 presents the average peak day temporal distribution of collection vehicles for the Hamilton Avenue Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the Hamilton Avenue Converted MTS is expected to vary from approximately 5 to 30 truck trips per hour in the late evening/early morning, 30 to 62 truck trips per hour in the mid-morning/early afternoon, and 10 to 30 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (62) occurs at approximately 9:00 a.m.

Employee trips generated as a result of the Hamilton Avenue Converted MTS are expected to be about 44 per shift (22 coming in and 22 leaving). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Therefore, during shift changes, employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m.

Because only the AM peak (8:15 a.m. to 9:15 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips from the Hamilton Avenue Converted MTS during the shift change (44) were considered as part of the net increase in site-generated traffic. Figures 4.14-10, 4.14-11 and 4.14-12 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 4.14-13, 4.14-14 and 4.14-15 show the intersections analyzed with only the net increase in site-generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the Hamilton Avenue Converted MTS. These projected net increases were routed through the intersections for each of the three peak hours. The highest net increase in trucks in the ingress or egress direction was 32. The highest net increase at any one intersection was 30 trucks. Both of these net increases occurred at the intersection of Hamilton Avenue and Hamilton Place and 14th Street.

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 68% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 62% of weekday traffic volumes. Table 4.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Hamilton Avenue Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 4.14-3
Weekday and Weekend Traffic
Hamilton Avenue Converted MTS

DSNY and Other Agency Collection Vehicle Traffic		Background Traffic NB and SB on Hamilton Avenue[1]	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday Average Vehicles/Day	Weekend Average Vehicles/Day
267	181	59,819	37,339

Note:
(1) NB and SB traffic data collected from ATR counts taken on Hamilton Avenue between Hamilton Place and 2nd Avenue from September 15 to 21, 2003.

Table 4.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Hamilton Avenue Converted MTS. Over an average peak day, the intersections should not experience an extended increase in delay. The two intersections that may experience potentially significant impacts are discussed in Section 4.14.4.2 and summarized in Table 4.14-5.

4.14.4.2 Impacts and Mitigation

Two of the three intersections may experience impacts great enough to be considered significant during only one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines require mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below. Their effectiveness is summarized in Table 4.14-5.

Notes:
(1) HCM output is included in technical backup submitted to the NYCDOT.
LTR = left, through and right movements
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
LT = left through movement
L = left movement
TR = through right movement

Hamilton Avenue/Hamilton Place/14th Street – During the AM peak hour, a potential impact was identified on the westbound approach when the delay is expected to increase from 178.3 seconds to 225.6 seconds (LOS F in both cases). During the Facility peak hour, the same (westbound) approach is expected to experience an increase in delay from 87.6 seconds to 111.4 seconds (LOS F in both cases). During the PM peak hour, the delay of the westbound approach is expected to increase from 99.0 seconds to 106.1 seconds (LOS F in both cases).

During the AM peak hour, an increase in green time of 13 seconds for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would eliminate the 13-second exclusive eastbound phase, leaving the northbound and southbound approach green time unchanged. This mitigation would improve the LOS for the westbound approach to below Future No-Build Condition levels.

During the Facility peak hour, an increase in green time of two seconds for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract two seconds from the northbound and southbound approach green time, but would improve the LOS for the westbound approach to below Future No-Build Condition levels with minimal increases to the delay of the northbound and southbound approaches.

During the PM peak hour, an increase in green time of one second for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract one second of green time from the northbound and southbound approach, but would improve the LOS for the westbound approach (again) to below Future No-Build Condition levels with minimal increases to the delay of the northbound and southbound approaches.

Prospect Avenue/Third Avenue – During the AM peak hour, a potential impact was identified on the westbound through and right movements when the delay increased from 53.3 seconds to 147.3 seconds (LOS D to LOS F). During the PM hour, the delay of the westbound approach is expected to increase from 109.6 seconds to 113.0 seconds (LOS F in both cases).

During the AM peak hour, an increase in green time of eight seconds for the westbound approach should eliminate this unacceptable increase in delay. This mitigation measure would subtract five seconds of green time from the northbound left and through movements and three seconds of green time from the northbound and southbound approach phases, but would reduce the delay for the westbound through and right movements from 147.3 seconds to 55.2 seconds. The delay of both the northbound and southbound approaches would increase within acceptable levels. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

During the PM peak hour, an increase in green time of one second for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would detract one second of green time from the northbound and southbound approach, but would improve the LOS for the westbound approach with minimal increase to the delay of the northbound and southbound approaches.

Overall, the mitigation measures suggested would greatly enhance the intersection performance by reducing delays to LOSs similar to those under the Future No-Build Condition.

4.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

4.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

4.15 Air Quality

4.15.1 Definition of the Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) from the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Hamilton Avenue Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersections listed in Section 4.15.4.2.

4.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 4.15.1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 4.15-1
Representative Ambient Air Quality Data
Hamilton Avenue Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	MTA, Flatbush Avenue between Tillary Street and Johnson Avenue	8-Hour	3,436 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	4,695 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	College Point Post Office	Annual	56 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}[(2)]	P.S. 321	Annual	20 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	45 $\mu g/m^3$	150 $\mu g/m^3$
SO_2	P.S. 321	3-Hour	152 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	94 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	24 $\mu g/m^3$	80 $\mu g/m^3$

Notes:
Source: NYCDEP, April 2003 and USEPA Air data – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.
(2) Values are the highest pollutant levels recorded during the 1998 calendar year.

4.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build air quality conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

4.15.4 Potential Impacts with the Hamilton Avenue Converted MTS

4.15.4.1 On-Site Analysis

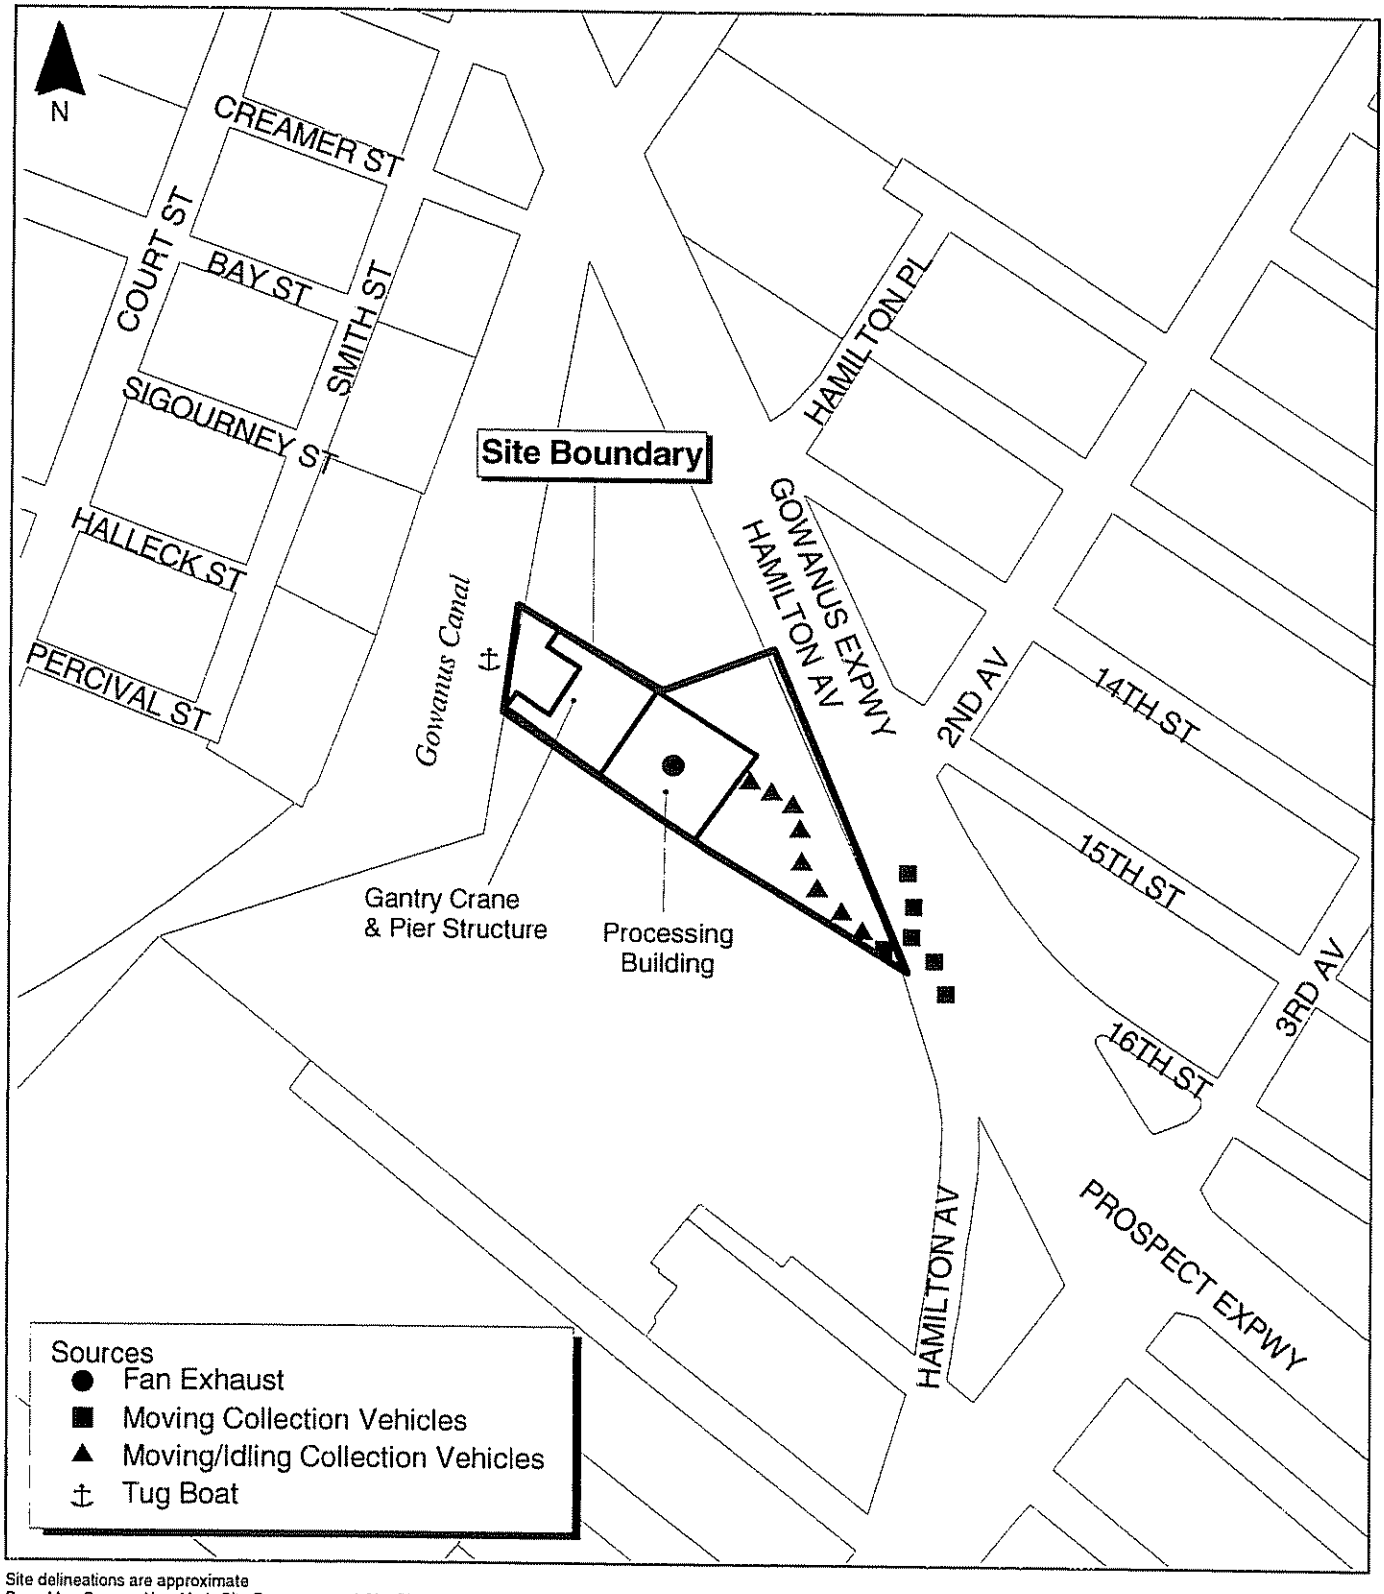
4.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 4.15-2. Figure 4.15-1 shows the locations of these sources within the site.

4.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 4.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from Hamilton Avenue Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 4.15-3, are below the STVs. The Hamilton Avenue Converted MTS would not, therefore, significantly impact air quality in the area.

Table 4.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
Hamilton Avenue Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweeper	1	1
Moving/Queuing Collection Vehicles	46	18
Space Heaters	6	4
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3]	12 in, 1 out	~~3~~ 4 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~ available upon request.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (one third of 12), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

Site delineations are approximate

Notes:

[1] The highest estimated pollutant concentrations found at any of the off-site receptor locations.

[2] Background concentrations were obtained from the NYCDEP ~~in April 2003~~memorandum dated February 18, 2005..

[3] NAAQS = National Ambient Air Quality Standard.

[4] Screening threshold value (STV) established by the NYCDEP and NYSDEC.

[5] Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

[6] The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

[7] The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

4.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 4.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Hamilton Avenue Converted MTS are not considered to be significant.

4.15.4.2 Off-Site Analysis

4.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines that are outlined in Section 3.17. Following these guidelines, the following detailed mobile source analyses were conducted for the applicable (i.e., worst-case) time periods:

- An analysis of the intersections of Hamilton Avenue at Hamilton Place and 14th Street, and 20th Street at 3rd Avenue and 4th Avenue to determine whether Hamilton Avenue Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and
- An analysis of the intersections of Hamilton Avenue at Hamilton Place and 14th Street, and 20th Street at 3rd Avenue and 4th Avenue to determine whether Hamilton Avenue Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 4.15-2. This selection was in accordance with the PM_{10} and $PM_{2.5}$ screening criteria discussed in Section 3.17.

Notes to Table 4.15-4:

(1) Estimated by multiplying the total 1-hour hydrocarbons (HCs) concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGCs) established by NYSDEC.

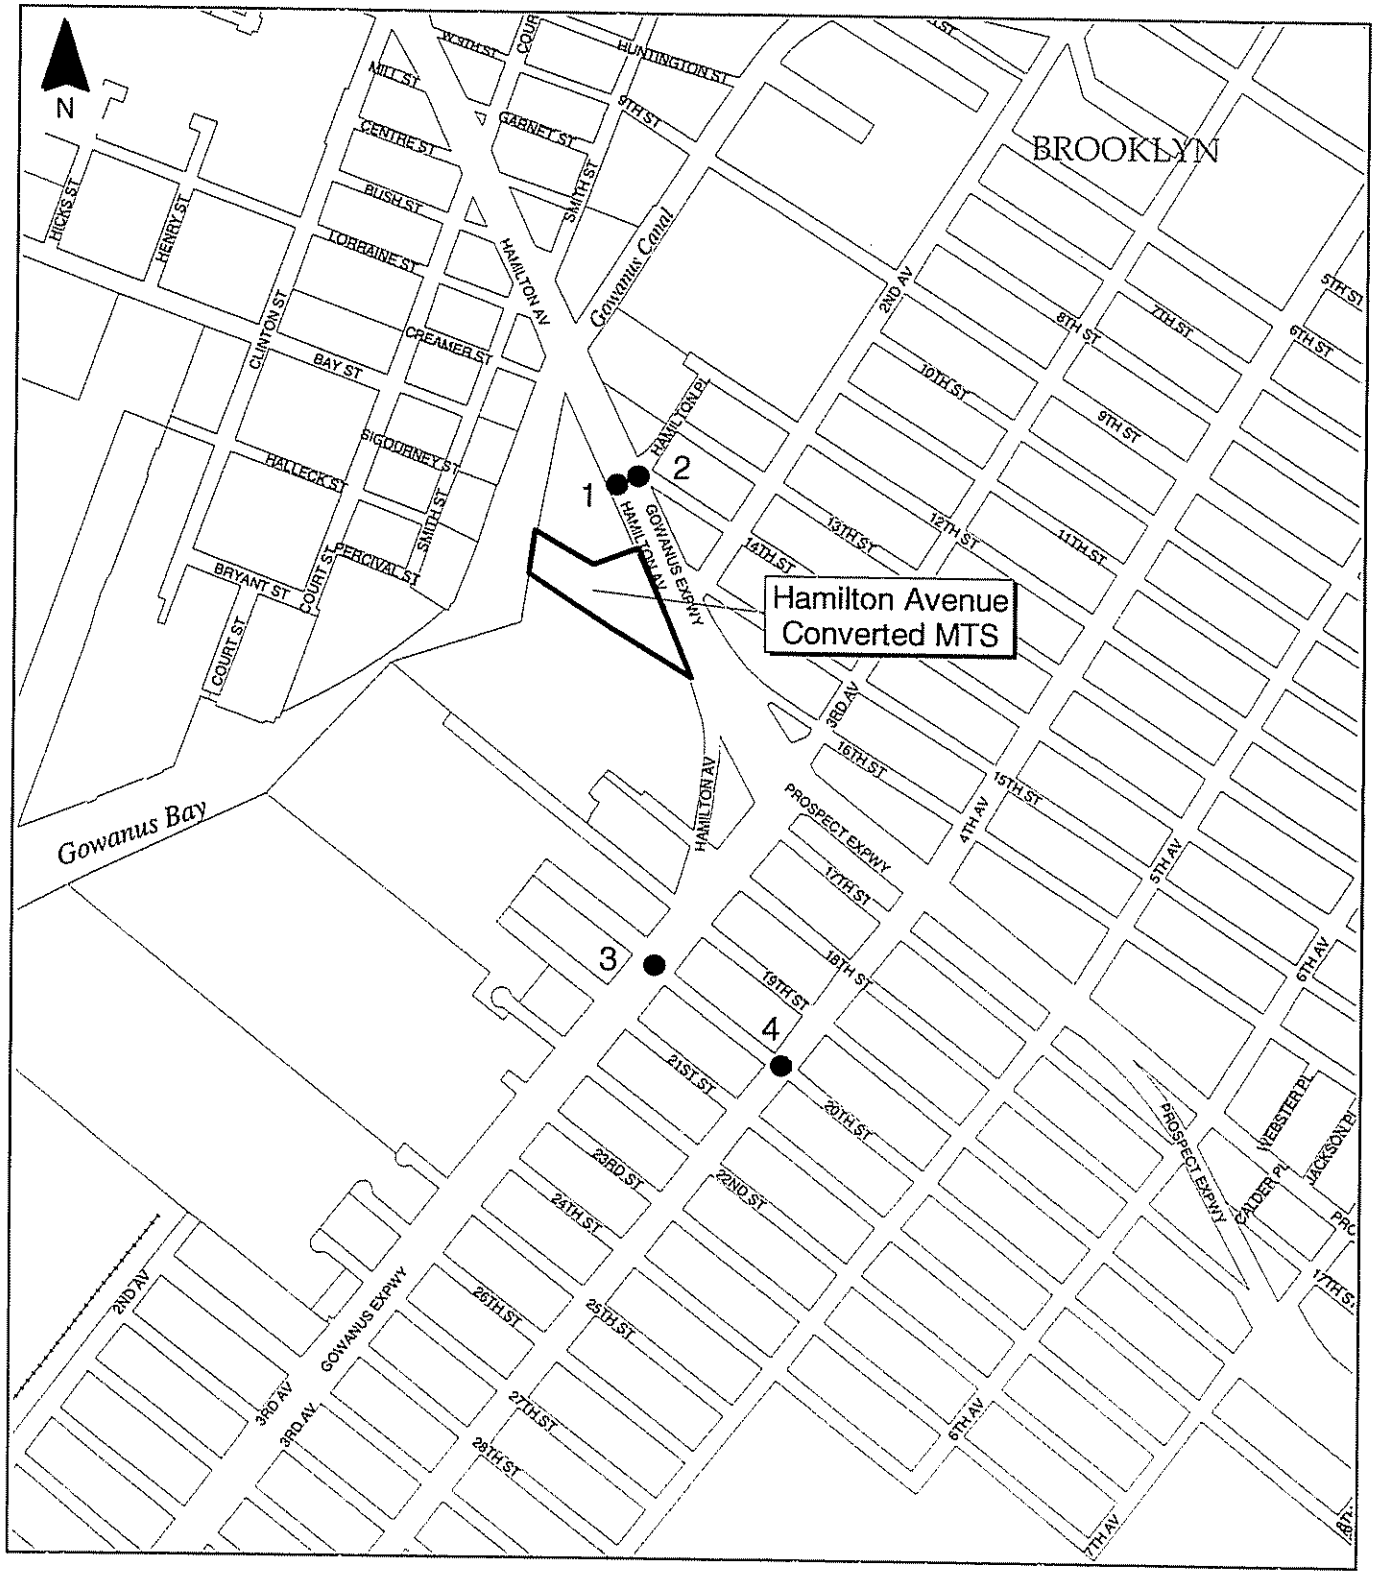
(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

4.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 4.15-5~~, are all within (less than) the applicable state and federal ambient air quality standards and STVs (for $PM_{2.5}$)~~. A Tier II analysis of the intersections at Hamilton Avenue and Hamilton Place and 14th Street, and 20th Street at 3rd Avenue and 4th Avenue was necessary to determine the off-site annual and 24-hour impacts for PM_{10}. and the annual neighborhood impacts for $PM_{2.5}$. The results of this Tier II analysis are within the applicable state and federal ambient air quality standards for PM_{10}. The off-site operations of the Hamilton Avenue Converted MTS, therefore, are not considered to be significant.

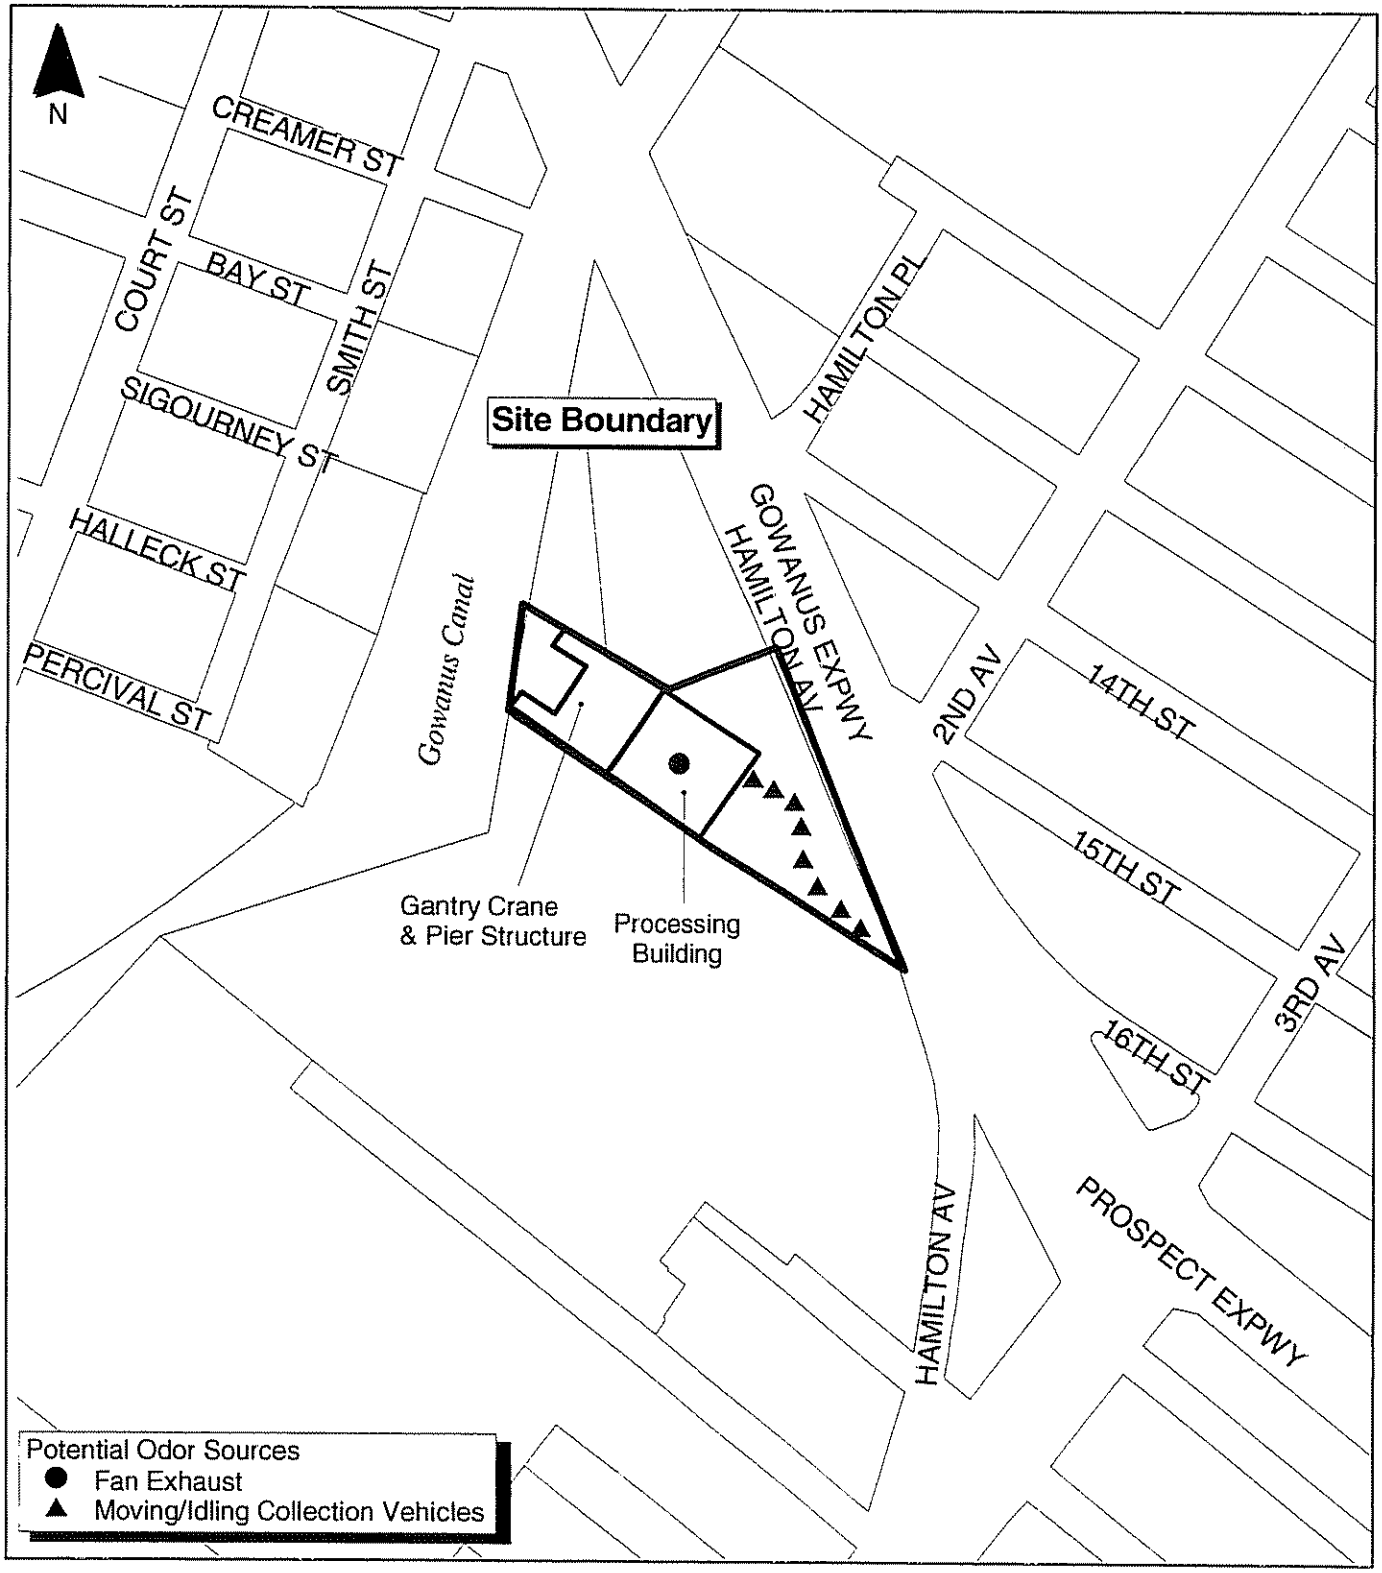
4.16 Odor

4.16.1 Existing Conditions

The existing MTS is not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is the row of apartment buildings located on 15th Street between 2nd Avenue and 3rd Avenue, approximately 372 feet from the site boundary.

4.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the Hamilton Avenue Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



4.16.3 Potential Impacts with the South Bronx Converted MTS

4.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Hamilton Avenue Converted MTS are provided in Table 4.16-1. Figure 4.16-1 shows the locations of these sources within the site.

Table 4.16-1
Odor Sources Included in Odor Analysis

Figure 4.16-1 Potential Odor Sources

Hamilton Avenue Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Hamilton Avenue Converted MTS.

4.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 4.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Hamilton Avenue Converted MTS at any nearby sensitive receptor is less than 1, so odors from the Hamilton Avenue Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 4.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Hamilton Avenue Converted MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	0.44
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result[2]	0.12
Type of Receptor	Apartment Buildings
Distance to Receptor[3]	372 Feet

Notes:
(1) ~~D/T ratio is dimensionless.~~ Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.
(2) Measured from the site boundary.
(3) ~~Measured from the site property line.~~

4.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Hamilton Avenue Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

4.17.1 Existing Conditions

4.17.1.1 Introduction

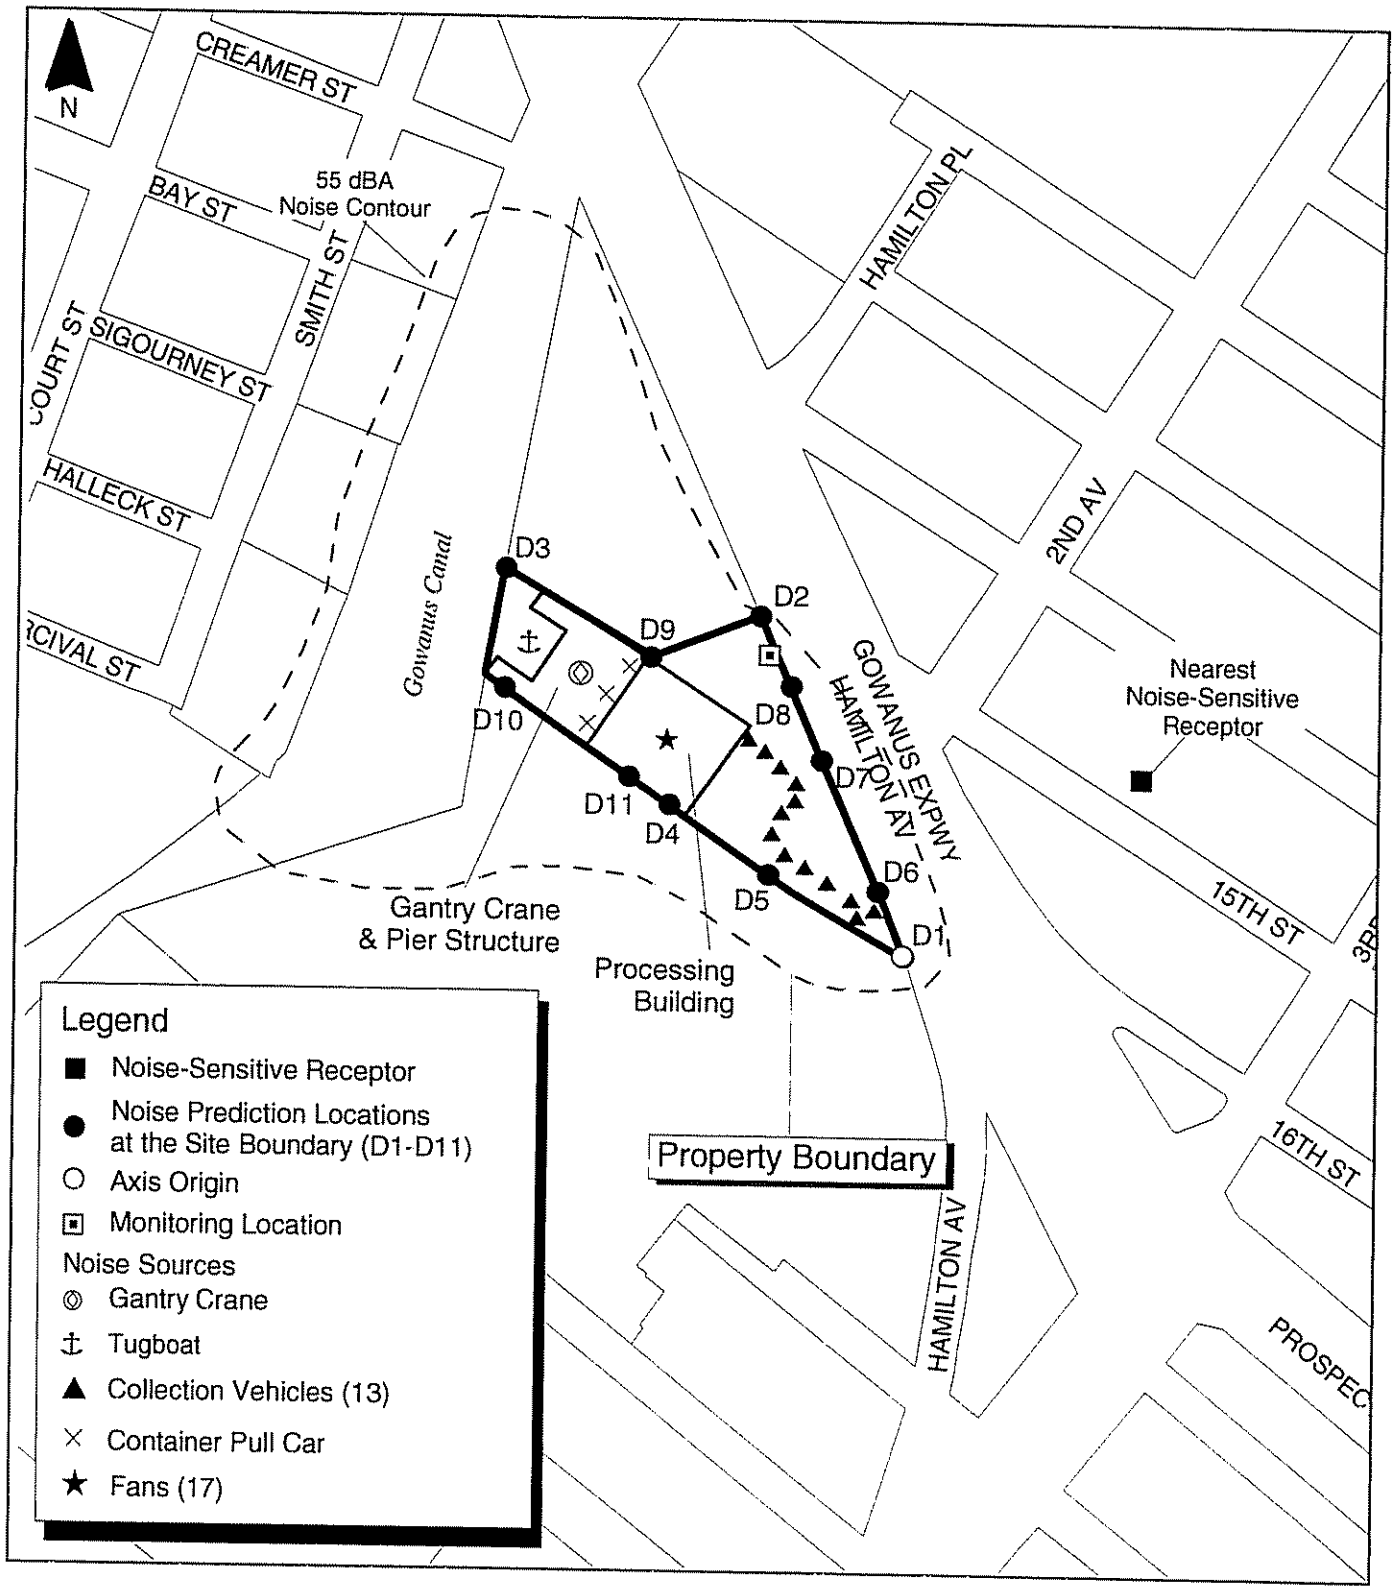

Figure 4.17-1 shows the location of the Hamilton Avenue Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is a row of apartment buildings on 15th Street between 2nd Avenue and 3rd Avenue, 136 meters (447 feet) from the Hamilton Avenue Converted MTS property line.

4.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptor. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[12] and the statistical metrics of L_{10}, L_{50} and L_{90}.[13] Table 4.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 2:00 a.m. and 3:00 a.m. and had an $L_{eq(1)}$ of 81.0 dBA on January 15, 2003. Activities and events that contribute to the on-site noise levels are as follows:

- Traffic due to the proximity of industrial and commercial areas and the BQE; and
- Boat traffic on Gowanus Bay.

[12] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[13] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

4.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from traffic and other background noise. A screening analysis was conducted to determine if noise monitoring would be required along the Hamilton Avenue Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required and, therefore, off-site noise monitoring was conducted. Table 4.17-2 presents monitored noise levels near noise-sensitive receptors during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) based on first-level screening.

Table 4.17-2
Existing Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor for Off-site Analysis
Hamilton Avenue Converted MTS

Location	Existing Noise Levels During Quietest Hour (dBA)[1][2]
20th Street West of 4th Avenue	63.4

Notes:
(1) A 1-hour noise level reading was measured at the nearest noise-sensitive receptor during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest).
(2) The existing noise level was measured on August 20, 2003 between 2:00 a.m. and 3:00 a.m.

4.17.2 Future No-Build Conditions

4.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

4.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 4.17-3 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on first-level screening.

Table 4.17-3
Off-Site Noise Traffic Volume
Hamilton Avenue Converted MTS

Location	Hour Beginning	Existing Traffic Volume [1] (Vehicles / Hour)	Future No-Build Traffic Volume [2] (Vehicles / Hour)
20th Street west of 4th Avenue	2:00 a.m.	19	20
20th Street west of 4th Avenue	12:00 p.m.	307	319
13th Street west of 4th Avenue	9:00 a.m.	104	109
~~**13th Street west of 4th Avenue**~~	~~2:00 a.m.~~	~~14~~	~~15~~
Prospect Avenue Westbound east of 3rd Avenue	3:00 a.m.	89	93

Notes:
[1] Existing Traffic Volumes are based on ATR data.
[2] Future No-Build Traffic Volumes are based on CEQR annual traffic growth.

4.17.3 Potential Impacts with the Hamilton Avenue Converted MTS

4.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Hamilton Avenue Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 4.17-4. The number and types of equipment assumed for this analysis were based on the Hamilton Avenue Converted MTS's peak design capacity. As described in Section 3.19, an analysis was performed to determine if the number and type of trucks queuing on the ramp that was analyzed

in the DEIS is more conservative than the greatest number of DSNY and Commercial Waste trucks expected to be queuing on the ramp based on the number of trucks that might be routed to the facility. The DEIS analysis was based on DSNY trucks queuing along the entire length of the ramp. For the Hamilton Avenue Converted MTS, the analysis of the greatest number of DSNY and Commercial Waste trucks that will be expected to be queuing on the ramp (based on the number of trucks that might be routed to the facility) is more conservative. Therefore, the results presented for the on-site analysis in this FEIS are based on the greatest number of DSNY and Commercial Waste trucks that is expected to be queuing on the ramp.

Spectral noise levels which were used in the Performance Standards analysis are shown in Table 4.17-5. The number and types of equipment assumed for this analysis were based on the Hamilton Avenue Converted MTS's peak design capacity. Shown earlier, Figure 4.17-1 indicates the Hamilton Avenue Converted MTS layout, the locations of the points along the Hamilton Avenue Converted MTS boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

4.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Hamilton Avenue Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 20 meters (67 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is 136 meters (447 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (see Figure 4.17-1); therefore, on-site noise monitoring and an on-site noise analysis were not required.

Table 4.17-4
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Hamilton Avenue Converted MTS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Tip Floor Wheel Loaders type CAT 966G (2)	80.6
Mini-Loader type CAT 908 (1)	69.3
Tamping Cranes type CAT 325 (1)	81
Spreader Crane/Hoist (1)	70
Skid Steer Loader (Bobcat S300) (1)	76
Vacuum Sweeper (1)	64.3
Exhaust Fans (17)	74[3]
Moving/Queuing DSNY Collection Vehicles (6)	79
Outdoor	
Container Shuttle Cars(3)	45
Gantry Cranes (1)[4]	67
Harbor Tug Boat (1)[5]	69
Exhaust Fans (17)	76[3]
Inbound Moving/Queuing DSNY Collection Vehicles (2)	67
Inbound Moving/Queuing Commercial Waste Collection Vehicles (10)	71.3
Outbound Moving/Queuing Commercial Waste Collection Vehicles [6](1)	71.3

Notes for Table 4.17-4:

(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative for each piece of equipment.
(3) Noise level representative of a total of 17 exhaust fans.
(4) Noise level will be specified for the gantry crane in DSNY's plans and specifications for construction of the Converted MTSs.
(5) Noise level will be specified for the harbor tugboat in DSNY's plans and specifications for construction of the converted MTSs.
(6) Since both DSNY and Commercial waste trucks are entering the facility, the outbound queuing collection vehicle was assumed to be a commercial waste vehicle, to be conservative.

Table 4.17-5
Equipment Modeled in the Noise Analysis and Spectral Noise Levels (L_{max})
Hamilton Avenue Converted MTS

4.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points along the Hamilton Avenue Converted MTS boundary to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (assuming ~~tugboats~~ both are ~~traffic~~ transportation facilities). (~~s~~See Table 4.17-6~~)~~. Based on this analysis, no exceedances of the Performance Standards are predicted.

4.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Hamilton Avenue Converted MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. The overall noise predictions were based on refined calculated noise levels for the on-site queuing collection vehicles on the Hamilton Avenue Converted MTS facility truck ramp. Individual, position-specific utilization factors were assigned to each inbound collection vehicle position on the inbound scale of the ramp, and to one collection vehicle position on the outbound scale based on the processing time at the Hamilton Avenue Converted MTS. The utilization factor for each truck was estimated based on the greatest number of DSNY and Commercial Waste trucks expected to be queuing on the ramp, totaling two (2) DSNY trucks and 12 Commercial Waste trucks and conservatively assuming these utilization factors would occur for 24 hours. The assumption was made that each inbound truck would be queuing on-site for approximately two minutes before proceeding one truck length further up the ramp toward the facility.

~~This is~~ The results of the Current NYC Noise Code Analysis are shown in Table 4.17-7. ~~Based on this analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.~~ The NYC Noise code (Title 24, Subchapter 6 of the Administrative Code and Charter of the City of New York) requires compliance with an L_{eq} of 70 dBA (daytime and nighttime for all commercial and manufacturing land-use zones) at the site property line. (This standard is proposed to be replaced by sensitive-receptor based standards in the proposed NYC Noise code.) The NYC Noise code language recognizes that the contributions from background sounds outside the boundaries of the noise source (such as public highways) are not considered in the measuring compliance with the standard. At the Hamilton Avenue site, four (4) of the boundary noise points along the southern sides of the site exceed the 70 dBA threshold by between 1.2 dBA and 7.6 dBA. However, 24-hour background noise levels monitored at the site boundary (that include the background noise of the Gowanus Expressway and 3rd Avenue traffic) are at levels between 81.0 dBA and 86.0 dBA (See Table 4.17-1). At these levels, the theoretical exceedance of the noise standard cannot be perceived at the property boundary and, therefore, no impact is predicted.

Table 4.17-7
Current Noise Code Analysis
Hamilton Avenue Converted MTS[(1)]

D11	68.4

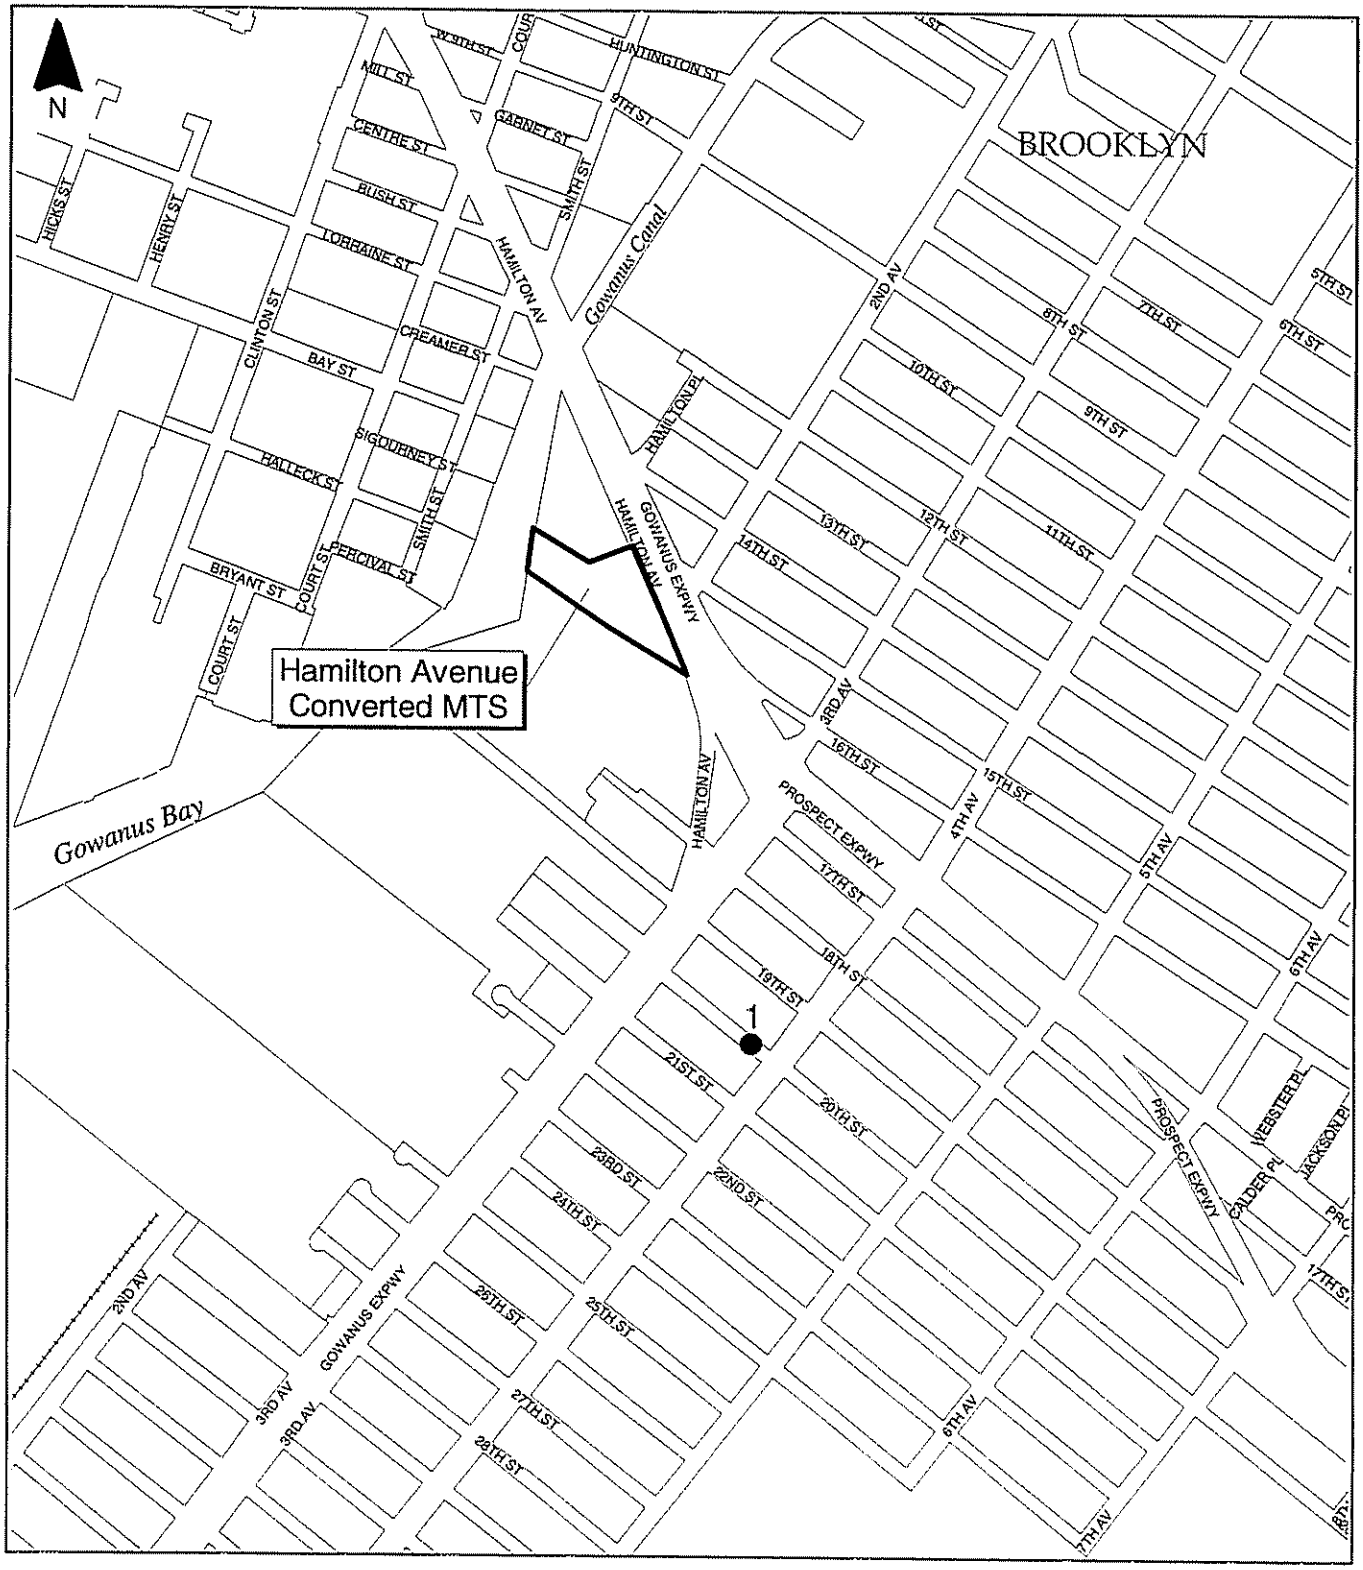
Notes:
(1) D1 through D11 are the points on the Hamilton Avenue Converted MTS site boundary that are used in all noise analyses.
Bold= Exceedance

4.17.3.5 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Hamilton Avenue Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 4.17-8.

Table 4.17-8
Off-Site Noise Screening Results
Hamilton Avenue Converted MTS

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
20th Street west of 4th Avenue	2:00 a.m.	30	6	0	282	312	**Yes**
20th Street west of 4th Avenue	12:00 p.m.	2,159	13	0	611	2,770	No
13th Street west of 4th Avenue	9:00 a.m.	312	5	0	235	547	No
~~**13th Street west of 4th Avenue**~~	~~2:00 a.m.~~	~~131~~	~~0~~	~~0~~	~~0~~	~~131~~	~~No~~
Prospect Avenue Westbound east of 3rd Avenue	3:00 a.m.	276	5	0	235	511	No



Note:
(1) Total PCEs are rounded to the nearest whole number.
(2) Future Build PCEs include Hamilton Avenue Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted to PCEs using a factor of 1.
(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

Because the screening results presented above showed that the PCEs would double on a roadway due to DSNY and other agency collection vehicles coming to or going from the Hamilton Avenue Converted MTS, a detailed off-site noise analysis was performed at that roadway using TNM for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime. Figure 4.17-2 depicts the locations of the roadways where a detailed noise analysis was performed.

TNM results for locations/hours that resulted in a possible impact based on second-level screening are presented in Appendix E of this FDEIS. Because this incremental noise-level change, which is calculated by obtaining the difference between the TNM predicted Future Build noise level and the TNM-predicted Future No-Build noise level, is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, an impact is predicted by TNM from the Hamilton Avenue Converted MTS-related collection and employee vehicles.

To determine if this TNM-predicted impact was accurate, site-specific truck simulations were conducted at the noise-sensitive receptor site. The truck simulation analysis provides a more realistic determination of DSNY collection vehicle noise impacts based on the proposed number of DSNY collection vehicles expected to travel through the roadways analyzed during the nighttime hours. Truck simulations were conducted with DSNY collection vehicles, as described in Section 3.19.7.2, for each roadway and hour that the first-level screening analysis resulted in potential impacts. For this procedure, two sets of noise measurements were taken, one with and one without DSNY trucks, by routing a set number of DSNY trucks during the affected nighttime hours past the noise-sensitive receptor. Table 4.17-9 contains the results of the site-specific DSNY collection vehicle simulations, which shows that only the 2:00 a.m. to 3:00 a.m. hour would have an impact as a result of the Hamilton Avenue Converted MTS-related collection vehicles.

A comparison of the simulation results for the 2:00 a.m. to 3:00 a.m. hour and the TNM results for the same traffic conditions and background noise levels estimated from recordings during the simulations is provided in Appendix E of this FDEIS. Based on this comparison, it is determined that TNM over-predicted the incremental change. The over-prediction can be attributed to the default assigned noise level for each type of vehicle, which appears to be greater than the actual noise levels that would be emitted by the Hamilton Avenue Converted MTS-related collection vehicles.

Site delineations are approximate

Off-Site Noise Analysis Truck Simulation
20th Street West of 4th Avenue
Hamilton Avenue Converted MTS

Hour Beginning	Existing Background Noise Level[1] (L_{eq}) (Estimated) (dBA)	Collection Vehicles	Truck Simulation[2] Noise Level (L_{eq}) for Existing Traffic plus Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
11:00 a.m.	65.5	3	67.1	No (1.6)
12:00 a.m.	65.1	5	66.9	No (1.8)
1:00 a.m.	65.3	4	67.2	No (1.9)
2:00 a.m.	63.4	6	67.0	Yes (3.6)
3:00 a.m.	67.0	4	68.1	No (1.1)

Note:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Simulations performed on August 19, 2003 and August 20, 2003.

Because both TNM and the site-specific truck simulations predict an impact at a noise-sensitive receptor during the 2:00 a.m. to 3:00 a.m. hour for the 20th Street west of 4th Avenue location, adjustments were made to the distribution of trucks. Only the number of trucks that can be routed through this location without causing an impact will be allowed. The remaining collection vehicles will be routed through this location during the 3:00 a.m. to 4:00 a.m. hour without causing an impact. This location was re-analyzed during both of these hours with the truck adjustments using the site-specific truck acoustic energy per hour as described in Section 3.19.7.2 to confirm that off-site noise impacts would not be caused by the reduced number of collection vehicles at this location. Table 4.17-10 shows the results of this analysis. Based on these results, with the truck adjustments, there is no predicted impact that would be caused by the Hamilton Avenue Converted MTS collection vehicles en route to and from the facility.

Table 4.17-10
Off-Site Noise Analysis using Truck Simulation Data and Adjusted Collection Vehicles
20th Street West of 4th Avenue
Hamilton Avenue Converted MTS

Hour Beginning	Existing Background Noise Level[1] (L_{eq}) (Estimated) (dBA)	Adjusted Collection Vehicles	Calculated[2] Noise Level (L_{eq}) for Existing Traffic plus Adjusted Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
2:00 a.m.	63.4	4	66.1	No (2.7)
3:00 a.m.	67.0	6	68.6	No (1.6)

Note:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Noise levels for existing traffic plus adjusted collection vehicles were calculated utilizing the per truck acoustic energy determined from the truck simulation data for this location.

4.17.3.6 Combined On-Site and Off-Site Noise Levels

An off-site noise analysis was performed for the Hamilton Avenue Converted MTS. The results of the on-site screening analysis showed that noise-sensitive receptors were not located within the 55 dBA contour line (see Figure 4.17-1); therefore, on-site noise monitoring and an on-site noise analysis were not required. Since an on-site analysis was not required, a combined noise analysis was not performed.

4.18 Commercial Waste to the Hamilton Avenue Converted MTS

4.18.1 Existing Conditions

No commercial waste is delivered to the Hamilton Avenue MTS site under Existing Conditions. Commercial waste generated in Brooklyn is delivered to privately owned and operated transfer stations in the City, or taken directly out of the City to remote disposal locations.

4.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the Hamilton Avenue Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

4.18.3 Potential Impacts of Sending Commercial Waste to the Hamilton Avenue Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

4.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the Hamilton Avenue Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 4.15, 4.16 and 4.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

4.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the Hamilton Avenue Converted MTS were evaluated in Sections 4.14, 4.15 and 4.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 4.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 32 (inbound trip ends) per hour, which occurred during the AM peak. These 32 DSNY and other agency collection vehicles are also more than the 25 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the Hamilton Avenue Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 32 DSNY and other collection agency vehicles at the Hamilton Avenue Converted MTS. Therefore, the addition of the 25 DSNY and other agency collection vehicles and commercial waste hauling vehicles at the Hamilton Avenue Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 32 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 32 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24-hour period. Results showed there would be no unmitigatible significant adverse environmental impacts at several analyzed intersections. Consequently, because the 25 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can travel through these intersections per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

For the intersections of Hamilton Avenue and Hamilton Place and 14th Street, and 20th Street at 3rd Avenue and 4th Avenue, a Tier II analysis was required. The estimated actual hourly distribution over 24 hours included the estimated 25 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that could potentially be processed at the Hamilton Avenue Converted MTS, and no unmitigatible significant adverse environmental impacts were identified.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the Hamilton Avenue Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 1,306 tons (or 124 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

CHAPTER 5 ENVIRONMENTAL REVIEW: SOUTHWEST BROOKLYN CONVERTED MTS

5.1 Introduction

The results of the environmental analyses of the Southwest Brooklyn Converted MTS are presented in the following sections:

5.2 Land Use, Zoning, and Public Policy
5.3 Socioeconomic Conditions
5.4 Community Facilities and Services
5.5 Open Space
5.6 Cultural Resources
5.7 Urban Design, Visual Resources, and Shadows
5.8 Neighborhood Character
5.9 Natural Resources
5.10 Hazardous Materials
5.11 Water Quality
5.12 Waterfront Revitalization Program
5.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
5.14 Traffic, Parking, Transit, and Pedestrians
5.15 Air Quality
5.16 Odor
5.17 Noise
5.18 Commercial Waste to the Southwest Brooklyn Converted MTS

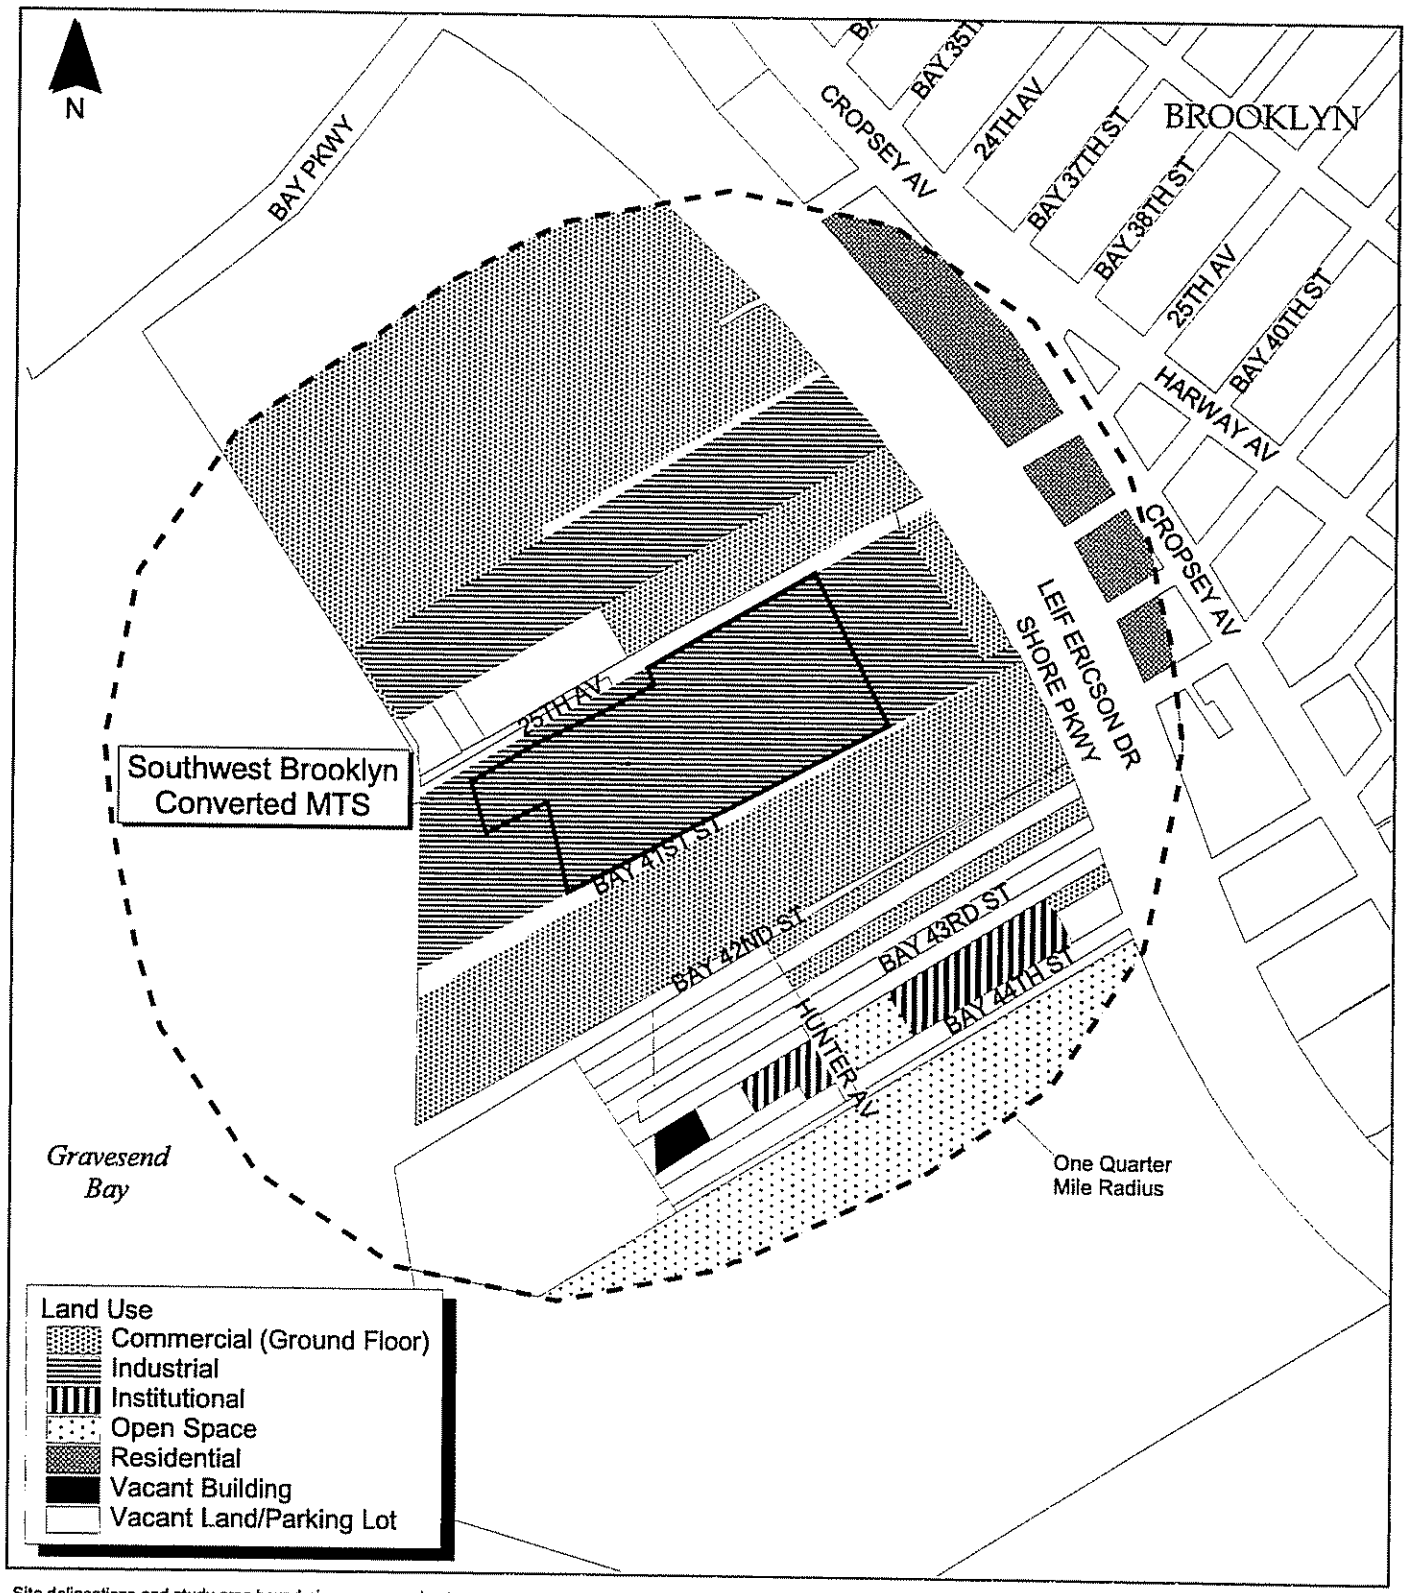
Section 2.2.2 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

5.2 Land Use, Zoning, and Public Policy

5.2.1 Existing Conditions

5.2.1.1 Definition of Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 5.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 5.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.2.2 provides information on existing land uses and operations on the site.



5.2.1.2 Land Use Patterns

5.2.1.2.1 General Context

The site is situated on Gravesend Bay in Bensonhurst, surrounded by a relatively mixed land use pattern. The site and immediate environs contain the only industrial uses found in the primary and secondary study areas, which are both characterized largely by commercial, recreational, residential and institutional uses.

5.2.1.2.2 Land Uses in the Primary Study Area

Directly to the northeast and east of the site are DSNY facilities, including one salt shed and DSNY garage. The Nellie Bly Amusement Park is also on the same block, fronting Shore Parkway, 500 feet east of the site. Fuel oil tanks and buildings associated with the Bayside Fuel Oil Corporation are located north of the site near Shore Parkway, as are the Atlantic Express Bus Company and various other automobile repair services. Further north-northwest of the site is a variety of commercial uses surrounded by fairly large parking areas. These uses include several banks; a shopping area with regional retail establishments, such as Best Buy and Toys "R" Us; several automobile service establishments; and a motel on the equivalent of 24th Avenue south of the Bay Parkway-Shore Parkway intersection.

Figure 5.2-2 Land Use in the Secondary Study Area

Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

East of Shore Parkway within the study area is a dense residential area, including the 167-unit Regina Pacis Residence for Senior Citizens on Bay 37th Street, various apartment houses and three-story row houses.

South of the site are several yacht clubs, including the Excelsior Yacht Club and Marina, where boats are moored south of Bay 41st Street. On Bay 44th Street and Hunter Avenue is a home for handicapped children. Across Hunter Avenue to the east are another assisted living facility and the Brooklyn School for Special Children. An unfinished residential development once known as "Rose Cove" stands within the primary study area north of and adjacent to Dreier-Offerman Park at Bay 44th Street and West Shore. This residential development was designed originally to include three buildings and some town homes, the remains of which are not publicly accessible. The model structures now stand vacant and dilapidated. The property is not being developed at this time.

5.2.1.2.3 Land Uses in the Secondary Study Area

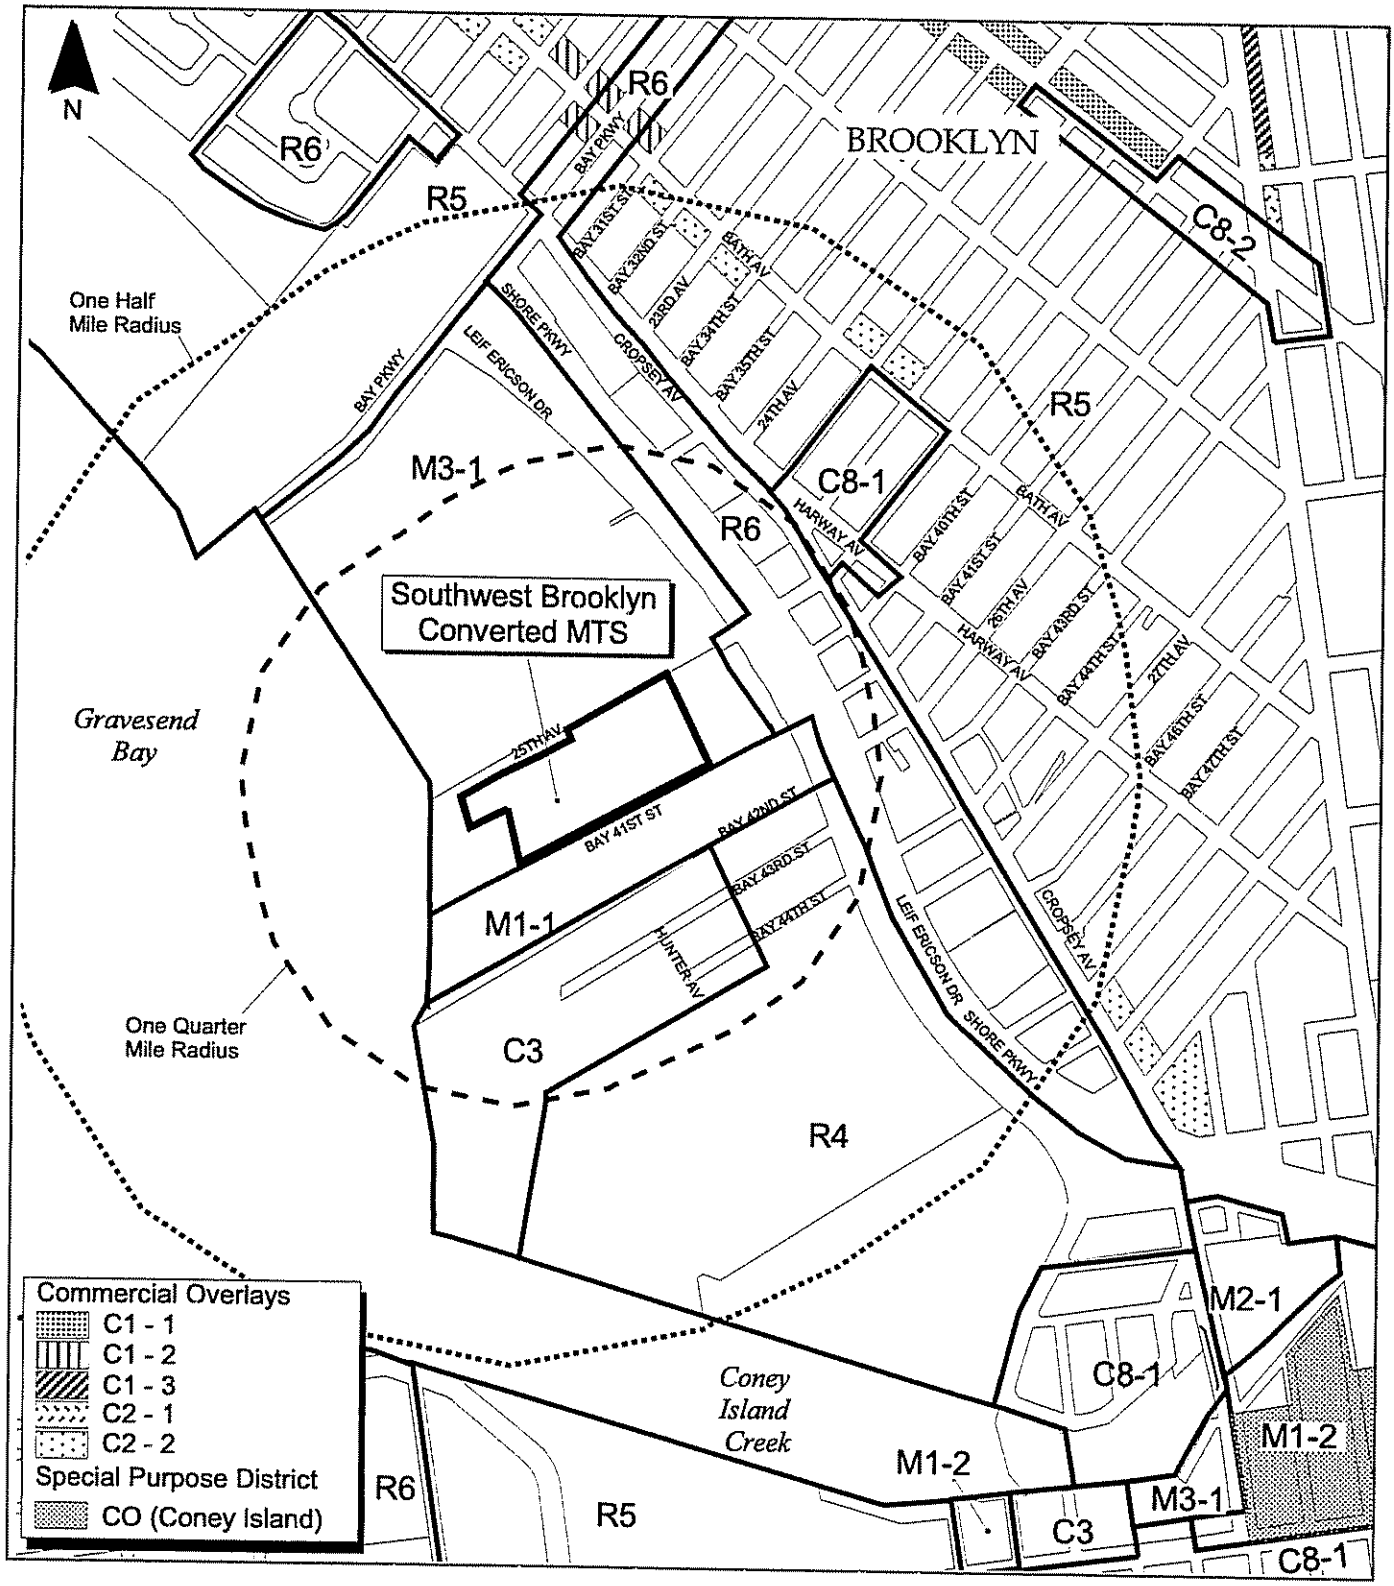
The secondary study area is characterized by waterfront, municipal parks and largely residential uses inland to the east. Bensonhurst Park is located southwest of the southern end of the Leif Ericson Drive Shore Road park system north of Bay Parkway and northwest of the site, while Dreier-Offerman Park, a large 73-acre waterfront public park, and the Coney Island Boat Basin are located south of the site along Coney Island Creek.

The remainder of the secondary study area lies northeast of Shore Parkway, where the land use pattern is primarily residential, consisting of single- and multi-family housing, mostly detached and semi-detached homes. The area also contains apartment towers, such as the Contello Towers Co-op, Sections I and II (between Shore Parkway and Cropsey Avenue at Bay 44th Street); senior housing; schools; and religious institutions, as well as some local professional offices, light industrial uses and automotive services, with a concentration along Bath Avenue. East of Cropsey Avenue on either side of 25th Avenue are the buildings, storage areas and parking areas associated with NYCT's Ulmer Park bus depot.

5.2.1.3 Zoning On and Near the Site

5.2.1.3.1 Zoning Within the Primary Study Area

The site is located in an M3-1 zoning district on Gravesend Bay, as is much of the primary study area. The area also includes a mix of M1-1, M3-1, C3 (waterfront recreation areas), R4 and R6 zoning districts. (See Figure 5.2-3 and Table 3.4-1: Zoning District Characteristics.)



5.2.1.3.2 Zoning Within the Secondary Study Area

The surrounding residential communities of Bensonhurst, Gravesend and Coney Island are characterized by medium density R4, R5 and R6 residential; C8-1 (automotive-related) commercial; and M3-1 zoning districts.

5.2.1.4 Plans and Policies

The FY 2004 CDNS for District 11, in which the site lies, provides no recommendations for physical development programs that would be relevant to the site or the study areas. The 2004 statement prepared by Brooklyn CD 13 (adjacent to the site on the south) indicates the need and the hope for overall development of the district. No specific development proposals are defined that would likely be relevant to the site or study areas, though mention is made of support for relocation of the District 13 DSNY garage from its location on Coney Island at Neptune Avenue at West 20th Street to a new location at the former Brooklyn Union Gas site (now KeySpan).

The site lies within Reach 15 of the City/Brooklyn Waterfront Development Plan, which extends along the waterfront from Owl's Head Park in Bay Ridge at the northern end to the northern shore of Coney Island at the southern end. The plan recommends that the Shore Road bicycle path, which currently ends at Bensonhurst Park, be extended south to Dreier-Offerman Park, which in turn should be developed to include bicycle/pedestrian access to the waterfront, perhaps via an esplanade. The plan recommends that mapped streets and parks be developed to

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

provide enhanced access to the water's edge and, in particular, the restoration of the bulkhead at Bay Parkway. The plan also recommends that Dreier-Offerman Park be developed for recreation and that the Nellie Bly Amusement Park be relocated from Shore Road and Bay 41st Street to the Dreier-Offerman Park.

The plan notes that existing M1 and M3 zoning should be maintained, specifically around the existing MTS, but that the commercial zoning south of the site just north of Dreier-Offerman Park could offer other development opportunities. While these recommendations for developing the parks in such a manner have public support, there are no definite plans for such development. (See Section 5.5 for details on NYCDPR park plans and Section 5.12 for a review of consistency with the WRP.)

5.2.2 Future No-Build Conditions

It is reasonable to anticipate that except for the demolition of the on-site incinerator, the Future No-Build Conditions in both the primary and secondary study areas will generally resemble Existing Conditions. The site itself will remain DSNY property; though inactive, the existing MTS will remain and the associated DSNY salt storage and garage facilities northeast of the site will continue to be fully utilized.

5.2.3 Potential Impacts with the Southwest Brooklyn Converted MTS

5.2.3.1 Land Use and Zoning

Development of the Southwest Brooklyn Converted MTS would entail the creation of a new facility with containerization functions that would replace the former functions of the existing MTS — though the existing MTS will remain standing — and would cover more of the site's upland area. The existing incinerator will have already been demolished and removed from the site, and the westernmost salt shed on the site (of the two that exist on the larger DSNY property) would be either moved off the property or dismantled. Delivered waste would be containerized for transport on barges for disposal outside the City — a change from the previous practice of loading loose waste onto hopper barges for intra-harbor transport to Fresh Kills Landfill.

Because the Southwest Brooklyn Converted MTS would reactivate a historic use on DSNY property, it would not be considered a substantial new use. It would, however, increase the intensity of use on the site without causing an accumulation of similar uses in the area. It is not likely to encourage or discourage other typical development in the area more than previous waste transfer operations had, and would not likely affect the existing C3, R4 or R6 zones, which permit residential development nearby.

5.2.3.2 Consistency with Public Plans and Policies

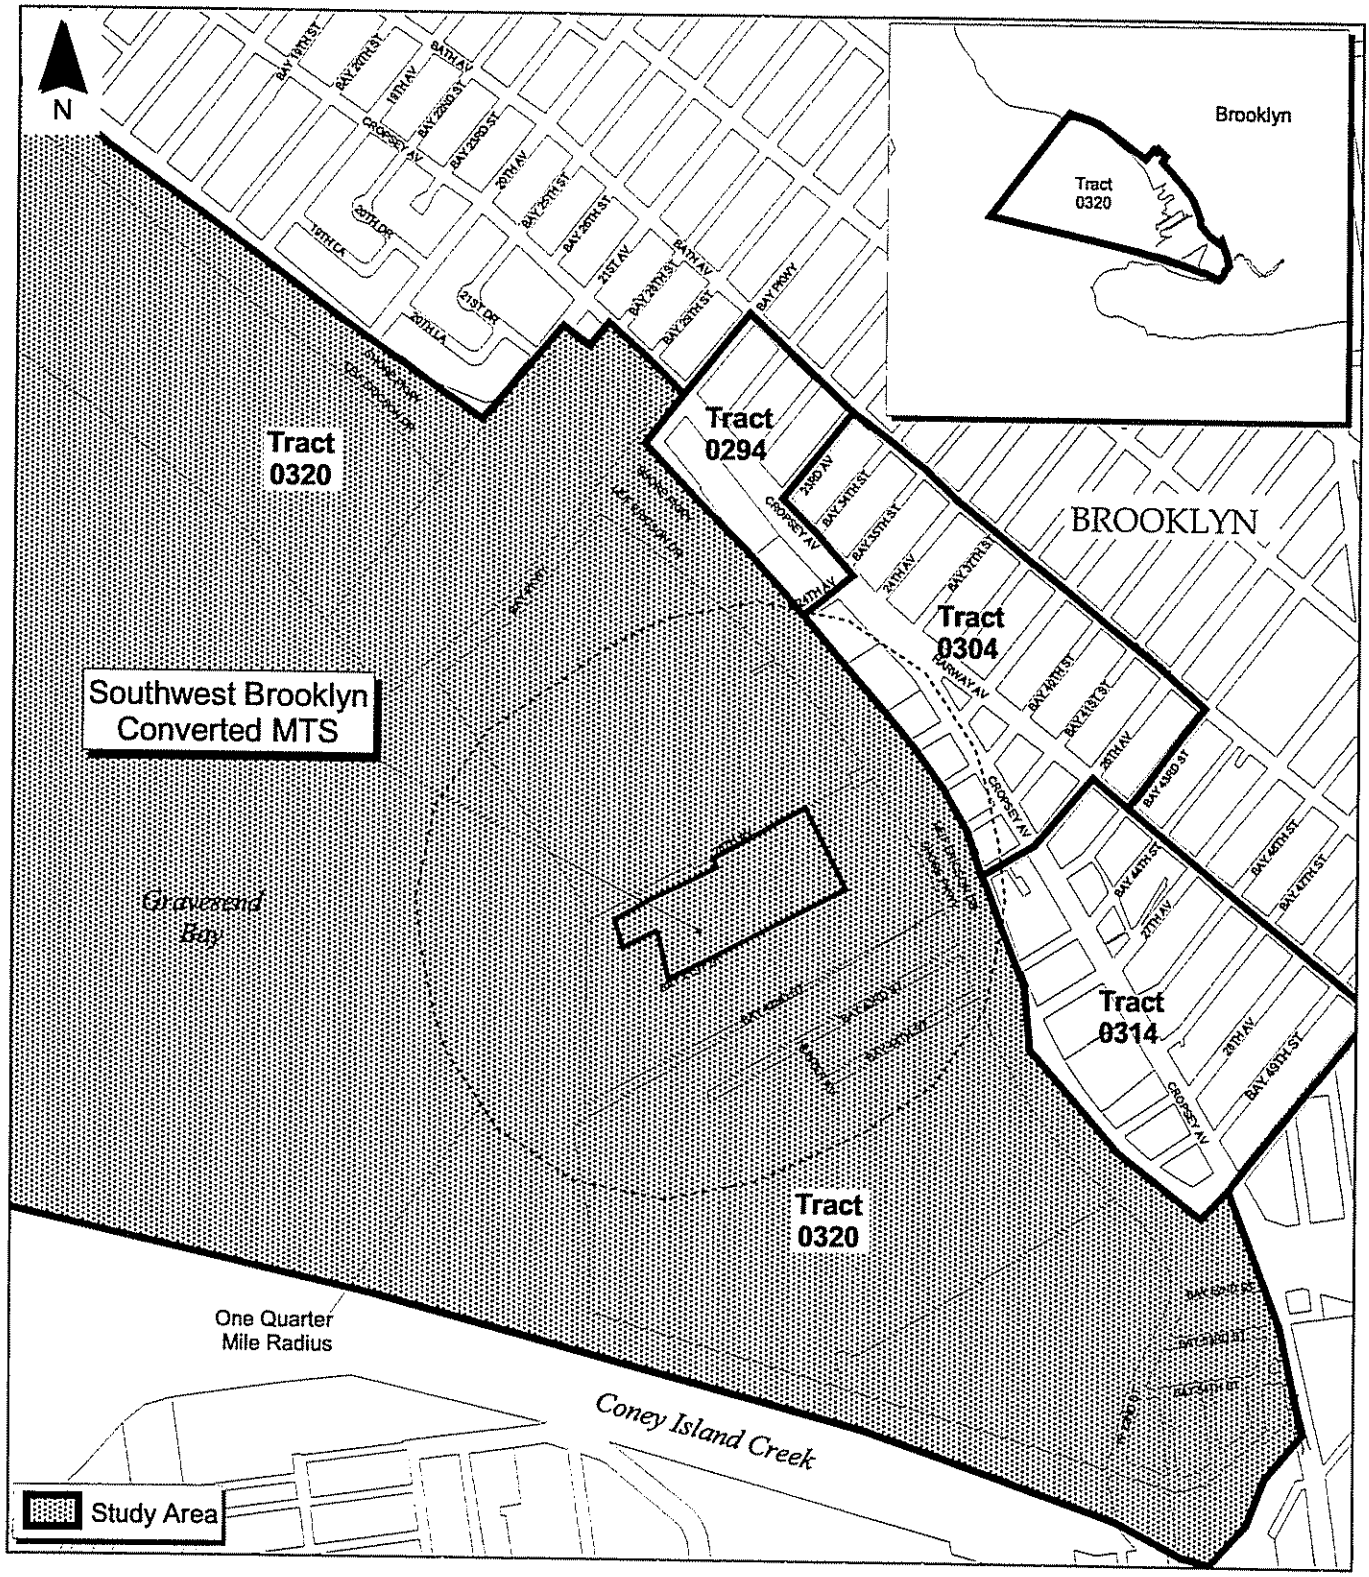
Because the Southwest Brooklyn Converted MTS would be the reactivation of a historic use on DSNY property and there are no definitive plans for the park development and bikeway recommended in the plan for Reach 15, it would be consistent with public plans and policies. The Southwest Brooklyn Converted MTS would also be consistent with the Waterfront Development Plan for this area, which recommends maintaining the existing manufacturing zones there.

5.3 Socioeconomic Conditions

5.3.1 Existing Conditions

5.3.1.1 Definition of the Study Areas

Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area is comprised of Census Tract 320 (see Figure 5.3-1), which covers industrial waterfront areas southwest of Shore Parkway between approximately 15th Avenue and Coney Island Creek.



5.3.1.2 Demographic Characteristics

Because the total 2000 demographic study area population consisted of only 60 individuals and 14 families, none of who would be directly displaced by the Southwest Brooklyn Converted MTS, a detailed demographic review is not presented here. Socioeconomic data (comparing 1990 and 2000 Census data for the study area, borough and City) were collected, however, and are provided in Appendix B.

5.3.1.3 Economic Conditions

The site is in an industrial area and is surrounded immediately by a mix of industrial and water-dependent recreational uses. Around the site, the industrial activities include fuel oil storage and other DSNY facilities. Also on the water are commercial establishments and recreational facilities, such as the Excelsior Yacht Club and Marina and Dreier-Offerman Park.

The dense residential neighborhood of Bensonhurst begins on the east side of Shore Parkway within ¼-mile of the site and extends beyond the economic study area. Most local retail services are found along Cropsey Avenue.

Site delineations and study area boundaries are approximate

Figure 5.3-1 Census Tracts
Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

5.3.2 Future No-Build Conditions

5.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Brooklyn CD 11 will remain about the same as current conditions.[1]

5.3.2.2 Economic Conditions

Areas surrounding the site on the Brooklyn waterfront have seen considerable new retail construction recently, but no new projects are anticipated that would generate additional jobs and economic activity.

The near-term economic health of industrial areas such as the study area may also be supported by recently established City programs. These programs are available through the IDA and include the Industrial Incentive Program and the Small Industry Incentive Program, both of which provide business tax incentives for capital renovation and expansion projects. However, no significant changes are expected through 2006 in the study area.

Regional projections indicate that employment in Brooklyn CD 11 will remain about 5% of the borough total.[2]

5.3.3 Potential Impacts with the Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS represents the reactivation of solid waste transfer operations on the site with added containerization operations. No significant direct or indirect impacts are anticipated related to socioeconomic conditions.

---

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.
[2] Ibid.

5.3.3.1 *Residential Impacts*

No residential uses would be displaced as a result of the Southwest Brooklyn Converted MTS, and land use and neighborhood character analyses predict no adverse impacts.

5.3.3.2 *Direct Business and Institutional Impacts*

The Southwest Brooklyn Converted MTS would not result in direct displacement of businesses or institutional uses.

5.3.3.3 *Indirect Business and Institutional Impacts*

The businesses adjacent to and near the Southwest Brooklyn Converted MTS are not expected to experience significant indirect impacts from the reactivation of solid waste transfer operations on the site and new containerization operations. The marina located directly to the south would not be significantly affected by the Southwest Brooklyn Converted MTS because the waste operations would be similar to former activities. Although the density of development on the site would increase, it would not be a significant change to the visual quality of this industrial property.

5.3.3.4 *Employment Impacts*

The Southwest Brooklyn Converted MTS would be expected to generate approximately 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

5.4 Community Facilities and Services

5.4.1 Existing Conditions

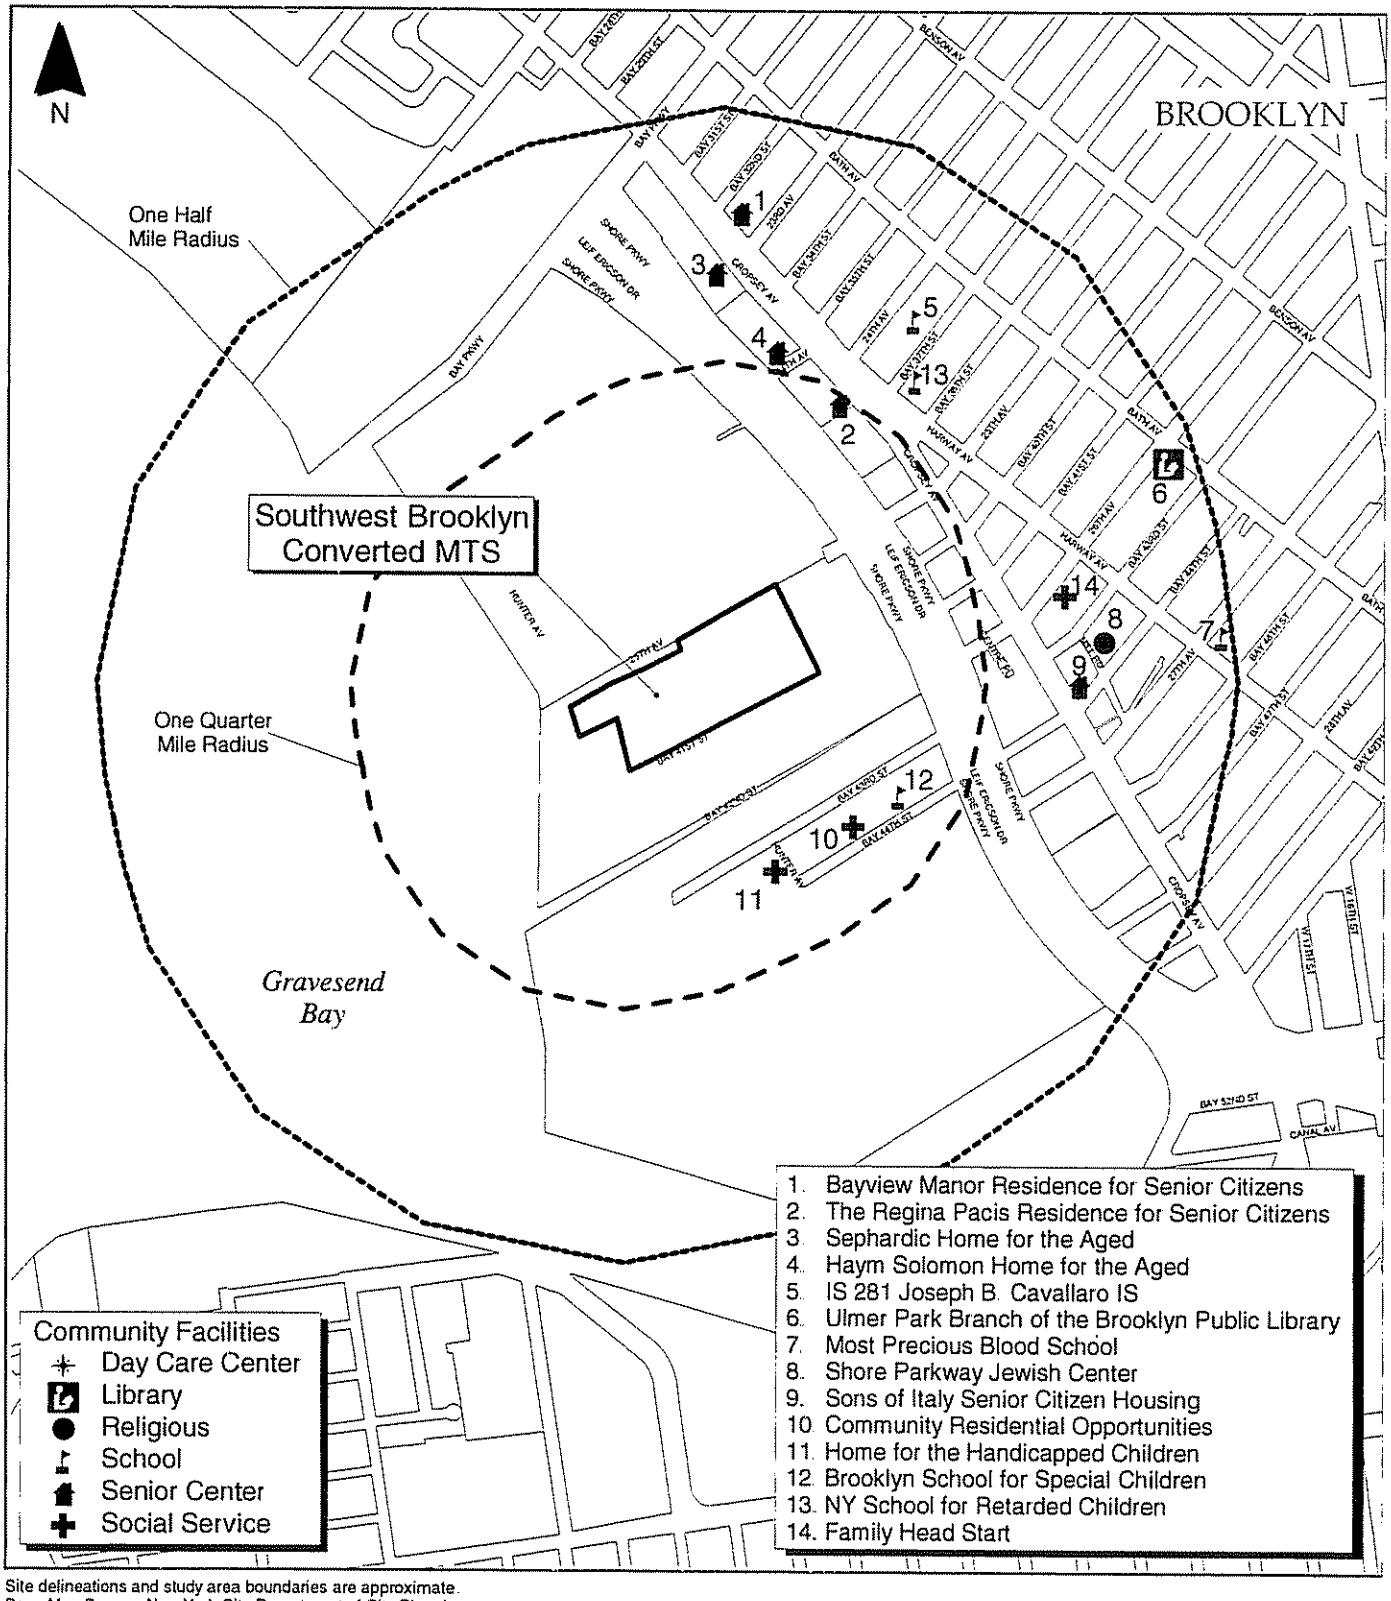
5.4.1.1 Definition of the Study Areas

The primary study area is defined as the area within ¼-mile of the site. The secondary area is defined as the area between ¼- and ½-mile from the site.

5.4.1.2 Summary of Community Facilities and Services

There are four community facilities in the primary study area and ten in the secondary study area. Seven additional facilities are either just beyond the secondary study area or otherwise serve the site environs. Community facilities serving or located within or near the study area are listed in Table 5.4-1 and shown in Figure 5.4-1.

5.4.2 Future No-Build Conditions



There are no known changes planned for the community facilities and services within the study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity and adequacy of delivery.

5.4.3 Potential Impacts with the Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS would not create any significant new demand on services and community facilities and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY stated that it would have no problem supporting the Southwest Brooklyn Converted MTS.

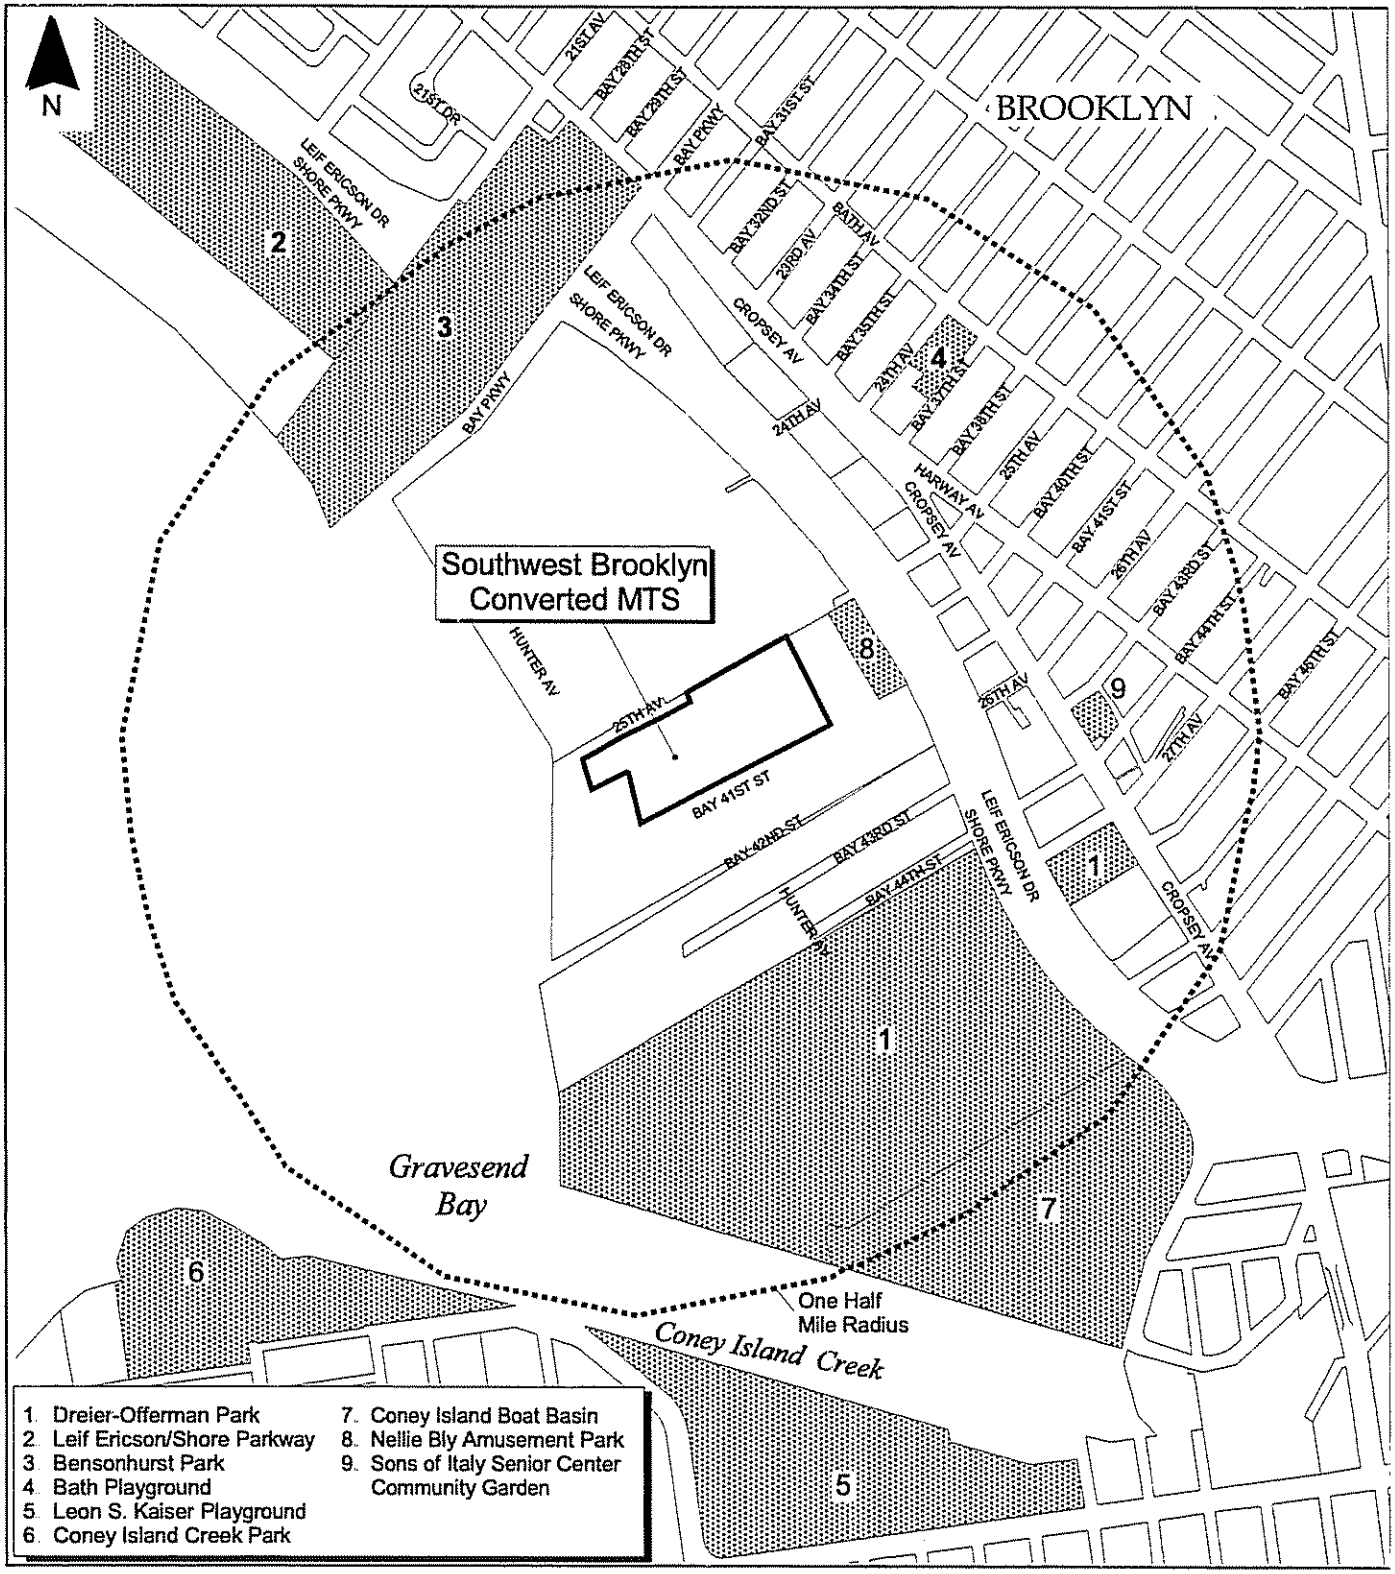
5.5 Open Space

5.5.1 Existing Conditions

5.5.1.1 Definition of the Study Area



The study area for open space is defined as being the area within a ½-mile radius of the site.

5.5.1.2 Summary of Open Space in the Study Area

There are 10 public parks and open spaces in the study area, two of which are regional facilities. They provide a variety of active and passive recreational opportunities. They are listed in Table 5.5-1 and shown on Figure 5.5-1.

Table 5.5-1

Figure 5.5-1 Open Space/Parkland
Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

5.5.2 Future No-Build Conditions

The reconstruction of the Bath Playground and the reconstruction of ball fields in Dreier-Offerman Park are expected to be complete by 2006.

5.5.3 Potential Impacts with the Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS would not physically change, diminish or eliminate an open space or reduce its utilization or aesthetic value. Likewise, it would not introduce a substantial new user population that would affect utilization of open space resources. Therefore, no impact on open space or parklands is expected from development of the Southwest Brooklyn Converted MTS.

5.6 Cultural Resources

5.6.1 Existing Conditions

5.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site.

5.6.1.2 Development History of the Area

Like other areas of southwestern Brooklyn, Bensonhurst had been populated by small farms from the early 1700s until steam railroads were constructed throughout Brooklyn in the 1870s to bring city dwellers to the ocean. In the 1880s, a developer named James Lynch bought large parcels of land from the Benson family on Gravesend Bay and created the 350-acre suburb of "Bensonhurst-by-Sea." The street grid laid out for this development remains to this day.

The 4th Avenue subway linked the area to Manhattan in 1915, spurring further development and great influxes of people from other parts of the City. Mostly Italians and Jews from the Lower East Side populated the four- to six-story apartment buildings and two- to three-family brick houses built in the 1920s. Local community educational and recreational facilities, such as the Jewish Community House, became popular among the resident Jewish population.

In the early 20th century, north of the site, "Bath Beach" had been a resort known for its yachting clubs, fashionable villas and restaurants until construction of Shore Parkway in 1939. Residential growth continued after World War II, and in 1949 Fred Trump built the then-largest private housing development in Brooklyn, Shore Haven Apartments, at 21st Avenue and Shore Parkway.

5.6.1.3 Cultural Resources on the Site

There are no elements of architectural or archaeological significance within the site.

5.6.1.4 Historic Resources Within the Study Area

There are no state, national or City designated landmarks or historic districts within the site or study area.

5.6.2 Future No-Build Conditions

There are no additional elements of potential architectural or archaeological significance slated for review; therefore, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

5.6.3 Potential Impacts with the Southwest Brooklyn Converted MTS

As there are no existing or eligible architecturally or archaeologically significant resources on the site or in the study area, the Southwest Brooklyn Converted MTS would have no effect on any cultural resources. Based upon its review, SHPO has confirmed that the Southwest Brooklyn Converted MTS would have no impact upon cultural resources in or eligible for inclusion in the SRHP and NR. The LPC has stated that the site contains no architectural or archeological significance (see Appendix A).

5.7 Urban Design, Visual Resources, and Shadows

5.7.1 Existing Conditions

5.7.1.1 Definition of the Study Area

The urban design and visual quality study area is basically the same as the neighborhood character study area (see Section 5.8), but also includes view corridors from nearby parks, recreational uses and residential areas (see Figure 5.8-1). The site is visible because it extends out over the water and because the buildings in this area are generally not densely arranged or tall enough to hide the facility from view. There are views to the site and environs from waterside recreational areas such as Dreier-Offerman Park, Coney Island Creek Park, and the Excelsior Yacht Club, and from the residential areas east of Shore Parkway, specifically the Regina Pacis Residence for Senior Citizens, and Bensonhurst Park.

5.7.1.2 Description of the Site

The site has been developed in a manner that is now inconsistent with the visual character of adjacent properties and the overall urban design of the study area. It contains the existing MTS facility built over the water in the western portion of the site, the Southwest Brooklyn Incinerator (building and stacks) inland from the existing MTS, and one of two salt sheds that stand on the larger DSNY property. There is much area devoted to parking on site and in the general area for workers, and for the storage of trucks and other vehicles associated with the various sanitation uses located there.

The shoreline of the site is rock-covered. There is grass and some scrub growth on the interior regions of the shore near the fence line and along the ramp leading up to the existing MTS. The few trees in the vicinity grow mostly on non-maintained shore areas as a result of natural growth. There is no vegetative landscaping on the site, which is entirely paved in asphalt.

The concrete ramp to the existing MTS runs alongside the northwestern side of the incinerator structure. The existing MTS building design differs from other MTS facilities in that it is asymmetrical. A single large entrance door opens onto the ramp and is topped with a low gable. The shell of the tipping floor is constructed of off-white pre-fabricated steel and the lower barge-level of the building is faced in red brick.

Below this portion of the building, a paved roadway runs in an easterly direction between the shore and the incinerator, toward its intersection with Bay 41st Street. It runs under what appears to be an enclosed loading belt that extends from the incinerator to a point about two stories above the shore. There is parking on the shore side of this road, and both sides of the road are lined with chain-link fencing about 10 feet high.

The brick incinerator facility is in the process of being demolished, with the two cylindrical incinerator stacks that rise approximately 200 feet to be taken down by September 2004.

The salt shed is in the northern portion of the site at the base of the existing MTS entrance ramp. It is essentially conical in shape, rising to approximately 40 feet at its peak. The base walls are constructed of prefabricated unpainted concrete panels topped by a dark brown conical roof.

Additionally, there are light poles located adjacent to the site and lights mounted on the exterior walls of the existing MTS facility and the ramp leading to it.

5.7.1.3 Urban Design and Visual Resources of the Study Area

The buildings that surround the site appear to have been constructed within the last 20 years for their current uses, which are light industrial or maritime in nature. They do not appear to have been developed originally for heavy industry or modified for such use, as buildings often are in older working waterfronts. The area immediately to the south of the site is characterized by marina and boating activities, and there is a mooring area for boats of the Excelsior Yacht Club immediately adjacent to the site, along a pier (see Figure 5.7-1).

Buildings adjacent to the site include one salt shed located next to the on-site salt shed of the same design, and the DSNY Garage and Borough Command Facility. This off-site portion of DSNY property is characterized by paved surfaces and DSNY-related facilities.

The Nellie Bly Amusement Park is just to the east of the site, beyond the off-site DSNY facilities (see Figure 5.7-2). This colorful small park, which faces east, features numerous amusement rides, as well as picnic, concession and video-game areas. It offers no direct views of the site, as the off-site DSNY buildings buffer the park from the site, but it is bordered on two sides by roads that serve the site.

North of the site along the shore and beyond the Bayside Fuel Company and the Atlantic Express Bus Company is a major commercial area. It includes a Toys "R" Us store and various strip mall-type commercial establishments organized around a large parking lot. Toys "R" Us impedes almost any view of the site from the shoreline north of Bay Parkway, including views from Shore Parkway and some of the parkland running between the shore and parkway (Leif Ericson Drive Shore Parkway park system). The northern portion of this park and Bensonhurst Park afford views of the site at a distance (see Figure 5.7-3).

Dreier-Offerman Park lies farther to the south of the site beyond the yacht club and marina. It affords views of the existing MTS as well as of the incinerator (see Figure 5.7-4). At the mouth of Coney Island Creek is Coney Island Creek Park, which is not an active recreational area. This park extends from the Sea Gate neighborhood into the bay with views of the site. The site is clearly visible from Coney Island across Gravesend Bay (see Figure 5.7-5).

The tallest building in the area is the Regina Pacis Residence for Senior Citizens (Regina Pacis Housing Corporation), at 24-24 Cropsey Avenue, which stands approximately 20 stories tall. The building is faced in light brick and has many windows and balconies with views toward the water and, consequently, the site and existing MTS.

5.7.2 Future No-Build Conditions

Other than the imminent demolition of the defunct 200-foot-tall incinerator stacks and building, there are no plans for the site or surrounding environs that would lead to a change in urban design and visual quality characteristics. The site will remain DSNY property, the existing MTS will remain, and the associated DSNY salt storage and garage facilities will continue to be fully utilized. The anticipated urban design and visual quality Future No-Build Conditions are, therefore, fundamentally the same as Existing Conditions on site and within the study area.

5.7.3 Potential Impacts with the Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS would be located further inland than the existing facility, in about the same location as the incinerator, which will be demolished by the time of MTS construction. The Southwest Brooklyn Converted MTS would be approached via a sharply curved drive to its south. Operation of the Southwest Brooklyn Converted MTS would require mooring of barges on its bay side. The existing MTS building would remain.

Because the new construction would be limited to the site that is already arranged to handle waste transfer operations, no impacts on urban design of the area would result. Likewise, the presence of a transfer station further inland, still bordered by DSNY salt storage sheds, would not significantly alter the industrial visual quality of the site.

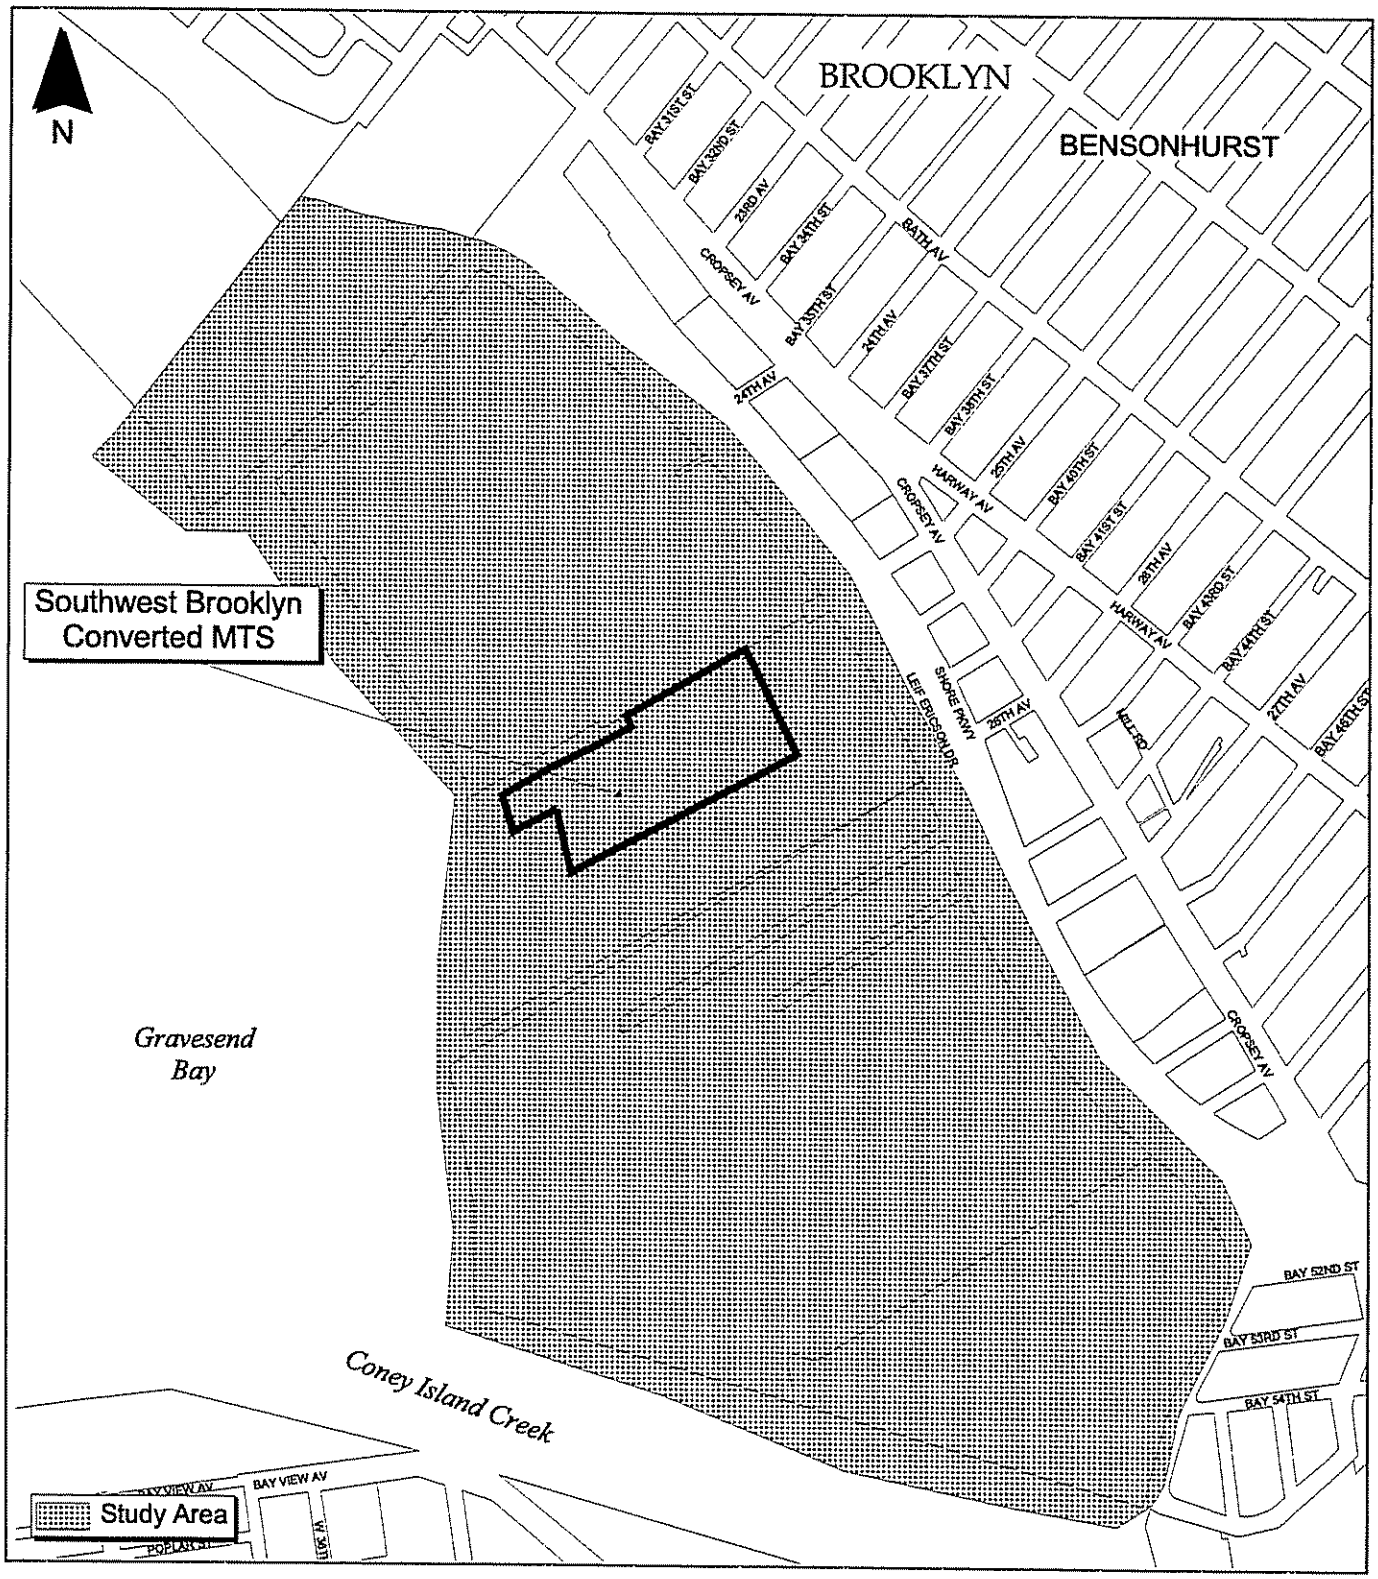
According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.) If this site were chosen and a noise wall used as the preferred mitigation, a supporting analysis would be conducted.

A survey was conducted within this 430-foot area and found that there were no parks, publicly accessible open spaces, historic resources or important natural features; therefore, no assessment of shadows was deemed necessary and no shadow impact is expected as a result of the proposed project.

5.8 Neighborhood Character

5.8.1 Existing Conditions

5.8.1.1 Definition of the Study Area



The site is on Gravesend Bay in Bensonhurst, a large mixed-use community in Southwest Brooklyn featuring mostly residential uses and water-related recreational activities. The site and other waterside uses are physically separated from the primary residential area inland by Shore Parkway, a six-lane arterial. Because Shore Parkway essentially buffers the residential neighborhood to the east, the study area considered for this assessment is defined by the mix of uses along the waterfront and includes Bensonhurst Park to the north, Dreier-Offerman Park to the south and Shore Parkway to the east (see Figure 5.8-1).

5.8.1.2 Description of Neighborhood Character

The study area has a wide range of mixed uses (e.g., industrial, commercial, institutional, recreational and open space land uses). It is generally developed at a low density and with fairly large lots. Waterfront access is provided to the public in Bensonhurst Park north of the site and Dreier-Offerman Park to the south. The Excelsior Yacht Club and Marina adjacent to the site affords private access to water recreation uses.

The site, which is on the waterfront portion of the larger DSNY property, is accessed from a local service road running parallel to Shore Parkway on its bay side. This road is also accessible from Cropsey Avenue at its intersection with Bay 52nd Street southeast of the site. It serves Bensonhurst Park, Dreier-Offerman Park, the Nellie Bly Amusement Park, commercial uses next to the amusement park, and the yacht club, marinas and all the other activities on the bay side of the parkway.

The yacht club and Nellie Bly Amusement Park, which are regional destination points adjacent to the site, contribute to the pedestrian, automobile and boat circulation activity nearby. These uses and the routes that are used to access them have direct views to the site, and virtually all

Site delineations are approximate

Figure 5.8-1 Neighborhood Location

Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

these uses within the immediate area are intended for outdoor activity and recreation. Dreier-Offerman Park and the institutional uses south of the site also contribute to the area's pedestrian and automobile activity; there is also direct visual connection to the site from these areas.

The institutional/residential uses on Bay 44th Street — Community Residential Opportunities, Home for Handicapped Children, and the Brooklyn School for Special Children — account for a well-maintained streetscape. The parks are also well maintained and, since the area is without through-traffic, this street is relatively quiet and peaceful.

5.8.2 Future No-Build Conditions

Although there would be no delivery of waste to the existing MTS, other DSNY operations would continue to produce truck traffic in the neighborhood. It is assumed that the site will remain DSNY property, the incinerator will be demolished, the existing MTS would remain standing and the associated DSNY salt storage and garage facilities would continue to operate fully. Moreover, there are no plans for development on the site or in the study area that would potentially lead to changes in neighborhood character. The anticipated Future No-Build Conditions are, therefore, expected to be the same as Existing Conditions.

5.8.3 Potential Impacts with the Southwest Brooklyn Converted MTS

Generally, no change to the mixed neighborhood character would be expected because the operation and appearance of the Southwest Brooklyn Converted MTS would resemble those of the existing MTS and DSNY and other collection agency vehicles would follow the same routes as before. The Southwest Brooklyn Converted MTS would differ from Future No-Build Conditions in that it would accept the delivery of waste to the existing MTS, as it had in the past, but for the containerization of waste for export. Technical studies were performed for potential site-generated environmental impacts and no significant, unmitigatible adverse traffic, air quality, odor or noise impacts were found.

Therefore, no significant adverse impacts to neighborhood character would result from the reactivation of this historic waste transfer use on DSNY property surrounded by DSNY uses and activities that are anticipated to remain largely unchanged in the Future No-Build Condition.

5.9 Natural Resources

5.9.1 Existing Conditions

Existing Conditions include moderately stressed aquatic and terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from the Southwest Brooklyn Converted MTS.

5.9.1.1 Definition of Study Area

The study area includes the site and the waterfront sections that are bounded by the waters of Gravesend Bay to the west (see Figure 2.2.2-1). The upland sections of the study area and surrounding neighborhood are fully developed and, therefore, have very limited terrestrial natural resources. Such resources that do exist will be discussed in following sections. Because Future Build Conditions would include dredging of bottom sediment and construction of a new MTS, a description of aquatic communities is included.

5.9.1.2 Geology

Boring data from the City Department of Public Works entitled "Record of Borings, Southwest Brooklyn Sanitation Center" (December 5, 1956), indicates that bedrock was not encountered in borings drilled to varying depths up to 100 feet.[3] The uppermost layer (between one to eight feet thick) generally consisted of "uncontrolled fill," and its content varied greatly and included concrete, brick mixed with sand and gravel and deleterious material such as cinders, wood and vegetation. Borings performed within the upland portions of the site indicated a sand stratum underlying this fill material. In borings in the vicinity of the existing MTS, a sand stratum was encountered at the mud line. This stratum typically consists of a loose to medium dense, red brown poorly graded sand, to poorly graded sand with silt. All previous borings terminated in

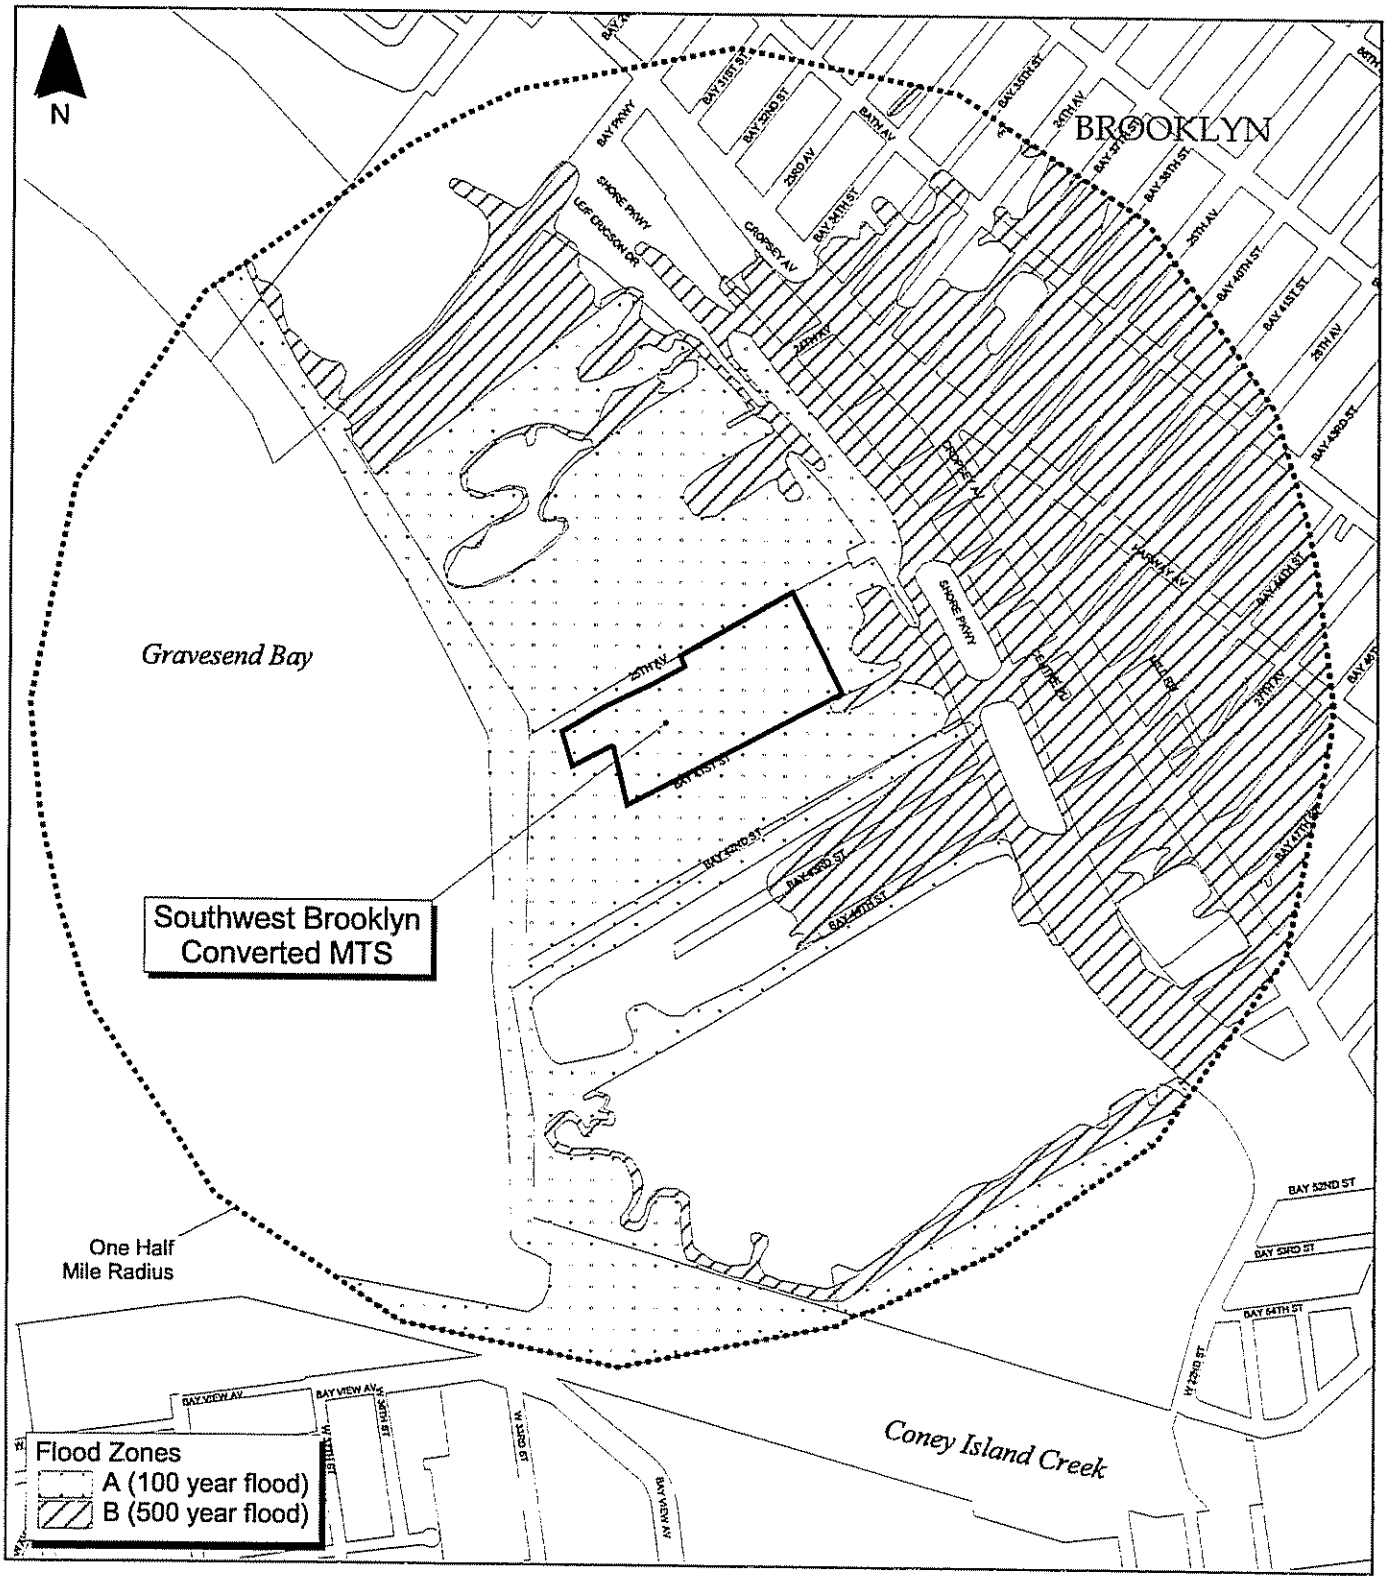
[3] Geology and Hydrogeology discussions based on "Record of Borings, Southwest Brooklyn Sanitation Center," December 1956, by the New York City Department of Public Works, as cited in the "MTS Conversion Conceptual Design Report," April 2003, by Greeley and Hansen, LLC.

this stratum. Results of the sediment samples collected for analysis in 2003 show that surficial sediment is characterized as light gray to gray sludge consisting of clay and silt with trace amounts of sand, with approximately 92,250 mg/kg TOC.[4] A grain-size analysis of sediment surrounding the MTS indicated the material to be 87.3% silt and clay, 11.1% sand and 1.7% gravel. Sediment was found to be somewhat degraded due to contaminants in the sample material. Lead had the highest concentrations in the sediment (106.33 mg/kg), followed by chromium, barium and arsenic (71.17 mg/kg, 62.42 mg/kg and 20.72 mg/kg, respectively).

5.9.1.3 Floodplains

The site is constructed within the 100-year coastal floodplain (see Figure 5.9-1). No intertidal wetlands exist on the site. Gravesend Bay, which is a NYSDEC-designated littoral zone, is a part of the study area (see Figure 5.9-2).

5.9.1.4 Ecosystems



Vegetative resources are virtually absent because nearly the entire site is covered with buildings or pavement. The few areas that are not hard surfaced exhibit typical opportunistic (weed) species including mugwort (*Artemisia vulgaris*) and tree-of-heaven (*Ailanthus altissima*). The vegetative cover in these areas was too sparse to be mapped.

The headwater of Gravesend Bay/Coney Island Creek is grossly contaminated, although the lower reaches exhibit adequate to good water quality. The reason for the good water quality is the proximity of the Upper Bight to the oceanic waters. Because Gravesend Bay has a large opening, the resultant tidal exchange facilitates circulation and replenishment.

A field program designed to fully characterize the marine biological resources of the study area took place in 2003. The program included monthly sampling for adult finfish, finfish eggs and larvae and water quality, and quarterly sampling for benthic organisms, sediment quality and sessile colonizing organisms. Results of the program are discussed in the following paragraphs.

Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

The Southwest Brooklyn Converted MTS was one of three MTSs with the greatest biological integrity. It housed a diverse benthic, larval finfish and adult finfish community. It also had the greatest number of EFH-listed adult finfish (8) and larvae (4) and the highest number of *Dyspanopeus sayi* (a mud crab whose presence indicates suitable dissolved oxygen levels in the water column).

A diverse finfish community exists at the Southwest Brooklyn Converted MTS.[5] Of 1,293 adult finfish collected, 69% were bay anchovy (*Anchoa mitchilli*). Weakfish (*Cynoscion regalis*) and scup (*Stenotomus chrysops*) were also abundant at this site. The Southwest Brooklyn Converted MTS site housed the greatest number of EFH species (8). The species collected were: scup (*S. chrysops*), windowpane (*Scophthalmus aquosus*), summer flounder (*Paralichthys dentatus*), Atlantic herring (*Clupea harengus*), winter flounder (*Pleuronectes americanus*), Atlantic butterfish (*Peprilus triacanthus*), bluefish (*Pomatomus saltatrix*) and black sea bass (*Centropristis striata*). The larvae of four EFH-listed species were also found at the Southwest Brooklyn Converted MTS: winter flounder, windowpane, scup and Atlantic butterfish; eggs of windowpane were also collected. Some of the highest finfish egg and larval densities and the greatest larval species richness were found at the Southwest Brooklyn Converted MTS. A Shannon-Weaver Index[6] indicates this MTS to have the greatest finfish egg and larval species diversity and a Jaccard's Index[7] indicates that the finfish eggs and larvae were most dissimilar at the Southwest Brooklyn Converted MTS in comparison to the other MTSs sampled.

The Southwest Brooklyn Converted MTS had one of the greatest species richnesses in the benthic communities. The dominant benthic organism collected from the sediment surrounding the Southwest Brooklyn Converted MTS was *Streblispio benedicti*, a polychaete worm. There were approximately 13,500 *S. benedicti* per square meter of sediment. This species, however, is tolerant of polluted environments. Dominant epibenthic colonizers were *Polydora* sp. (polychaete worms), *Crepidula fornicata* (common Atlantic slippersnail), *Nereis succinea* (yellow-jawed clam worm), *Mytilus edulis* (blue mussel), and hydrozoa, mud, and algal film. Many of these species also are tolerant of degraded environmental conditions.

---

[5] Ibid.

[6] The Shannon-Weaver Index is a measure of community diversity. If an individual of the community is selected at random, the index gives a measure of the uncertainty that the selected individual will be of a particular species. The higher the index, the more diverse the community.

[7] A Jaccard's Index is a statistical test that shows the similarity of organisms present at compared MTSs. It shows the proportion of the number of species observed in either of two MTSs that occurred in both MTSs. The index ranges from zero to one. An index of zero means that the MTSs are completely dissimilar and have no species in common. An index of one means the MTSs have all the same species.

The peregrine falcon (*Falco peregrinus)*, a federally listed endangered species, was not listed as present for this site in the recent response from the USF&WS.

5.9.2 Future No-Build Conditions

If the Southwest Brooklyn Converted MTS were not to be constructed, the study area would remain as is, except that the incinerator would be demolished and removed from the site. The site would remain DSNY property and the existing MTS would remain. The limited aquatic and terrestrial natural resources would also remain and the study area would continue to be a moderately ecologically productive area in a stressed urban area.

5.9.3 Potential Impacts with the Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS would be built at about the same location as the incinerator, which will have already been demolished and removed. The above-water platform for this facility will remain in place. Barges would be located along the dock on the southwest side of the study area. Since this facility will not require the removal of the old platform and construction of a new one, the impacts from suspended sediment, as a result of construction, will be minimal. There will, however, be construction of a king pile wall, a barrier to protect neighboring marina from wave action. Water depth in this area is approximately eight to ten feet, so dredging would be necessary to accept the retrofitted DSNY barges that would be used to transport the containerized waste. Dredging and construction of a king pile wall, however, will cause the upper organic silts to be disturbed to some degree, resulting in re-suspension of the sediments. Because of the swift currents in the area, mitigation measures, such as silt curtains, would not be feasible. However, the amount of re-suspended sediments is expected to be low and the impacts, if any, highly localized. Turbidity and short-term, lowered, dissolved oxygen are possible, but not measurable, against the normal background fluctuations.

5.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

5.9.3.2 *Floodplains*

Implementation of the Southwest Brooklyn Converted MTS would not affect the elevation of the site. It would be constructed within the 100-year floodplain and would not include any provisions for raising any portions of the site over this level.

5.9.3.3 *Ecosystems*

The limited vegetative resources that are present on the small patches of unpaved areas of the study area are not rare, endangered or particularly important species from an ecological perspective. Development of the Southwest Brooklyn Converted MTS would produce no consequences to the natural resources. Existing on-site buildings and paved parking areas have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the study area since the original construction of the buildings in 1965.

Construction of the Southwest Brooklyn Converted MTS would involve dredging to accommodate the deeper draft of the coastal barges and construction of a king pile wall, resulting in an immediate, short-term destruction of the benthic invertebrates in the area. Because the benthic diversity is high and dredging and construction causes turbidity and siltation that could smother the benthic organisms, there is expected to be a short-term degree of impact. However, because there is no platform construction slated, the impact should be minimal and recolonization of the area by benthic invertebrates can be expected to occur within 6 to 12 months after cessation of dredging activities.[8] Given the relatively small size of the project and the fact that periodic maintenance dredging has been performed repeatedly at the study area since its original construction, minimal impact is expected from the Southwest Brooklyn Converted MTS. The plan to use the existing platform will prove beneficial to epibenthic organisms. Because the platform will remain, an already established, complex epibenthic community will remain in existence. This community will also colonize the new king pile wall.

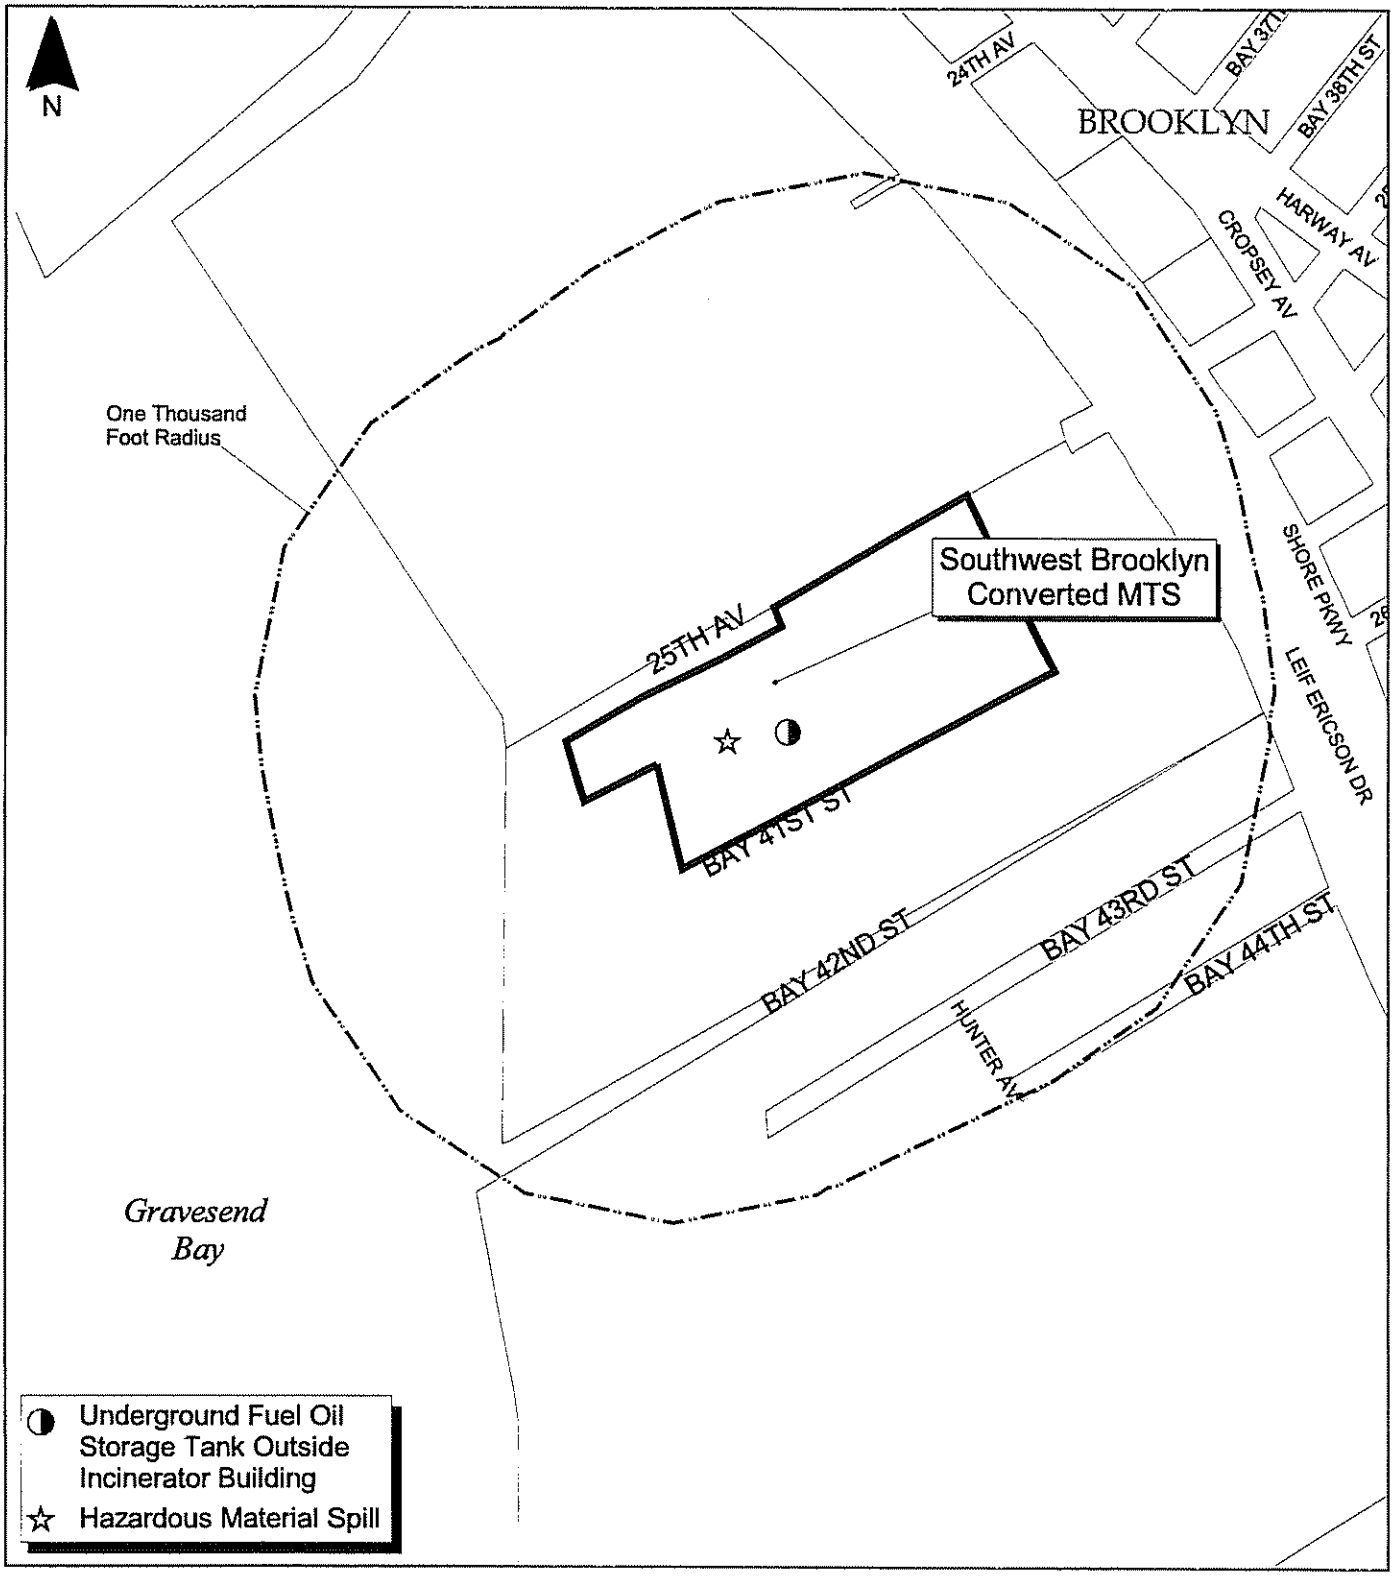
[8] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

The dredging and construction activity will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to suspended sediment and flatfish (flounders) are least sensitive. Flounder catch was much higher at the Southwest Brooklyn Converted MTS than herring catch, so it can be assumed that this site is not an important herring habitat that will be temporarily impacted. Finfish eggs and larvae are more sensitive to suspended sediment and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. Also, larvae will be able to swim away from the impacted environments.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The Southwest Brooklyn Converted MTS, however, does not have a proposed change in platform footprint. Therefore, there will be no impact as a result of increased shading of the water column at this MTS.

The existing MTS had operated as a solid waste transfer station for 35 years and does not contain or abut any environmentally sensitive areas. Modifications to the study area would pose little, if any, adverse ecological impacts and no loss of habitat to rare or endangered species.

5.10 Hazardous Materials



5.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in April 1999 and updated in February 2003. It included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the FDNY for UST records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted, most recently in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors. Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

5.10.1.1 Definition of Study Area

The study area includes the site and neighboring properties within a 1,000-foot radius (see Figure 5.10-1).

Site delineations and study area boundaries are approximate.

5.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater and building components/equipment within the study area where the presence or likely presence of hazardous materials exists and implementation of the Southwest Brooklyn Converted MTS could lead to an increased exposure of people or the environment to those materials. The areas of concern at the subject site include:

- Possible groundwater contamination migrating beneath the site from the adjacent DSNY Garage and Borough Command Facility on the east side. Evidence of on-site USTs (i.e., fuel pumps, fills and vents, and NYSDEC Petroleum Bulk Storage listings) was noted at the Borough Command Facility site. Numerous monitoring wells were noted inside and around this facility, strongly suggesting the presence and/or a release of contaminants to the environment. Four "active status" NYSDEC spill incidents consisting of test failure of USTs (#2 fuel oil, gasoline and hoist oil) are believed to have occurred at this facility. These include Spill No. 8911519 dated March 7, 1990, at 1824 Shore Parkway; Spill No. 9001807 dated May 15, 1990, at 380 Bay 41st Street/DSNY); and Spill Nos. 0001699 and 0001700 dated April 25, 2000, at 1824 Shore Parkway/NYSDEC. An "active status" spill listing DSNY as the spiller, and noted during the April 1999 assessment, was not found during the 2003 assessment.

- Potential subsurface contamination associated with what appeared in 1999 to be USTs within the fenced-in exterior areas of the closed Southwest Brooklyn Incinerator building.

- The probable presence of lead-based paint in underlying layers of the existing MTS (based on the age of the building). Painted surfaces were in relatively good condition, with only minor areas of damaged paint noted. Underlying paint in good condition does not represent any risk to current employees.

- Probable presence of lead-based paint on the Southwest Brooklyn Incinerator building based on its age (circa 1960). In addition, due to the age and nature of operations performed within this building, it is highly likely that its interior portions contain ACMs. Suspected asbestos-containing corrugated cement panels in relatively good condition were noted on exterior portions of the building and adjacent conveyor structure at the time of the site visit in 1999.

A field program to investigate the potential impacts to the soil and groundwater from the historic use of the property as an incinerator and MTS was completed in November 2003 in accordance with a NYSDEC-approved work plan.[9] The field investigation included:

- Performing a ground-penetrating radar and magnetometer survey over accessible areas of the site.
- Collection of one subsurface soil sample from 14 boring locations.
- Collection of one surface soil sample from four boring locations.
- Collection of one soil/ash sample for TCLP analysis.
- Collection of one groundwater sample from three boring locations.
- Collection of one groundwater sample from three permanent monitoring wells.
- Laboratory analysis of all soil samples for asbestos, VOCs, SVOCs, pesticides/PCBs, and RCRA metals.
- Laboratory analysis of all water samples for VOCs, SVOCs, pesticides/PCBs and RCRA metals.
- Determination of the direction of groundwater flow by land survey and measurement to the top of the groundwater surface.
- Comparison of the analytical results obtained from the soil and groundwater sampling program with the NYSDEC technical and TAGM guidelines.
- Preparation and submittal of a detailed site investigation report.[10]

Low-level soil and groundwater contamination was discovered during this investigation and is consistent with the historic construction and use of this facility as an incinerator and MTS.

5.10.2 Future No-Build Conditions

The site would remain as is except for the demolition of the on-site incinerator. Any ACMs that are found in the incinerator building would be removed prior to demolition in a manner that is consistent with City building codes and practices. Contamination may exist on the subject site from suspected on-site USTs; however, DSNY has plans to close all USTs in accordance with New York State regulations (6 NYCRR 613.9).

---

[9] New York City Department of Sanitation, October 2003. Final Phase II Site Investigation Work Plan, Southwest Brooklyn Marine Transfer Station, Brooklyn, New York.

[10] New York City Department of Sanitation, June 2004. Phase II Site Investigation, Southwest Brooklyn Marine Transfer Station, Brooklyn, New York. Prepared by EEA, Inc.

5.10.3 Potential Impacts with the Southwest Brooklyn Converted MTS

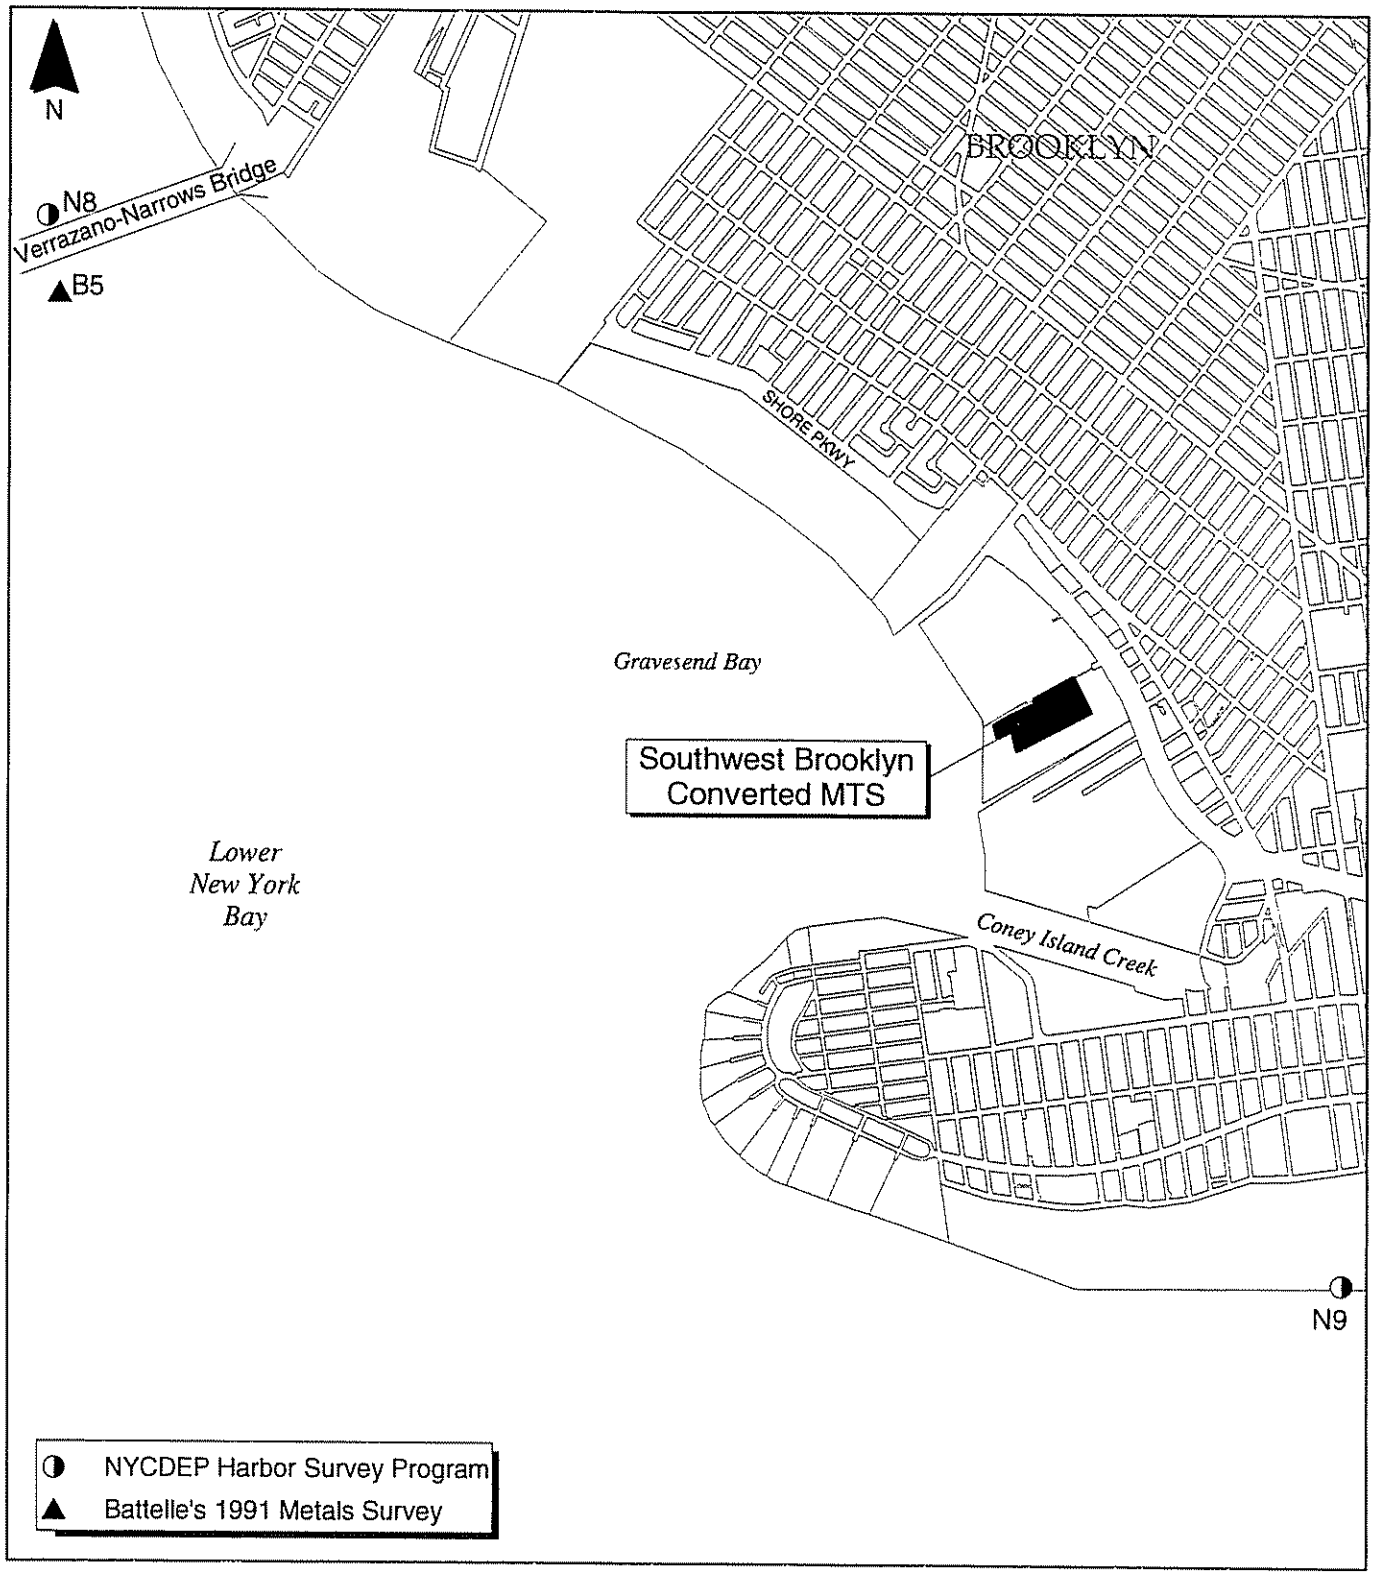
Historical low-level soil and groundwater contamination is present at the existing MTS facility; however, this contamination should not prevent development of the site. If the Southwest Brooklyn Converted MTS were implemented, any residual contaminated soil discovered would require appropriate disposal according to current regulatory guidelines in a manner that is consistent with the level of contamination found during the demolition/construction phase. The necessary and appropriate health and safety measures would be used to mitigate and minimize any exposure risk to workers or the general public.

5.11 Water Quality

5.11.1 Existing Conditions

5.11.1.1 Definition of the Study Area

The water quality study area encompasses Gravesend Bay and Lower New York Bay, and also includes discharges from point sources located within ½-mile of the site.



5.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 5.11-1, are generally representative of water quality conditions in the study area:

- NYCDEP Harbor Survey Program – Stations N-8 at the Verrazano Narrows and N-9 at Steeplechase Pier in Lower New York Bay; and
- Battelle's 1991 Metals Survey – Station B-5 in the Lower New York Bay.

These data along with NYSDEC's water quality standards and guidance values are presented in Table 5.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class I," which indicates waters suitable for secondary contact recreation (i.e., fishing and boating).

As shown in Table 5.11-1, on average, NYSDEC standards and guidance values are met. The mercury concentration for Battelle Station B-5, however, did not conform to the water quality standard for mercury.

Site delineations are approximate

BOD = biochemical oxygen demand
NH_3-N = ammonia
NO_3 = nitrate; NO_2 = nitrite
PO_4 = phosphate
mg/L = milligrams per liter
MPN/100 ml = most probable number per 100 milliliters
MF = membrane filter
µg/L = micrograms per liter

5.11.1.3 Permitted Discharges

A review of the most recently available NYSDEC and USEPA databases indicated that there is one permitted discharge in the vicinity of the site. The existing discharge within a ½-mile radius is listed in Table 5.11-2 and shown in Figure 5.11-2. This discharge consists of one industrial site, which is permitted by the NYSDEC. It is located in Brooklyn, north of the site, and discharges into Gravesend Bay.

Table 5.11-2

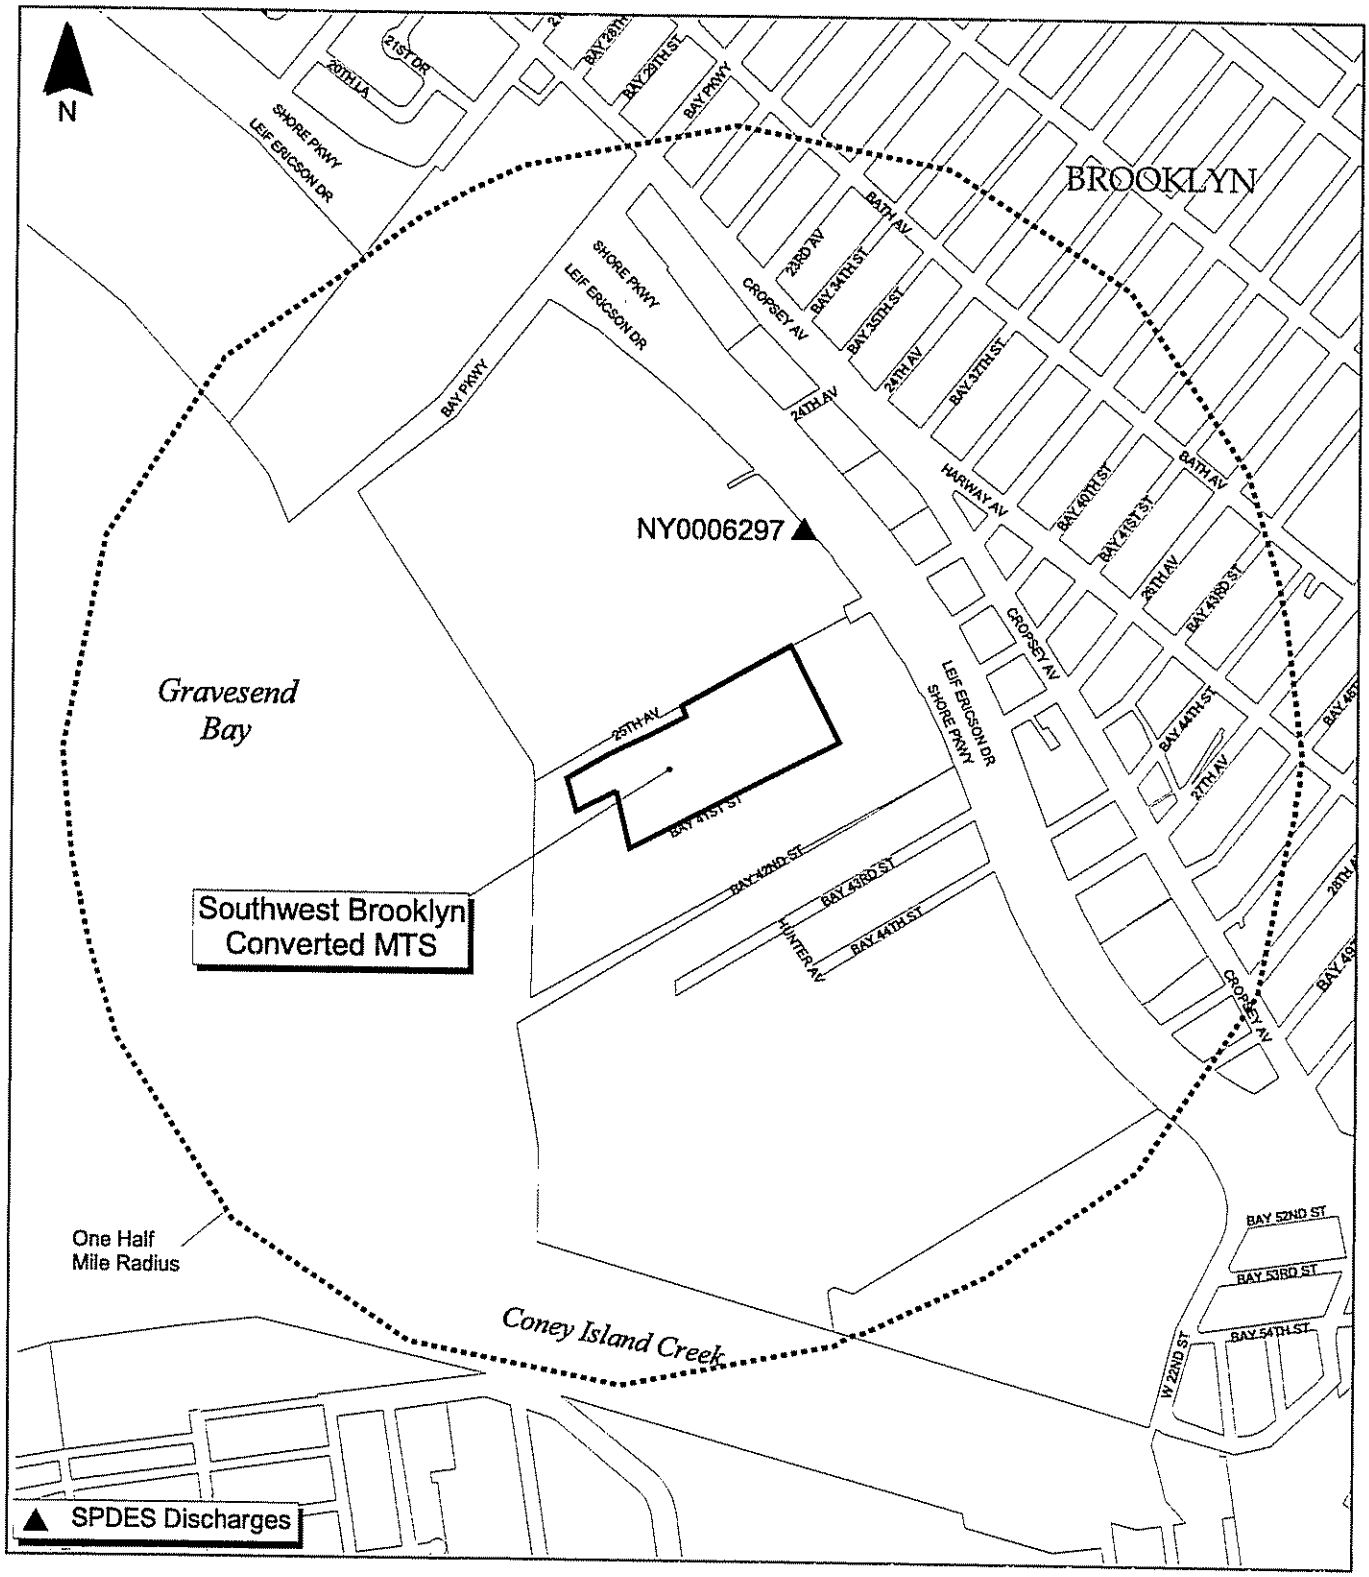
Southwest Brooklyn Converted MTS Study Area



Point Sources			
Company Name	**Permit Number**	**County**	**Receiving Water Body**
Bayside Fuel Oil Depot Corp.	NY0006297	Kings	Gravesend Bay

5.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, an estimate of existing stormwater pollutant loadings was calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% infiltration and/or storage. A runoff flow of 0.341 cfs was calculated using the impervious site area (6.5 acres), an average rainfall intensity of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 5.11-3, represent the existing loads at the site.

5.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to the NYCDEP CSO Abatement Program, which will reduce untreated discharges to receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from City WPCPs; and other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

Site delineations and study area boundaries are approximate

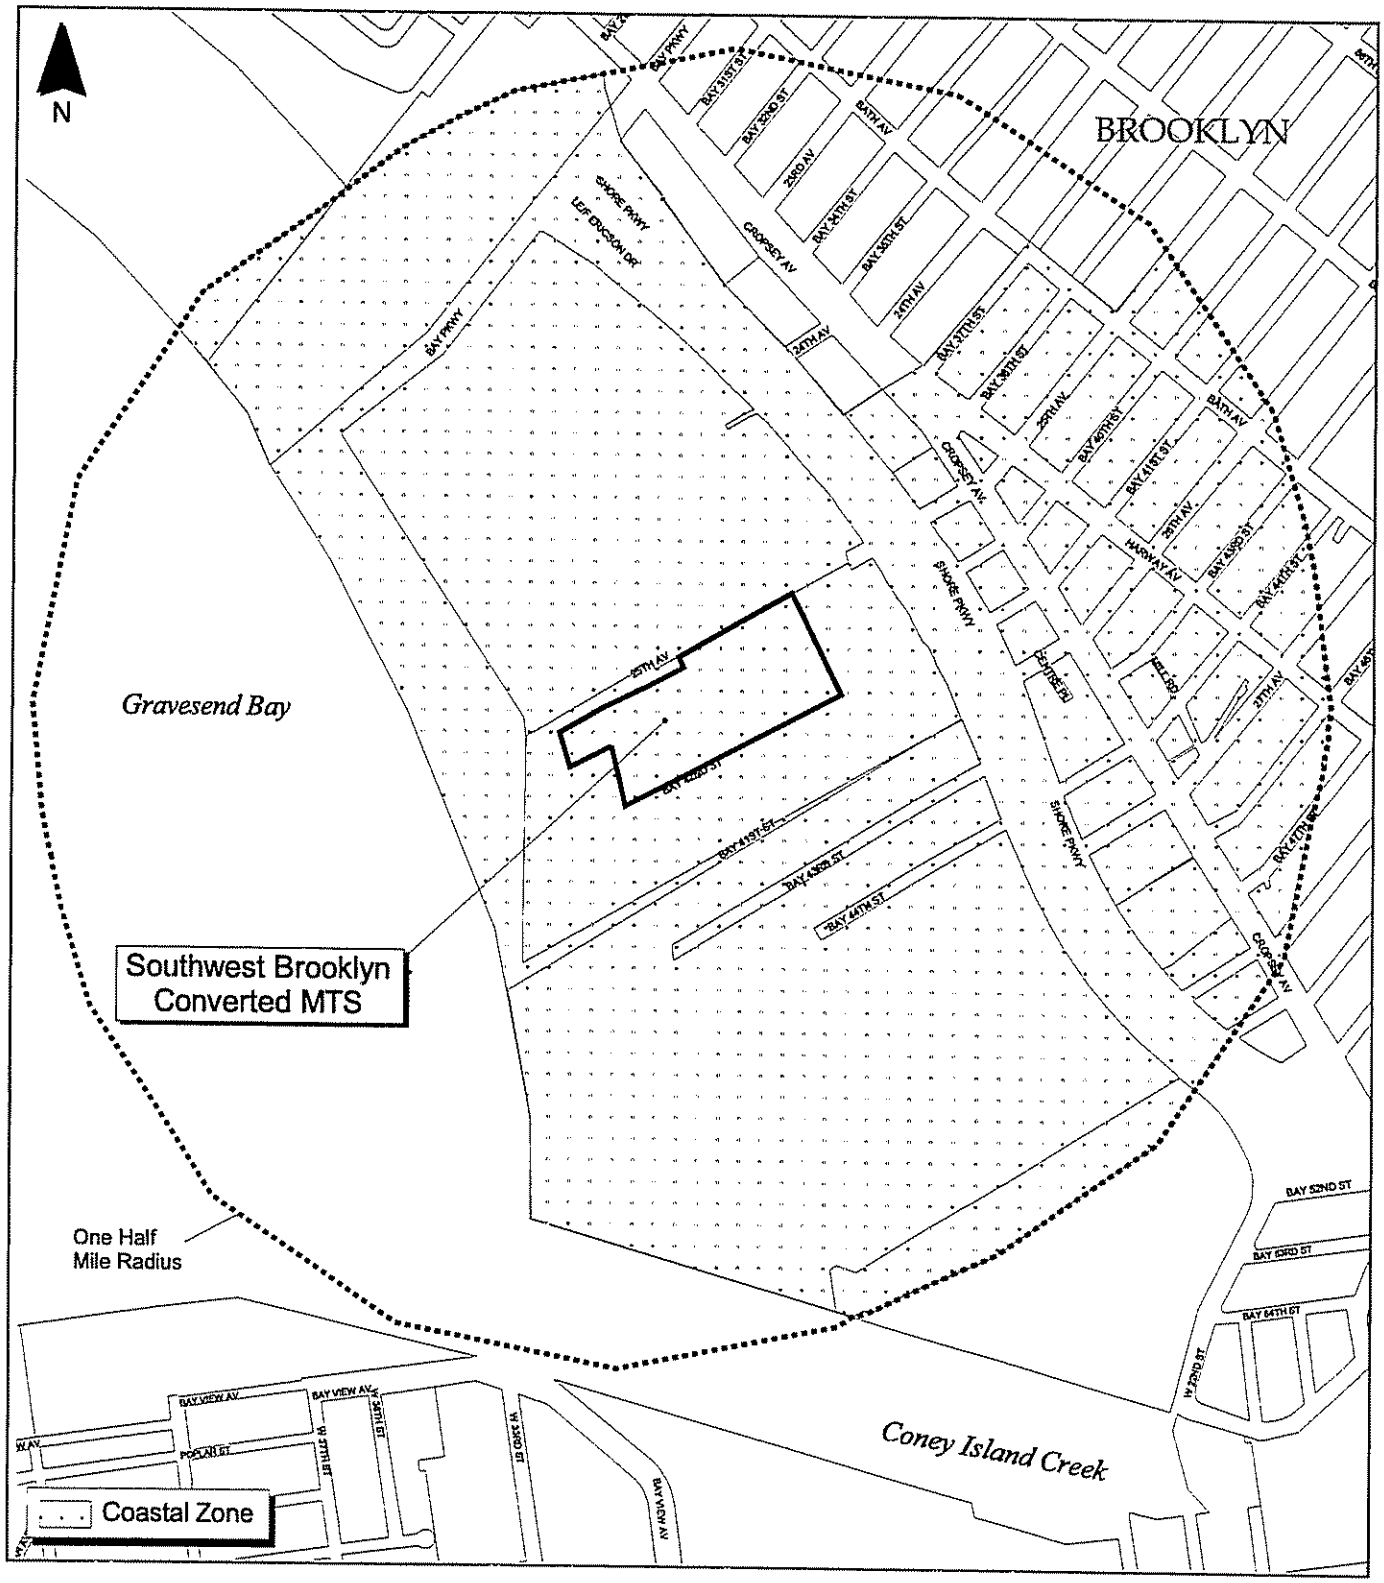
5.11.3 Potential Impacts with the Southwest Brooklyn Converted MTS

With the development and operation of the Southwest Brooklyn Converted MTS, there would be no change to the impervious area and, therefore, the stormwater loadings at the site would remain unchanged. Table 5.11-4 shows the existing impervious area, the change in impervious area and pollutant loads. With the development of the Southwest Brooklyn Converted MTS, conditions would not be significantly different from Future No-Build Conditions. After treatment, the processed wastewater would be discharged to the municipal sewer system and, ultimately, to the Owls Head WPCP, where it would be treated prior to discharge to the Lower New York Bay and, therefore, would not adversely affect water quality. The Southwest Brooklyn Converted MTS may also require dredging activities to construct the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired prior to any proposed dredging activities. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant adverse long-term impacts.

Table 5.11-4
Impervious Area and Estimated Pollutant Loads
Southwest Brooklyn Converted MTS

Impervious Area Change			Estimated Pollutant Loadings/Incremental Change [1]				
Condition	Total Impervious Area (acres)	Change in Impervious Area (acres)	Fecal Coliform[2]	BOD (lbs/day)	Copper (lbs/day)	Lead (lbs/day)	Zinc (lbs/day)
Existing Conditions	6.5	0.0	71,446/NA	23/NA	0.074/NA	0.059/NA	0.324/NA
Future Build Conditions	6.5	0.0	71,446/0	23/0	0.074/0	0.059/0	0.324/0



Notes:
[1] Incremental change refers to the difference in pollutant loading between the Existing Conditions and the Future Build Conditions.
[2] Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable

5.12 Waterfront Revitalization Program

5.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of Gravesend Bay, the Southwest Brooklyn Converted MTS would be within the City's coastal zone boundary (see Figure 5.12-1). According to "The New Waterfront Revitalization Program," the Southwest Brooklyn Converted MTS, once operational, would be classified as a water-dependent, industrial use. It would be located within Reach 15 Brooklyn/Lower Bay as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Brooklyn Waterfront." It is not currently within an NYCDCP-designated SNWA or SMIA. Due to its location, it is subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The Southwest Brooklyn Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable, including subpolicies 1.1, 1.2, 2.1, 3.1, 4.4, 6.2, 6.3, 8.5 and 10.2. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. In instances where a component of the Southwest Brooklyn Converted MTS required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below. A description of waste handling operations that would occur at the Southwest Brooklyn Converted MTS is provided in Section 2.2.2.

Site delineations and study area boundaries are approximate.

Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

5.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the new Southwest Brooklyn Converted MTS. As part of the Southwest Brooklyn Converted MTS, connections from the new facility to existing utilities (e.g., sewer connections, etc.) in the vicinity would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.2 Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.

The site of the Southwest Brooklyn Converted MTS is not located within an NYCDCP-designated SMIA. The existing MTS would remain in its current configuration for potential future use by DSNY. Development of the Southwest Brooklyn Converted MTS would involve its construction within the upland portion of the site that is currently occupied by a former incinerator, which is in the process of being demolished. This incinerator previously had the ability to transport ash by barge from the site. The Southwest Brooklyn Converted MTS would involve the development of an upland TCB transfer station that would transport DSNY-managed Waste by marine transport to remote out-of-City disposal facilities.

The site redevelopment, as described in Section 2.2.2, would help to restore and revitalize industrial waterfront property and would be compatible with existing industrial and maritime uses. The majority of reconstruction activity would occur within the upland portions of the site and would consist of four primary components: (1) an enclosed processing building which would include a tipping floor, loading floor and pier level; (2) an elevated access ramp with accompanying retaining walls; (3) a gantry crane, outside of the processing building and at the waterfront; and (4) a ~~rehabilitated bulkhead and~~new fendering system and new ~~breakwater groin~~king pile wall. The Southwest Brooklyn Converted MTS would be consistent with existing land uses in the vicinity of the site and with the "Plan for the Brooklyn Waterfront," which recommends the continued industrial use of the area. Although it would not encourage or facilitate the siting of any additional water-dependent uses, the Southwest Brooklyn Converted MTS would involve the redevelopment of the former incinerator site with a new waterfront use that would expand the previous waterfront activities at the site, which are currently inactive and would be compatible with surrounding uses.

The Southwest Brooklyn Converted MTS would, therefore, be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The Southwest Brooklyn Converted MTS would involve the development of a new facility within the upland portion of the site that is currently occupied by the former incinerator, which is in the process of being demolished. It would allow for marine transport of solid waste to licensed out-of-City disposal facilities. The development would consist of four primary components: (1) an enclosed processing building which would include the tipping floor, loading floor and pier level; (2) an elevated access ramp; (3) a gantry crane; and (4) a ~~rehabilitated bulkhead and~~ new fendering system and ~~breakwater groin~~king pile wall. In

addition, an 18-inch concrete stormwater outfall would be constructed within the bulkhead. It is likely the construction of the king pile wall, fendering system and new outfall would be done from a crane-mounted work barge. The stormwater outfall would drain stormwater runoff from the facility into the Gravesend Bay. Some of the stormwater would also drain to ~~tan~~ existing 8-foot by 8-foot storm outfall, located north of the site. Prior to discharging to these outfalls, the stormwater runoff would pass through a stormwater treatment system. The Southwest Brooklyn Converted MTS would be consistent with existing waterfront uses at and in the vicinity of the site.

In addition, the Southwest Brooklyn Converted MTS would require dredging to improve existing water depths at and in the immediate vicinity of the site to allow for unimpeded operation of barges and tugboats once it became operational. All required dredging would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The development of the Southwest Brooklyn Converted MTS would involve the reactivation of a historic waterfront use and would not interfere with any maritime industrial, commercial or recreational vessel activities in the area. Activities within Gravesend Bay resulting from the Southwest Brooklyn Converted MTS would be limited to barge loading along the pier level and the periodic swapping of loaded barges. ~~Four or five~~Two barges would be filled on a daily basis. These swapping activities would be similar to previous barge activities at the site. Therefore, no adverse impact to other uses within the waterbody would be anticipated. The Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The Southwest Brooklyn Converted MTS would be an upland TCB transfer station where DSNY-managed Waste would be transferred into containers that would be sealed and placed onto flat deck barges, then transported to out-of-City disposal locations and, therefore, would be protective of the aquatic environment and surrounding land and water uses. All solid waste handling would occur within an enclosed processing building. All waste would be placed in sealed containers before leaving the building for loading on barges.

Building ventilation would be maintained under negative pressure, which would maintain dust inside the enclosed processing building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environment. Litter control methods, such as routine sweeping and washing of the tipping floor, would be implemented to minimize or eliminate the potential for litter entering surface waters. All process wastewaters generated on site (e.g., washdown waters, etc.) would be treated prior to their discharge to the municipal sewer system. In addition, on-site storage of petroleum products and hazardous materials related to the operation of the Southwest Brooklyn Converted MTS would be done in accordance with applicable federal, state and local regulations. Therefore, the Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs, as described in "The Waterfront Revitalization Program," as well as Recognized Ecological Complexes and SCFWH information, the Southwest Brooklyn Converted MTS is not within a designated area. The Southwest Brooklyn Converted MTS would involve the redevelopment of the former incinerator site, which is in the process of being taken down, with a new waterfront use that would expand the previous waterfront activities at the site. It would not be anticipated to result in any long-term impacts to natural resources in the vicinity of the site. The Southwest Brooklyn Converted MTS would, therefore, be consistent with this subpolicy.

4.2 Protect and restore tidal and freshwater wetlands.

A review of NYSDEC tidal and freshwater wetland maps was conducted to determine the presence of wetlands within the site. As noted in Section 5.9.1, the Southwest Brooklyn Converted MTS would front Gravesend Bay, a NYSDEC-designated littoral zone. No freshwater wetlands exist on the site. The Southwest Brooklyn Converted MTS would involve the construction of a new facility within the upland portion of the site that is currently occupied by the former incinerator, which is in the process of being demolished. Required dredging associated with construction activities would result in limited, short-term ~~impact~~ effects to these tidal wetlands.

Construction of a 300-foot ~~breakwater groin~~king pile wall within Gravesend Bay would be needed to protect existing waterfront facilities located southeast of the site. The ~~breakwater~~ king pile wall would consist of the placement of steel sheet piling and rip rap.

Dredging activities associated with the development of the Southwest Brooklyn Converted MTS are not anticipated to have significant ~~impacts~~ effects on wetland areas in the vicinity of the site, primarily due to previous activities and dredging that historically occurred at the site. ~~Mitigation for potential~~Potential ~~impacts~~ effects upon wetlands would be ~~proposed~~ addressed during the environmental review and permitting of the Southwest Brooklyn Converted MTS. ~~This mitigation, if required, would address potential impacts that may occur due to the Southwest Brooklyn Converted MTS and would effectively restore these wetlands~~

~~and their associated value.~~ DSNY in coordination with the NYSDEC and other involved agencies would determine the appropriate measure to address potential effects that may occur due to the Southwest Brooklyn Converted MTS and would effectively restore these wetlands and their associated value. The Southwest Brooklyn Converted MTS would, therefore, be consistent with this subpolicy.

4.3 Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.

A review of NYSDEC NHP database indicates that no known species of concern were located in the vicinity of the site. The Southwest Brooklyn Converted MTS would be constructed within the upland portion of the site that is currently occupied by the former incinerator, which is in the process of being demolished. Development of a new king pile wall and the replacement of the existing fendering system would be required. Dredging would also be required to accommodate ~~larger~~ barges and tugboats once the site is operational. As stated in Section 5.9.3, modifications to the site would pose little, if any, adverse ecological impacts or loss of habitat to rare or endangered species. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer system. Stormwater runoff from the Southwest Brooklyn Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The Southwest Brooklyn Converted MTS would not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The Southwest Brooklyn Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site treatment system, which may consist of oil/water separators, etc., discharging eventually to the municipal sewer system. In

addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. A new stormwater outfall would be constructed in the bulkhead to manage stormwater runoff from the proposed action. In addition, some of the stormwater runoff from the Southwest Brooklyn Converted MTS would discharge to an existing 8-foot by 8-foot outfall located north of the site. The runoff to both of these outfalls would pass through a stormwater treatment system. Stormwater runoff from the Southwest Brooklyn Converted MTS would be managed in accordance with all applicable federal, state and local regulations.

In addition, the majority of activities associated with the Southwest Brooklyn Converted MTS would be conducted within an enclosed processing building. Only sealed, air- and watertight containers would be transferred to barges outside of the processing building by gantry cranes installed at the pier level. Inside the facility, several measures would be taken to minimize the potential for environmental degradation as a result of the facility. Building ventilation would be maintained under negative pressure, which would be intended to keep dust inside the enclosed processing building. Litter control methods, such as routine sweeping and washing of the tipping floor, would be implemented to minimize or eliminate the potential for litter entering surface waters. The Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

5.2 *Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.*

BMPs would be used to the extent possible during all phases of construction and operation of the Southwest Brooklyn Converted MTS in order to minimize any nonpoint discharges. The Southwest Brooklyn Converted MTS would comply with federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be conducted within an enclosed processing building. During construction, non-structural and, if necessary, structural, measures would be used to minimize nonpoint source pollution.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

A 300 foot long king pile wall would be placed within Gravesend Bay, perpendicular to the southeastern corner of the existing bulkhead. Construction of the king pile wall would consist of the placement of steel sheet piling and rip rap. The king pile wall would serve to protect existing Marine structures, including a marina and a concrete seawall, located south and southeast of the site. The king pile wall would provide stability to the seawall during construction and dredging and will protect the seawall against wave action and tugboat prop-wash during facility operations. Development of this king pile wall would result in temporary impacts to water quality, which would be short-term and highly localized. It is likely that all construction activities associated with the king pile wall would occur from crane-mounted barges.

In addition, as part of the Southwest Brooklyn Converted MTS, dredging would be necessary to provide sufficient water depths for unimpeded operations. Dredging would be conducted with the use of an environmental bucket, which is an overlapping, sealed clamshell style bucket that prevents sediments from entering the waterway. Dredging done as part of construction would result in temporary impacts and would be conducted in a manner to minimize siltation and erosion and other short-term impacts to water quality. Non-structural and, if necessary, structural, measures would be used to minimize siltation and potential adverse impacts to tidal wetlands in the vicinity. All dredged materials would be disposed of at a permitted upland facility in accordance with applicable federal, state and local regulations. Therefore, the Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The Southwest Brooklyn Converted MTS would have no impact on the quality or quantity of surface or ground waters. Process wastewaters (e.g. washdown waters, etc.) would be conveyed to an on-site treatment system and would then discharge to the municipal sewer system. A new stormwater outfall would be constructed within the existing bulkhead. In addition, stormwater runoff from the Southwest Brooklyn Converted MTS would also discharge to an existing

stormwater outfall located north of the site. Prior to being discharged to Gravesend Bay, stormwater would travel through a stormwater treatment system. Stormwater runoff from the Southwest Brooklyn Converted MTS would be managed in accordance with all applicable federal, state and local regulations. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer or water supply. The Southwest Brooklyn Converted MTS would be consistent with this policy.

~~*5.3 Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*~~

~~A 300-foot breakwater groin would be placed within Gravesend Bay, perpendicular to the southeastern corner of the existing bulkhead. Construction of the breakwater would consist of the placement of steel sheet piling and rip rap. The breakwater would serve to protect existing waterfront facilities located south of the site. Development of this breakwater would result in temporary impacts to water quality, which be short-term and highly localized.~~

~~In addition, as part of the Southwest Brooklyn Converted MTS, dredging would be necessary to provide sufficient water depths for unimpeded operations. Any dredging done as part of construction would result in temporary impacts and would be conducted in a manner to minimize siltation and erosion and other short-term impacts to water quality. Non-structural and, if necessary, structural, measures would be used to minimize siltation and potential adverse impacts to tidal wetlands in the vicinity. All dredged materials would be disposed of at a permitted upland facility in accordance with applicable federal, state and local regulations. Therefore, the Southwest Brooklyn Converted MTS would be consistent with this subpolicy.~~

~~*5.4 Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*~~

~~The Southwest Brooklyn Converted MTS would have no impact on the quality or quantity of surface or ground waters. Process wastewaters (e.g. washdown waters, etc.) would be conveyed to an on-site treatment system and would then~~

~~discharge to the municipal sewer system. Stormwater runoff from the Southwest Brooklyn Converted MTS would be managed in accordance with all applicable federal, state and local regulations. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer or water supply. The Southwest Brooklyn Converted MTS would be consistent with this policy.~~

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to a review of the FEMA National Flood Insurance Program maps, the Southwest Brooklyn Converted MTS would be situated within the 100-year floodplain boundary (Zone A). It would be constructed within the upland portion of the site that is currently occupied by a former incinerator, which is currently being demolished. Dredging would be required to provide sufficient water depths in the vicinity of the Southwest Brooklyn Converted MTS for unimpeded barge and tugboat operations once the facility is operational. In addition, the proposed action would involve the construction of a 300-foot ~~breakwater groin~~ king pile wall that would be placed perpendicular to the existing bulkhead. The breakwater is intended to allow for dredging activities to take place, while protecting a rip-rap bulkhead on the adjacent property that is constructed of loose concrete blocks. Construction of the king pile wall would be done from crane-mounted barges. To the extent practicable, non-structural and, if necessary, structural, measures would be used to minimize damage from flooding and erosion during construction of the proposed facility. Construction of the new Southwest Brooklyn Converted MTS would not affect the potential for flooding or erosion. All structures would comply with applicable building code requirements.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The Southwest Brooklyn Converted MTS would not involve the storage, treatment or disposal of hazardous waste, but would facilitate the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours of tipping. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the Southwest Brooklyn Converted MTS. The majority of activities would occur within the enclosed processing building. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility. Only sealed, air- and watertight containers would be used outside of the facility.

On-site storage of petroleum or hazardous materials related to the operation of the Southwest Brooklyn Converted MTS would be in accordance with applicable federal, state and local regulation. The Southwest Brooklyn Converted MTS would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 Prevent and remediate discharge of petroleum products.

Soil and groundwater contamination is present at the existing site and is discussed in further detail in Section 5.10.3. Existing contamination would be addressed as part of the proposed development of the site, if required. This contamination

would not be expected to prevent the proposed development of the Southwest Brooklyn Converted MTS. Removal and disposal of contaminated materials, if required, would be done in accordance with applicable regulatory guidelines. In addition, as appropriate, health and safety measures would be used to mitigate and minimize any exposure risk to worker or the general public. Also see response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicies 7.1 and 7.2.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

Due to the existing industrial uses at and in the immediate vicinity of the Southwest Brooklyn Converted MTS, public access would generally not be compatible with the principal use of the site. The Excelsior Yacht Club and Marina is located adjacent and immediately south of the site; however, the Southwest Brooklyn Converted MTS would not impact this marina or other existing, public water-related recreational resources or access and, therefore, would be consistent with this subpolicy.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

According to "The New Waterfront Revitalization Plan," the Southwest Brooklyn Converted MTS would be a stand-alone, water-dependent and industrial facility fronting Gravesend Bay. Public access would not be compatible with the Southwest Brooklyn Converted MTS; however, its development would not preclude any future development of public access at other locations along the Gravesend Bay waterfront.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

Development of the Southwest Brooklyn Converted MTS would involve the redevelopment of the site of a former incinerator and the restoration of the waterfront uses at the site, and would not impair visual access to coastal lands, waters or open space. The new building would be constructed upland in about the same location as the former incinerator, which is currently being demolished. It would not allow for additional visual access, but its development would not preclude visual access from other locations along the Gravesend Bay waterfront. See also response to Subpolicy 9.1.

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

Several open space and outdoor recreational areas have been identified within the study area. The nearest areas include the Nellie Bly Amusement Park, located approximately 500 feet to the east of the site; Bensonhurst Park, located approximately 2,000 feet north of the site; and Dreier-Offerman Park, approximately 1,000 feet to the south of the site. It is not anticipated that the Southwest Brooklyn Converted MTS, once operational, would have any impact on these facilities. Waterfront activities associated with the new facility would be centralized in the vicinity of the MTS and, as such, would not result in adverse impacts to these parklands or open space areas. Therefore, the Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The Southwest Brooklyn Converted MTS would involve the development of a new facility at the site of a former incinerator, and the restoration and expansion of waterfront use at the site. It would be compatible with the existing urban design context and visual conditions of this portion of the Gravesend Bay waterfront, as noted in Section 5.7.3. Based on the information presented in that section, the Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The Southwest Brooklyn Converted MTS would pose no impact to scenic values associated with natural resources. The ongoing removal of the incinerator would open views westward, but would not necessarily create additional visual access because the Southwest Brooklyn Converted MTS would be constructed in approximately the same location. The Southwest Brooklyn Converted MTS would be compatible with existing uses in the vicinity, which do not allow for scenic views. Therefore, the Southwest Brooklyn Converted MTS is consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

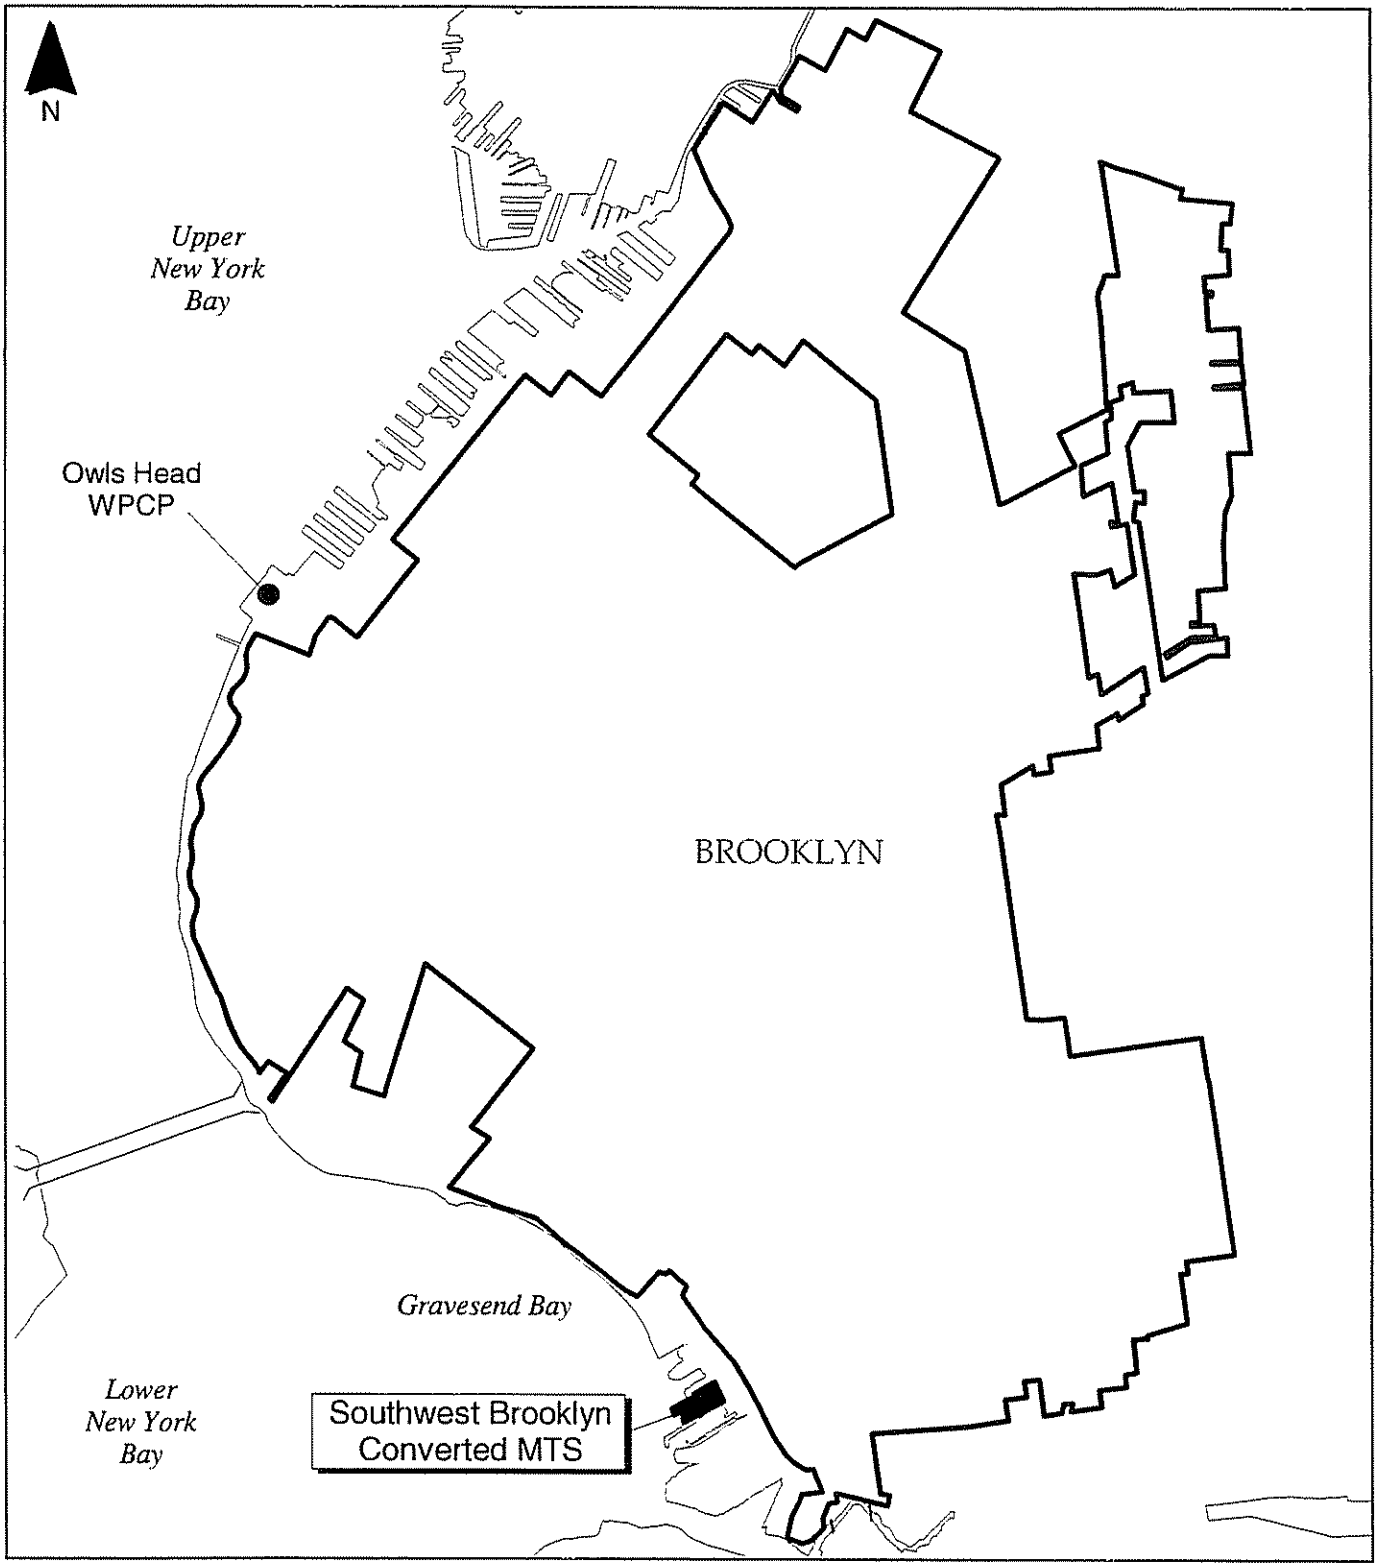
The Southwest Brooklyn Converted MTS would have no effect on any cultural resources on or near the site, as noted in Section 5.6.3. Based on the information presented in that section, the Southwest Brooklyn Converted MTS would be consistent with this subpolicy.

10.2 *Protect and preserve archaeological resources and artifacts.*

No archaeologically significant resources are located at the site or in the study area. This subpolicy, therefore, is not applicable.

5.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

5.13.1 Existing Conditions



5.13.1.1 Water Supply

Water is supplied to the existing Southwest Brooklyn MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. A 12-inch-diameter water main line along Shore Parkway provides potable water for both process and sanitary requirements. A pump is used on site to maintain adequate pressure. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

5.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Owls Head WPCP, which serves the southwestern portion of Brooklyn. The WPCP drainage area is illustrated in Figure 5.13-1. From July 2002 through June 2003, the WPCP treated an average of 95 mgd of wastewater under dry weather flow conditions and an average flow of 104 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 5.13-1). The maximum dry weather flow during this period was 99 mgd in October 2002 and the maximum average flow was 114 mgd during June 2003. Effluent from the plant is discharged to the Upper New York Bay and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the Owls Head WPCP is 120 mgd. It is estimated that current on-site employee water usage is about 75 gpd. This estimate is based on three security employees (one guard per shift, three shifts per day) using 25 gallons per person per day (2001 CEQR Technical Manual). As the facility is not currently accepting waste, no additional potable water is used and no operational personnel are assigned to the site.

As shown on the I&I maps, the site is served by a 6-inch-diameter pipe that flows to a 36-inch sanitary sewer line that flows in a southeast direction along Shore Parkway. Stormwater runoff discharges to a 96-inch storm sewer line flowing southeast along Shore Parkway. Wastewater is eventually discharged to the Owls Head WPCP for treatment.

Site delineations are approximate

Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Table 5.13-1
Average Monthly Dry Weather and Average Flows
Owls Head Water Pollution Control Plant
Fiscal Year 2003

Month	Dry Weather Flow (mgd)	Average Monthly Flow[1] (mgd)
July 2002	90	93
August	94	99
September	97	107
October	99	113
November	96	111
December	96	104
January 2003	93	99
February	91	101
March	94	103
April	95	105
May	94	102
June	98	114
Average Effluent	**95**	**104**

Note:
(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

5.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each of the three security employees at the existing MTS produces approximately 9 pounds of solid waste per week for a facility total of 27 pounds per week (approximately 4 pounds per day). The solid waste is collected by DSNY personnel and transported by truck to an appropriately licensed solid waste management facility.

5.13.1.4 Energy

Consolidated Edison of New York supplies electricity to the facility. A review of utility maps from Consolidated Edison shows electric lines along the Shore Parkway service road. Utility maps from KeySpan, which supplies gas to the existing MTS, show a 1.5-inch gas main that extends from the Shore Parkway Service Road and runs along 25th Avenue serving the facility.

The existing Southwest Brooklyn MTS utilizes a negligible amount of gas and electricity due to the current staffing levels used for security purposes only.

5.13.2 Future No-Build Conditions

The existing Southwest Brooklyn MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near the Existing Conditions levels for security employees. Wastewater flows to the Owls Head WPCP would continue to increase and would be projected to be 104.6 mgd by 2006.

5.13.3 Potential Impacts with the Southwest Brooklyn Converted MTS

5.13.3.1 Water Supply

The Southwest Brooklyn Converted MTS would have up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The Southwest Brooklyn Converted MTS would have no impact on the existing system's ability to supply water reliably. According to NYCDEP, the water pressure in the area is about 45 psi. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

5.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,300 gpd for the Southwest Brooklyn Converted MTS, the small quantities of wastewater sent to the Owl's Head WPCP would not significantly impact the sewage flow rate or the ability of the Owl's Head WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately

104.6 mgd in 2006, which would be well below the permitted capacity of 120 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

5.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees per day, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the Southwest Brooklyn Converted MTS and would not significantly impact the system.

5.13.3.4 Energy

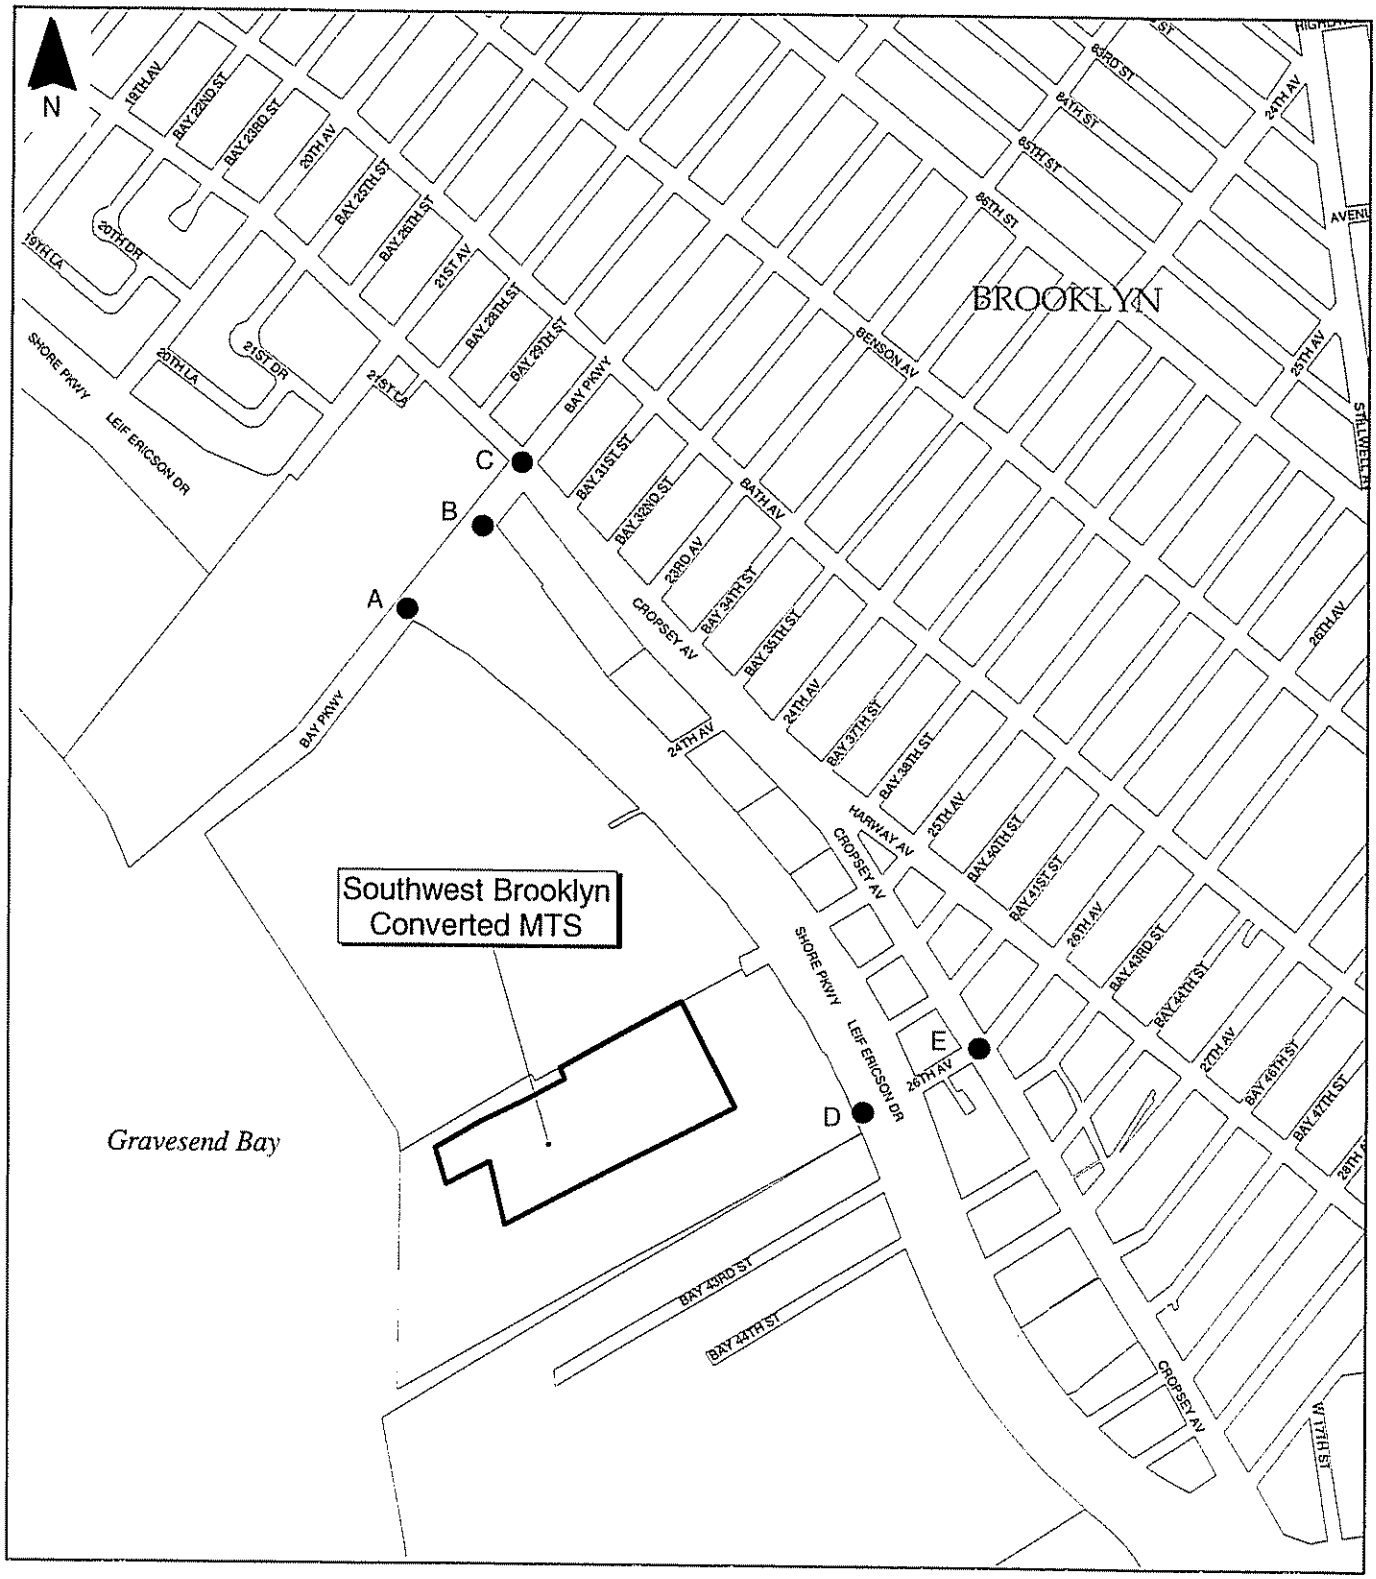
The Southwest Brooklyn Converted MTS would require approximately 5.51E+10 BTU/year of electricity to operate the facility. Natural gas facility heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the Southwest Brooklyn Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

Keyspan has been notified of the natural gas requirements of the Southwest Brooklyn Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts on the utility.

5.14 Traffic, Parking, Transit, and Pedestrians

5.14.1 Introduction



The Southwest Brooklyn Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

5.14.2 Existing Conditions

5.14.2.1 Definition of Study Area

The traffic analysis study area is broad, covering portions of the Gravesend sections of Brooklyn. It includes the corridors along Cropsey Avenue and Shore Road that are bounded by Bay Parkway on the north and 26th Avenue on the south. Commercial and residential areas are included in the traffic study area. There are no CEQR-defined areas of concern located within the study area. Figure 5.14-1 shows the locations of the intersections selected for analysis (locations A through E). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points within ½-mile of the site in conjunction with local truck routes. Section 5.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the Southwest Brooklyn Converted MTS.

DEPARTMENT OF SANITATION

5.14.2.2 Surface Network

One major parkway, the predominantly north-south Shore Parkway (Lief Ericson Drive), services the traffic analysis study area. The Shore Parkway is a controlled access highway, which prohibits commercial vehicle traffic. Cropsey Avenue is a local truck route that provides access from the south and north of the site and Bay Parkway is a local truck route that provides access to the site from the east. A map showing all major truck routes and local truck routes in Brooklyn is provided in Section 3.16 (see Figure 3.16-3).

25th and 26th Avenues are collector roads that provide access to and from the arterials of Cropsey Avenue and Shore Road (one-way southbound). Bay Parkway, another arterial, provides access to and from traffic on the Shore Parkway and Shore Road. Southbound traffic on the Shore Parkway enters and exits on Shore Road (one-way southbound) in the traffic study area.

DSNY and other agency collection vehicles traveling to the Southwest Brooklyn Converted MTS from the north or south would generally approach the area using either Cropsey Avenue or 86th Street. Vehicles approaching from the east would approach the area on Bay Parkway or 25th Avenue. All incoming traffic converges at the intersection of Cropsey Avenue and Bay Parkway and proceeds west along Bay Parkway to Shore Road (one-way southbound). Vehicles then access the Southwest Brooklyn MTS via 25th Avenue on the west side of Shore Parkway. Shore Road and 25th Avenue on the west side of Shore Parkway are not designated as truck routes. All DSNY and other agency collection vehicles exiting the facility must turn south onto Shore Road. At 26th Avenue, the vehicles turn east and then proceed to Cropsey Avenue. From Cropsey Avenue, vehicles proceed back to their respective CDs along the same truck routes that they used to access the area close to the Southwest Brooklyn Converted MTS. Figure 5.14-2 depicts NYCDOT-designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

5.14.2.3 *Existing Traffic Operations*

The five intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the Southwest Brooklyn Converted MTS. All of them are on major arterials and/or collection vehicle routes. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Shore Road (southbound) and Bay Parkway – Signalized Intersection (see Figure 5.14 -1 location A)
- Bayview Place (Shore Road - northbound) and Bay Parkway – Signalized Intersection (see Figure 5.14-1 – location B)
- Cropsey Avenue and Bay Parkway – Signalized Intersection (see Figure 5.14-1 - location C)
- Shore Road (southbound) and 26th Avenue – Unsignalized Intersection (see Figure 5.14-1 – location D)
- Cropsey Avenue and 26th Avenue – Signalized Intersection (see Figure 5.14-1 - location E)

25th and 26th Avenues are collector roads that provide access to and from the arterials of Cropsey Avenue and Shore Road (southbound). Bay Parkway, another arterial, provides access to and from northbound traffic on the Shore Parkway. Southbound traffic on the Shore Parkway enters and exits on Shore Road (southbound) in the traffic study area.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between February 5, 2003 and February 11, 2003, while ATR counts were conducted between February 3, 2003 and February 9, 2003. Figures 5.14-3, 5.14-4 and 5.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:45 a.m. and 8:45 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 5:00 p.m. and 6:00 p.m. Table 5.14-1 presents the v/c ratio, delay and LOS for the five intersections during the AM, Facility, and PM peaks.

Notes for Table 5.14-1:
(1) HCM output is included in technical backup submitted to the NYCDOT.
DFL = defacto left
LTR = left, through and right movements
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
LT = left through movement
L= left movement
TR = through right movement
R = right movement
T = through movement

Existing truck traffic varies throughout the intersections in the traffic study area. On roads that provide access to and from the Shore Parkway, truck percentages held constant between 4% and 10% throughout the day. On truck routes in the study area, the percentages of trucks generally increased throughout the morning hours, remained between 15% and 25% during midday hours, and then decreased during the PM peak hours to 5% to 15%.

5.14.2.3.1 LOS at Signalized Intersections

Table 5.14-1 shows that the existing signalized intersections generally operated at an overall LOS of B or C with the following exceptions:

- During the AM and PM peak hours, the intersections of Cropsey Avenue at Bay Parkway and Shore Road (southbound) at Bay Parkway operate at an overall LOS D;
- The eastbound left/through/right lane group at Cropsey Avenue and 26th Avenue operates at LOS D for the AM, Facility, and PM peak hours; and
- During the AM and PM peak hours, the intersection of Shore Road and Bay Parkway operates at an overall LOS D or E.

5.14.2.3.2 LOS at Unsignalized Intersections

The one unsignalized intersection analyzed operates at LOS A or B throughout the day as shown in Table 5.14-1.

5.14.2.4 Existing DSNY-Related Traffic

Under Brooklyn's Interim Export, there are no commercial vendors located close to the Southwest Brooklyn Converted MTS. However, DSNY and other agency collection vehicles pass through the traffic study area on truck routes from Queens CDs 11 and 13 to the commercial vendor, IESI, located at 110 50th Street in Brooklyn. Collection vehicles from these two CDs pass through all intersections analyzed in the study area.

5.14.2.5 Public Transportation

Public transportation in the study area consists predominantly of bus trips. The B6 travels in a loop entering the study area going west on Bay Parkway, then south on Shore Road, east on 26th Avenue, north on Cropsey Avenue and exits the study area on Bay Parkway; and the X28, X38 and B82 run north-south along Cropsey Avenue. Bus stops are located at some of the study area intersections analyzed, and scheduled stops occur at various times during the day.

5.14.2.6 Pedestrian Activity

Light pedestrian activity occurs along Cropsey Avenue in the traffic study area where restaurants and commercial and residential areas produce and attract pedestrians throughout the day. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.

5.14.3 Future No-Build Conditions

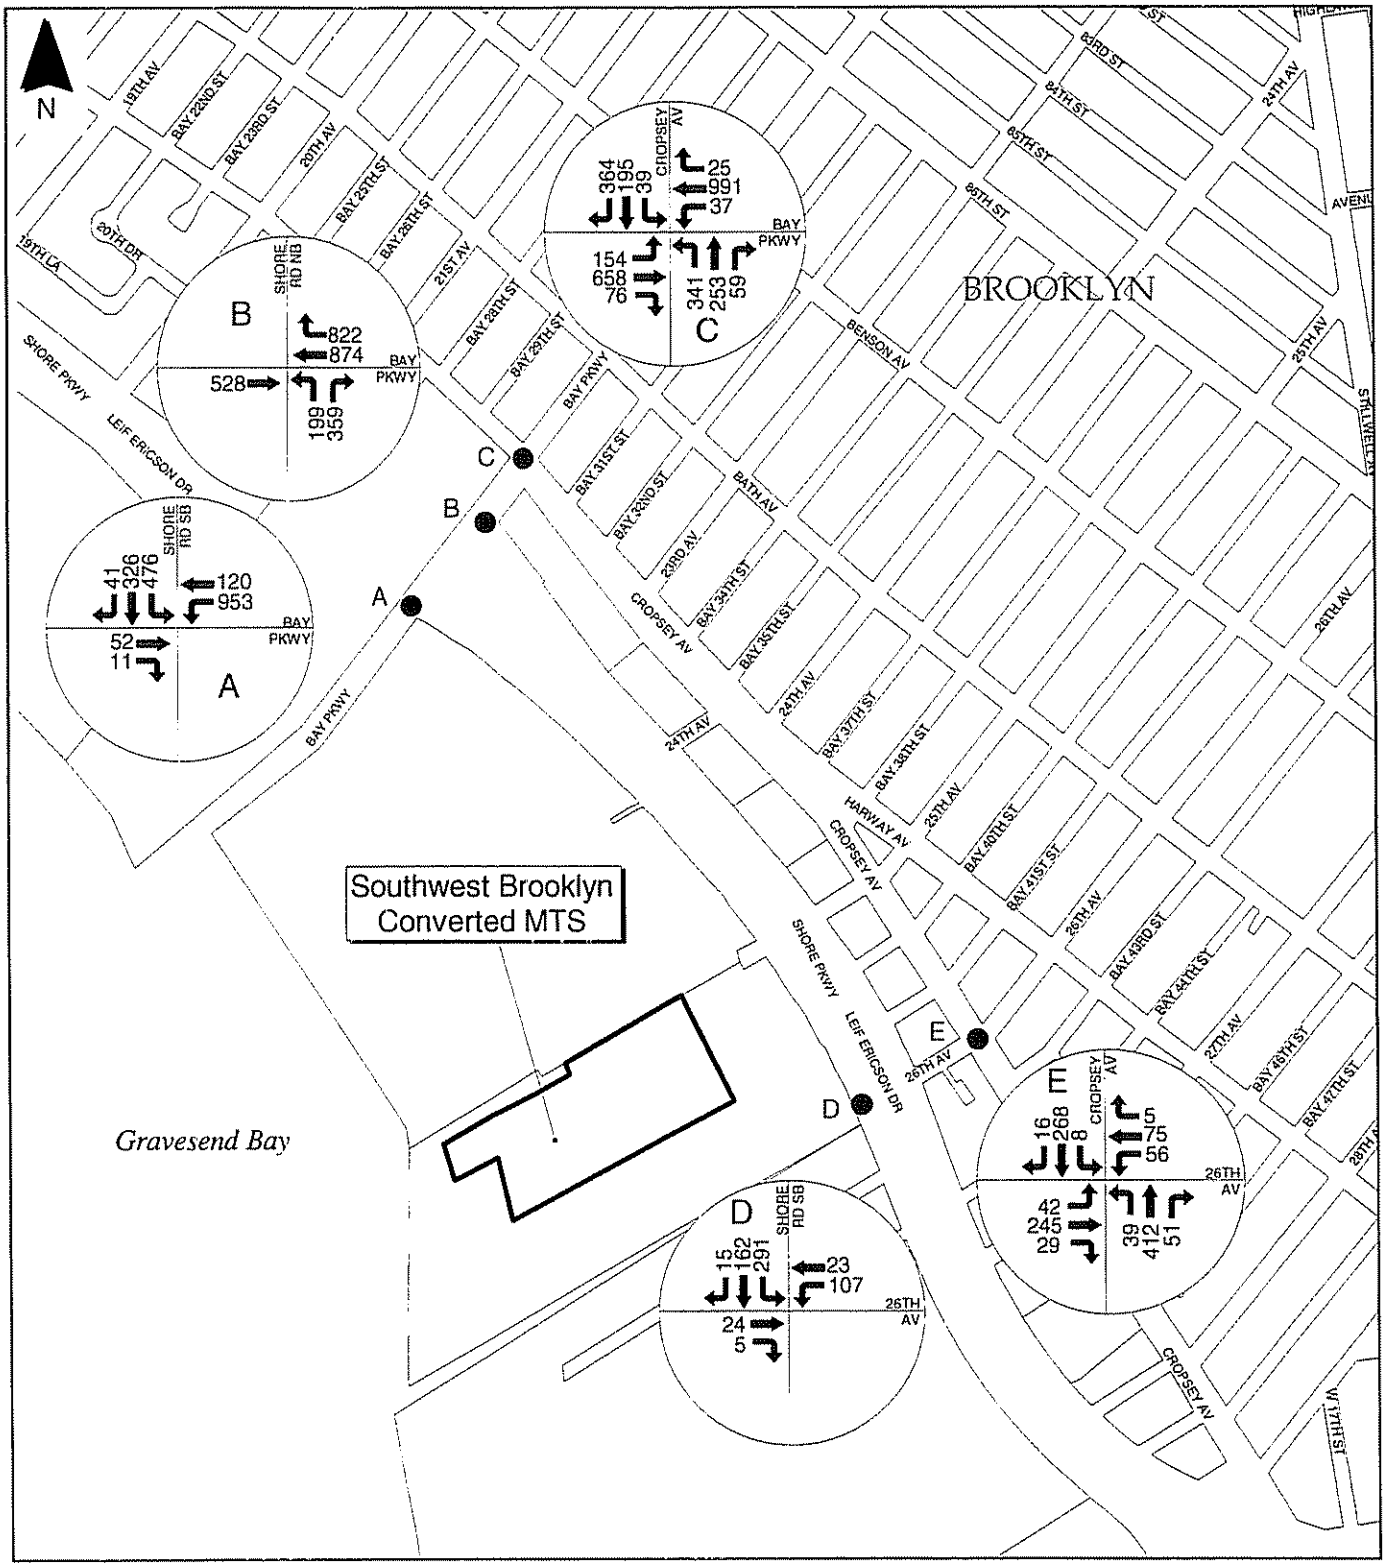
5.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 130 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes.

Figures 5.14-6, 5.14-7 and 5.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 5.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, signalized intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their existing condition LOS, with the following exceptions:

- During the PM peak hour, the overall LOS of the Shore Road (southbound) and Bay Parkway intersection deteriorated from D to E; and
- During the PM peak hour, the overall LOS of the Shore Road (southbound) and 26th Avenue intersection deteriorated from A to B.

5.14.3.2 Public Transportation



Future No-Build Conditions are expected to remain the same as Existing Conditions.

5.14.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

5.14.4 Potential Impacts with the Southwest Brooklyn Converted MTS

The Southwest Brooklyn Converted MTS would receive waste from four CDs in Brooklyn - BK 11 through BK 13 and BK 15. Additionally, the waste collected from Brooklyn self-help bulk (SHBLK) operations would be delivered to the Southwest Brooklyn Converted MTS. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Employee trips to and from the site may also result in traffic impacts during the AM peak hour.

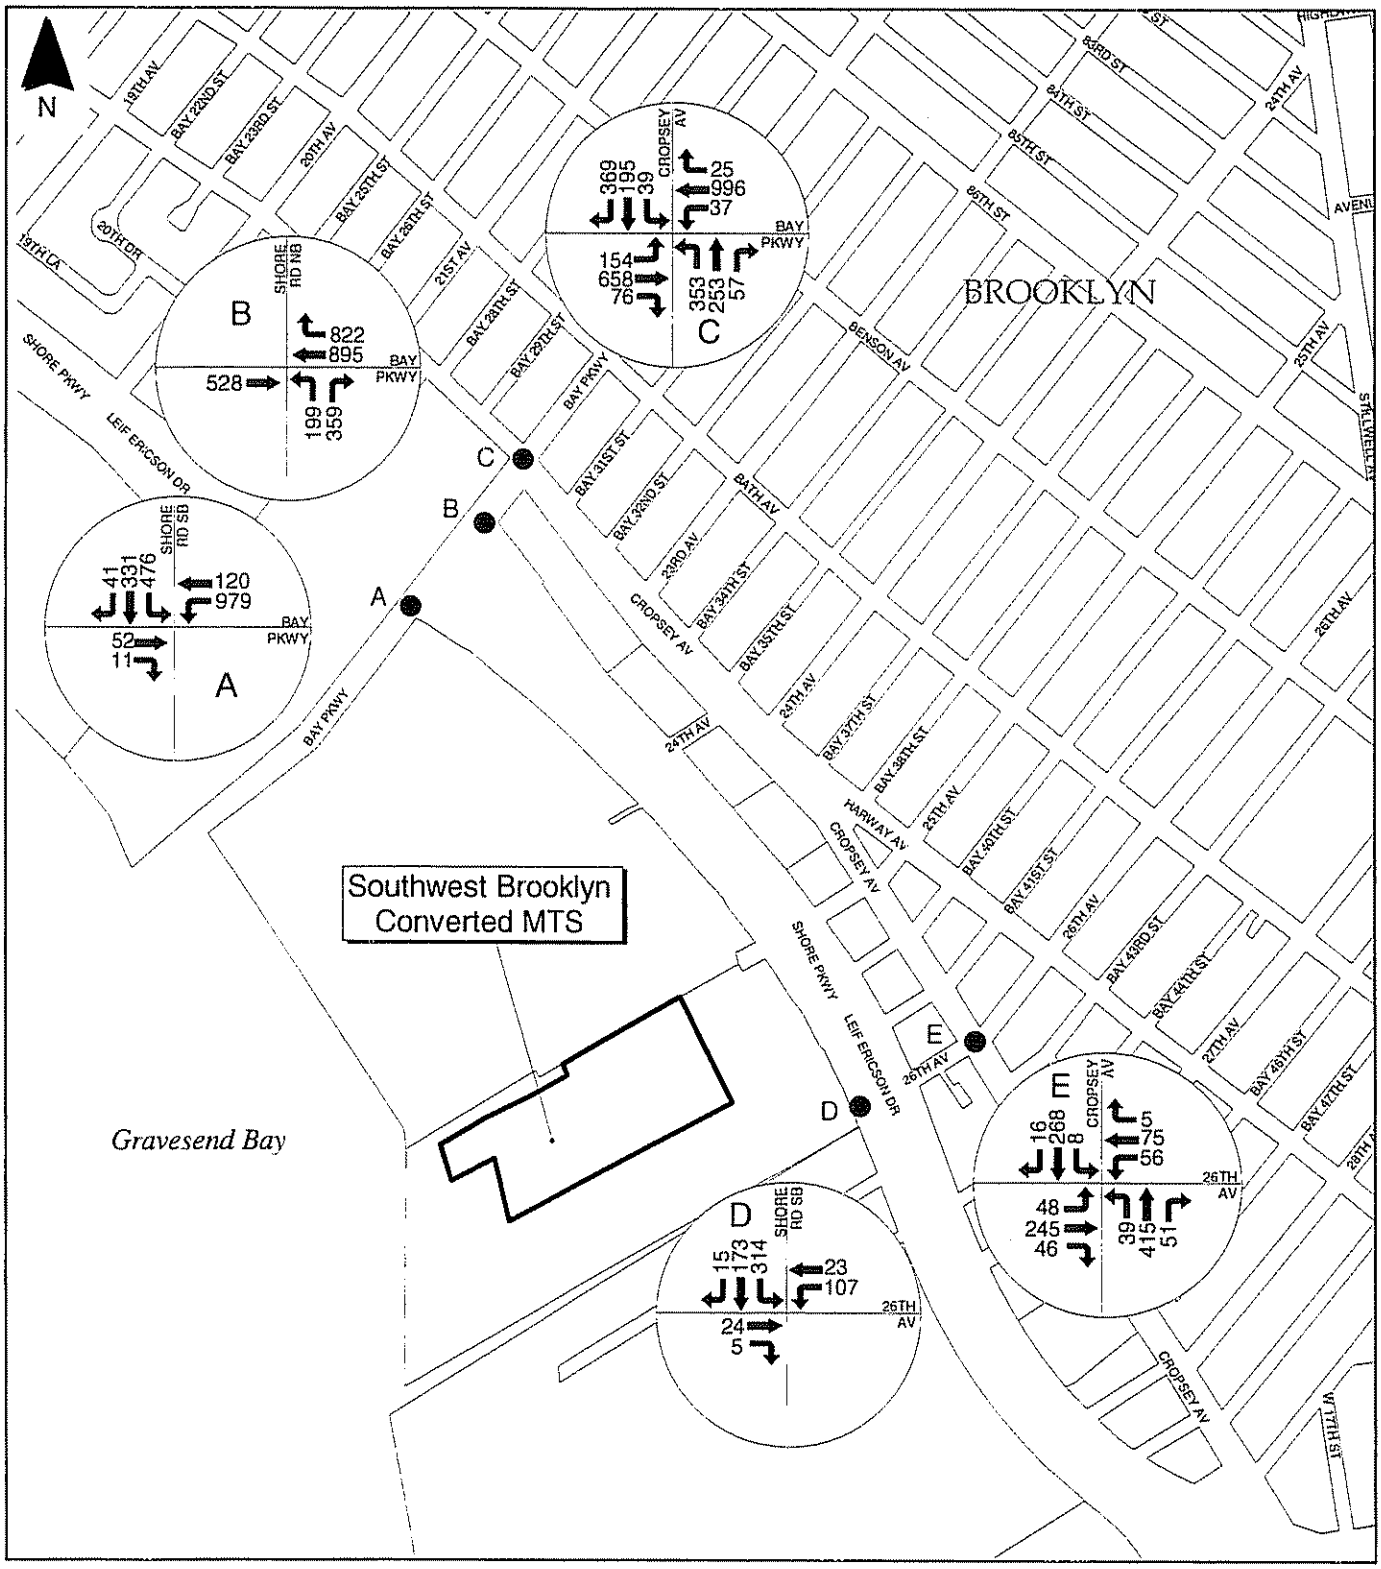
5.14.4.1 2006 Future Build Traffic Conditions



2006 Future Build Traffic Conditions assume that the Southwest Brooklyn Converted MTS would generate 166 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site of the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The collection vehicle truck routes for the Southwest Brooklyn Converted MTS are shown in Figure 5.14-2.

Figure 5.14-9 presents the average peak day temporal distribution of collection vehicles for the Southwest Brooklyn Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the Southwest Brooklyn Converted MTS is expected to vary between approximately 0 to 13 truck trips per hour in the late evening/early morning, 4 to 28 truck trips per hour in the mid-morning/early afternoon, and 1 to 5 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (28) occurs at approximately 10:00 a.m. Figures 5.14-10, 5.14-11 and 5.14-12 depict the Future Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Figures 5.14-13, 5.14-14 and 5.14-15 depict the net future traffic volumes added to the Future No-Build Conditions to generate Future Build Conditions for AM, Facility, and PM peaks at the intersections analyzed.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 85% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 98% of weekday traffic volumes.

Table 5.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Southwest Brooklyn Converted MTS would not operate on Sundays. It was~~,~~ therefore~~,~~ ~~judged~~ determined that a peak weekday analysis would represent the worst overall case conditions.

Table 5.14-3
Weekday and Weekend Traffic

DSNY and Other Agency Collection Vehicle Traffic		**Background Traffic EB and WB on Bay Parkway [1]**	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday Average Vehicles/Day	Weekend Average Vehicles/Day
166	142	49,605	48,773

Note:
(1) EB and WB traffic data collected from ATR counts taken on Bay Parkway between Bayview Place and Cropsey Avenue from September 11 to 17, 2003.

Table 5.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Southwest Brooklyn Converted MTS. Over an average peak day, the intersections should not experience an extended increase in delay. The three intersections that may experience potentially significant impacts are discussed in Section 5.14.4.2 and summarized in Table 5.14-5.

5.14.4.2 Impacts and Mitigation

Three of the five intersections may experience impacts great enough to be considered significant during only one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines require mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below; their effectiveness is summarized in Table 5.14-5.

L= left movement

TR = through right movement

R = right movement

T = through movement

Cropsey Avenue/Bay Parkway – During the AM peak hour, a potential impact was identified on the northbound left-turn lane group when the delay increased from 61.1 seconds to 67.1 seconds (LOS E in both cases). An increase in green time of one second for the northbound-only approach should eliminate this unacceptable increase in delay. To avoid this timing change causing impacts to other lane groups, it would be necessary to increase the eastbound only approach by one second and decrease the eastbound and westbound approach green time by one second. In addition to signal timing changes, new movements would be added to two of the signal phases. During the eastbound-only phase, a southbound right-turn-only movement would be added from the right-turn-only lane of the southbound approach. Also during the eastbound-only phase, a semi-actuated left turn from the westbound left-turn-only approach would be added. During the northbound-only phase, a semi-actuated movement would be added from the southbound approach. The two semi-actuated movements would create a left-turn-only phase during which vehicles would simultaneously make left turns from two directions when a queue forms in the semi-actuated lanes. When no queues are present in the semi-actuated left-turn-only lanes, the signals would allow traffic movements from one direction only (eastbound or northbound) during the phase. Compared to Future No-Build Conditions, eastbound approach delay times would remain approximately the same, westbound and northbound approach delay times would increase between two and four seconds, and southbound approach times would decrease by over 25 seconds.

Cropsey Avenue/26th Avenue – During the AM peak hour, a potential impact was identified on the eastbound left/through/right lane group when the delay increased from 49.1 seconds to 64.1 seconds. An increase in the green time of two seconds for the eastbound and westbound approaches should eliminate the delay increase. This mitigation measure decreases the northbound and southbound approach green time by two seconds. The northbound, southbound and eastbound approach delay times would increase by approximately one to two seconds and the westbound approach delay would decrease by less than three seconds compared to Future No-Build Conditions. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

Shore Road (southbound)/Bay Parkway – During the AM peak hour, a potential impact was identified on the southbound left-turn lane group when the delay increased from 71.4 seconds to 76.1 seconds (LOS E in both cases). An increase in green time of one second for the southbound approach should eliminate this unacceptable increase in delay. This mitigation measure decreases the eastbound and westbound approach green time by one second. With this mitigation, the westbound and eastbound approach delay time would increase by one second and the southbound approach time would decrease three seconds compared to Future No-Build Conditions. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

In addition to the two intersections that may experience impacts, the Shore Road (southbound) and site entrance/exit intersection (section of 25th Avenue) may also require low-cost and easily implemented mitigation. Even though traffic operations at this intersection should not affect traffic significantly along Shore Road, some improvements near the intersection would need to be considered, such as restricting parking along Shore Road within the vicinity of the intersection to improve site distance at the site entrance/exit. There is an existing stop sign at the site exit. This mitigation should not generate any adverse impacts on other lane groups during any time periods.

Overall, the mitigation measures suggested would greatly enhance the intersection performance by reducing delays to LOSs similar to those under the Future No-Build Conditions.

5.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

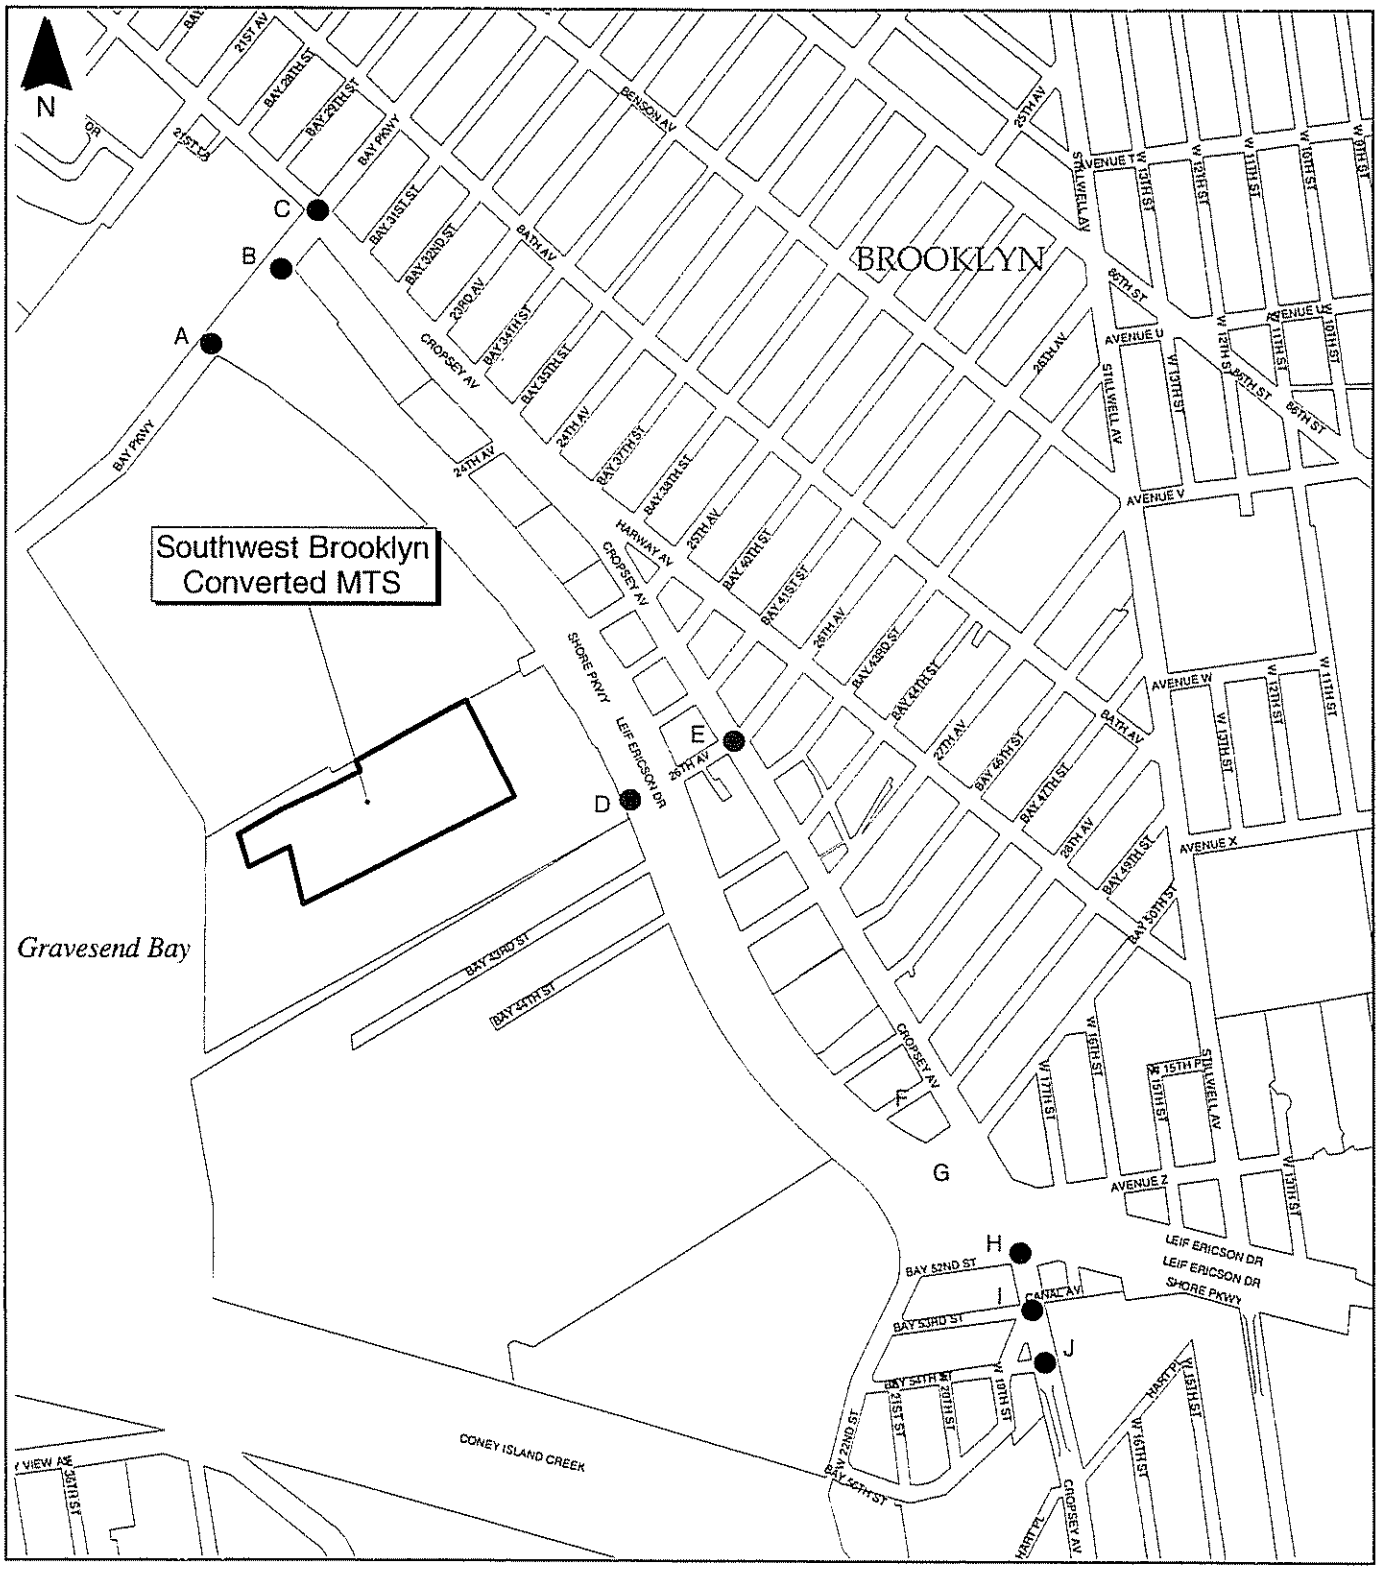
5.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

5.14a Traffic, Parking, Transit, and Pedestrians - Alternative Route

5.14a.1 Introduction

The Southwest Brooklyn Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)



Due to comments received at the CB 11 ULURP public meeting, an alternate route for vehicles exiting the facility was selected for analysis. The original and alternate routes are described below in section 5.14a2.2.

5.14a.2 Existing Conditions

5.14a.2.1 Definition of Study Area

The traffic analysis study area is broad, covering portions of the Gravesend sections of Brooklyn. It includes the corridors along Cropsey Avenue and Shore Road that are bounded by Bay Parkway on the north and Bay 54th Street on the south. Commercial and residential areas are included in the traffic study area. There are no CEQR-defined areas of concern located within the study area. Figure 5.14a.-1 shows the locations of the intersections selected for analysis (locations A through J). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points within ¾-mile of the site in conjunction with local truck routes. Section 5.14a.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the Southwest Brooklyn Converted MTS.

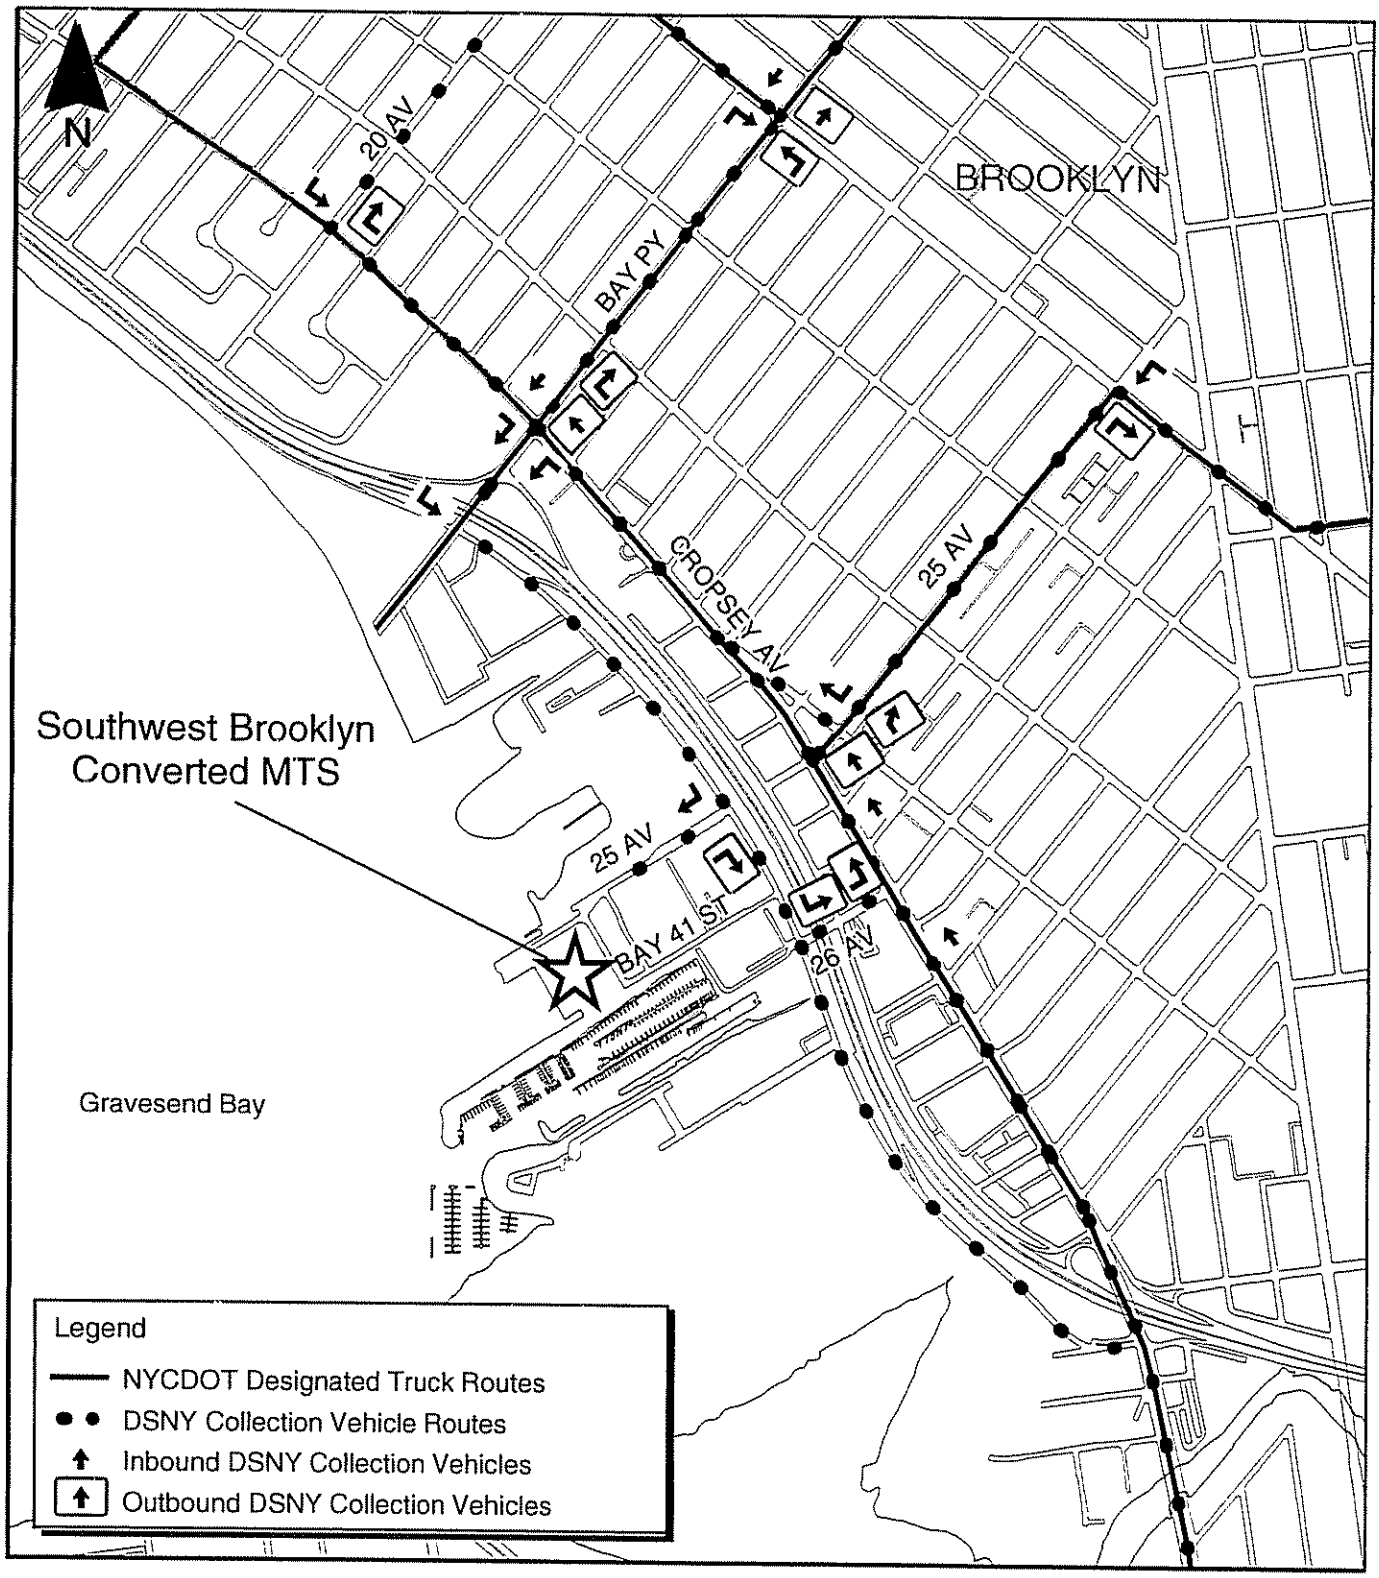
5.14a.2.2 Surface Network

One major parkway, the predominantly north-south Shore Parkway (Lief Ericson Drive), services the traffic analysis study area. The Shore Parkway is a controlled access highway, which prohibits commercial vehicle traffic. Cropsey Avenue is a local truck route that provides access from the south and north of the site and Bay Parkway is a local truck route that provides access to the site from the east. A map showing all major truck routes and local truck routes in Brooklyn is provided in Section 3.16 (see Figure 3.16-3).

25th and 26th Avenues are collector roads that provide access to and from the arterials of Cropsey Avenue and Shore Road (one-way southbound). Bay Parkway, another arterial, provides access to and from traffic on the Shore Parkway and Shore Road. Southbound traffic on the Shore Parkway enters and exits on Shore Road (one-way southbound) in the traffic study area.

For this Alternate route, DSNY and other agency collection vehicles traveling to the Southwest Brooklyn Converted MTS from the north or south would generally approach the area using either Cropsey Avenue or 86th Street. Vehicles approaching from the east would approach the area on Bay Parkway or 25th Avenue. All incoming traffic converges at the intersection of Cropsey Avenue and Bay Parkway and proceeds west along Bay Parkway to Shore Road (one-way southbound). Vehicles then access the Southwest Brooklyn MTS via 25th Avenue on the west side of Shore Parkway. Shore Road and 25th Avenue on the west side of Shore Parkway are not designated as truck routes. All DSNY collection vehicles exiting the facility must turn south onto Shore Road. At 26th Avenue, the collection vehicles from only CD 11 turn east and then proceed to Cropsey Avenue. All collection vehicles from CDs 12, 13, and 15 will continue south on Shore Road past 26th Avenue to Bay 52nd Street. Shore Road merges into Bay 52nd Street and then intersects Cropsey Avenue.[11] From Cropsey Avenue, collection vehicles from all CDs proceed back to their respective CDs along the same truck routes that they used to access the area close to



[11] In the original traffic analysis discussed in Section 5.14, collection vehicles from all CDs assigned to the Southwest Brooklyn converted TMS turned east onto 26th Avenue from Shore Road to proceed to Cropsey Avenue.

the Southwest Brooklyn Converted MTS. Figure 5.14a-2 depicts NYCDOT-designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

5.14a.2.3 Existing Traffic Operations

The five intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the Southwest Brooklyn Converted MTS. All of them are on major arterials and/or collection vehicle routes. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Shore Road (southbound) and Bay Parkway – Signalized Intersection (see Figure 5.14a -1 location A)
- Bayview Place (Shore Road - northbound) and Bay Parkway – Signalized Intersection (see Figure 5.14a-1 – location B)
- Cropsey Avenue and Bay Parkway – Signalized Intersection (see Figure 5.14a-1 - location C)
- Shore Road (southbound) and 26th Avenue – Unsignalized Intersection (see Figure 5.14a-1 – location D)
- Cropsey Avenue and 26th Avenue – Signalized Intersection (see Figure 5.14a-1 - location E)
- Cropsey Avenue and Bay 49th Street – Signalized Intersection (see Figure 5.14a-1 - location F)
- Cropsey Avenue and Bay 50th Street – Signalized Intersection (see Figure 5.14a-1 - location G)
- Cropsey Avenue and Canal Avenue and Bay 52nd Street – Signalized Intersection (see Figure 5.14a-1 - location H)
- Cropsey Avenue and Bay 53rd Street – Signalized Intersection (see Figure 5.14a-1 - location I)
- Cropsey Avenue and Bay 54th Street – Signalized Intersection (see Figure 5.14a-1 - location J)

Site delineations are approximate.

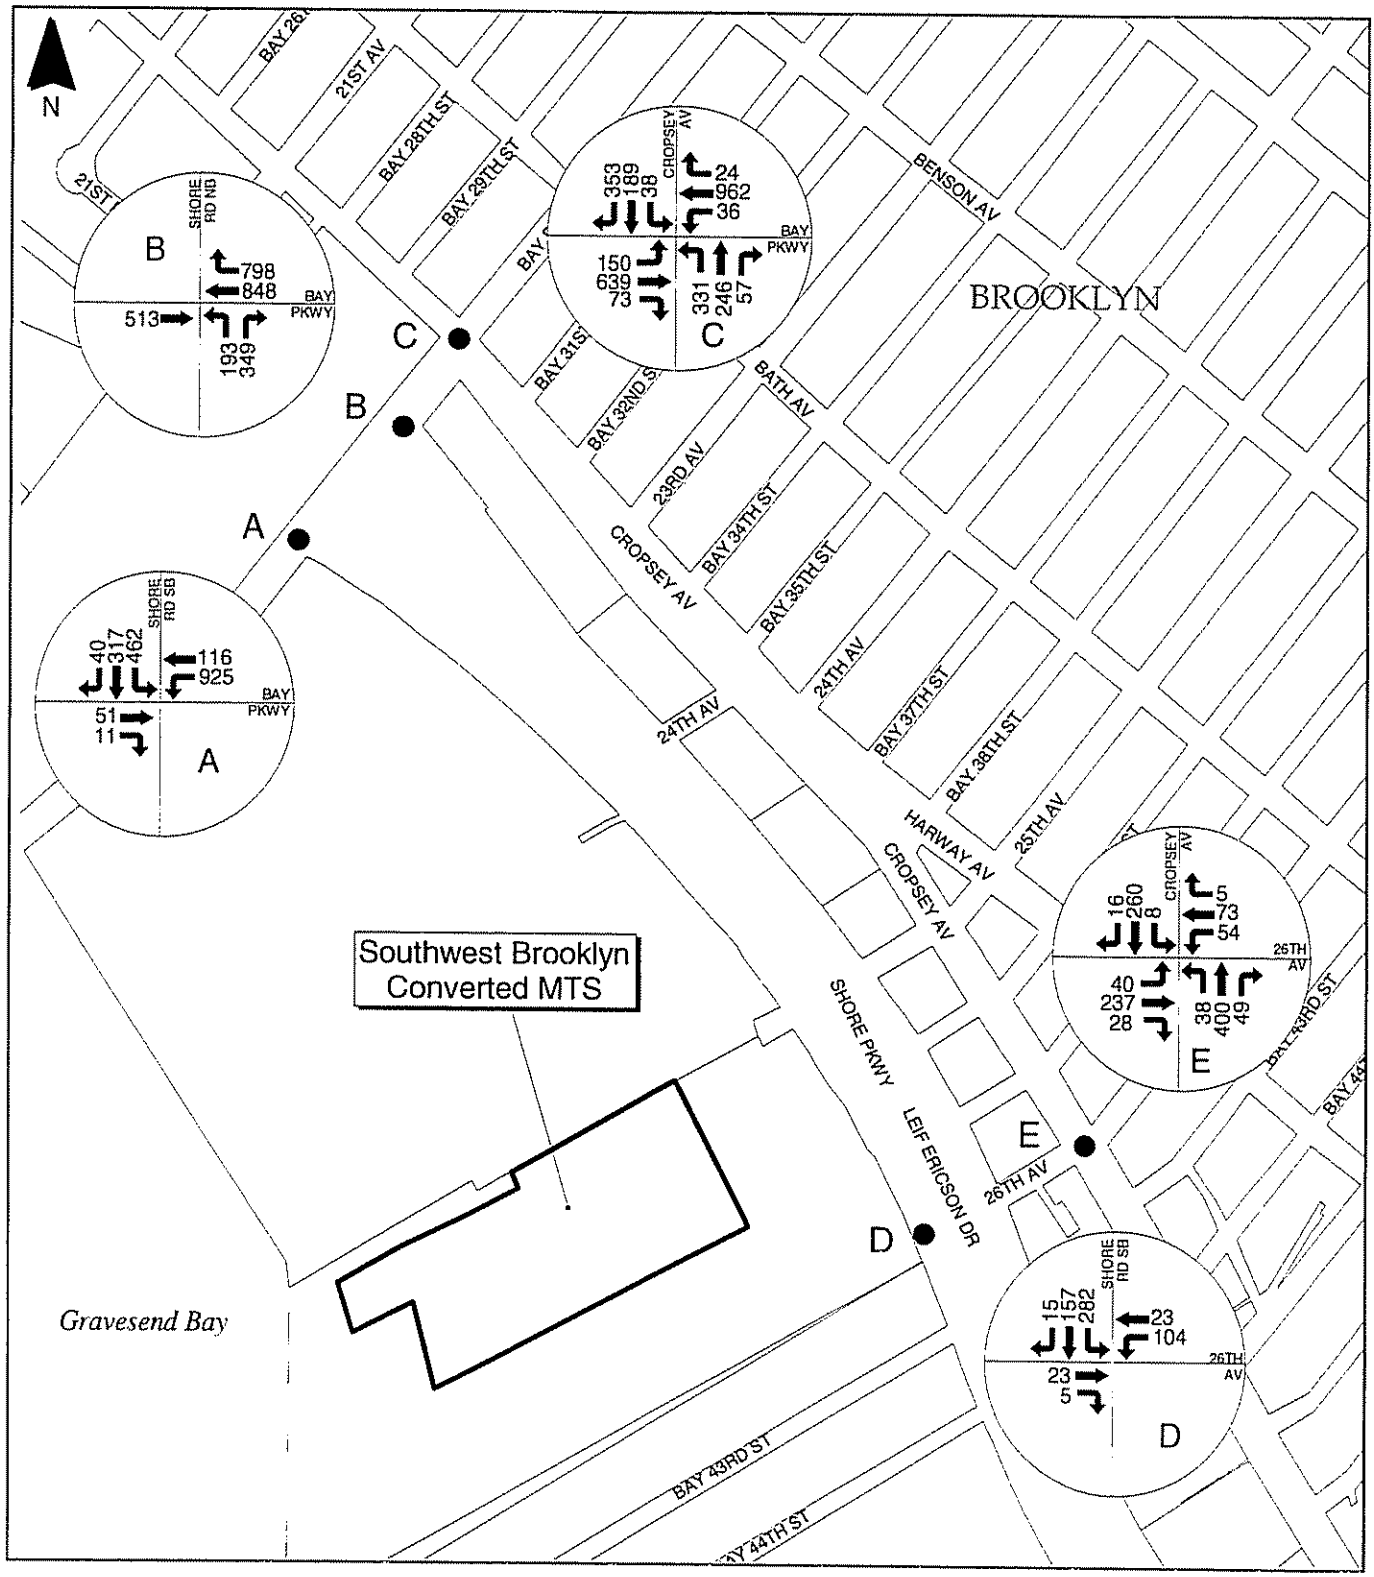
THE CITY OF NEW YORK DEPARTMENT OF SANITATION

25th and 26th Avenues are collector roads that provide access to and from the arterials of Cropsey Avenue and Shore Road (southbound). Bay Parkway, another arterial, provides access to and from northbound traffic on the Shore Parkway. Southbound traffic on the Shore Parkway enters and exits on Shore Road (southbound) in the traffic study area. Bay 49th, 50th, 52nd, 53rd, and 54th Streets, and Canal Avenue are all local roads.



A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). For locations A through E, manual turning movement counts were conducted between February 5, 2003 and February 11, 2003, while ATR counts were conducted between February 3, 2003 and February 9, 2003. Since this Alternate route was proposed in January 2005, for additional locations F through J, manual turning movement counts were conducted on January 27, 2005, while ATR counts were conducted between January 26, 2005 and February 2, 2005. Figures 5.14a-3, through 5.14a-8 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:45 a.m. and 8:45 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 5:00 p.m. and 6:00 p.m. Table 5.14a-1 presents the v/c ratio, delay and LOS for the ten intersections during the AM, Facility, and PM peaks.

Existing truck traffic varies throughout the intersections in the traffic study area. On roads that provide access to and from the Shore Parkway, truck percentages held constant between 4% and 10% throughout the day. On truck routes in the study area, the percentages of trucks generally increased throughout the morning hours, remained between 15% and 25% during midday hours, and then decreased during the PM peak hours to 5% to 15%.

5.14a.2.3.1 LOS at Signalized Intersections

Table 5.14a-1 shows that the existing signalized intersections generally operated at an overall LOS of B or C with the following exceptions:

- During the AM and PM peak hours, the intersections of Cropsey Avenue at Bay Parkway and Shore Road (southbound) at Bay Parkway operate at an overall LOS D;

OVERALL		17.4	B		15.4	B		16.0	B

Notes for Table 5.14a-1:

[1] HCM output is included in technical backup submitted to the NYCDOT.

DFL = defacto left

LTR = left, through and right movements

NB = northbound

SB = southbound

EB = eastbound

WB = westbound

LT = left through movement

L= left movement

TR = through right movement

R = right movement

T = through movement

- The eastbound left/through/right lane group at Cropsey Avenue and 26th Avenue operates at LOS D for the AM, Facility, and PM peak hours;
- During the AM and PM peak hours, the intersection of Shore Road and Bay Parkway operates at an overall LOS D or E;
- The northbound left lane group at Cropsey Avenue and Bay 50th Street operates at LOS E for the PM peak hour; and
- The eastbound left lane group at Cropsey Avenue and Bay 54th Street operates at LOS D for the AM peak hour.

5.14a.2.3.2 LOS at Unsignalized Intersections

The one unsignalized intersection analyzed operates at LOS A or B throughout the day as shown in Table 5.14a-1.

5.14a.2.4 Existing DSNY-Related Traffic

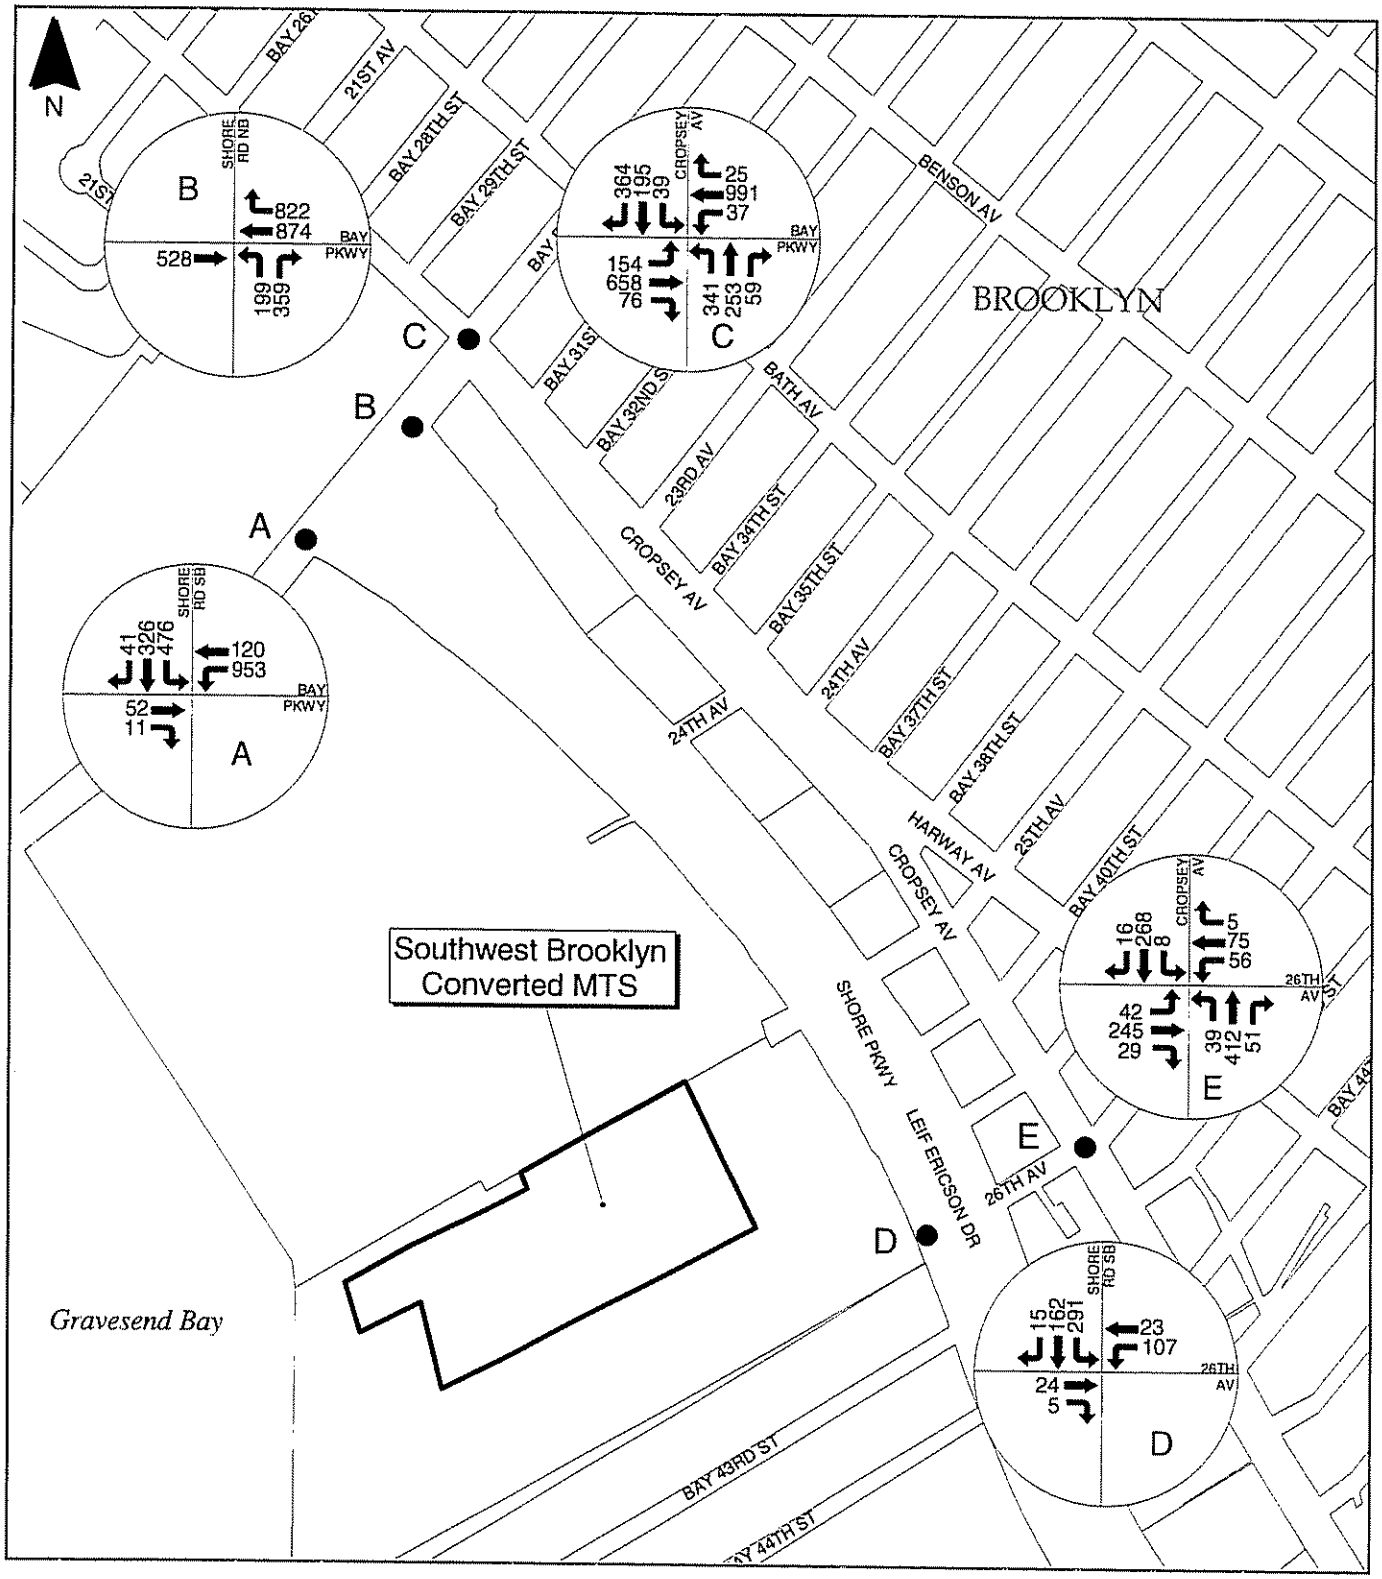
Under Brooklyn's Interim Export, there are no commercial vendors located close to the Southwest Brooklyn Converted MTS. However, DSNY and other agency collection vehicles pass through the traffic study area on truck routes from Queens CDs 11 and 13 to the commercial vendor, IESI, located at 110 50th Street in Brooklyn. Collection vehicles currently pass through all intersections analyzed in the study area under the Interim Export Program.

5.14a.2.5 Public Transportation

Public transportation in the study area consists predominantly of bus trips. The B6 travels in a loop entering the study area going west on Bay Parkway, then south on Shore Road, east on 26th Avenue, north on Cropsey Avenue and exits the study area on Bay Parkway; and the X28, X38 and B82 run north-south along Cropsey Avenue. Bus stops are located at some of the study area intersections analyzed, and scheduled stops occur at various times during the day.

5.14a.2.6 Pedestrian Activity

Light pedestrian activity occurs along Cropsey Avenue in the traffic study area where restaurants and commercial and residential areas produce and attract pedestrians throughout the day. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.



5.14a.3 Future No-Build Conditions

5.14a.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 130 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes.

Figures 5.14a-9 through 5.14a-14 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 5.14a-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, signalized intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their existing condition LOS, with the following exceptions:

- During the PM peak hour, the overall LOS of the Shore Road (southbound) and Bay Parkway intersection deteriorated from D to E;
- During the PM peak hour, the overall LOS of the Shore Road (southbound) and 26th Avenue intersection deteriorated from A to B;
- During the AM peak hour, the LOS of the southbound left/ through lane group at the intersection of Cropsey Avenue and Bay 49th Street deteriorated from C to D;
- During the Facility peak hour, the LOS of the southbound through/ right lane group at the intersection of Cropsey Avenue and Bay 50th Street deteriorated from B to C;
- During the PM peak hour, the LOS of the westbound left/ through/ right lane group at the intersection of Cropsey Avenue and Bay 50th Street deteriorated from C to D;
- During the PM peak hour, the LOS of the northbound left lane group at the intersection of Cropsey Avenue and Bay 50th Street deteriorated from D to E;
- During the PM peak hour, the LOS of the eastbound left lane group at the intersection of Cropsey Avenue and Bay 52nd Street deteriorated from B to C; and
- During the AM peak hour, the LOS of the northbound left lane group at the intersection of Cropsey Avenue and Bay 54th Street deteriorated from B to C.

5.14a.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

5.14a.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

5.14a.4Potential Impacts with the Southwest Brooklyn Converted MTS

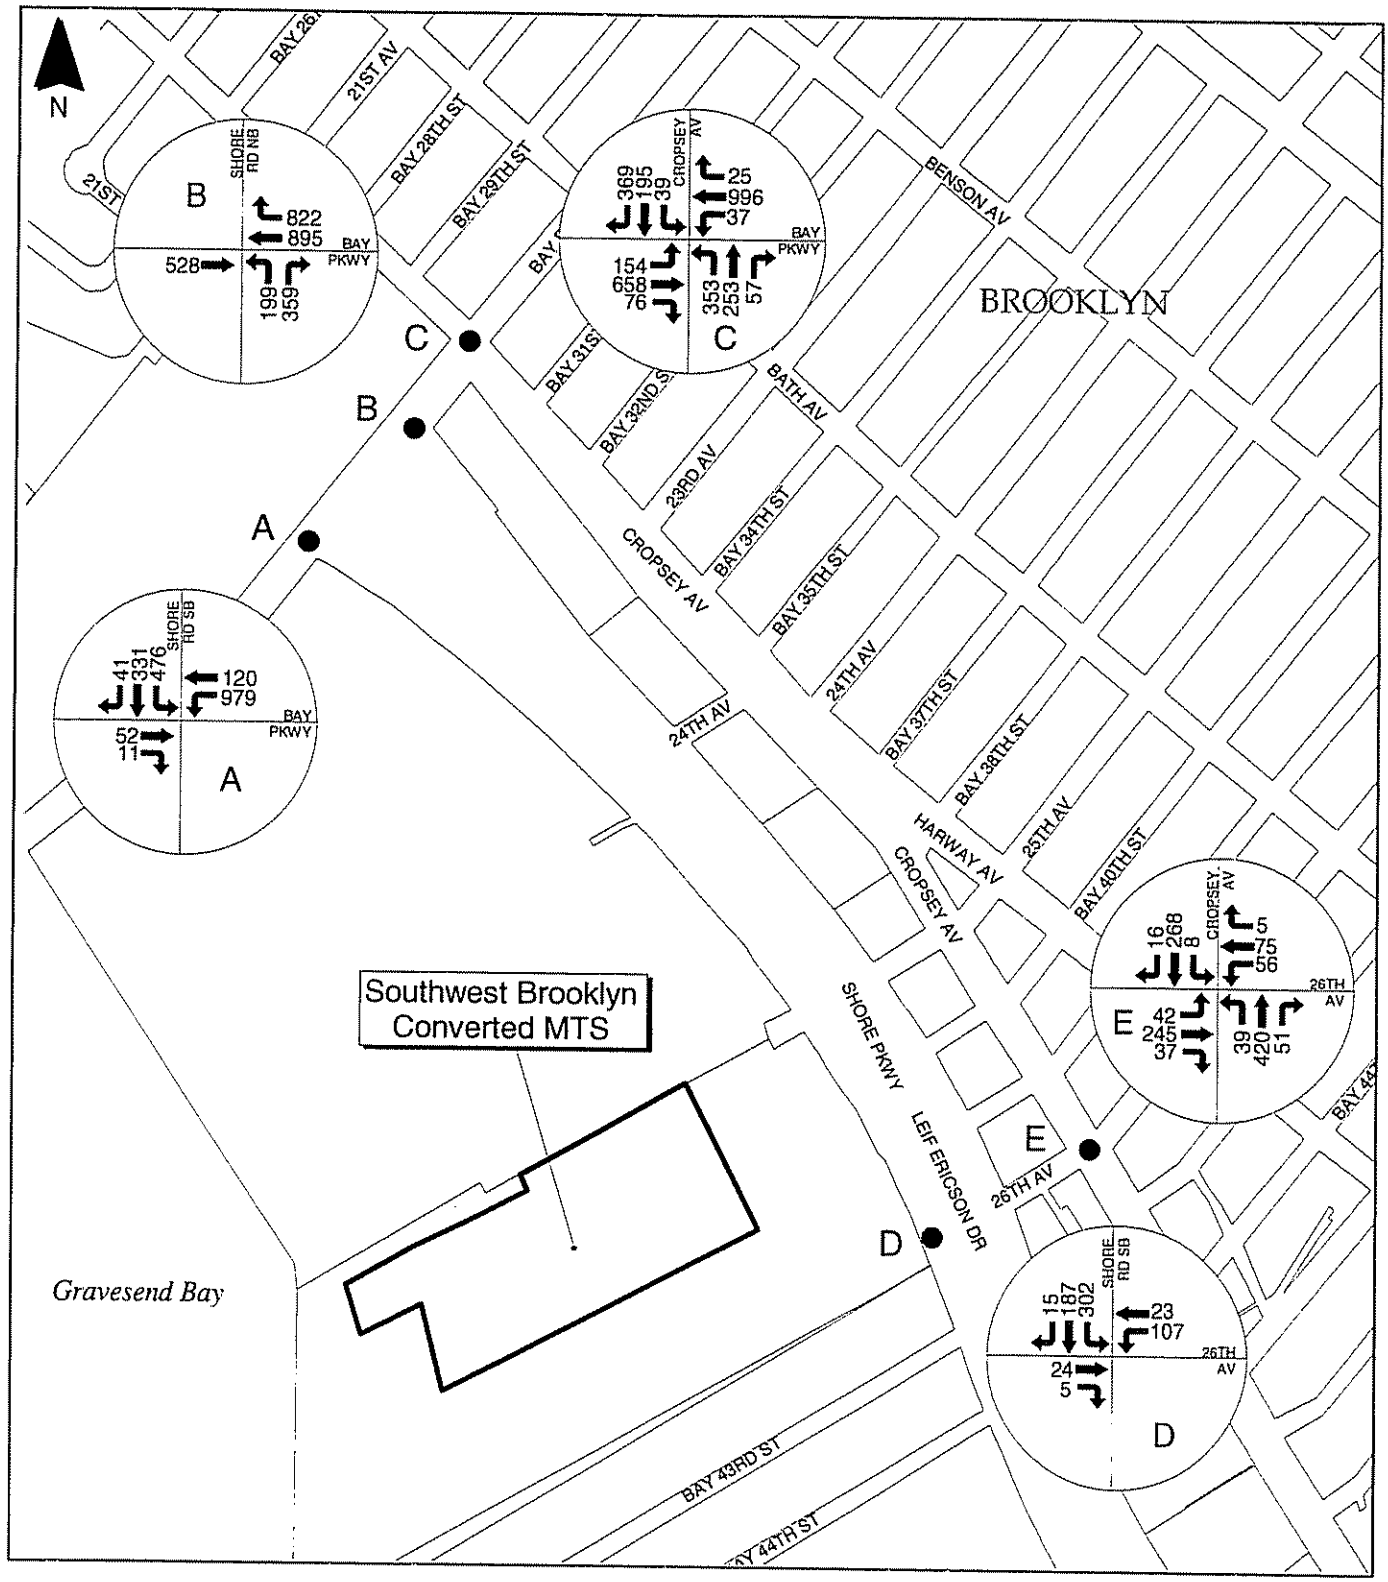
The Southwest Brooklyn Converted MTS would receive waste from four CDs in Brooklyn - BK 11 through BK 13 and BK 15. Additionally, the waste collected from Brooklyn self-help bulk (SHBLK) operations would be delivered to the Southwest Brooklyn Converted MTS. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Employee trips to and from the site may also result in traffic impacts during the AM peak hour.

5.14a.4.1 2006 Future Build Traffic Conditions

2006 Future Build Traffic Conditions assume that the Southwest Brooklyn Converted MTS would generate 166 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site of the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The collection vehicle truck routes for the Southwest Brooklyn Converted MTS are shown in Figure 5.14a-2.

Figure 5.14-9 in Section 5.14 presents the average peak day temporal distribution of collection vehicles for the Southwest Brooklyn Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the Southwest Brooklyn Converted MTS is expected to vary between approximately 0 to 13 truck trips per hour in the late evening/early morning, 4 to 28 truck trips per hour in the mid-morning/early afternoon, and 1 to 5 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection

vehicle truck trips (28) occurs at approximately 10:00 a.m. Figures 5.14a-15, through 5.14a-20 depict the Future Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Figures 5.14a-21 through 5.14a-26 depict the net future traffic volumes added to the Future No-Build Conditions to generate Future Build Conditions for AM, Facility, and PM peaks at the intersections analyzed.



The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 85% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 98% of weekday traffic volumes.

Table 5.14a-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Southwest Brooklyn Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the worst overall case conditions.

Table 5.14a-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Southwest Brooklyn Converted MTS. Over an average peak day, the intersections should not experience an extended increase in delay. The two intersections that may experience potentially significant impacts are discussed in Section 5.14a.4.2 and summarized in Table 5.14a-5.

5.14a.4.2 Impacts and Mitigation

Two of the ten intersections may experience impacts great enough to be considered significant during only one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines require mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below; their effectiveness is summarized in Table 5.14a-5.

NB = northbound
SB = southbound
EB = eastbound
WB = westbound
L= left movement
TR = through right movement
R = right movement
T = through movement

Cropsey Avenue/Bay Parkway – During the AM peak hour, a potential impact was identified on the northbound left-turn lane group when the delay increased from 61.1 seconds to 67.1 seconds (LOS E in both cases). An increase in green time of one second for the northbound-only approach should eliminate this unacceptable increase in delay. To avoid this timing change causing impacts to other lane groups, it would be necessary to increase the eastbound only approach by one second and decrease the eastbound and westbound approach green time by one second. In addition to signal timing changes, new movements would be added to two of the signal phases. During the eastbound-only phase, a southbound right-turn-only movement would be added from the right-turn-only lane of the southbound approach. Also during the eastbound-only phase, a semi-actuated left turn from the westbound left-turn-only approach would be added. During the northbound-only phase, a semi-actuated movement would be added from the southbound approach. The two semi-actuated movements would create a left-turn-only phase during which vehicles would simultaneously make left turns from two directions when a queue forms in the semi-actuated lanes. When no queues are present in the semi-actuated left-turn-only lanes, the signals would allow traffic movements from one direction only (eastbound or northbound) during the phase. Compared to Future No-Build Conditions, eastbound approach delay times would remain approximately the same, westbound and northbound approach delay times would increase between two and four seconds, and southbound approach times would decrease by over 25 seconds.

Shore Road (southbound)/Bay Parkway – During the AM peak hour, a potential impact was identified on the southbound left-turn lane group when the delay increased from 71.4 seconds to 76.1 seconds (LOS E in both cases). An increase in green time of one second for the southbound approach should eliminate this unacceptable increase in delay. This mitigation measure decreases the eastbound and westbound approach green time by one second. With this mitigation, the westbound and eastbound approach delay time would increase by one second and the southbound approach time would decrease three seconds compared to Future No-Build Conditions. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

In addition to the two intersections that may experience impacts, the Shore Road (southbound) and site entrance/exit intersection (section of 25th Avenue) may also require low-cost and easily implemented mitigation. Even though traffic operations at this intersection should not affect traffic significantly along Shore Road, some improvements near the intersection would need to be considered, such as restricting parking along Shore Road within the vicinity of the intersection to improve site distance at the site entrance/exit. There is an existing stop sign at the site exit. This mitigation should not generate any adverse impacts on other lane groups during any time periods.

Overall, the mitigation measures suggested would greatly enhance the intersection performance by reducing delays to LOSs similar to those under the Future No-Build Conditions.

5.14a.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

5.14a.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

5.15 Air Quality

5.15.1 Definition of Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Southwest Brooklyn Converted MTS. The study area for the off-site air quality analysis is the intersections listed in Section 5.15.4.2.

5.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 5.15.1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 5.15-1
Representative Ambient Air Quality Data
Southwest Brooklyn Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	MTA, Flatbush Avenue between Tillary Street and Johnson Avenue	8-Hour	3,436 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	4,695 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	College Point Post Office	Annual	56 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}[(2)]	P.S. 314	Annual	25 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	55 $\mu g/m^3$	150 $\mu g/m^3$
SO_2	P.S. 321	3-Hour	152 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	94 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	24 $\mu g/m^3$	80 $\mu g/m^3$

Notes:
Source: NYCDEP, April 2003 & USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.
(2) Values are the highest pollutant levels recorded during the 1998 calendar year.

5.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the No-Build analysis year (2006). As such, no significant changes to air quality levels are anticipated, and Future No-Build Conditions are expected to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be reduced by increasingly stringent, federally mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

5.15.4 Potential Impacts with the Southwest Brooklyn Converted MTS

5.15.4.1 On-Site Analysis

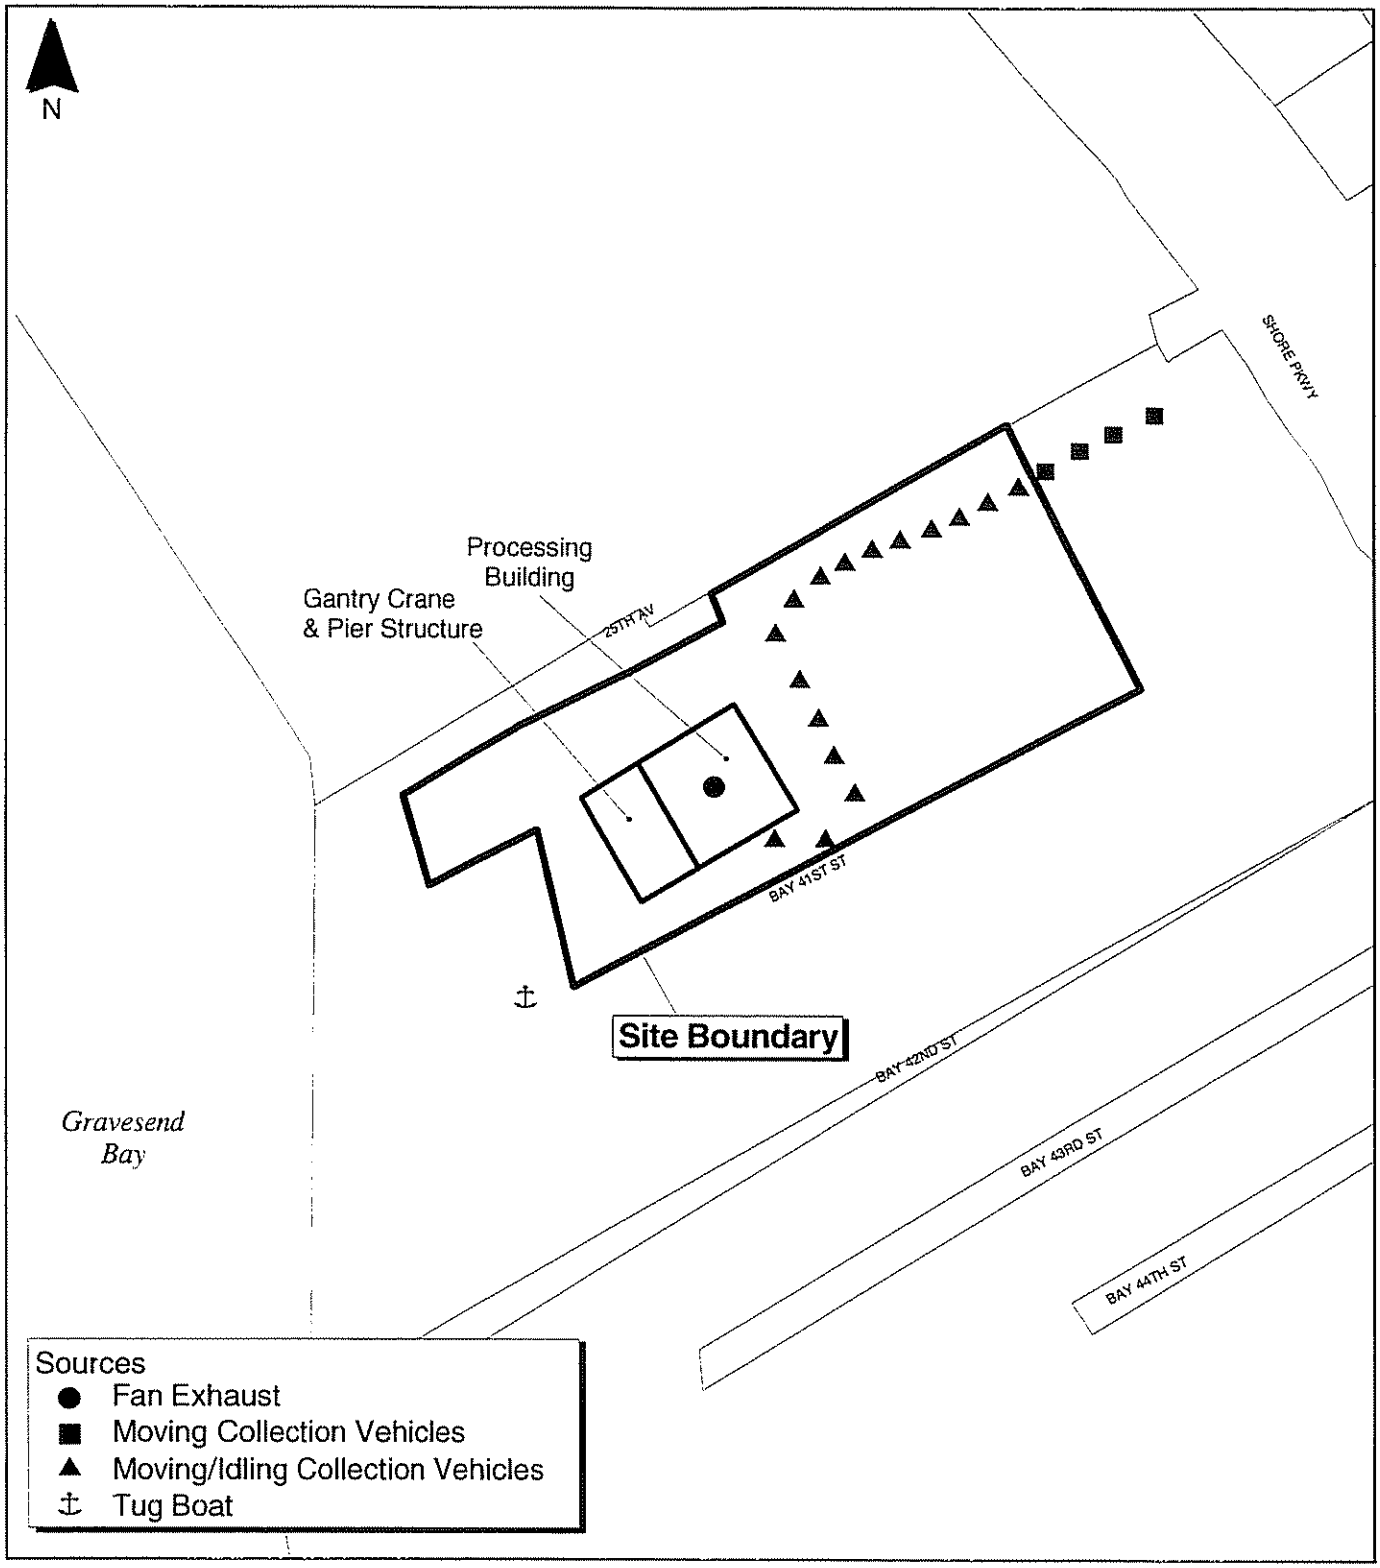
5.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 5.15-2. Figure 5.15-1 shows the locations of these sources within the site.

5.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 5.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from Southwest Brooklyn Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 5.15-3, are below the STVs. Based on the results presented in Table 5.15-3, operations at the Southwest Brooklyn Converted MTS would not significantly impact air quality in the area.

Table 5.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
Southwest Brooklyn Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated Over 24-hour and Annual Average Periods
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	46	6
Space Heaters	6	4
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3]	35 in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~to be provided upon request.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (one third of 35), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

Site delineations are approximate

	Annual Neighborhood Average	0.025[5]	NA	NA	NA	0.1
Sulfur Dioxide (SO_2), $\mu g/m^3$	3-hour[6]	35	~~152~~186	~~187~~221	1,300	NA
	24-hour[6]	2	~~94~~107	~~96~~109	365	NA
	Annual	0.3	~~24~~18	~~24~~18	80	NA

Notes:
(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.
(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~ memorandum dated February 18, 2005..
(3) NAAQS = National Ambient Air Quality Standard.
(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.
(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.
(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.
(7) The 24-hour PM_{10} NAAQS is based on a 99_{th} percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.
NA = Not Applicable

5.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 5.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by USEPA as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Southwest Brooklyn Converted MTS are not considered to be significant.

5.15.4.2 Off-Site Analysis

5.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations that may be significantly impacted by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, detailed mobile source analyses were conducted at the following locations for the applicable (i.e., worst-case) time periods:

- The intersections of 26th Avenue at Cropsey Avenue, 26th Avenue at Shore Parkway Service Road South, Bay Parkway at Cropsey Avenue, and Bay Parkway at Shore Parkway (North and South) to determine whether Southwest Brooklyn Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and

- The intersections of 26th Avenue at Cropsey Avenue, 26th Avenue at Shore Parkway Service Road South, Bay Parkway at Cropsey Avenue, and Bay Parkway at Shore Parkway (North and South) to determine whether Southwest Brooklyn Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

Notes to Table 5.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGCs) established by NYSDEC.

(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGCs) established by NYSDEC

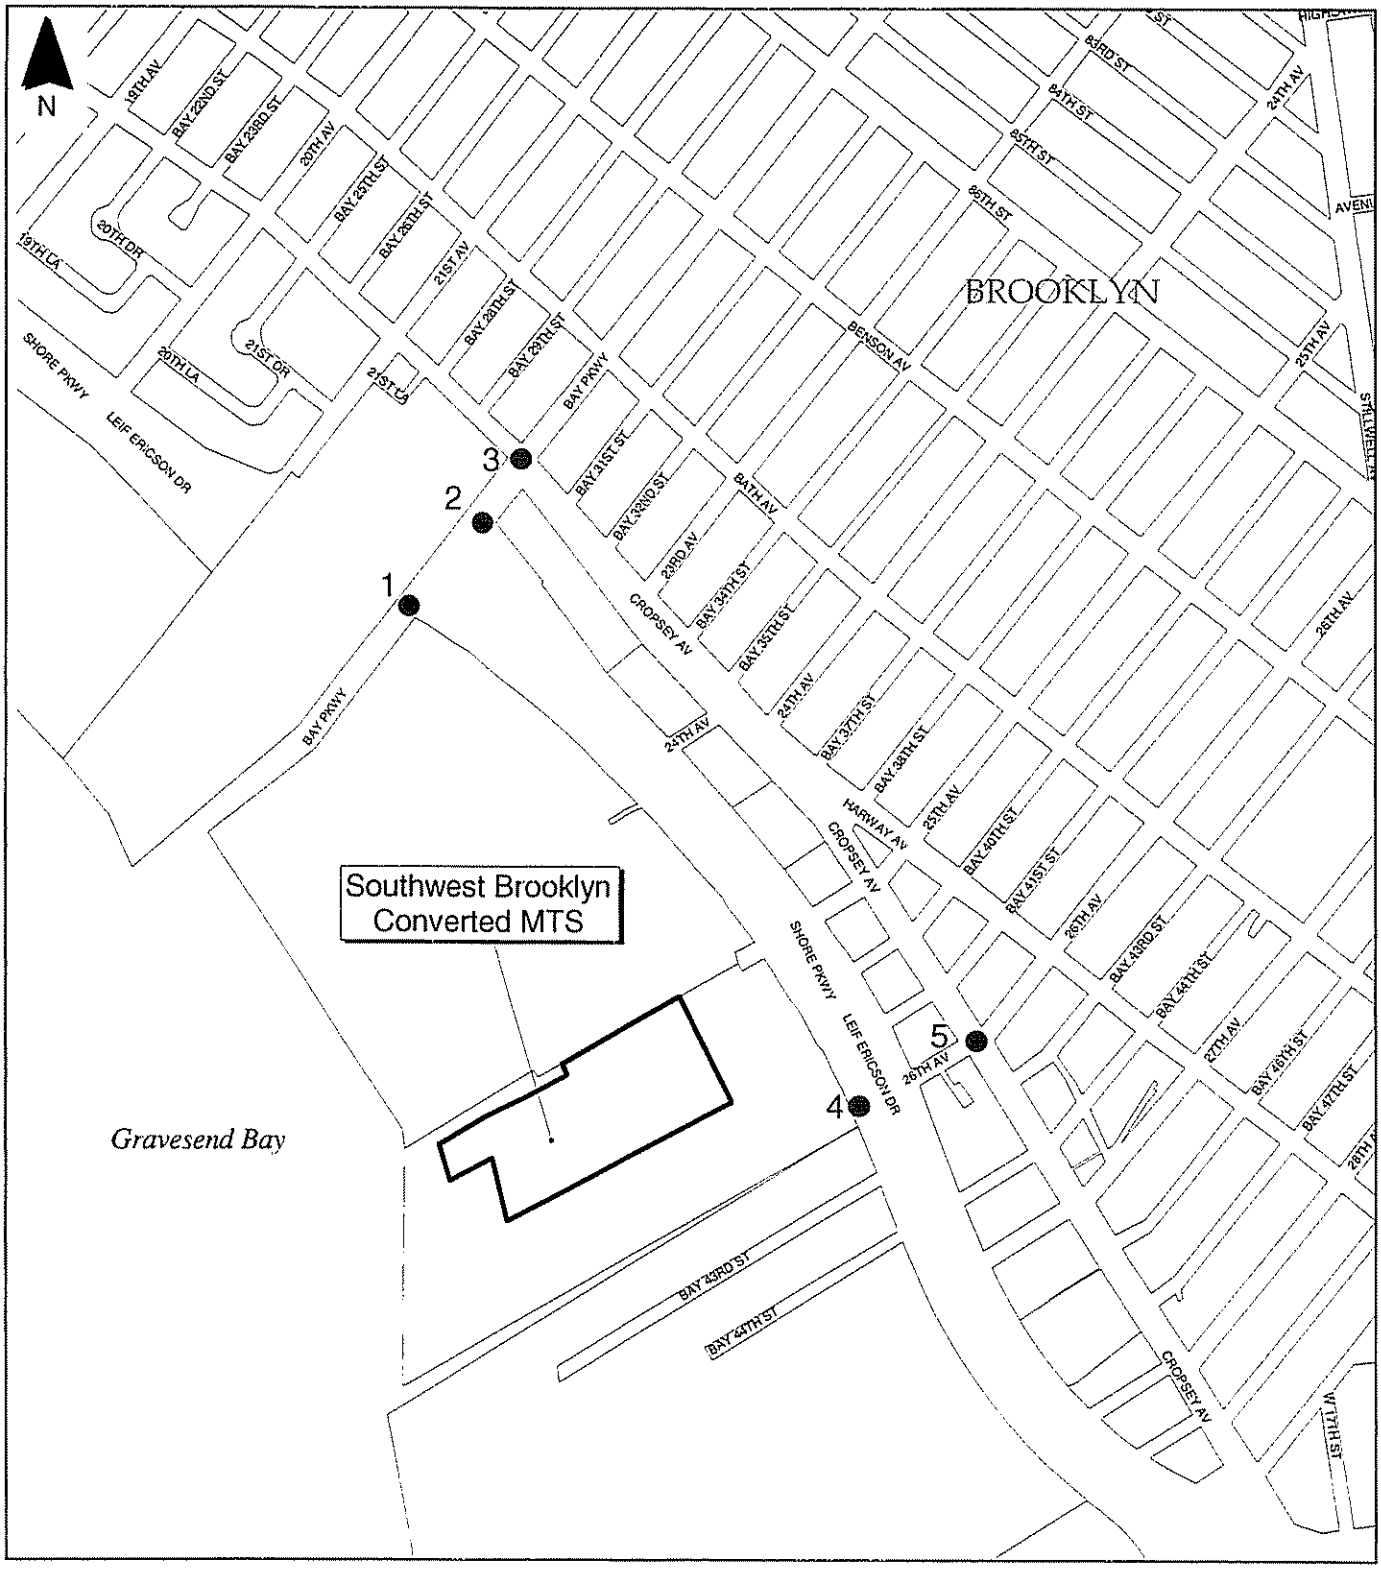
(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.

(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.



(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

NA = Not Applicable

The roadway intersections selected for the mobile source analysis are shown in Figure 5.15-2.

5.15.4.2.2 Results of the Off-Site Analysis

Applicable maximum pollutant concentrations estimated near the selected intersections are shown in Table 5.15-5. The results for all applicable pollutants at the intersections of 26th Avenue at Cropsey Avenue and 26th Avenue at Shore Parkway Service Road South were within (less than) the applicable state and federal ambient air quality standards and STVs (for $PM_{2.5}$). A Tier II analysis for the intersection at Bay Parkway at Cropsey Avenue and Shore Parkway (North and South) was necessary to determine the off-site annual and 24-hour impacts for PM_{10}, and the annual neighborhood impacts for $PM_{2.5}$. The results of this Tier II analysis for all pollutants at this intersection are within the applicable state and federal ambient air quality standards STVs (for $PM_{2.5}$). Therefore, the off-site operations of the Southwest Brooklyn Converted MTS are not considered to be significant.

5.15a Air Quality - Alternative Route

5.15a.1 Definition of Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Southwest Brooklyn Converted MTS. The study area for the off-site air quality analysis of this Alternative route is the intersections listed in Section 5.15a.4.2.

5.15a.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 5.15a.1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 5.15a-1
Representative Ambient Air Quality Data
Southwest Brooklyn Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[1]	MTA, Flatbush Avenue between Tillary Street and Johnson Avenue	8-Hour	3.436 µg/m^3	10.000 µg/m^3
		1-Hour	4.695 µg/m^3	40.000 µg/m^3
NO_2	College Point Post Office	Annual	56 µg/m^3	100 µg/m^3
PM_{10}[2]	P.S. 314	Annual	25 µg/m^3	50 µg/m^3
		24-Hour	55 µg/m^3	150 µg/m^3
SO_2	P.S. 321	3-Hour	152 µg/m^3	1.300 µg/m^3
		24-Hour	94 µg/m^3	365 µg/m^3
		Annual	24 µg/m^3	80 µg/m^3

Notes:
Source: NYCDEP. April 2003 & USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(3) Values are the highest pollutant levels recorded during the 2003 calendar year.
(4) Values are the highest pollutant levels recorded during the 1998 calendar year.

5.15a.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the No-Build analysis year (2006). As such, no significant changes to air quality levels are anticipated, and Future No-Build Conditions are expected to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be reduced by increasingly stringent, federally mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

5.15a.4 Potential Impacts with the Southwest Brooklyn Converted MTS

5.15a.4.1 On-Site Analysis

5.15a.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are the same as those in Table 5.1.5-2 and the locations of these sources within the site are the same as those shown in Figure 5.15-1.

5.15a.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are the same as those presented in Table 5.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from Southwest Brooklyn Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 5.15-3, are below the STVs. Based on the results presented in Table 5.15-3, operations at the Southwest Brooklyn Converted MTS using this Alternative route would not significantly impact air quality in the area.

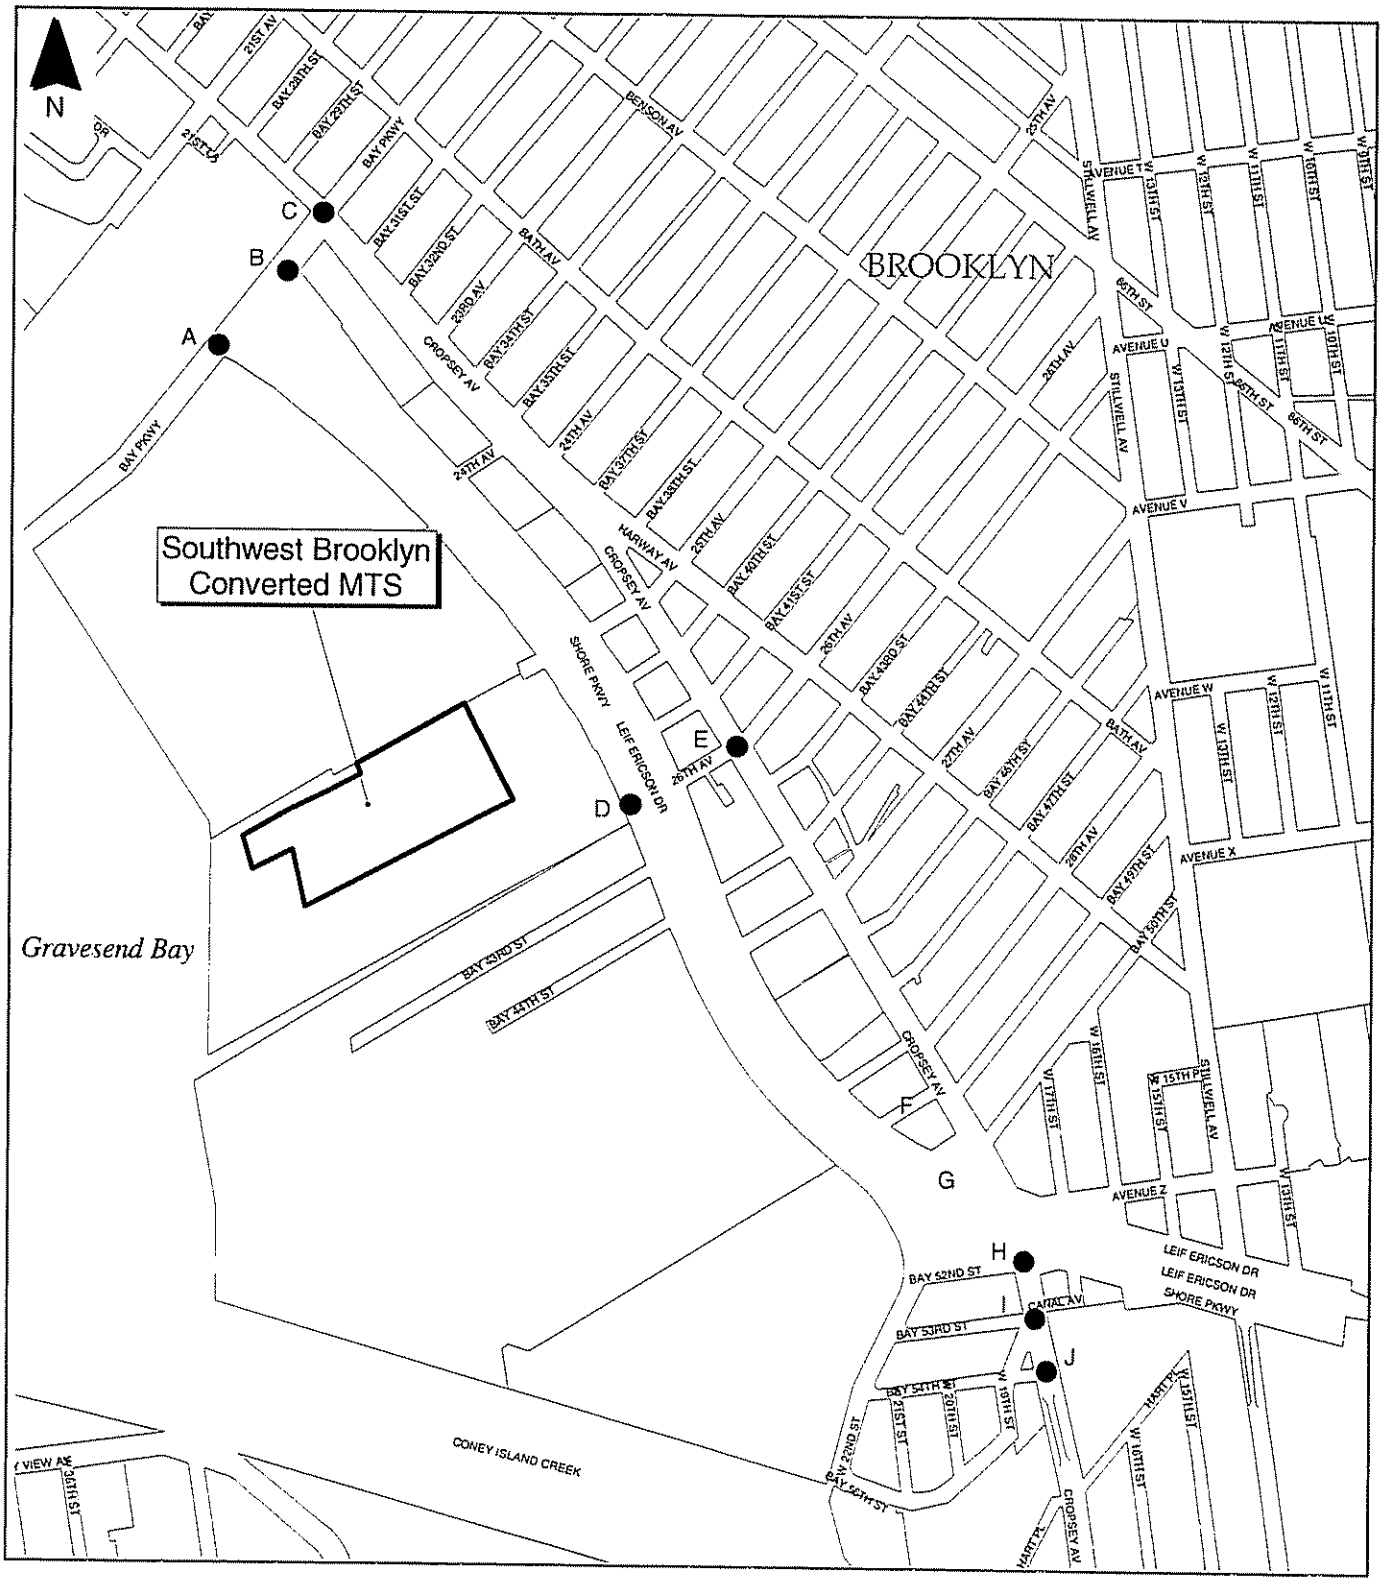
5.15a.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are the same as those presented in Table 5.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by USEPA as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Southwest Brooklyn Converted MTS using this Alternative route are not considered to be significant.

5.15a.4.2 Off-Site Analysis

5.15a.4.2.1 Pollutants Considered and Analyses Conducted

Locations that may be significantly impacted by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, detailed mobile source analyses were conducted at the following locations for the applicable (i.e., worst-case) time periods:



- The intersections of 26th Avenue at Cropsey Avenue, 26th Avenue at Shore Parkway Service Road South, Bay Parkway at Cropsey Avenue, Bay Parkway at Shore Parkway (North and South), and Cropsey Avenue at Bay 52nd Street, to determine whether Southwest Brooklyn Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and

- The intersections of 26th Avenue at Cropsey Avenue, 26th Avenue at Shore Parkway Service Road South, Bay Parkway at Cropsey Avenue, Bay Parkway at Shore Parkway (North and South), and Cropsey Avenue at Bay 52nd Street, to determine whether Southwest Brooklyn Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 5.15a-2.

5.15a.4.2.2 Results of the Off-Site Analysis

Applicable maximum pollutant concentrations estimated near the selected intersections are shown in Table 5.15a-2. The results for all applicable pollutants at the intersections of 26th Avenue at Cropsey Avenue and 26th Avenue at Shore Parkway Service Road South were within (less than) the applicable state and federal ambient air quality standards and STVs (for $PM_{2.5}$). A Tier II analysis for the intersection at Bay Parkway at Cropsey Avenue and Shore Parkway (North and South) and Cropsey Avenue at Bay 52nd Street was necessary to determine the off-site annual and 24-hour impacts for PM_{10}, and the annual neighborhood impacts for $PM_{2.5}$. The results of this Tier II analysis for all pollutants at this intersection are within the applicable state and federal ambient air quality standards STVs (for $PM_{2.5}$). Therefore, the off-site operations of the Southwest Brooklyn Converted MTS using this Alternative route are not considered to be significant.

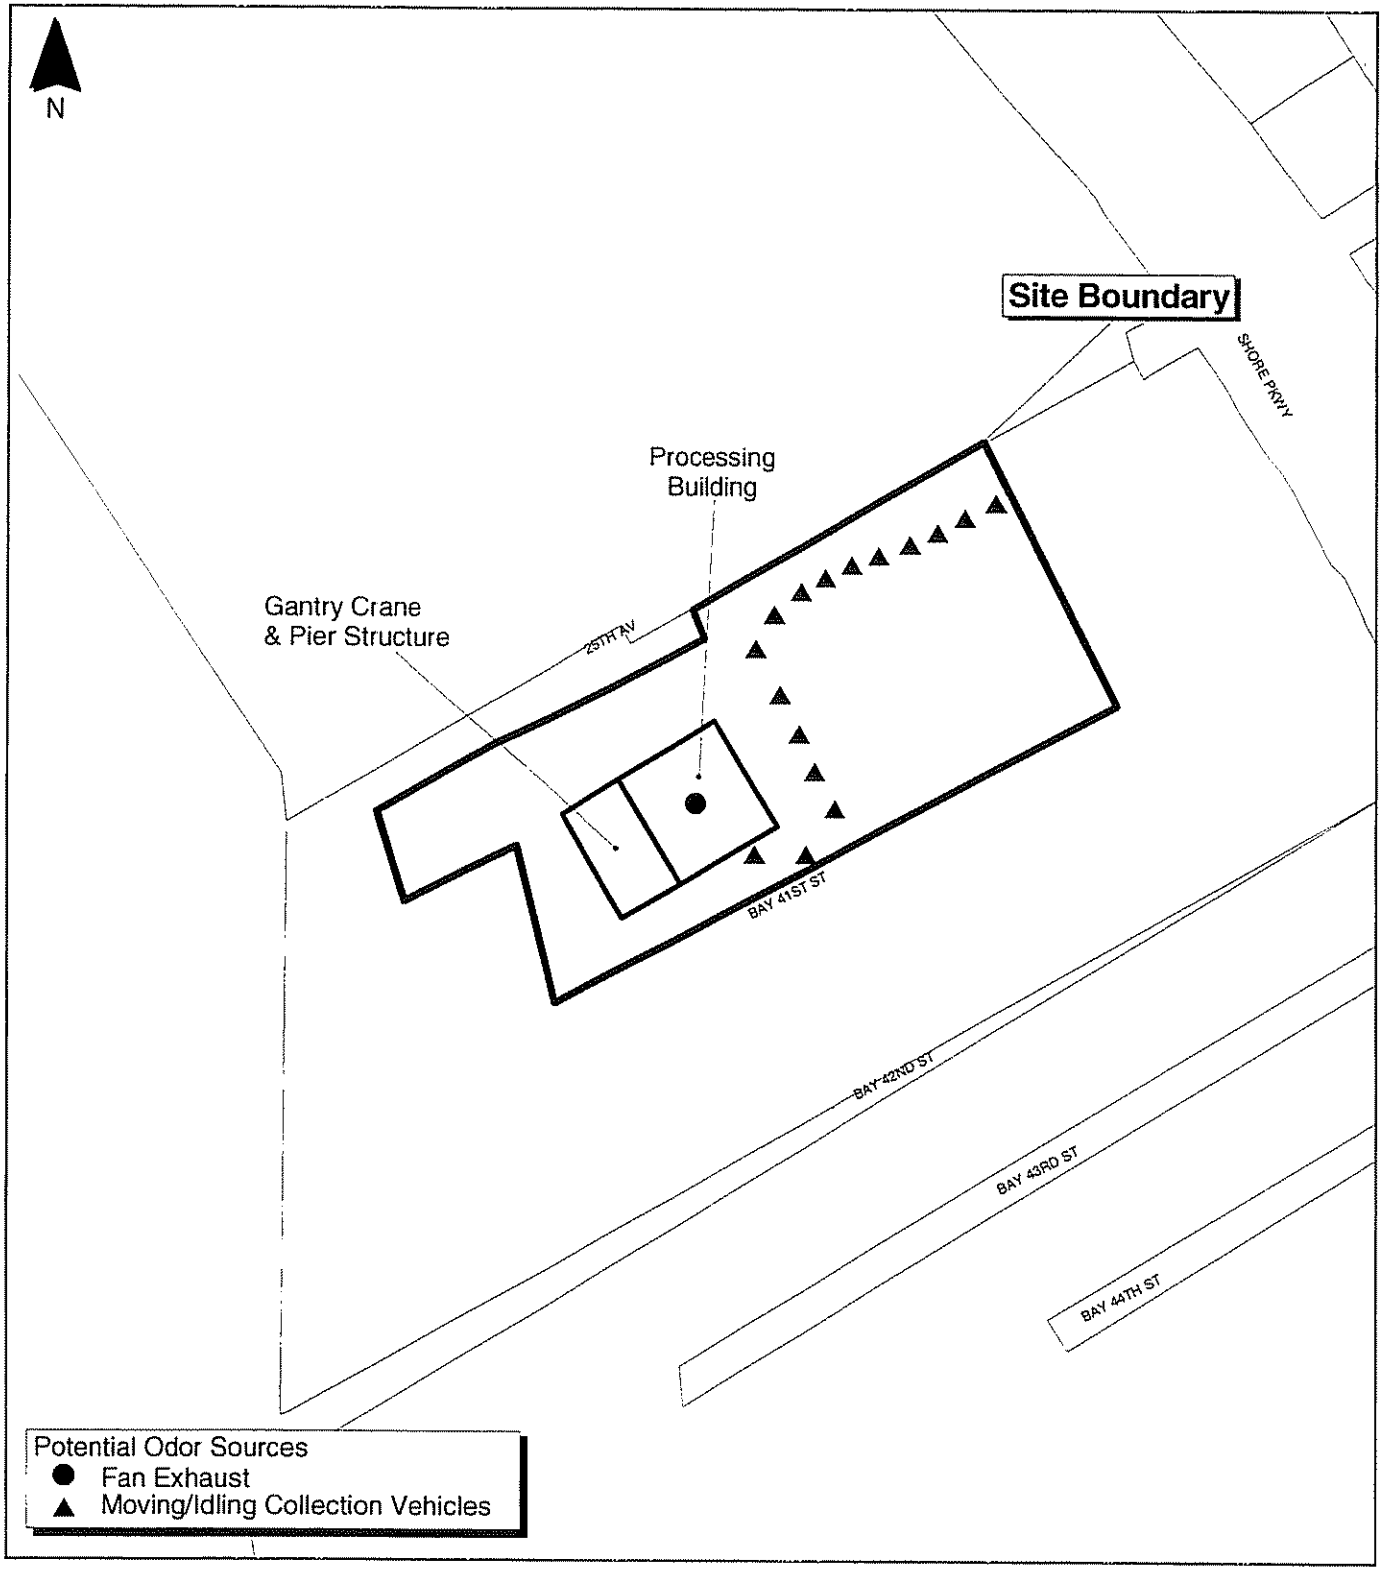
5.16 Odor

5.16.1 Existing Conditions

The existing MTS is not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest noise-sensitive receptors are a rehabilitation center on Bay 44th Street west of the Shore Parkway, approximately 277 meters (910 feet) from the Southwest Brooklyn Converted MTS property boundary, a residential house on Bay 44th Street west of the Shore Parkway, approximately 239 meters (785 feet) from the Southwest Brooklyn Converted MTS property boundary and a public school on Bay 44th Street west of the Shore Parkway, approximately 228 meters (749 feet) from the Southwest Brooklyn Converted MTS property boundary, and a baseball field on Bay 44th Street west of the Shore Parkway, approximately 340 meters (1,114 feet) from the Southwest Brooklyn MTS property boundary. The nearest sensitive receptor is the rehabilitation center on Bay 44th Street, approximately 780 feet from the site boundary.

5.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the Southwest Brooklyn Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



5.16.3 Potential Impacts with the Southwest Brooklyn Converted MTS

5.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Southwest Brooklyn Converted MTS are provided in Table 5.16-1. Figure 5.16-1 shows the locations of these sources within the site.

Table 5.16-1
Odor Sources Included in Odor Analysis
Southwest Brooklyn Converted MTS

Southwest Brooklyn Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Southwest Brooklyn Converted MTS.

5.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 5.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Southwest Brooklyn Converted MTS at any nearby sensitive receptor is less than 1, so odors from the Southwest Brooklyn Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 5.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Southwest Brooklyn Converted MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	~~0.29~~0.47

[2]~~Measured from the site boundary.~~ Receptor at the same locations as noise sensitive receptor.
~~[2]~~[1] ~~Measured from the site property line~~.

5.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Southwest Brooklyn Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

5.17.1 Existing Conditions

5.17.1.1 Introduction

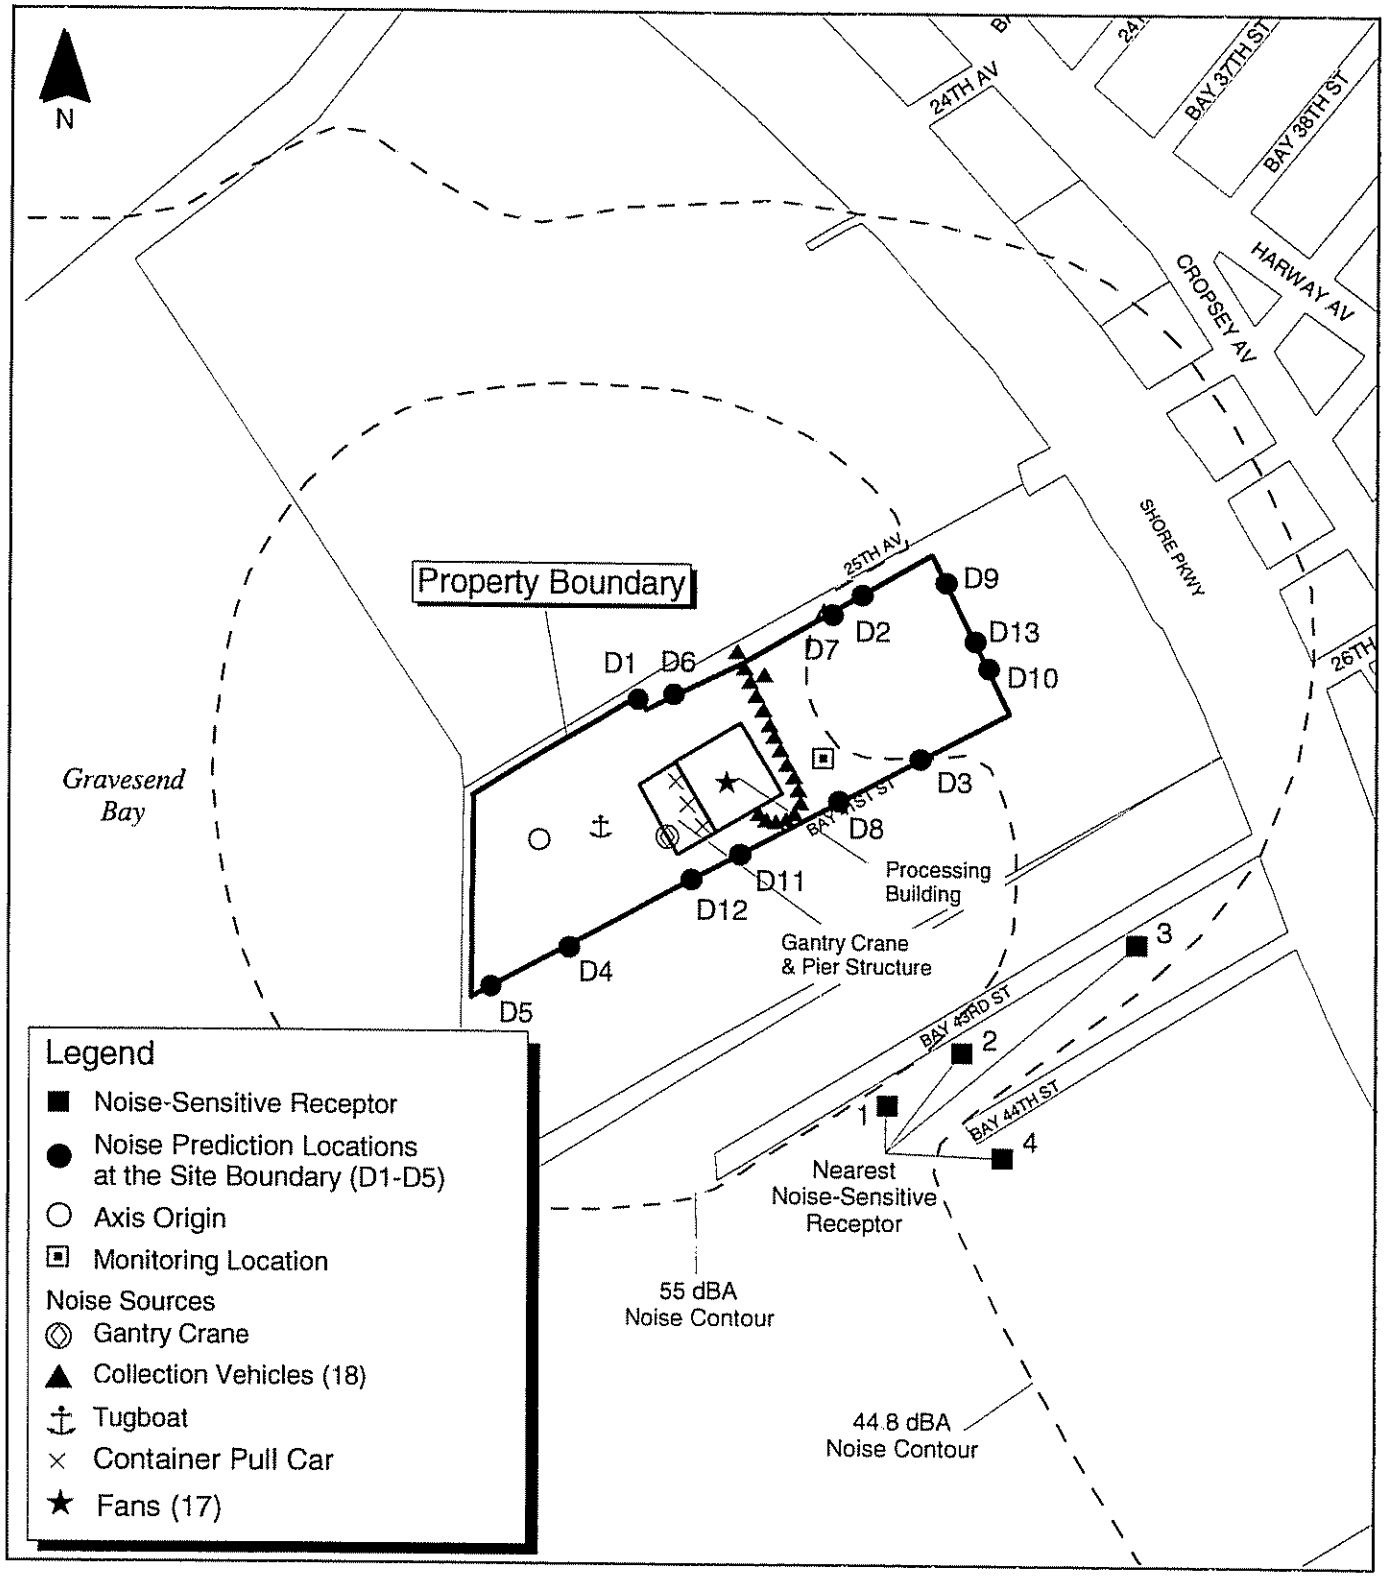

Figure 5.17-1 shows the location of the Southwest Brooklyn Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptors are a rehabilitation center on Bay 44th Street west of the Shore Parkway, approximately 277 meters (910 feet) from the Southwest Brooklyn Converted MTS property boundary, a residential house on Bay 44th Street west of the Shore Parkway, approximately 239 meters (785 feet) from the Southwest Brooklyn Converted MTS property boundary and a public school on Bay 44th Street west of the Shore Parkway, approximately 228 meters (749 feet) from the Southwest Brooklyn Converted MTS property boundary, and a baseball field on Bay 44th Street west of the Shore Parkway, approximately 340 meters (1,114 feet) from the Southwest Brooklyn MTS property boundary.

5.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptors. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[12] and the statistical metrics of L_{10}, L_{50} and L_{90}.[13] Table 5.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 4:00 a.m. and 5:00 a.m. and had an $L_{eq(1)}$ of 51.3 dBA on January 15, 2003. Activities and events that contribute to the on-site noise levels are as follows:

- Traffic on Shore Parkway and the surrounding area.

[12] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[13] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2

9:00-10:00 a.m.	56.9	51.5	53.3	57.4	49.4	80.1
10:00-11:00 a.m.	57.1	51.2	53.2	57.6	49.2	76.2

Note:

(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

5.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the Southwest Brooklyn Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required and, therefore, off-site noise monitoring was conducted. Table 5.17-2 presents monitored noise levels near noise-sensitive receptors during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) based on first-level screening.

Table 5.17-2
Existing Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor for Off-site Analysis
Southwest Brooklyn Converted MTS

Location	Existing Noise Levels During Quietest Hour (dBA)[1]
26th Avenue South of Cropsey Avenue[2]	54.7
Cropsey Avenue South of Bay 34th Street[3]	64.1

Notes:
(1) A 1-hour noise level reading was measured at the closest noise-sensitive receptor during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest).
(2) The existing noise level was measured on May 21, 2003 between 3:00 a.m. and 4:00 a.m.
(3) The existing noise level was measured on August 13, 2003 between 2:00 a.m. and 3:00 a.m.

5.17.2 Future No-Build Conditions

5.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

5.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 5.17-3 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 5.17-3
Off-Site Noise Traffic Volume
Southwest Brooklyn Converted MTS

Location	Hour Beginning	Existing Traffic Volume [1] (Vehicles / Hour)	Future No-Build Traffic Volume [2] (Vehicles / Hour)
Cropsey Avenue northwest of 26th Avenue	2:00 a.m.	97	101
25th Avenue northeast of Harway Avenue	2:00 a.m.	29	30
25th Avenue northeast of Harway Avenue	9:00 a.m.	265	276
26th Avenue south of Cropsey Avenue	3:00 a.m.	26	27
26th Avenue south of Cropsey Avenue	9:00 a.m.	306	319
Cropsey Avenue south of Bay 34th Street	2:00 a.m.	104	109

Notes:
[1] Existing Traffic Volumes are based on ATR data.
[2] Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

5.17.3 Potential Impacts with the Southwest Brooklyn Converted MTS

5.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Southwest Brooklyn Converted MTS and its reference noise levels used in the CEQR and Current Noise Code Noise Code analysis are shown in Table 5.17-4. The number and types of equipment assumed for this analysis were based on the Southwest Brooklyn Converted MTS's peak design capacity. As described in Section 3.19, an analysis was performed to determine if the number and type of trucks queuing on the ramp that was analyzed in the DEIS is more conservative than the greatest number of DSNY and

Commercial Waste trucks expected to be queuing on the ramp based on the number of trucks that might be routed to the facility. The DEIS analysis was based on DSNY trucks queuing along the entire length of the ramp. For the Southwest Brooklyn Converted MTS, the analysis of the greatest number of DSNY and Commercial Waste trucks that might be expected to be queuing on the ramp (based on the number of trucks that might be routed to the facility), is more conservative. Therefore, the results presented for the on-site analysis in this FEIS are based on the greatest number of DSNY and Commercial Waste trucks that might be expected to be queuing on the ramp.

Spectral noise levels used in the Performance Standards analysis are shown in Table 5.17-5. The number and types of equipment assumed for this analysis were based on the Southwest Brooklyn Converted MTS's peak design capacity. Shown earlier, Figure 5.17-1 indicates the Southwest Brooklyn Converted MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 5.17-4
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Southwest Brooklyn Converted MTS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Tip Floor Wheel Loaders type CAT 966G (2)	80.6
Mini-Loader type CAT 908 (1)	69.3
Tamping Cranes type CAT 325 (1)	81
Spreader Crane/Hoist (1)	70
Skid Steer Loader (Bobcat S300) (1)	76
Vacuum Sweeper (1)	64.3
Exhaust Fans (17)	74[3]
Moving/Queuing DSNY Collection Vehicles (7)	79
Outdoor	
Container Shuttle Cars (3)	45
Gantry Cranes (1)[4]	67
Harbor Tug Boat (1)[5]	69
Exhaust Fans (17)	76[3]
Inbound Moving/Queuing DSNY Collection Vehicles (see Table 5.17-4(a))	67
Inbound Moving/Queuing Commercial Waste Collection Vehicles (see Table 5.17-4(a))	71.3
Outbound Moving/Queuing Collection Vehicle (1)	67 or 71.3[6]

Notes for Table 5.17-4:

(1) Instantaneous maximum number of pieces of equipment on site at any given time.

(2) Noise level representative of each piece of equipment.

(3) Noise level representative of a total of 17 exhaust fans.

(4) Noise level will be specified for the gantry crane in DSNY's plans and specifications for construction of the Converted MTSs.

(5) Noise level will be specified for the harbor tug boat in DSNY's plans and specifications for construction of the Converted MTSs.

(6) For each hour, the type of truck assumed to be queuing on the outbound scale varied depending on the type of trucks entering the facility. If both DSNY and Commercial Waste trucks enter the facility, the outbound truck was assumed to be a Commercial Waste truck, to be conservative. However, if only DSNY trucks enter the facility, the outbound truck was assumed to be a DSNY truck. Similarly, if only Commercial Waste trucks enter the facility, the outbound truck was assumed to be a Commercial Waste truck. If a Commercial Waste truck was assumed, 71.3 dBA was used as a noise level. If a DSNY truck was assumed, 67 dBA was used as a noise level.

5.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Southwest Brooklyn Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 148 meters (487 feet) from the property boundary in the direction of the Rehabilitation Center, approximately 205 meters 673 feet) from the property boundary in the direction of the residential house, approximately 207 meters (680 feet) from the

property boundary in the direction of the school and approximately 207 meters (680 feet) from the property boundary in the direction of the baseball field. The distance from these noise-sensitive receptors to the property boundary is provided in Section 5.17.1.1. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA), is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. Background noise monitoring was conducted at the nearest noise-sensitive receptor. Since the background noise level at the receptor is 44.8 dBA, which is less than 55 dBA, the contour of the predicted facility L_{eq} equivalent to the background noise level is also shown in Figure 5.17-1. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line, however they are located within the contour based on the background noise level (see Figure 5.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptors, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 5.17-1 above. A detailed noise analysis was performed to calculate the Southwest Brooklyn Converted MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The difference between this combined noise level and the existing noise level at the noise-sensitive receptor represents the predicted incremental change in noise level from the Southwest Brooklyn Converted MTS. According to CEQR, an increase of 3 dBA or more at nighttime is considered an impact. In addition, if the daytime background noise level is 62 dBA or more, an increase of 3 dBA or more is considered an impact. Because this incremental change is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor for the quietest nighttime hour, there is a predicted impact that would be caused by the Southwest Brooklyn Converted MTS on-site operations based on this conservative analysis.

On-site queuing collection vehicles were further analyzed to refine the calculated noise levels from the Southwest Brooklyn Converted MTS facility truck ramp on the ~~Rehabilitation Center and Residential House~~noise sensitive receptors. Individual, position-specific utilization factors were assigned to each inbound collection vehicle position on the inbound side of the ramp, and

to one collection vehicle position on the outbound scale based on the processing time at the Southwest Brooklyn Converted MTS. The utilization factor for each truck was ~~estimated~~ calculated for each hour on a 24-hour basis based on the ~~peak hour of~~actual number of inbound collection vehicles~~, totaling 20 trucks and conservatively assuming these utilization factors would occur for 24 hours.~~ The assumption was made that each inbound truck would be queuing on-site for approximately two minutes before proceeding one truck length further up the ramp towards the facility. The actual number of DSNY and Commercial collection vehicles used in the 24-hour analysis is shown in Table 5.17-4(a). A restriction on the number of: (1) relayed DSNY collection vehicles delivering waste between 2:00 a.m. and 3:00 a.m.; and (2) commercial waste hauling vehicles at certain hours between 8:00 p.m. and 8:00 a.m. will mitigate predicted on-site impacts at nearby noise sensitive receptors.

Table 5.17-6 below shows the results of the CEQR analysis for the quietest hour with the ~~conservative~~ refined queuing analysis at the Public School and Baseball Field. Table 5.17-6(a) below shows the results of the CEQR analysis with ~~and~~ a refined ~~queuing~~ 24-hour analysis at the ~~Rehabilitation Center and~~ Residential House. Since the Rehabilitation Center and the Residential House are across the street from each other, the background noise levels used for both are the same. Therefore, the results provided in Table 5.17-6(a) represent the noise levels predicted for both the Residential House and the Rehabilitation Center. The Tables includes the existing noise level at the noise-sensitive receptors, ~~and~~ the Southwest Brooklyn Converted MTS-related noise levels and the combined noise level. The table also provides the difference between this combined noise level and the existing noise level at the sensitive receptors. This difference represents the predicted incremental change in noise level from the Southwest Brooklyn Converted MTS. Because this incremental change is less than the CEQR threshold of 3 dBA during nighttime hours, or during daytime hours when the daytime background noise level is greater than 62 dBA, for all of the noise-sensitive receptors analyzed, there is no predicted impact that would be caused by the Southwest Brooklyn Converted MTS on-site operations.

5.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points representative of the Southwest Brooklyn Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for

Manufacturing Districts (assuming ~~tugboats~~ both are transportation facilities) (see Table 5.17-7). Based on this analysis, no exceedances to the Performance Standards are predicted.

5.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Southwest Brooklyn Converted MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. The overall noise predictions were based on the refined queuing analysis. ~~This is~~ The results are shown in Table 5.17-8. Based on this conservative analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 5.17-6
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptors
Southwest Brooklyn Converted MTS

Noise Sensitive Receptor ID	Distance from Facility (meters/ feet)	Existing Noise Levels During Quietest Hour (dBA)[1]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[4]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Level (dBA)	Impact[5] (yes or no)
~~Rehabilitation Center [2][6]~~	~~277 / 910~~	~~44.8~~	~~44.2~~	~~47.5~~	~~2.7~~	~~No~~

~~Residential House [2][6]~~	~~239 / 785~~	~~44.8~~	~~44.1~~	~~47.5~~	~~2.7~~	~~No~~
Residential House [2]	239 / 785	See Table 5.17-6(a)				
Public School [3]	228 / 749	50.5~~64.6~~	44.3~~57.3~~	51.4~~65.4~~	0.9~~0.8~~	No
Baseball Field [3]	340 / 1114	50.5~~64.6~~	43.0~~55.7~~	51.2~~65.1~~	0.7~~0.5~~	No

Notes:

(1) Twenty-minute noise level readings measured at the closest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

(2) Existing noise levels measured on February 10, 2004 at 2:00 a.m.

(3) Existing noise levels were measured on February 10th, 2004 at ~~9~~1:00 a~~p~~.m. This was the quietest daytime hour. The quietest nighttime hour was not used since the Baseball Field and Public School are assumed to be closed during nighttime hours.

(4) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.

(5) According to CEQR, an increase over 65 dBA at daytime is considered an impact. However, if the existing noise level at the receptor during the daytime is 62 dBA or greater or if the analysis is for a nighttime hour, an increase over 3 dBA would be considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the Southwest Brooklyn Converted MTS with the quietest background noise levels that occur during facility operation.

~~(6) These results are based on refined on-site queuing collection vehicles utilization factors.~~

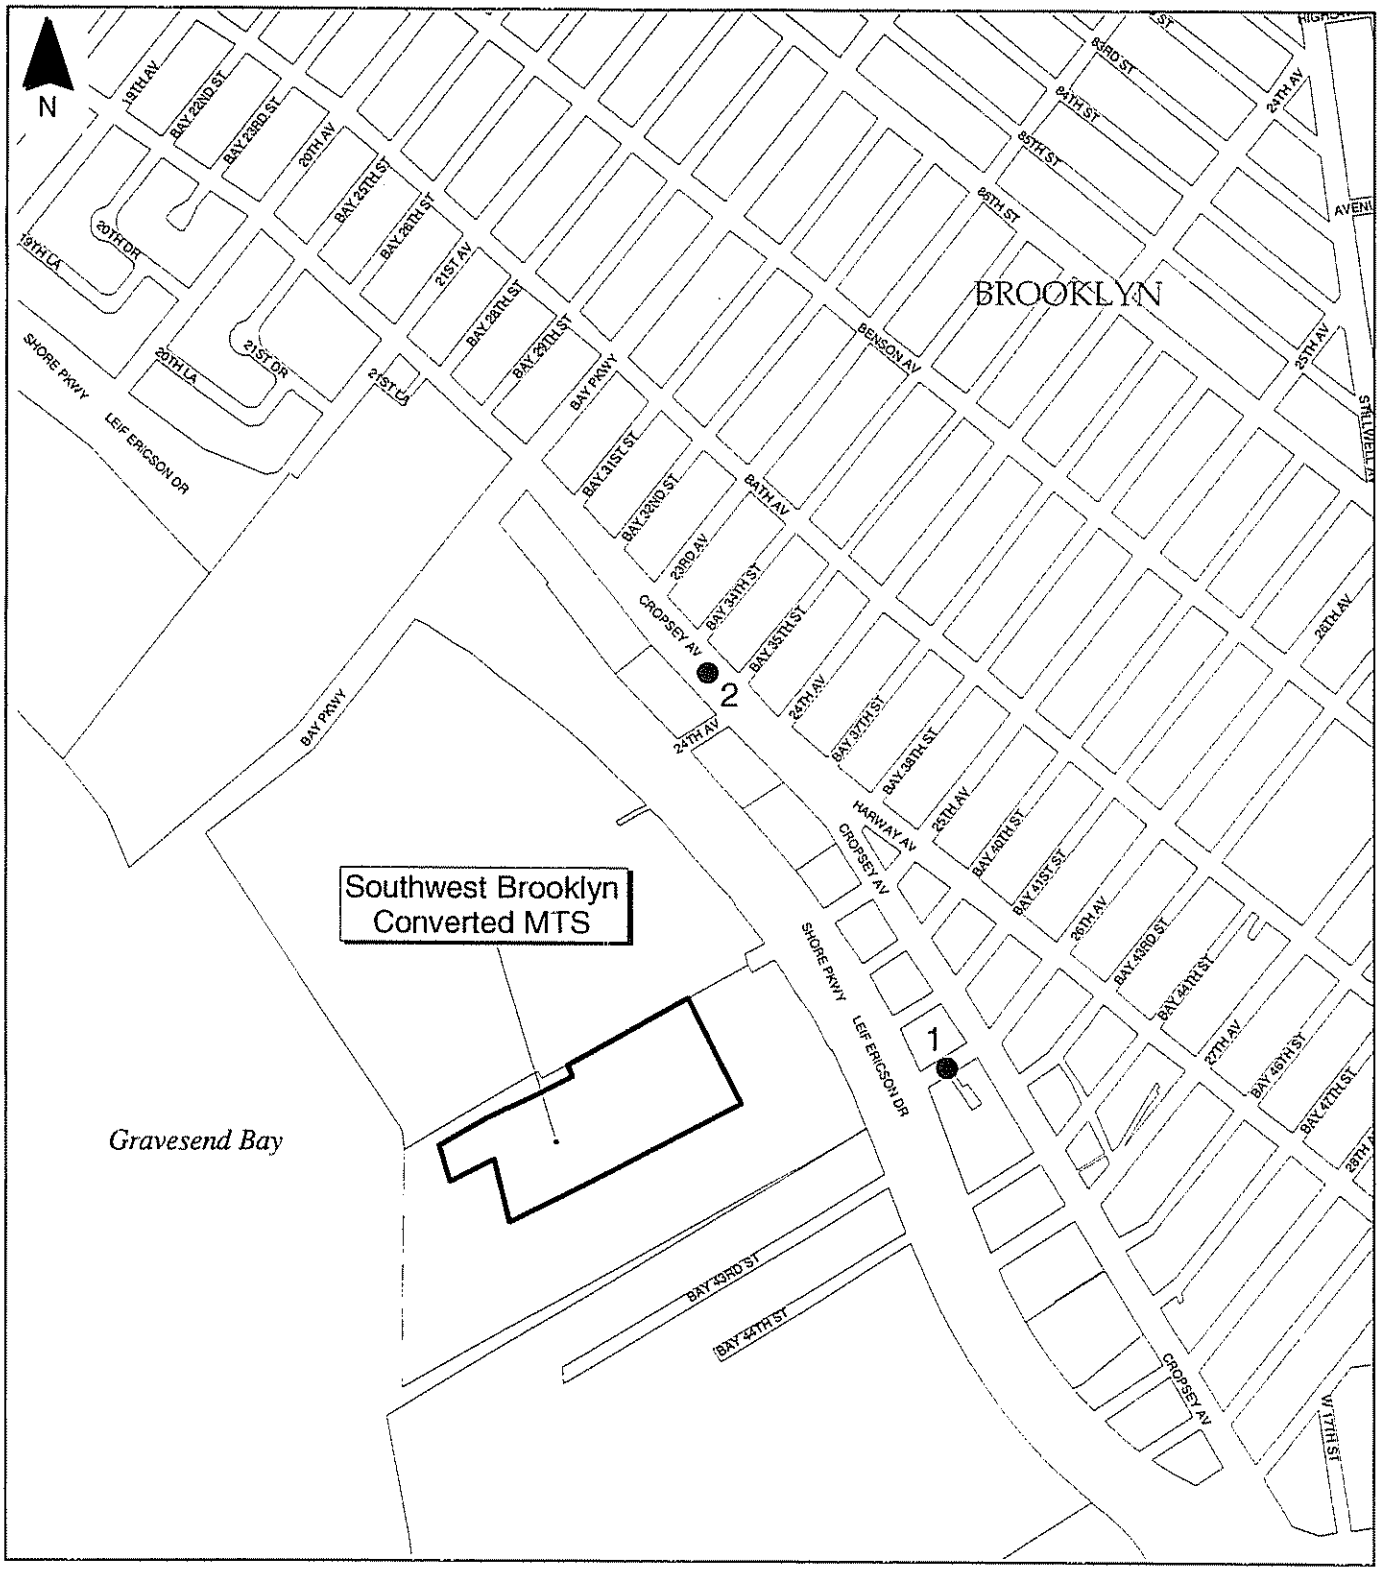
5.17.3.5 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Southwest Brooklyn Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 5.17-9.

Because the screening results presented above showed that the PCEs would double on a roadway due to DSNY and other agency collection vehicles ~~coming~~ traveling to or departing ~~going~~ from the Southwest Brooklyn Converted MTS, a detailed off-site noise analysis was performed at that roadway using TNM for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime and nighttime. Figure 5.17-2 depicts the locations of the roadways where a detailed off-site noise analysis was performed.

TNM results for locations/hour that resulted in a possible impact based on second-level screening are presented in Table 5.17-10. The table shows existing background noise levels monitored at the nearest noise-sensitive receptor at the location, TNM-predicted noise levels for the existing traffic, TNM-predicted Future No-Build noise levels for 2006 for the location, the number of Southwest Brooklyn Converted MTS collection vehicles and employee vehicles, TNM-predicted Future Build noise levels for 2006 as a result of the Southwest Brooklyn Converted MTS-related collection vehicles, and the incremental change caused by these trucks, which is calculated by obtaining the difference between this TNM Future Build noise level and the TNM-predicted Future No-Build noise level. Because the incremental noise-level change that would be caused by the Southwest Brooklyn Converted MTS is not greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor for any of the analyzed roadways, no impact is predicted based on the detailed off-site noise analysis.

Table 5.17-9
Off-Site Noise Screening Results
Southwest Brooklyn Converted MTS



Location	Hour Beginning	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
Cropsey Avenue northwest of 26th Avenue	2:00 a.m.	732	4	0	188	920	No
25th Avenue northeast of Harway Avenue	2:00 a.m.	1,155	4	0	188	1,343	No
25th Avenue northeast of Harway Avenue	9:00 a.m.	3,038	8	0	376	3,414	No
26th Avenue south of Cropsey Avenue	3:00 a.m.	36	3	0	141	177	Yes
26th Avenue south of Cropsey Avenue	9:00 a.m.	1,210	19	0	893	2,103	No
Cropsey Avenue south of Bay 34th Street	2:00 a.m.	184	4	0	188	372	Yes

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include Southwest Brooklyn Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

Site delineations are approximate

Note:
(1) Existing noise level and traffic count used for input into TNM was recorded on May 21, 2003.

5.17.3.6 Combined On-Site and Off-Site Noise Levels

On- and off-site noise analyses were performed for the Southwest Brooklyn Converted MTS, however the potential impacts of these analyses did not affect the same noise-sensitive receptor. Therefore, a combined noise analysis was not performed.

5.17a Noise - Alternative Route

The noise analysis addresses off-site sources of noise emissions from the increase in traffic caused by DSNY and other agency collection vehicles traveling from the Southwest Brooklyn Converted MTS using the Alternative truck route. It is based on Section R of the 2001 CEQR Technical Manual for off-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis. An analysis was performed only for: (1) new locations; or (2) locations identified in Section 5.17 with revised DSNY and other agency collection vehicle totals.

5.17a.1 Existing Conditions

5.17a.1.1 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the Alternative truck route due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required, therefore, off-site noise monitoring was conducted. Table 5.17a-1 presents monitored noise levels near noise-sensitive receptors during the hour expected to receive the largest noise levels (when the difference between traffic noise levels and background noise levels is the greatest) based on first-level screening.

5.17a.2 Future No-Build Conditions

5.17a.2.1 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 5.17a-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 5.17a-1
Existing Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor for Off-Site Analysis
Southwest Brooklyn Converted MTS
Alternative Route

Location	Existing Noise Levels During Quietest Hour (dBA)[1]
Shore Road between 26th Avenue & Bay 43rd Street[2]	70.1
Shore Road South of Shore Parkway exit[3]	62.3
Bay 52nd Street between Shore Road & Cropsey Avenue[3]	61.7

Notes for Table 5.17a-1:

[1] A 1-hour noise level reading was measured at the closest noise-sensitive receptor during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest).

[2] The existing noise level was measured on February 18, 2005 between 10:00 a.m. and 11:00 a.m. The school is not in operation during nighttime hours, therefore the quietest nighttime hour was not analyzed.

[3] The existing noise level was measured on February 17, 2005 between 3:00 a.m. and 4:00 a.m.

Table 5.17a-2
Off-Site Noise Traffic Volume
Southwest Brooklyn Converted MTS
Alternative Route

Location	Hour Beginning	Existing Traffic Volume [1] (Vehicles / Hour)	Future No-Build Traffic Volume [2] (Vehicles / Hour)
26th Avenue South of Crospey Avenue	3:00 a.m.	26	27
Cropsey Avenue South of Bay 34th Street	2:00 a.m.	104	109
Shore Road between 26th Avenue & Bay 43rd Street	10:00 a.m.	156	159
Shore Road South of Shore Parkway exit	3:00 a.m.	66	67
Bay 52nd Street between Shore Road & Cropsey Avenue	3:00 a.m.	63	64
Cropsey Avenue between Bay 53rd Street & Bay 54th Street	2:00 a.m.	238	243
Cropsey Avenue between Bay 49th Street & Bay 50th Street	3:00 a.m.	116	118

Notes for Table 5.17a-2:
[1] Existing Traffic Volumes are based on ATR data.
[2] Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

5.17a.3 Potential Impacts with the Southwest Brooklyn Converted MTS – Alternative Route

5.17a.3.1 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Southwest Brooklyn Converted MTS alternative route. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 5.17a-3.

Table 5.17a-3
Off-Site Noise Screening Results
Southwest Brooklyn Converted MTS – Alternative Route

Location	Hour Beginning	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
Shore Road between 26th Avenue & Bay 43rd Street	10:00 a.m.	528	22	0	1034	1562	Yes
Shore Road South of Shore Parkway exit	3:00 a.m.	205	5	0	235	440	Yes
Bay 52nd Street between Shore Road & Cropsey Avenue	3:00 a.m.	64	5	0	235	299	Yes

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include Southwest Brooklyn Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

Because the screening results presented above showed that the PCEs would double on a roadway due to DSNY and other agency collection vehicles traveling to or departing from the Southwest Brooklyn Converted MTS via the alternative route, a detailed off-site noise analysis was performed at that roadway using TNM for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime and nighttime. Figure 5.17a-1 depicts the locations of the roadways where a detailed off-site noise analysis was performed.

TNM results for locations/hour that resulted in a possible impact based on second-level screening are presented in Table 5.17a-4. The table shows existing background noise levels monitored at the nearest noise-sensitive receptor at the location, TNM-predicted noise levels for the existing traffic, TNM-predicted Future No-Build noise levels for 2006 for the location, the number of Southwest Brooklyn Converted MTS collection vehicles and employee vehicles, TNM-predicted Future Build noise levels for 2006 as a result of the Southwest Brooklyn Converted MTS-related collection vehicles, and the incremental change caused by these trucks, which is calculated by obtaining the difference between this TNM Future Build noise level and

Site delineations are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

the TNM-predicted Future No-Build noise level. Because the incremental noise-level change that would be caused by the Southwest Brooklyn Converted MTS is predicted by TNM to be greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor for two of the analyzed roadways, TNM predicts an impact.

Table 5.17a-4
Off-Site Noise Analysis TNM Results
Southwest Brooklyn Converted MTS – Alternative Route

Location	Hour Beginning	Existing Background Noise Level[1] (L_{eq}) (Measured) (dBA)	TNM-Predicted Noise Level (L_{eq}) for Existing Traffic (dBA)	TNM Future No-Build Noise Level (L_{eq}) (dBA)	Collection Vehicles	Employee Vehicles	TNM Future Build Noise Level (L_{eq}) (dBA)	Impact (Noise Level Difference) (dBA)
Shore Road between 26th Avenue & Bay 43rd Street	10:00 a.m.	70.1	62.7	62.7	22	0	65.9	Yes (3.2)
Shore Road South of Shore Parkway exit	3:00 a.m.	62.3	56.2	56.2	5	0	58.6	No (2.4)
Bay 52nd Street between Shore Road & Cropsey Avenue	3:00 a.m.	61.7	52.1	52.2	5	0	55.6	Yes (3.4)

Note:
[1] Existing noise level and traffic count used for input into TNM was recorded on February 17th and 18th, 2004.

To determine if these TNM-predicted impacts were overpredicted, site-specific truck simulations would normally be conducted at the noise sensitive receptors, based on the methodology described in Section 3.19. However, due to the precipitation (noise monitoring cannot be conducted when it is raining) and the lack of time, a site-specific truck simulation analysis could not be performed for the FEIS. Based on: (1) the truck simulations performed for other Converted MTS facilities; and (2) the small increment of 0.2 and 0.4 dBA over the CEQR 3 dBA threshold that has been predicted by TNM, it is expected that the truck simulation analysis would not predict an impact at the two nearest noise-sensitive receptors where TNM predicts impacts.

5.17a.3.2 Combined On-Site and Off-Site Noise Levels

On-site and off-site noise analyses were performed for the Southwest Brooklyn Converted MTS. Since the potential impacts of these analyses can affect the same noise-sensitive receptor, a screening analysis was conducted to determine if a combined noise analysis would be required for the operations at the Southwest Brooklyn Converted MTS. The combined analysis study area was defined by the 55 dBA isopleth contours from the on-site source and the bottom driveway entrance to the site. The other limits for the combined analysis study area were defined by the first row of buildings along the roadway between the 55 dBA contour and the driveway entrance to the site. The results of the screening analysis show that the School on the corner of Shore Road and Bay 44th Street is the nearest noise-sensitive receptor located within the study area that can be impacted by both on-site and off-site Southwest Brooklyn Converted MTS operations; therefore, a combined noise analysis, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest daytime hour based on the off-site analysis discussed in Section 6.17.3.5 above. The school is not in operation during nighttime hours, therefore the quietest nighttime hour was not analyzed. Table 5.17a-5 shows the distance from the Southwest Brooklyn Converted MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, Southwest Brooklyn Converted MTS predicted noise levels at the noise-sensitive receptor, and the predicted off-site noise level at the noise-sensitive receptor. The table also provides the combined on-site and off-site noise level and the difference between these combined noise levels. This difference

represents the predicted incremental change in noise level from the Southwest Brooklyn Converted MTS on-site and off-site operations at the noise-sensitive receptor. Because this incremental change is not greater than the CEQR threshold of 3 dBA during nighttime hours for the school receptor analyzed, there is no predicted impact that would be caused by the Southwest Brooklyn Converted MTS combined on-site operations and off-site operations.

Table 5.17a-5
Combined On-Site and Off-Site Noise Analysis
Existing and Predicted Noise Levels (Leq) at the Nearest Noise-Sensitive Receptor with Southwest Brooklyn Converted MTS based on the Alternative Truck Route

Noise-Sensitive Receptor ID	Distance from Facility (meters /feet)	Hour Analyzed	Existing Noise Levels During Quietest Hour (dBA)[1]	Predicted On-Site Noise Level at Noise-Sensitive Receptor (dBA)[2]	Collection Vehicles	Predicted Off-site Noise Level at Noise-Sensitive Receptor (dBA)	Combined On-Site and Off-Site Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[3] (yes or no)
School on Shore Road between 26th Avenue and Bay 44th Street	228 / 749	10:00 a.m.	70.1	53.6	22	65.9	71.6	1.5	No

Notes:
(1) Existing noise level and traffic count used for input into TNM was recorded on February 18th, 2004.
(2) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.
(3) According to CEQR, an increase over 3 dBA during daytime hours where the existing noise level is 62 dBA or greater is considered an impact.

5.18 Commercial Waste to the Southwest Brooklyn Converted MTS

5.18.1 Existing Conditions

No commercial waste is delivered to the Southwest Brooklyn MTS site under Existing Conditions. Commercial waste generated in Brooklyn is delivered to privately owned and operated transfer stations in the City, or taken directly out of the City to remote disposal locations.

5.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the Southwest Brooklyn Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

5.18.3 Potential Impacts of Sending Commercial Waste to the Southwest Brooklyn Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

5.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the Southwest Brooklyn Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 5.15, 5.16 and 5.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the

analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

5.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the Southwest Brooklyn Converted MTS were evaluated in Sections 5.14, 5.15 and 5.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 5.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 27 (inbound trip ends) per hour, which occurred during the AM peak. These 27 DSNY and other agency collection vehicles are also more than the 23 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the Southwest Brooklyn Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 27 DSNY and other collection agency vehicle trip ends at the Southwest Brooklyn Converted MTS. Therefore, the addition of the 23 DSNY and other agency collection vehicles and

commercial waste hauling vehicles at the Southwest Brooklyn Converted MTS during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 27 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 27 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24-hour period for most of the analyzed intersections. Results showed there would be no unmitigatible significant adverse environmental impacts at several analyzed intersections. Consequently, because the 23 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can travel through these intersections per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

For the intersection of Bay Parkway at Cropsey Avenue and Shore Parkway (north and south), a Tier II analysis was required. The estimated actual hourly distribution over 24 hours included the estimated 23 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that could potentially be processed at the Southwest Brooklyn Converted MTS, and no unmitigatible significant adverse environmental impacts were identified.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the Southwest Brooklyn Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. Based on the revised analysis in this FEIS, ~~T~~the amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is ~~828~~ 718 tons (or approximately ~~766~~ commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

CHAPTER 6 ENVIRONMENTAL REVIEW: EAST 91ST STREET CONVERTED MTS

6.1 Introduction

The results of the environmental analyses of the East 91st Street Converted MTS are presented in the following sections:

6.2 Land Use, Zoning, and Public Policy
6.3 Socioeconomic Conditions
6.4 Community Facilities and Services
6.5 Open Space
6.6 Cultural Resources
6.7 Urban Design, Visual Resources, and Shadows
6.8 Neighborhood Character
6.9 Natural Resources
6.10 Hazardous Materials
6.11 Water Quality
6.12 Waterfront Revitalization Program
6.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
6.14 Traffic, Parking, Transit, and Pedestrians
6.15 Air Quality
6.16 Odor
6.17 Noise
6.18 Commercial Waste to the East 91st Street Converted MTS

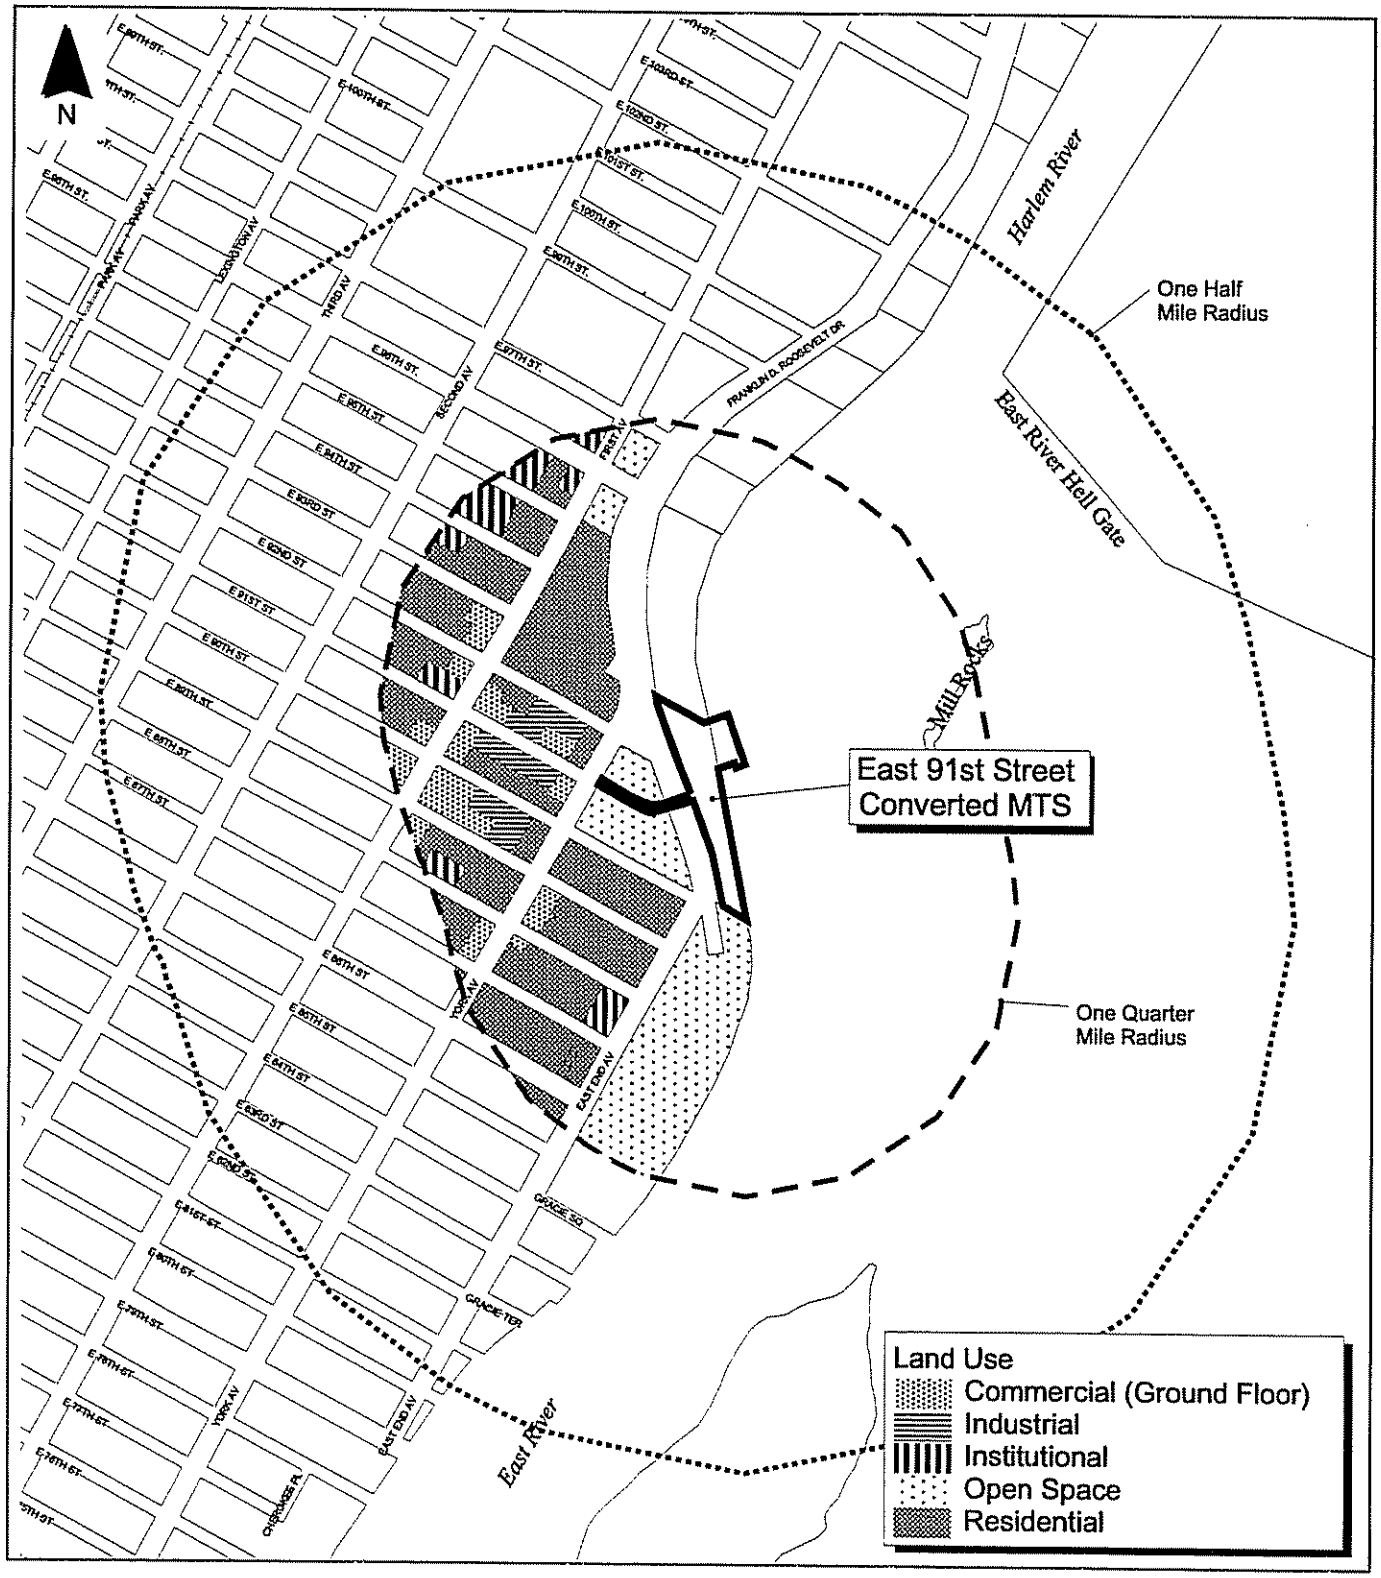
Section 2.2.3 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

6.2 Land Use, Zoning, and Public Policy

6.2.1 Existing Conditions

6.2.1.1 Definition of the Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 6.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 6.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.2.3 provides information on existing land uses and operations on the site.



6.2.1.2 Land Use Patterns

6.2.1.2.1 General Context

Set in the larger context of Manhattan's Upper East Side and East River waterfront, the site is surrounded primarily by parks and recreational areas, transportation infrastructure and dense residential developments.

6.2.1.2.2 Land Uses in the Primary Study Area

The site is located on the waterfront, separated from the mainland street network, by the at-grade FDR Drive. Carl Schurz Park, the setting of Gracie Mansion, the mayor's formal residence, lies immediately to the south of the site and runs adjacent to the western side of the FDR Drive to 84th Street. The park provides a buffer to residential uses adjacent to it on East End Avenue. At its northern end nearest the site, the park extends over the FDR Drive to the waterfront. The East River Esplanade, alongside the FDR Drive, provides public access to the waterfront – south of East 84th Street and north of East 90th Street. The esplanade runs along the waterfront, adjacent to the site beneath the existing MTS access ramp. A commuter ferry pier is located just south of the existing MTS at East 90th Street. The park and promenade extend south along the water beyond the primary study area.

East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Asphalt Green, another major open space and community facility within the primary study area, stretches between East 90th and 92nd Streets east of York Avenue. It consists of a sports and training complex, featuring indoor and outdoor facilities, soccer field, basketball courts, running track, aquatic center and fitness center. The former Municipal Asphalt Plant (now a landmark) houses a gymnasium as part of the complex. (See Section 6.6 for additional discussion of cultural resources in the study area.) Access to the existing MTS site is provided by an unmapped drive that ramps up through the Asphalt Green complex from the intersection of East 91st Street and York Avenue to clear the FDR Drive.

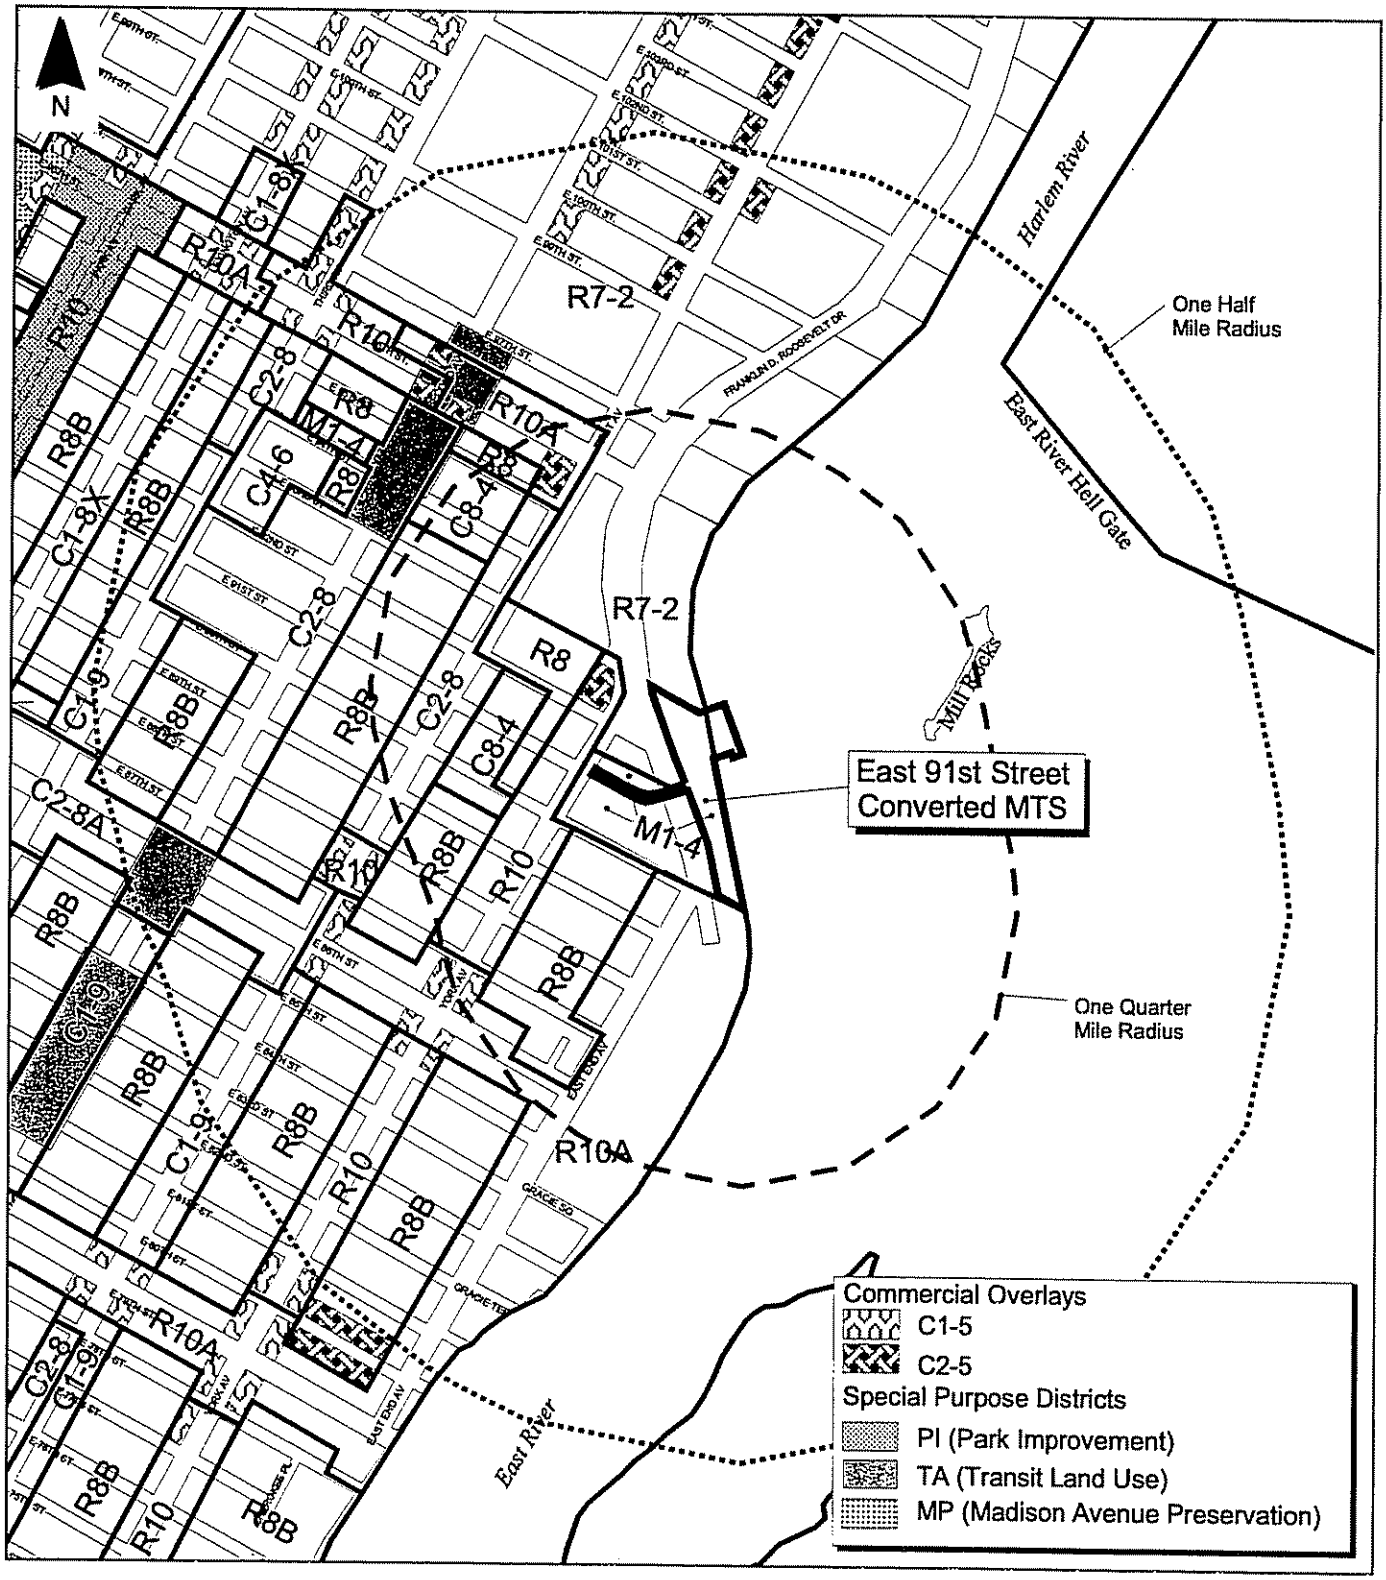
The remainder of the primary study area primarily consists of residential land uses with multi-story towers on the west side of East End Avenue facing the river and row houses lining the cross streets. A few blocks feature ground-floor commercial space along York Avenue and First Avenue. The study area's strongly residential nature is only somewhat interrupted by the presence of a few warehouses and auto-related uses between East 89th Street, East 92nd Street and York and First Avenues. A gourmet grocery (Eli's) with a restaurant above (The Vinegar Factory) and an arts-and-crafts shop are located on the north side of East 91st Street (a local route for DSNY and other agency collection vehicles leaving the site) just west of York Avenue, and a pizzeria is located on the south side of the street. On the local inbound truck route (East 90th Street between York and First Avenues) there is a combination of residential buildings and automobile-related uses (e.g., car rental, automobile repair and parking garages). Beth Israel Hospital (North) is also located in the primary study area on East End Avenue and East 87th Street, and the High School of Teaching and P.S. 66 are located on East 88th Street, between York and First Avenues. Stanley M. Isaacs Park is located on both sides of East 91st Street, east of First Avenue.

6.2.1.2.3 Land Uses in the Secondary Study Area

Land use within the secondary study area is also generally characterized by residential uses, with ground-floor commercial uses lining the avenues, except for the portion of the study area north of East 95th Street, where institutional uses abound. Metropolitan Hospital and associated parking is located at East 97th Street, J.H.S. 99 and other institutional uses are east of First Avenue (north of the Metropolitan Hospital complex), and the School of Cooperative Technical Education is at East 97th Street, to the south.

6.2.1.3 Zoning On and Near the Site

6.2.1.3.1 Zoning Within the Primary Study Area



The MTS site is located within a small irregularly shaped M1-4 (light industrial) zoning district, which extends from East 90th to East 93rd Streets along the shoreline, between the FDR Drive and the East River waterfront. It continues west of the site to York Avenue between East 90th and East 92nd Streets to encompass most of the Asphalt Green complex. Beyond the site on all sides are high-density residential zoning districts that allow for dense apartment buildings. The northern portion of Asphalt Green is situated within a large R7-2 zoning district that extends about one mile to the north. Immediately south of the site is an R10A high-density residential district and is surrounded by other high-density residential districts: R8, R8B, R10 and R10A. An area covering the interiors of three blocks south of East 92nd Street between York and First Avenues, where warehouses and auto-related uses are located west of the site, is zoned C8-4. The remainder of the study area is zoned for high-density residential development with the exception of a strip of C2-8 zoning lining First Avenue. (See Figure 6.2-3 and Table 3.4-1: Zoning District Characteristics.)

6.2.1.3.2 Zoning Within the Secondary Study Area

The secondary study area is zoned primarily for high-density residential development (R7-2, R8, R8-B, R10 and R10A). Commercial zoning applies to the avenues and East 86th Street, and a Transit Land Use Special Purpose District covers several blocks of Second Avenue around East 86th Street and East 95th Street in the secondary study area to allow for the proposed Second Avenue subway, in design stages at the time of this writing.

6.2.1.4 Plans and Policies

Neither the FY 2004 CDNS for Manhattan CD 8, in which the site is located, or that for CD 11, in which a portion of the secondary study area is located, make reference to recommended or anticipated physical development affecting the site or primary or secondary study areas.

Site delineations and study area boundaries are approximate

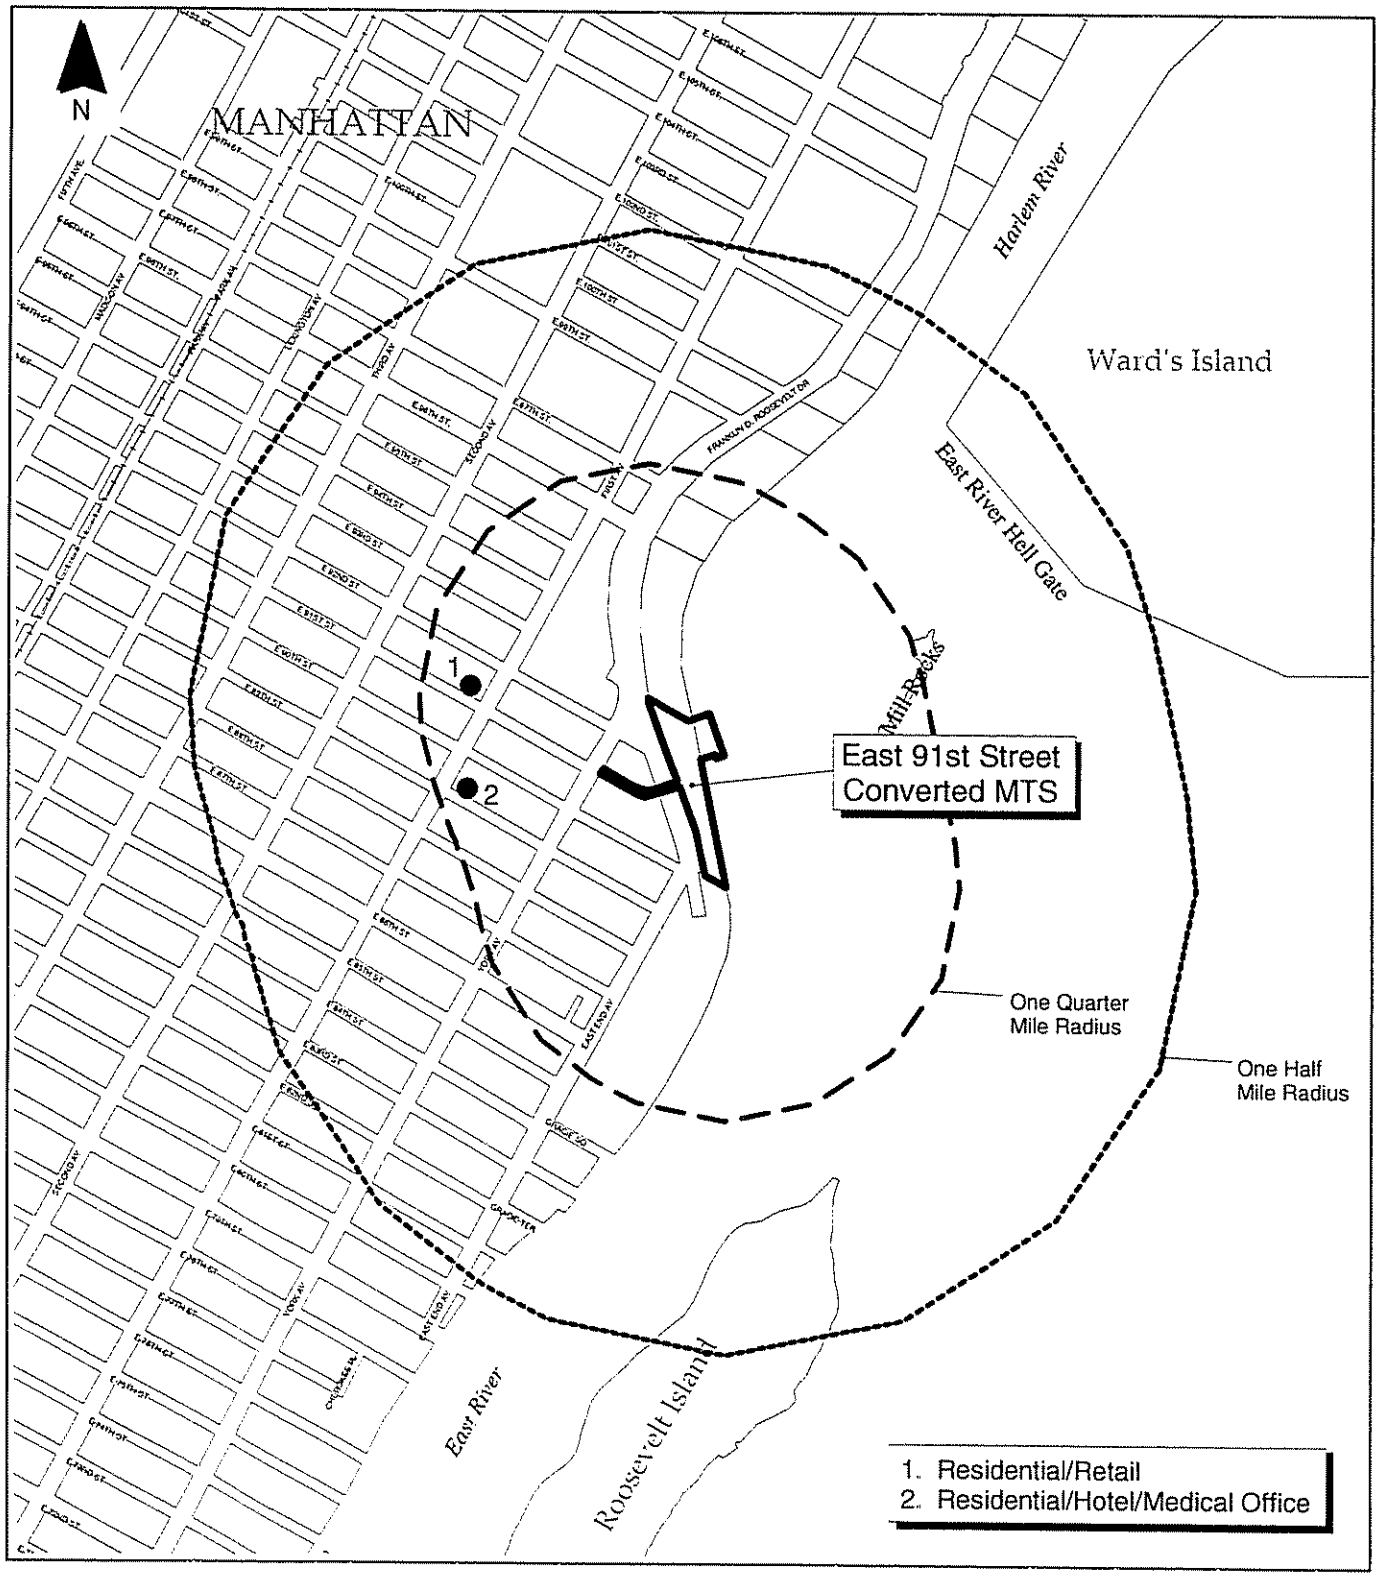
Figure 6.2-3 Zoning

East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION



The Plan for Reach 1 makes several recommendations pertinent to the site. As part of planning for the public waterfront, it recommends that the esplanade throughout the reach be developed to accommodate both bicycles and pedestrians safely and that waterfront access from inland areas be enhanced. The plan also recommends that where public funds are invested in waterfront municipal facilities, allocations should be included for esplanade construction, and, for waterfront uses that may block access to or along the waterfront, public access should be incorporated into site plans. Specifically, RFPs for the development or use of City-owned waterfront property should require esplanades or waterfront parks and maintenance agreements to ensure their upkeep.

The plan also recommends that the fireboat pier at East 90th Street be renovated for use as an environmental education center and that a new pedestrian bridge be constructed from Asphalt Green to the pier. As part of its working waterfront recommendations, the plan for Reach 1 speaks to the commuter ferry service which, subsequent to the preparation of the plan, has begun service at East 90th Street. It also specifically notes that the adjacent MTS at East 91st Street should be considered when siting or locating a ferry landing at this location.

6.2.2 Future No-Build Conditions

Two multi-use residential towers will be completed within the primary study area by 2006, one at 389 East 89th Street and one, which will include a hotel, at East 91st Street and First Avenue (see Figure 6.2-4). Other new residential construction is underway on 90th Street at the western edge of the secondary study area. In addition, a feasibility study is currently underway for a potential new school to be located at 340-342 East 92nd Street. Otherwise, NYCDCP has no information of new development planned to occur within the study area, and notes that most new development in the broad vicinity occurs in the East 60s, south of the site and outside the secondary study area.

A large section of East Harlem (East 99th to East 122nd Streets) between First Avenue and Lexington Avenue has been rezoned for higher-density contextual residential development. The site would remain DSNY property and the existing inactive MTS would remain.

Figure 6.2-4 Planned Development Sites
East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

6.2.3 Potential Impacts with the East 91st Street Converted MTS

6.2.3.1 Land Use and Zoning

The East 91st Street Converted MTS entails replacement of the existing MTS with a new facility that includes containerization functions; it would represent a slight physical upgrading of the site. The East 91st Street Converted MTS operation would be designed to containerize waste and prepare containers for transfer to barge for disposal outside the City. The existing MTS, which extends over the water, would be demolished, and the new one would be built in approximately the same place, still hugging the shore and extending to the pierhead line. ~~The ramped entrance to the site would remain unchanged.~~ The new ramp constructed as part of the East 91st Street Converted MTS would follow the same footprint as the existing ramp.

The reactivation of waste transfer activities on the site would have no effect on land uses nearby. (See Section 6.8 for a discussion of potential impacts to neighborhood character.) Neither the reactivation of waste transfer activities on the site nor the volume of truck traffic would encourage similar types of land uses or discourage other types of land use such as those already present in the study areas. Therefore, no significant adverse impacts to land use or zoning in the built-out study area would result.

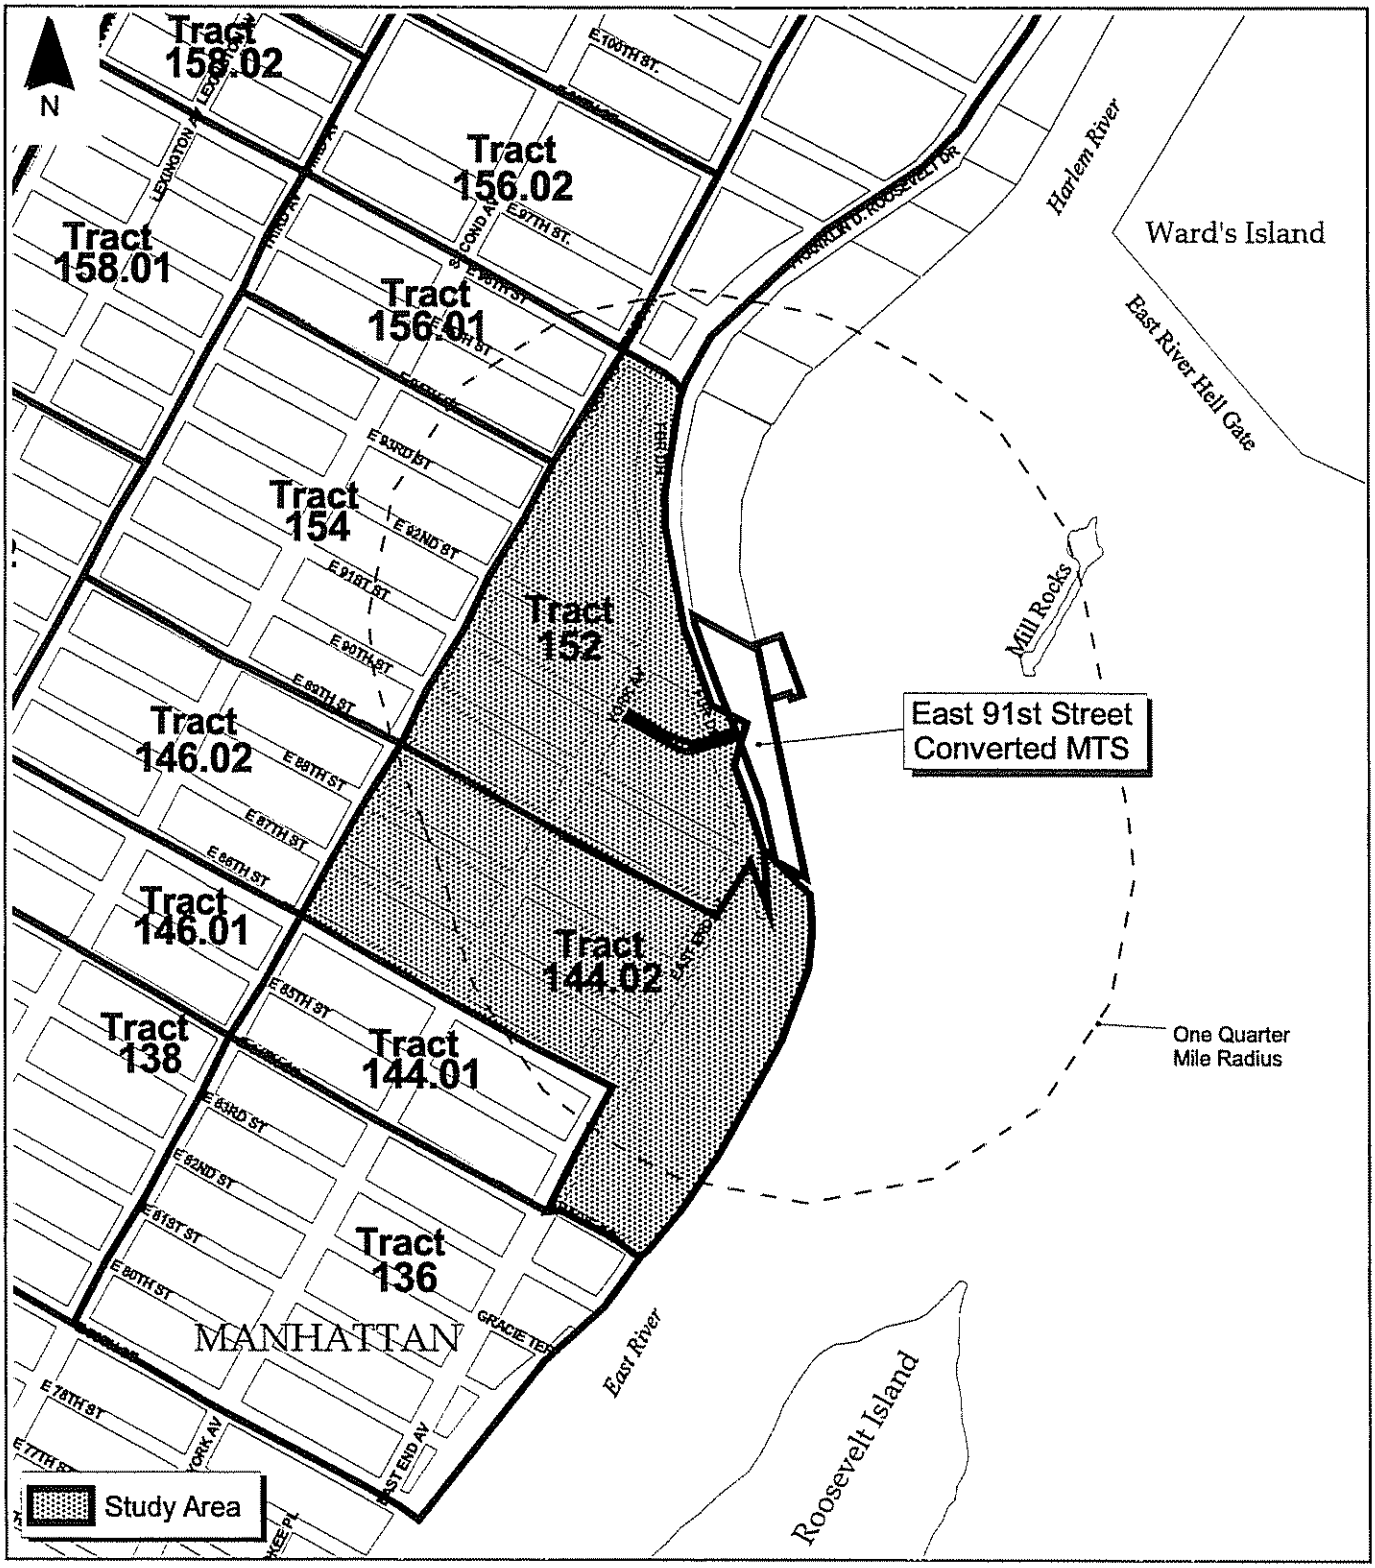
6.2.3.2 Consistency with Public Plans and Policies

There are no recommendations or objectives stated in relevant plans and policies that specifically relate to the site or the study area. The East 91st Street Converted MTS would be consistent with the applicable 197-a Plan (the Comprehensive Manhattan Waterfront Plan [CMWP]). Development of a ferry terminal at East 90th Street and the waterfront promenade in the area near the site has already occurred.

6.3 Socioeconomic Conditions

6.3.1 Existing Conditions

6.3.1.1 Definition of the Study Areas



Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) The demographic study area is comprised of Census Tracts 152 and 144.02 (see Figure 6.3-1). Census Tract 152 covers East River waterfront areas to the east of First Avenue between East 89th Street and East 96th Street. Census Tract 144.02 covers the six blocks directly south of Census Tract 152 and the area stretching east of East End Avenue between East 90th Street and East 84th Street. For comparison purposes, Census data were gathered at the borough and City levels. The study area for the assessment of potential impacts on economic conditions extends as far north as East 102nd Street, as far south as East 81st Street and as far west as Third Avenue.

Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

6.3.1.2 Demographic Characteristics

6.3.1.2.1 Population

The total 2000 study area population was 13,417 persons (see Table 6.3-1). In terms of population growth from 1990 to 2000, the study area experienced a greater rate of increase in residents (7%) than did the borough (3%) during the same period, but its population did not grow as rapidly as the City's (9%) as a whole.

Site delineations and study area boundaries are approximate.

1990-2000 Population

	Study Area	Manhattan	City
2000	13,417	1,537,195	8,008,278
1990	12,601	1,487,536	7,322,564
Percent Change	+6.5%	+3.3%	+9.4%

Source: U.S. Census 1990, 2000

The age-sex distribution was slightly different from the population distribution of the borough and the City, with an even greater proportion of females to males. The study area contained a slightly smaller percentage of children and teenagers than the borough, but a considerably smaller percentage of children and teens than the City: 16% of the study area population was under the age of 20, compared to 19% for the borough and 27% for the City.

6.3.1.2.2 Racial and Ethnic Characteristics

The 2000 study area population had a smaller proportion (12%) of people of Hispanic origin (all races) than did Manhattan or the City (both at 27%). Of the 88% not of Hispanic origin in the study area, 84% were White and 7% were Black. In Manhattan and the City, Blacks represented approximately 21% and 33% of the non-Hispanic populations, respectively, while Whites represented 63% and 48%, respectively.

From 1990 to 2000, the number of study area residents of Hispanic origin increased by a greater rate than in the borough and in the City during the same period. People of Hispanic origin increased by 30% in the study area, compared with 10% in the borough and 24% in the City. Because the 2000 Census introduced the option for respondents to identify themselves as two or more races, racial categories are not directly comparable with 1990.

6.3.1.2.3 Families and Households

There were 2,980 families in the study area in 2000. Approximately the same percentage of these families (42%) had children under the age of 18 as families in Manhattan (43%). In the City, the percentage of families with children was somewhat higher (49%). There was a larger

percentage of married-couple families in the study area than in the borough or the City, and 39% of these families had children, the same percentage as in Manhattan but a somewhat lower percentage than found within the City (48%).

Twenty-four percent (24%) of the families in the study area were headed by a female householder, a smaller percentage than in the borough (30%) or the City (also 30%). Fifty-one percent (51%) of the female householder families in the study area had children under the age of 18, similar to percentages in the borough (53%) and the City (55%).

There were 7,487 households in the study area in 2000, with an average household size of 1.8 persons, which was smaller than the number in Manhattan (2.0 persons per household) and the City (2.6 persons per household). From 1990 to 2000, the number of households in the study area increased by 4%, compared with a 3% increase in the borough and a 7% increase in the City.

6.3.1.2.4 Employment

Seventy-two percent (72%) of persons aged 16 and older participated in the labor force in 2000, compared to 64% in Manhattan and 58% in the City. The majority of employed in all three areas were engaged as private wage and salary workers.

Nine percent of employed persons 16 and over were government workers, compared to Manhattan (10%) and the City (16%). Moreover, 9% of the study area's working population was self-employed, the same proportion as in Manhattan and a somewhat higher proportion than in the City (6%).

From 1990 to 2000, the number of persons in the labor force increased at a faster rate in the study area (4%) than in the borough (less than 1%) or the City (1%). Among employed persons, those engaged in government jobs increased by 8% in the study area, compared with a 15% decrease in the borough and a 10% decrease in the City.

Current forecasts indicate that about 149,866 employees worked in Manhattan CD 8 in 2005, which was about 7% of the borough's total employment.[1]

6.3.1.2.5 Housing

In 2000, most housing units in the two-census-tract study area were built before 1969; the majority of housing units in both Manhattan and the City were slightly older, built before 1959. As of 2000, there were 7,961 housing units in the study area with a vacancy rate of about 6%, lower than the borough (8%) but about the same as the City. About three-quarters of housing units were renter-occupied, which was about the same as in the borough and greater than the City (66%). Median monthly rent ($781) was about the same as in the borough, but higher than in the City ($705).

The majority of study area householders moved into their units between 1990 and 2000 (65%), slightly greater than the percentages in the borough and City (61%).

From 1990 to 2000, a total of 176 housing units were added in the study area, representing a 2% increase, the same as in the borough, but a somewhat lower proportional increase than in the City (7%).

6.3.1.2.6 Education

Consistent with the lower percentage of children in the study area than in the borough or the City, there was a lower rate of school enrollment (19%) than in either the borough (24%) or the City (29%). Of those people enrolled in school, 48% were attending elementary or high school and about 37% were attending college or beyond. The study area witnessed a 19% increase in the number of persons enrolled in school from 1990 to 2000, with the largest increase in enrollment occurring at the pre-primary school level.

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

The study area had higher educational attainment levels than either the borough or the City. Compared to the larger areas, a larger percentage (81%) of the study area population aged 25 and over had a college degree or some college education. Compared to Manhattan (14%), the study area had a slightly lower percentage of people with only high school diplomas (5%).

From 1990 to 2000, the study area witnessed rising levels of educational attainment. The number of college graduates increased 21%; the same trend was evident in the borough and the City. Meanwhile, the numbers of people with less than a college education declined in the study area.

6.3.1.2.7 Income and Poverty

In 2000, both median household income ($51,150) and median family income ($60,606) were higher than in Manhattan (median household: $47,030; median family: $50,229) and the City (median household: $38,293; median family $41,887). Compared to the larger two areas, a lower percentage of study area households were concentrated at the lowest income levels, with the majority of annual household incomes above $50,000 and about 32% above $100,000. Only 23% of households in the study area had incomes below $25,000, compared with 30% in the borough and 35% in the City.

The study area had a lower percentage of families living below the poverty level (11%) than in Manhattan (18%) or the City (19%). A significant percentage of these families below the poverty level (45%) had children under the age of 18, lower than Manhattan (48%) or the City (55%).

A lower percentage of persons in the study area under the age of 18 were living below the poverty level in 2000 (18%) than in Manhattan (32%) and the City (30%). The 2000 Census also reported that 11% of persons 65 and older were living below the poverty level in the study area, compared to 19% in Manhattan and 18% in the City.

From 1990 to 2000, the percentage of people living below the poverty level in the study area increased by 35%, as compared with a minimal change in the borough and a 21% increase in the City.[2]

6.3.1.3 Economic Conditions

The portion of the Upper East Side within approximately ½-mile of the site contains dense residential development, schools and other institutional uses. Ground-floor commercial establishments serving the neighborhood line First and Second Avenues, and several specialized commercial enterprises (such as wine shops, gourmet groceries and some restaurants) can be found on the side streets. Automobile-related uses, such as gas stations, repair, rental and garages are present along First Avenue and some side streets. The residents of the area are not necessarily employed within the same area and, likewise, the employees staffing the commercial and institutional establishments in the neighborhood do not necessarily reside there.

6.3.2 Future No-Build Conditions

6.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Manhattan CD 8 will remain about the same as current conditions.[3]

6.3.2.2 Economic Conditions

No notable changes to economic conditions are predicted for the area by 2006, although a new hotel will be in operation at East 91st Street and First Avenue.

---

[2] Census 2000 may capture greater numbers of persons and families living below the poverty level than earlier census counts due to Service-Based Enumeration (SBE). The SBE operation was designed for Census 2000 to improve the count of individuals who might not be included through standard enumeration methods, and was conducted in service locations, such as shelters and soup kitchens, and at targeted outdoor locations.

[3] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

Regional projections indicate that employment in Manhattan CD 8 will remain about 7% of the borough total.[4]

6.3.3 Potential Impacts with the East 91st Street Converted MTS

The East 91st Street Converted MTS represents the reactivation of solid waste transfer operations with added containerization functions at the site~~. Therefore, it~~, which would not result in socioeconomic changes in the study area. The land use patterns have not changed dramatically since this MTS discontinued its operation in 1998. Technical analyses indicate that no traffic, air, odor, noise or other impacts would result from the operation of the East 91st Street Converted MTS. ~~–~~No significant direct or indirect impacts are anticipated related to socioeconomic conditions.

6.3.3.1 Residential Impacts

No direct residential displacement would occur as a result of the East 91st Street Converted MTS, and land use and neighborhood character analyses predict no adverse impacts (see Sections 6.2.3 and 6.8.3, respectively).

6.3.3.2 Direct Business and Institutional Impacts

The East 91st Street Converted MTS would not result in the direct displacement of businesses or institutional uses.

6.3.3.3 Indirect Business and Institutional Impacts

The East 91st Street Converted MTS would not result in indirect impacts to study area businesses or institutions. Of the few businesses located on nearby side streets that will once again serve as DSNY and other agency collection vehicle access routes (East 90th and 91st Streets between York and 1st Avenues), patronage would not likely be affected by the reactivation of solid waste transfer operations at the East 91st Street MTS. Since no adverse impacts to neighborhood

[4] Ibid.

character are predicted (see Section 6.8.3), and these businesses (in particular, Eli's grocery and the Vinegar Factory Restaurant) are entirely enclosed and rely primarily on pedestrian traffic, they would not be particularly sensitive to any associated increases in truck traffic on the street. As indicated in Section 6.14.4.4, no impacts to pedestrians are predicted, per CEQR screening methodology. The remain~~der of smaller~~ing businesses, located as they are on heavily traveled avenues, would similarly not likely be affected. The Asphalt Green recreation complex was constructed around the once active existing MTS entrance drive and ramp. The complex (building and field) is surrounded by protective fencing and landscaping to physically ~~and visually~~ buffer it ~~itself~~ from the existing MTS ramp that bisects the property. With the East 91st Street Converted MTS, visual buffering between the ramp and adjacent property would be provided by a wall designed for this purpose. (See Figure 2.2.3-7). Given this design and the fact that no operable windows open onto the entrance drive or face the MTS on FDR Drive, reactivation of the MTS would have minimal effects on the recreation center's function. Therefore, no indirect business and institutional impacts are predicted.

6.3.3.4 Employment Impacts

The East 91st Street Converted MTS is expected to generate a total of approximately 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts (likely beyond the study area), the new workers would generate a minor amount of indirect economic benefits in the study area through local spending.

6.4 Community Facilities and Services

6.4.1 Existing Conditions

6.4.1.1 Definition of the Study Areas

The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼-mile and ½-mile of the site.

6.4.1.2 Summary of Community Facilities and Services

There are 10 community facilities in the primary study area and 25 in the secondary study area. These facilities and others serving the site but located outside the secondary study area are listed in Table 6.4-1 and shown on Figure 6.4-1.

6.4.2 Future No-Build Conditions

There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

6.4.3 Potential Impacts with the East 91st Street Converted MTS

The East 91st Street Converted MTS would not create any significant new demand on services and community facilities and would not displace facilities or disrupt services. The FDNY states that it would have no problem supporting the reactivation of the site (see Appendix A). No significant adverse impacts to service delivery are expected.

6.5 Open Space

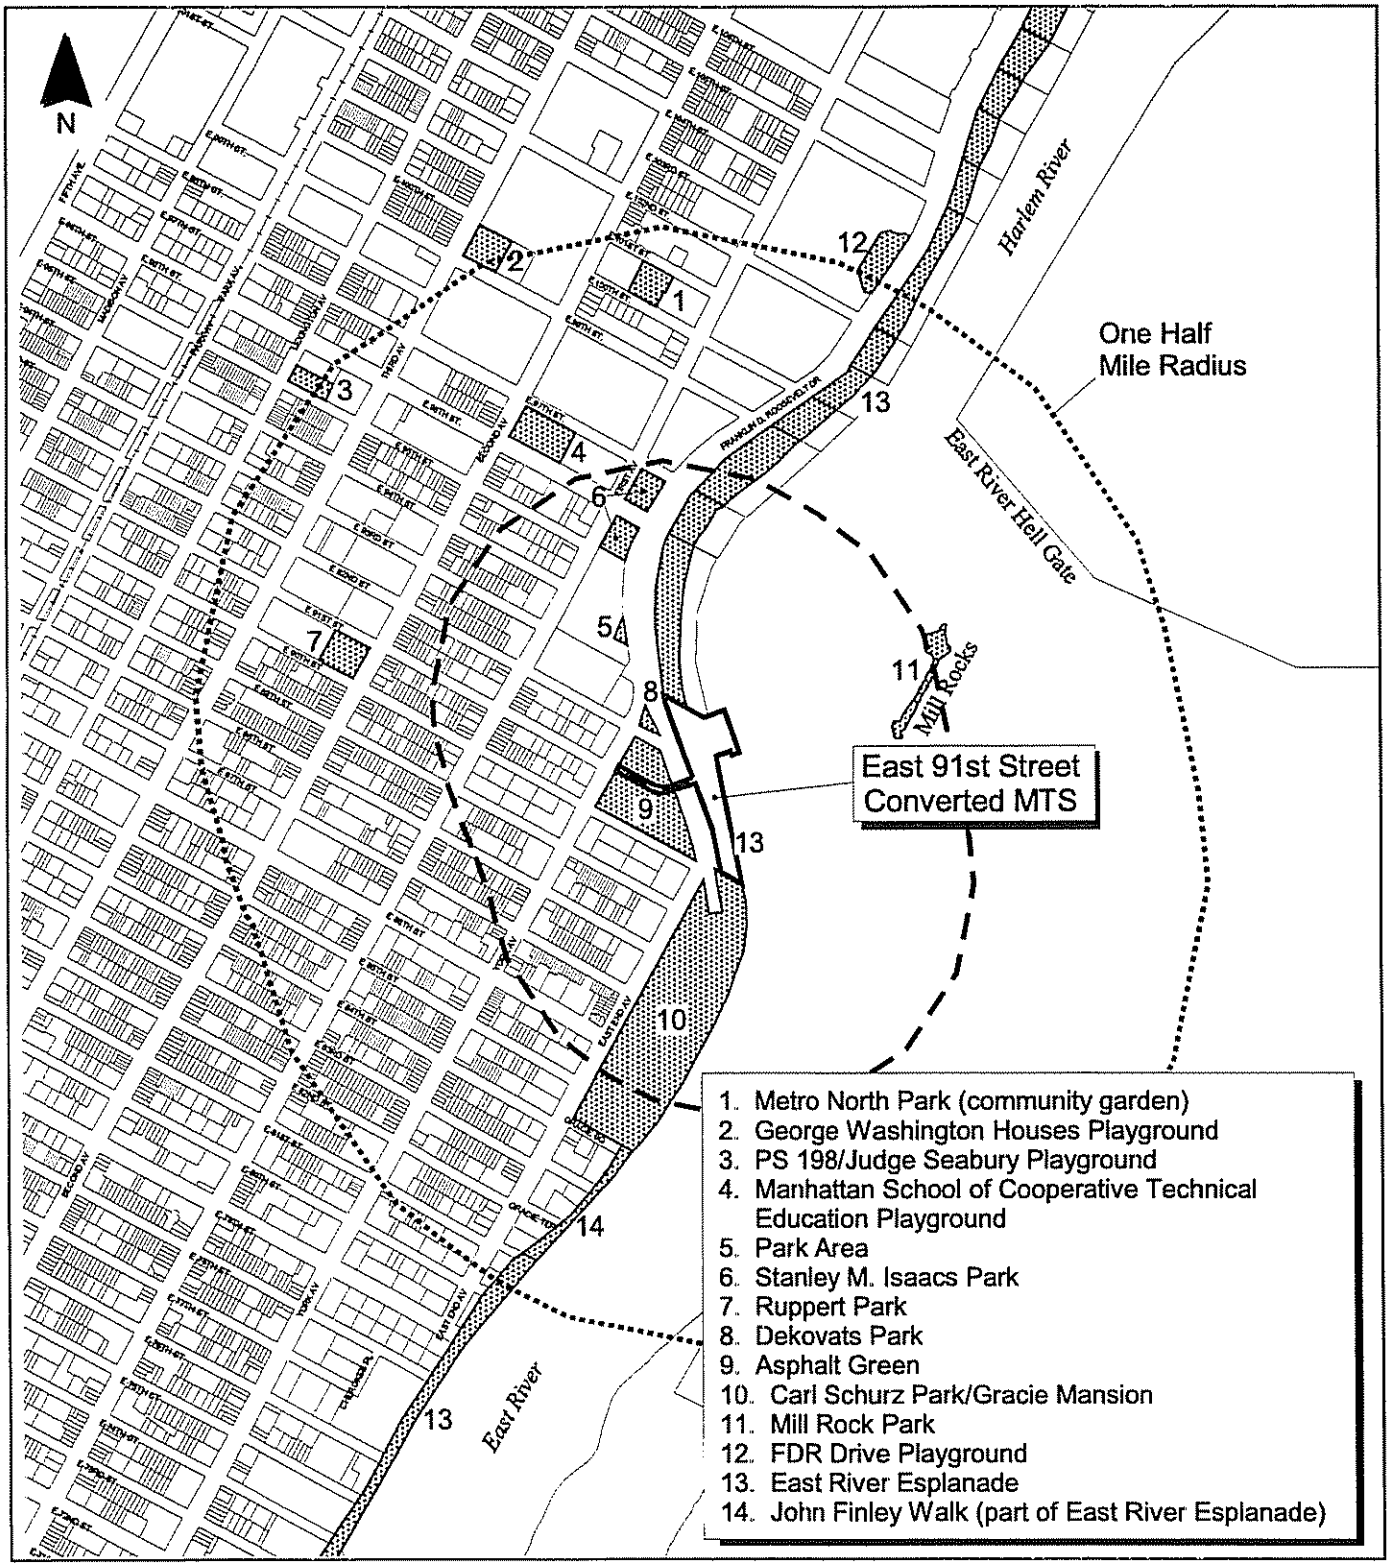
6.5.1 Existing Conditions

6.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

6.5.1.2 Summary of Open Space in the Study Area

There are 11 public parks and open spaces within the study area~~,~~ and three just outside to the north. They are shown on Figure 6.5-1 and listed in Table 6.5-1.



Of particular interest are the closest facilities: Asphalt Green, Carl Schurz Park ~~and~~, the East River Esplanade that runs along the water~~-~~, adjacent to the MTS and DeKovats Park. Asphalt Green is a 4.35 acre park and community facility that contains a variety of indoor and outdoor recreational opportunities, including an aquatics ~~center~~ center, private rooftop center, and playground north of the existing MTS ramp (between East 91st and 92nd Streets)~~,~~; and a gym, track and theater in the old municipal asphalt plant, and an outdoor field and track on the parcel between East 90th and 91st Streets, south of the ramp approximately 100 feet west of the MTS site.

Carl Schurz Park, is a 15-acre City park situated between East 84th Street (Gracie Square) and East 90th Street east of East End Avenue, is home to Gracie Mansion. It extends over the FDR Drive, approximately 200 feet south of the site. It features benches, play areas, a small-dog park, lawn and an esplanade that overlooks the waterfront and beyond.

The East River Esplanade follows the river and extends over three miles from just north of the Queensboro Bridge (East 63rd Street) north to the Triborough Bridge (East 126th Street). The Esplanade includes over 14 acres of pedestrian/biking space and passive recreation benches~~, outboard of the FDR Drive, to the north and south of Carl Schurz Park.~~ The northern portion of the Esplanade near the MTS site is accessible via a ramp from Carl Schurz Park at East 88th

Street, and the southern portion is accessible via stairs at Gracie Square. The paved esplanade is planted with trees and offers wonderful riverside views, but the park experience is greatly affected by its location beside the heavily-traveled FDR Drive.

DeKovats Park is located at East 92nd Street and the FDR Drive. This 0.05-acre greenspace is a landscaped traffic island, which does not offer direct space for public activity.

Site delineations and study area boundaries are approximate.

6.5.2 Future No-Build Conditions

NYCDPR has no new long-term development plans or notable development projects associated with the open spaces in the study area, except for possible enhancements of Asphalt Green and the new irrigation and fencing to be installed at Ruppert Park several blocks west of the site that will be completed within the next few years. The site will remain DSNY property and the existing MTS will remain, though inactive.

6.5.3 Potential Impacts with the East 91st Street Converted MTS

The East 91st Street Converted MTS would not introduce a new population to the study area and, therefore, the utilization of the nearby open spaces would not be increased. Although a new ramp would be constructed, it would follow the same footprint as the existing ramp; therefore, no parkland would be taken, and access between areas north and south of the drive would not be changed.

The site is, however, within close proximity to several open space resources, and its associated trucks would likely queue on the ramp that currently bisects the Asphalt Green complex and passes over the East River Esplanade. The results of the odor analysis (see Section 6.16), which analyzed potential effects of the queuing trucks and operations of the East 91st Street Converted MTS, indicate that there would be no odor impacts at the site boundary, along the esplanade, within Carl Schurz Park, or within the Asphalt Green property. Therefore, no permanent impacts to open space would result. (See Chapter 32 for discussion of potential impacts to open space associated with construction activities.) ~~to nearby sensitive receptors resulting from the queuing trucks or operations of the proposed East 91st Street Converted MTS.~~

6.6 Cultural Resources

6.6.1 Existing Conditions

6.6.1.1 Definition of the Study Area

The cultural resources study area is defined as that area within ½-mile of the site.

6.6.1.2 Development History of the Area

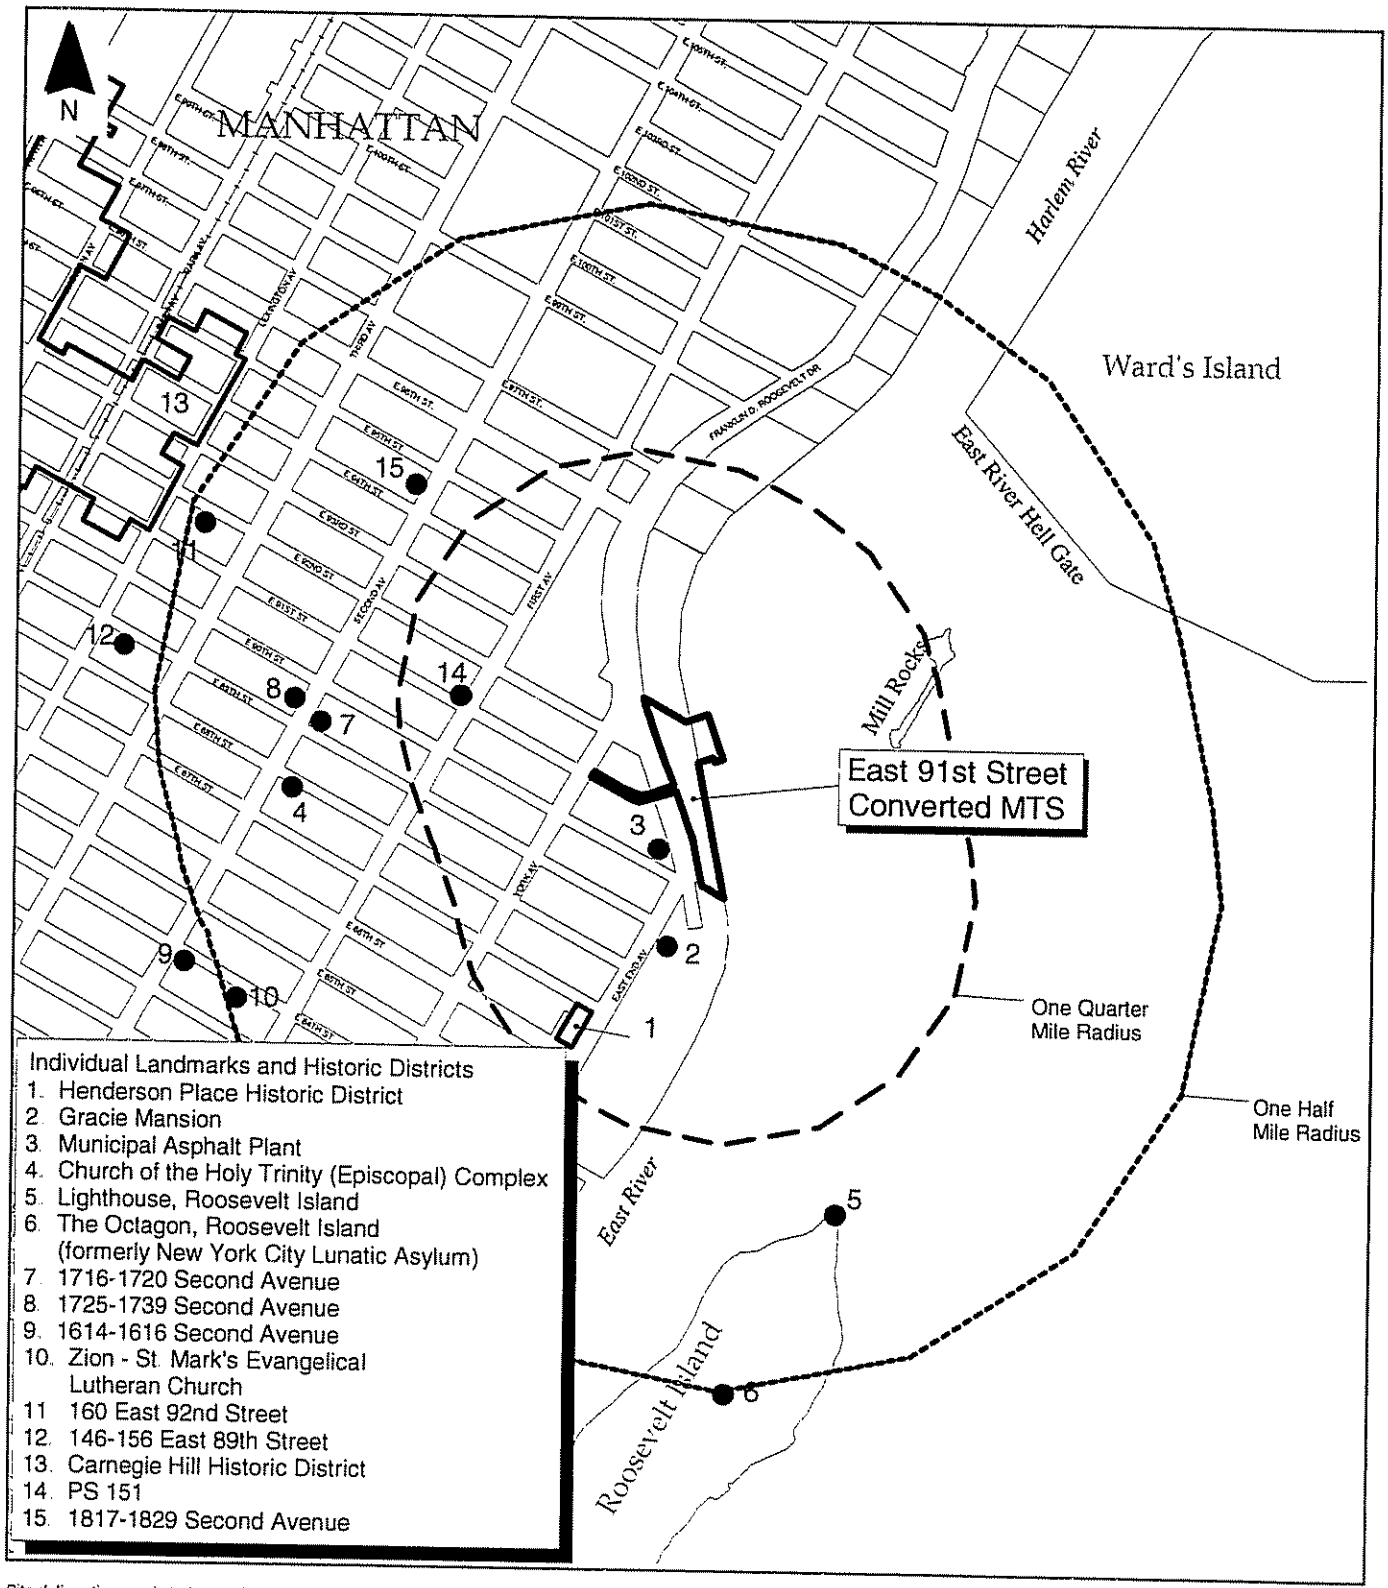
The study area is located in Yorkville, a historic neighborhood on the Upper East Side of Manhattan. It was once a rural village centered at East 86th Street and Third Avenue between the farmlands of Harlem to the north and the urban settlement of New Amsterdam to the south. By 1850, Yorkville was a predominantly German community about 1½ miles from the northern edge of the City. The hamlet could be reached from the City by a regularly scheduled stagecoach that ran to Third Avenue and East 86th Street. It was also home to Hazzard's roadhouse, the first stop for coaches carrying passengers from the Hell Gate Ferry at the eastern terminus of East 86th Street.

By the turn of the 20th century, Yorkville's population was more diverse, with the largest ethnic groups being Irish, Germans, Hungarians, Jews, Czechs, Slovaks and Italians, each living in distinct enclaves. The center of the neighborhood remained East 86th Street, which featured local commercial establishments.

Following the Civil War, squatters' shacks in the community were replaced by two-story houses for the wealthy, who moved to new luxury mansions and then apartment buildings on Madison, Fifth and Park Avenues in the late 19th and early 20th centuries. Many of these surviving buildings (some of which have become museums and other institutions) are now included in the Upper East Side Historic District, a locally and nationally recognized district. Many brownstones and tenements became or were replaced by multi-family dwellings with ground-floor shops. The Third Avenue elevated line began service in 1878 followed by the Second Avenue line the next year.

Tenement buildings, many of which still stand today, lined many of the easternmost streets and avenues. In fact, several on Second Avenue are historically notable and considered eligible for listing in the SRHP.

Gracie Mansion, originally the country home of Archibald Gracie, a successful Scottish businessman, is located at East 88th Street and East End Avenue overlooking the East River. In 1942, after several owners, additions and renovations, the 18th-century house became the mayor's official residence. The park in which Gracie Mansion is situated is named for Carl Schurz (1829-1906), a reformer, avid conservationist, editor of the New York Evening Post and The Nation, and the neighborhood's most famous 19th-century resident.



After World War II, the Third Avenue elevated line was dismantled and when many brownstones and tenements were demolished and replaced with high-rise apartment buildings, their eastern European residents moved to the suburbs. Gentrification in the years following continued to change the character of the neighborhood. Today, for example, the Rhinelander Mansion, once the home of the most influential family in Yorkville is now home to Ralph Lauren's Polo enterprise.

6.6.1.3 Cultural Resources on the Site

There are no elements of architectural or archaeological significance within the site.

6.6.1.4 Historic Resources Within the Study Area

One historic district and several other historic properties are located within the study area, representing different stages of the neighborhood's development over the last 200 years (see Figure 6.6-1). These properties are listed in Table 6.6-1.

Site delineations and study area boundaries are approximate

Notes:
SRHP = New York State Register of Historic Places
NR= National Register of Historic Places
NYCL= New York City Landmark

6.6.2 Future No-Build Conditions

Several individual tenement buildings on Second Avenue and P.S. 151 on First Avenue have been determined to be eligible for listing on the SRHP. Except for these properties, there is no reason to anticipate the designation of other resources in this area in the near future. Even with their potential designation, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

6.6.3 Potential Impacts with the East 91st Street Converted MTS

Based upon its review, SHPO has stated that the East 91st Street Converted MTS would have no impact upon cultural resources in, or be eligible for inclusion in, the SRHP and NR. The LPC has stated that the site contains no architectural or archeological significance (see Appendix A). The East 91st Street Converted MTS would not result in adverse impacts to cultural resources and no mitigation measures would be warranted.

6.7 Urban Design, Visual Resources, and Shadows

6.7.1 Existing Conditions

6.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (see Figure 6.8-1). The site is separated from nearby residential uses by the FDR Drive and Carl Schurz Park, which itself screens some street-level views to the waterfront. Upper floors of apartment towers on East 91st Street and York Avenue likely have views of the site, as do outdoor field users of the Asphalt Green complex that borders both sides of the existing MTS entrance drive, and the users of East River Esplanade that runs along the river, beneath the MTS entrance ramp and adjacent to the facility itself. Due to the site's location on the waterfront, view corridors from points of waterfront access are the areas of primary concern in assessing potential impacts to urban design and visual quality.

6.7.1.2 Description of the Site

An existing inactive MTS is on the site. When it was operating, full DSNY trucks drove into the existing MTS (a 56-foot-tall prefabricated steel building), unloaded within the building and drove out of the building and off the property. The facility is accessible via a drive/ramp that bisects the Asphalt Green complex to the west. The ramp crosses above the FDR Drive and the East River Esplanade, entering an elevated platform over the water. There is no land portion of the site (see Figures 6.7-1 and 6.7-2).

6.7.1.3 Urban Design and Visual Resources of the Study Area

The East River Esplanade provides an attractive waterfront edge to Carl Schurz Park. It features benches and decorative fencing and lighting, and is wide enough to comfortably accommodate runners, walkers and cyclists (see Figure 6.7-3). Open views of the waterfront, Randall's Island, Astoria (Queens) and Wards Island are as attractive as the views of the nearby landscaped Carl Schurz Park. Traffic is unseen, as the FDR Drive runs beneath the esplanade in the

Figure 6.7-1 : View of East 91st Street MTS from adjacent East River Esplanade.

Figure 6.7-2 : View of East 91st Street entrance ramp on York Avenue, bisecting the Asphalt Green Complex.

This page intentionally left blank.

Figure 6.7-3 : View of East River Esplanade, facing south from approximately East 88th Street (FDR Drive visible beneath the esplanade).

Figure 6.7-4 : Ferry Terminal at East 90th Street.

This page intentionally left blank.

area of the park. The esplanade, which is elevated over the FDR Drive near the park, descends to the elevation of the FDR, running alongside the FDR north of the park, where a ferry terminal is located at East 90th Street (see Figure 6.7-4). Alongside the existing MTS, the esplanade is traversed by the access ramp to the MTS. Trees planted in the esplanade near the existing MTS and park streetlights soften the appearance of the structure's industrial facade.

Views toward the west from the esplanade are of the 20- to 30-story apartment towers located in the neighborhood below East 96th Street, including the George Washington Houses complex (see Figures 6.7-5 and 6.7-6). Further inland near these residences are the busy First and Second Avenue corridors, which are lined with active commercial and automotive uses. East End Avenue, an 11-block long street, is relatively quiet and lined almost exclusively with tall residential complexes with attractive views of Carl Schurz Park from the street.

6.7.2 Future No-Build Conditions

There are no plans for the site or surrounding environs that would lead to significant changes in urban design or visual conditions. The new residential developments on East 89th and East 91st Streets (see Section 6.2.2) would not alter the general visual quality or design of the study area. The anticipated Future No-Build Conditions, therefore, are fundamentally the same as Existing Conditions.

6.7.3 Potential Impacts with the East 91st Street Converted MTS

6.7.3.1 Visual Quality and Urban Design

The East 91st Street Converted MTS would resemble the existing MTS it would replace in terms of its building typology, massing and position and elevated access, as well as adjacency to the esplanade. However, it would stand nearly double in height (approximately 100 feet tall). Associated cranes used to transfer containerized waste to waiting barges are expected to be approximately 80 feet at their highest point. Additionally, the ramp will include 12- to 14-foot ~~noise~~ walls running along its edges, designed to hide queuing trucks on the ramp from users of the Asphalt Green complex. these~~which~~ will make the crossing over the FDR and esplanade more visually prominent, though without blocking significant views.

This page intentionally left blank.

Figure 6.7-5 : View south toward East 91st Street MTS from East River Esplanade at approximately East 92nd Street. The MTS is visible to the left and a portion of the Asphalt Green Complex is visible to the right, with high-rise residences on York Avenue visible in the distance.

Figure 6.7-6 : View south toward East 91st Street MTS from East River Esplanade at East 96th Street.

This page intentionally left blank.

The nearly 50-foot increase in height over the existing MTS is not expected to affect inland views toward the waterfront since these views are largely screened by trees within Carl Schurz Park, which is set approximately 20 to 25 feet above the MTS site elevation. The MTS site is visible from the East 88th Street ramp to the esplanade, ~~or~~ and from a vantage point further south on the Carl Schurz Park promenade. The closest possible views of the MTS – at the northern edge of the park near Gracie Mansion – are no longer open to the public. Views from nearer the waterfront, such as from the promenade, are already obstructed to some extent by the existing facility. The overall scale and appearance of the new facility would not likely contribute to a substantial change of views toward the waterfront from upper-story residential uses along East End Avenue.

It is assumed that the landscaping of the walkway near the existing MTS would be retained or replaced, and the esplanade and water area below the entrance around the facility would be properly maintained when the new facility is constructed and operating. As with the previous MTS operations, ~~The appearance of the new structure would resemble that of the existing one, with~~ the barges would be located on the northern side of the facility, which is less visible from the park and buffered from inland street-level views. Therefore, the new facility and reactivation of the former ramp would result in no significant impact to the visual quality of the area, and the urban design of the area would remain virtually unchanged.

6.7.3.2 Shadows

According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.)

These parks were identified within the shadow impact study area:

- Asphalt Green: ~~Asphalt Green includes 5½ acre sports and training campus across York Avenue between East 90th and 92nd Streets in Manhattan. Outdoor activities include an AstroTurf field for team sports, running track, basketball courts, two outdoor parks, and rooftop terrace overlooking the East River.~~

- East River Esplanade~~: Lying between the FDR Drive and the East River, the East River Esplanade extends over three miles from just north of the Queensboro Bridge (East 63rd Street) north to the Triborough Bridge (East 126th Street). The Esplanade includes over 14 acres of pedestrian/biking space and passive recreation benches.~~
- Carl Schurz Park~~/Gracie Mansion between East 84th and East 90th Streets, is home to Gracie Mansion, pedestrian/bikeways and playgrounds for multiple age groups.~~
- DeKovats Park: ~~Located at East 92nd Street and the FDR Drive, this 0.05 acre greenspace is a landscaped traffic island, which does not offer direct space for public activity.~~

There are no expected physical changes to the project site or vicinity that might create new shadows on these resources in the Future No-Build Condition. Therefore, the shadow assessment considered only the consequences of the East 91st Street Converted MTS development.

An impact analysis of the 100-foot-tall East 91st Street Converted MTS and 80-foot-tall cranes determined that only two open spaces in the vicinity would be potentially affected by shadows. These two resources, Asphalt Green and the East River Promenade, would be affected to different degrees throughout the year. It should be noted that the existing 50-foot-tall MTS and ramp cast shadows on these resources currently, and the movement between Existing and proposed conditions is considered in this evaluation.

Asphalt Green: Analysis of December 21st indicates that the resource would not be affected by shadows. During the three other analysis periods, the northern portion of Asphalt Green would be shaded for 30 to 40 minutes in the early morning:(7:30 a.m. to 8:00 a.m. in March and June, 7:30 a.m. to 8:10 a.m. in May). As shadows would only affect lawn, benches and a playground for 30 to 40 minutes during three periods, ~~the East 91st Street Converted MTS is~~ this would not be considered ~~to cause~~ a significant shadow impact at this resource. (See Figure 6.7-7.)

Figure 6.7-7 Shadow Diagram

East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

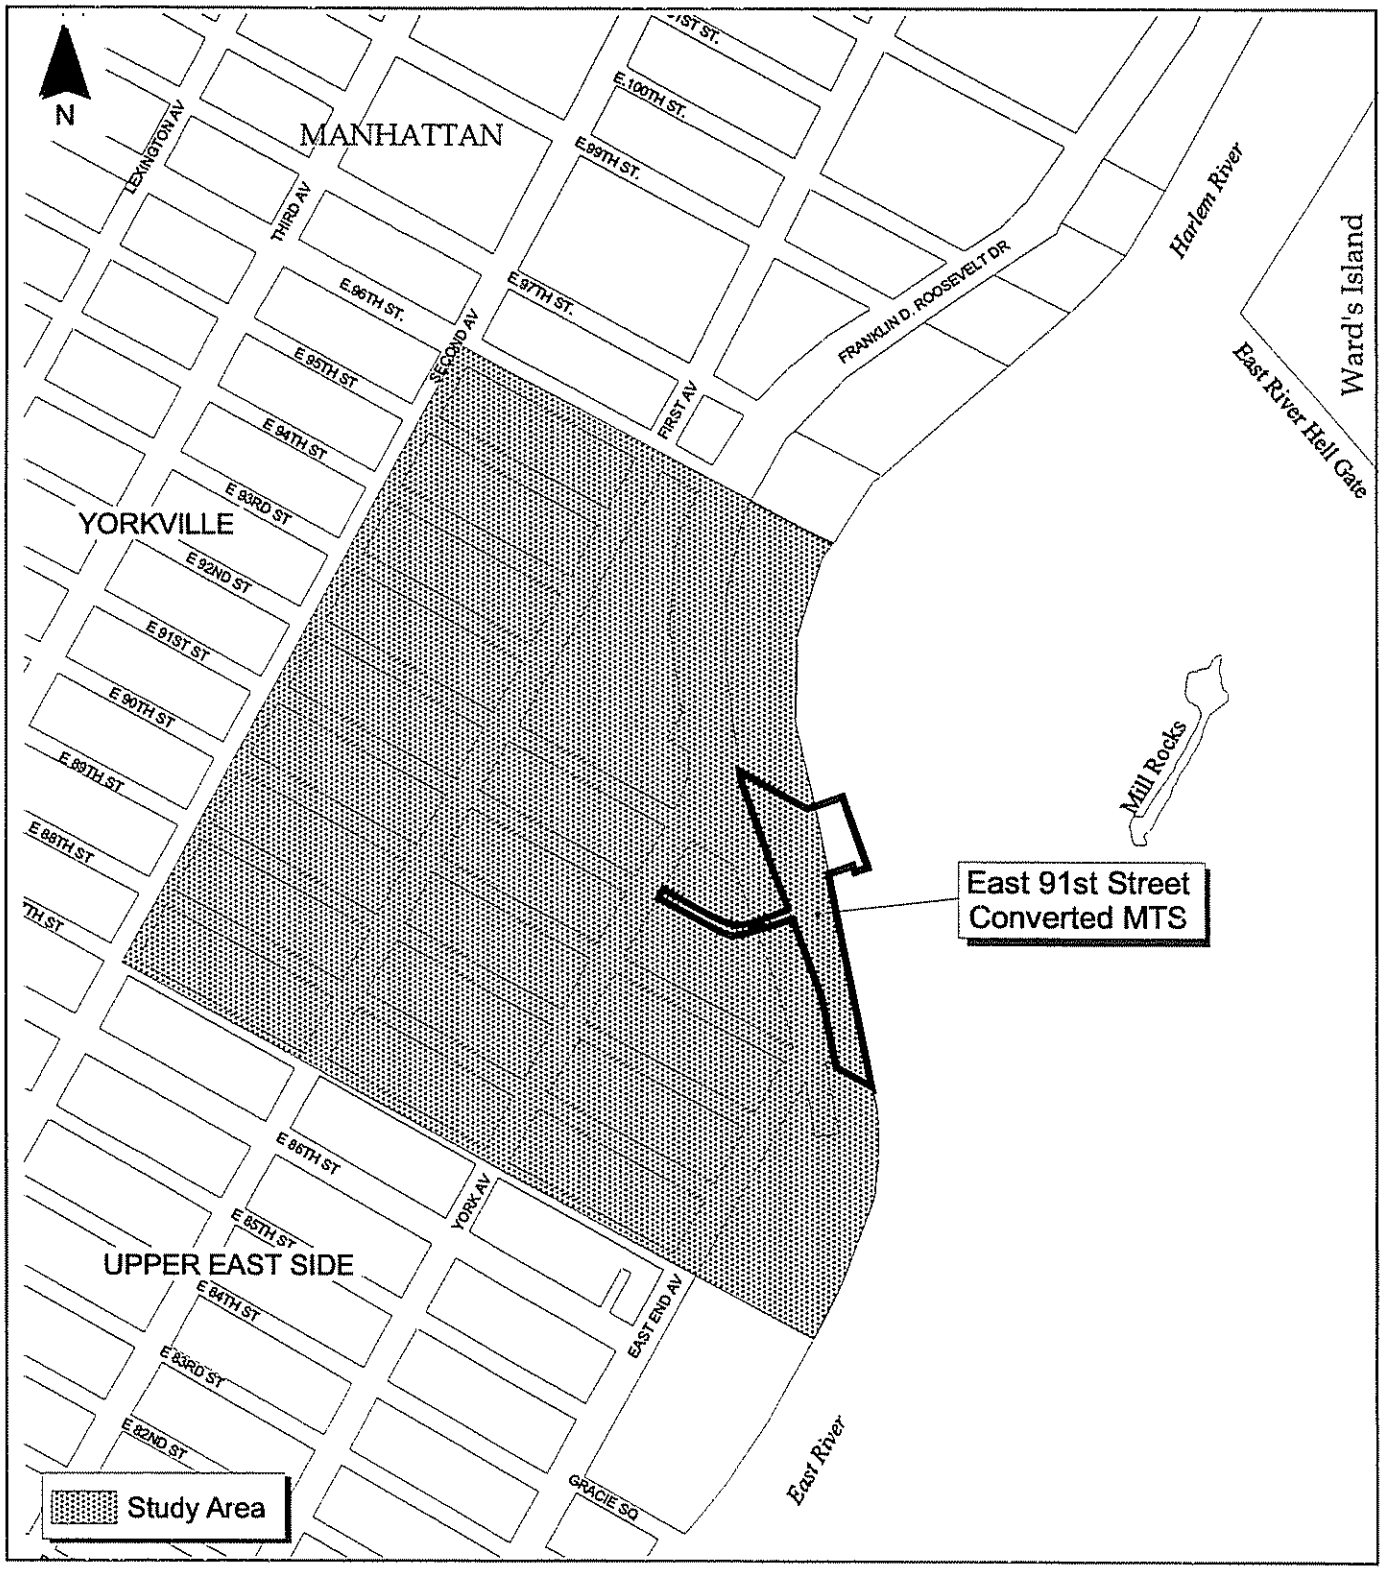
East River Esplanade: Similar to the existing MTS, ~~The~~ the East 91st Street Converted MTS would cast shadows on up to 200 feet of the 3.15-mile-long ~~Esplanade~~ esplanade adjacent to the MTS, for the following durations primarily in the morning hours:

- 7:30 a.m. – 11:00 a.m. (3 hours, 30 minutes) on March 21st;
- 7:30 a.m. – 11:50 a.m. (4 hours, 20 minutes) on May 6th;
- 7:00 a.m. – 12:10 p.m. (5 hours, 10 minutes) on June 21st; and
- 8:50 a.m. – 10:30 a.m. (1 hours, 40 minutes) on December 21st.

While five hours of shadow is a significant portion of the day, ~~the affected area of this resource is limited, comprising a small segment of the Esplanade.~~ This is not a new shadow. In addition, the majority of the uses of this section (biking and pedestrian activities) are transient and not dependent upon direct sunlight. These activities would be anticipated to continue in shadow for the minimal affected area. Due to the affected area's small size and the negligible impact on activities, the East 91st Street Converted MTS is not considered to cause a significant shadow impact at this resource.

6.8 Neighborhood Character

6.8.1 Existing Conditions



6.8.1.1 Definition of the Study Area

Unlike the other sites studied, this site is within fairly close proximity to both residential and open space resources, which are the two major factors contributing to the neighborhood character of the area. It is, however, somewhat separated from inland residential neighborhoods by the FDR Drive. Though the site is approximately 100 feet from the Asphalt Green complex and 200 feet from Carl Schurz Park, where Gracie Mansion is located, these park areas separate the residential areas from the site. The points of public access nearest the site are the East River Esplanade that runs outboard of the FDR Drive, and Asphalt Green. These two open space areas and Carl Schurz Park are included in the neighborhood character study area, which is defined by East 96th Street to the north, East 87th Street to the south, Second Avenue to the west and the East River shore to the east (see Figure ~~10-8.1~~6.8-1).

6.8.1.2 Description of Neighborhood Character

The visual quality of the area is pleasant, with well-maintained apartment blocks lining the streets, sidewalk trees and well appointed parks and recreational facilities. As with much of the Upper East Side, this area is conducive to pedestrians, though the nearest "convenience" stores (groceries, delis, etc.) tend to be located further west, along York Avenue and the busier First and Second Avenues, rather than East End Avenue. Lacking such commercial activity and given the 11-block length of East End Avenue, which is almost exclusively residential in the study area and not a major through street, the streets in that portion of the study area nearest the site are relatively quiet.

A few small warehouses and auto-related uses are intermingled with the residential uses in the interiors of three blocks south of East 92nd Street between York and First Avenues. Their presence, however, does not detract from the otherwise solidly residential nature of the area, either in appearance or in relatively limited activity, given that streets running through residential areas in Manhattan generally have more through traffic than many residential areas in other boroughs.

Site delineations and study areas are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Carl Schurz Park buffers the residential areas from the activity and visual presence of the FDR Drive, and in the study area the park extends over the highway, where a promenade provides access to the waterfront along the perimeter of the park and runs adjacent to the existing MTS.

The Asphalt Green complex is another major non-residential component, adding to the character and image of the neighborhood. Featuring several acres of outdoor sporting areas, as well as indoor pool and training facilities, the complex is an Upper East Side destination.

6.8.2 Future No-Build Conditions

There are no known plans for development on the site, the neighborhood parks or the overall study area, except for the construction of two multi-use/residential towers at 389 East 89th Street and at East 91st Street and First Avenue, both of which are fairly typical of the neighborhood. Therefore, it is reasonable to assume that Future No-Build Conditions will resemble Existing Conditions. The site will remain DSNY property and the existing MTS will remain standing.

6.8.3 Potential Impacts with the East 91st Street Converted MTS

The East 91st Street Converted MTS is not expected to result in significant impacts on neighborhood character because it would be a reactivation of waste transfer facilities on a site formerly used for that purpose, although compared to Future No-Build Conditions, the re-introduction of trucks into the neighborhood would be noticeable. DSNY and other collection agency vehicles would utilize York Avenue south of East 91st Street, also a busy thoroughfare that accesses the FDR, in addition to East 90th Street and East 91st Street, and First and Second Avenues north of East 91st Street; however, no unmitigatible traffic impacts are predicted. (See Section 6.14 for a discussion of potential traffic impacts.) Likewise, technical analyses predict no significant adverse air quality, odor or noise impacts. (See Sections 6.15, 6.16 and 6.17, respectively, for discussions of potential air quality, odor and noise impacts.) As indicated in Section 3.16, no impacts to pedestrians are predicted, per CEQR screening methodology.

The proposed East 91st Street Converted MTS ~~potentially could result in impacts to neighborhood character, however, due to potential odor conditions. The~~ site is unique among sites analyzed in that in addition to its proximity to dense residential uses, its operation places trucks on a drive that bisects an open space and passes over a completed waterfront esplanade. ~~In these two particularly sensitive locations, the presence of DSNY trucks may be detectable if they are not kept clean at all times, and if liquid residue spills onto the drive and ramp nearby.~~ Detailed odor analyses that analyzed potential effects on these sensitive receptors predict no impacts, however. Likewise, no impacts to air quality (Section 6.15), and no impacts resulting from noise (Section 6.17) are predicted. Therefore, the East 91st Street Converted MTS result in no impacts to neighborhood character.

6.9 Natural Resources

6.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Manhattan. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from the implementation of the East 91st Street Converted MTS.

6.9.1.1 Definition of Study Area

The study area includes the project site and the waterfront section that is bulkheaded and bounded by the Harlem River to the north and the East River to the south and east (see Figure 2.2.3-1). The upland sections of the study area and the surrounding neighborhood are completely developed and, therefore, have very limited terrestrial natural resources. Because the Future Build Conditions would include construction of a new MTS and dredging of bottom sediments, a description of aquatic communities is included.

6.9.1.2 Geology

Boring data from the City Department of Public Works drawing entitled "Record of Borings, Asphalt Green Sports and Recreation Center"[5] (September 16, 1980), indicated that no borings were collected within the footprint of the existing MTS. The closest borings were collected approximately 400 feet to the west and 1,500 feet to the southwest. Borings indicated that bedrock is expected at an elevation of 50 feet below grade (Borough of Manhattan datum) or shallower. The uppermost layer consisted of organic soils comprised of soft, dark gray to black organic soils, shells and thin clay and sand lenses. Based upon a review of data for sites in proximity to the East 91st Street site, it would be expected that a sand stratum would underlie these organic soils. Bedrock is described as hard, slightly weathered, gray fine-grained Gneissic schist. Previous boring data terminated in this stratum.

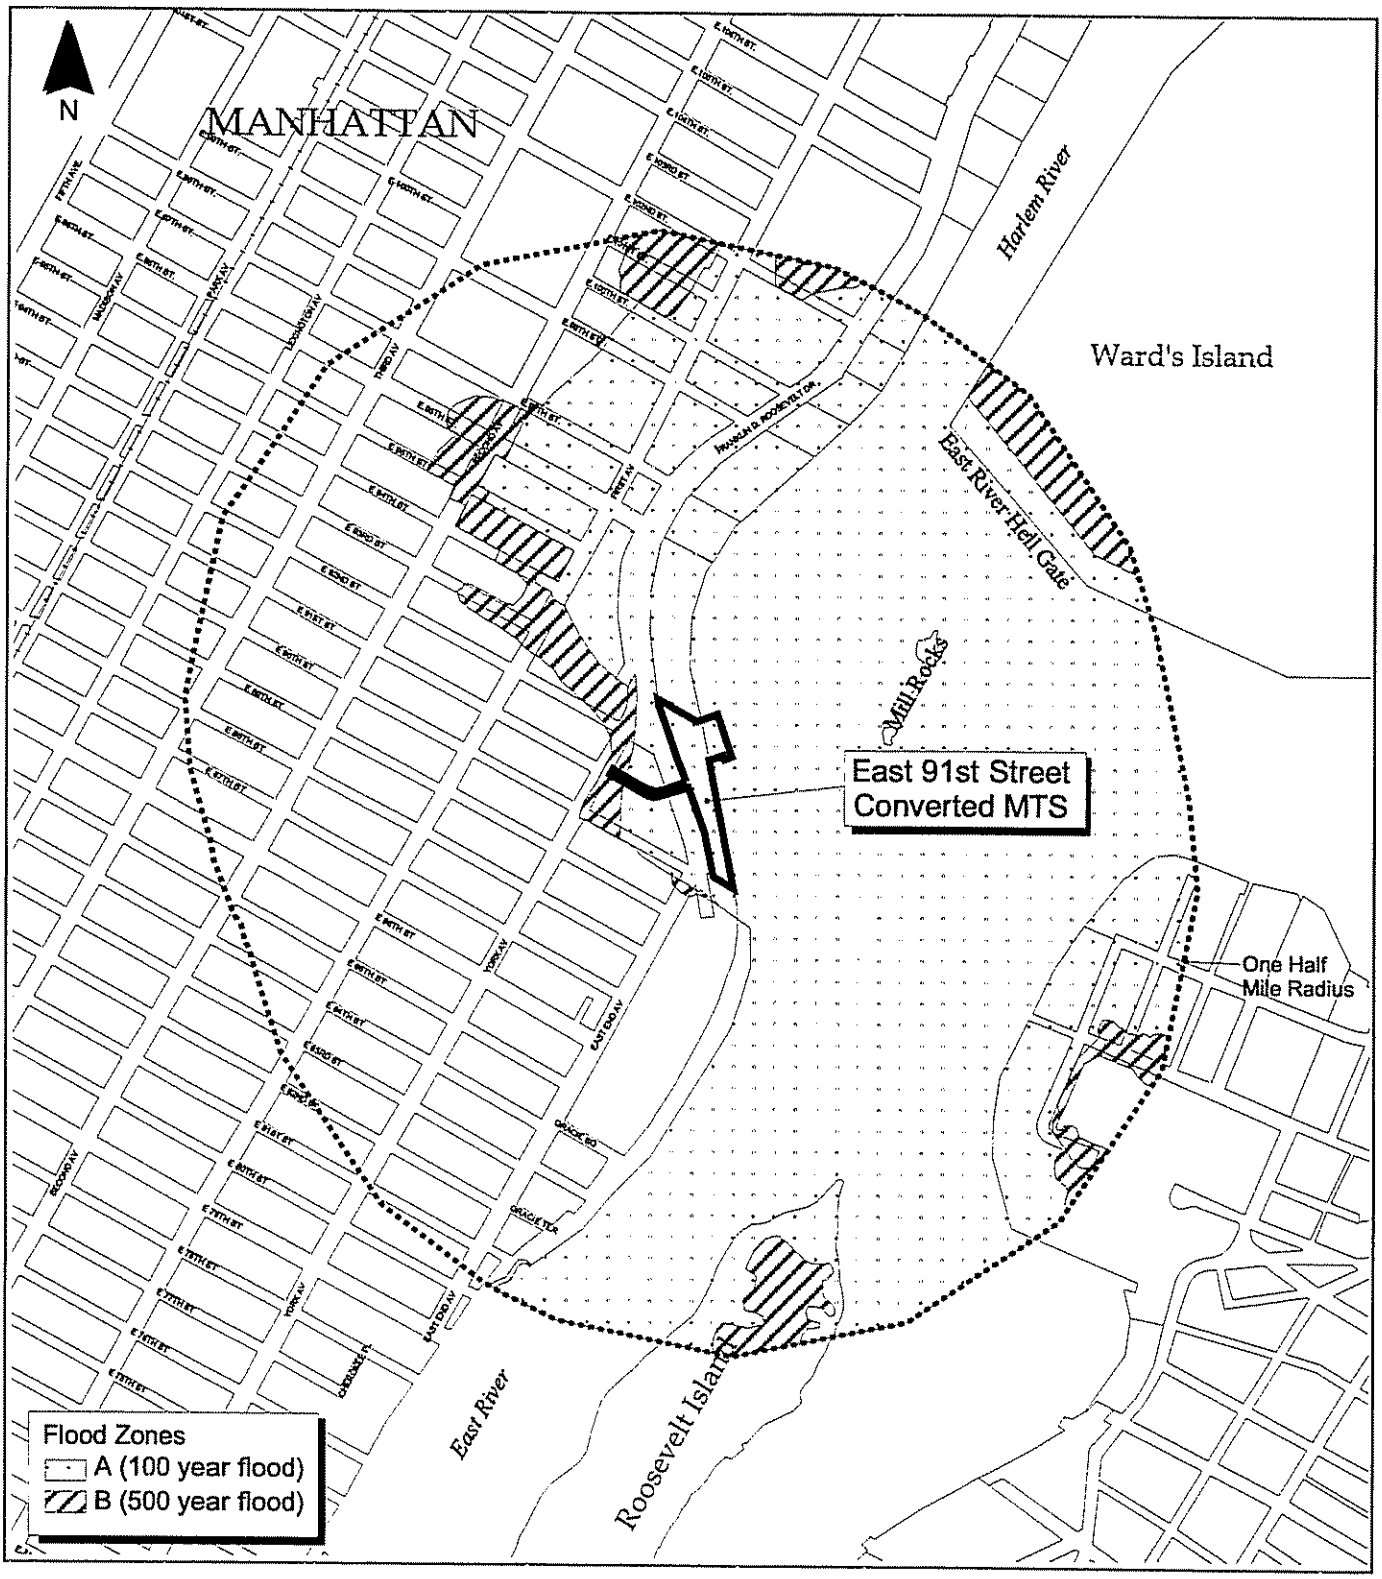
---

[5]"Record of Borings, Asphalt Green Sports and Recreation Center," September 16, 1980, by the New York City Department of Public Works, as cited in the "MTS Conversion Conceptual Design Report," April 2003, by Greeley and Hansen, LLC.

Surface sediment collected from the site in 2003 indicates the sediment to be 94.5% silt and clay, 5.2% sand and 0.5% gravel, and to have 58,363 mg/kg TOC.[6] Sediment was found to be somewhat degraded due to contaminants in the sample material. The metals in the sediment with the highest concentrations were lead, barium and chromium (123.90 mg/kg, 72.18 mg/kg and 71.73 mg/kg, respectively).

6.9.1.3 Floodplains

The study area is within the 100-year coastal floodplain (see Figure 6.9-1). There are no wetlands other than the East River, which is a NYSDEC-designated littoral zone, located in the study area (see Figure 6.9-2).



6.9.1.4 Ecosystems

The existing MTS is located on a platform above the East River and connected to Manhattan on the west side of the structure. The waters surrounding the study area are dominated by the East River, and aquatic resources are typical of the eastern sections of the East River. The terrestrial ecology of the upland portion of the study area is limited because the site is mostly developed and covered by structures and hard surfaces. The portions not developed have been altered by clearing and leveling and have no substantial ground cover other than opportunistic weeds.

A field program that took place in 2003 was designed to fully characterize the marine biological resources of the study area. The program included monthly sampling for finfish eggs and larvae and water quality, and quarterly sampling for benthic organisms and sessile colonizing organisms. Results of the program are presented in the following paragraphs.

The most abundant finfish eggs collected at the East 91st Street Converted MTS were cunner (*Tautogolabrus adspersus*), bay anchovy (*Anchoa mitchilli*) and Atlantic menhaden (*Brevoortia tyrannus*). The most abundant larvae were winter flounder (*Pleuronectes americanus*), anchovy

spp. (*Anchoa* spp.) and goby spp (*Gobiosoma* spp.).[7] Three species with an EFH listing were collected at the East 91st Street Converted MTS. Eggs and larvae of winter flounder and windowpane (*Scophthalmus aquosus*) and larvae of one summer flounder (*Paralichthys dentatus*) were identified during the sampling season.

The second highest number of benthic organisms was collected at the East 91st Street Converted MTS. The polychaete worm, *Streblospio benedicti*, was the most abundant and was present at approximately 61,000 individuals per square meter at this facility. A Jaccard's Index[8] suggested that the benthic community was less distinct than some of the other MTSs sampled. The most abundant epibenthic colonizers collected at the East 91st Street Converted MTS were *Corophium insidiosum* (amphipod), *Jassa falcata* (amphipod), *Polydora* sp. (polychaete worm), *Microdeutopus* sp. (amphipod), *Elasmopus levis* (amphipod), *Molgula manhattensis* (sea grape), and hydrozoa, mud and algal film.

The NYSDEC Natural Heritage Report on Rare Species and Ecological Communities reports the peregrine falcon (*Falco peregrinus*), a federally listed endangered species, to be found near the site on Wards Island and the Hell Gate Railroad Bridge.[9]

6.9.2 Future No-Build Conditions

If the East 91st Street Converted MTS were not to be built, the study area would remain as is. The absence of terrestrial natural resources would remain, and the upland portion of the study area would continue to be an ecologically unproductive and stressed urban area. Reasonably diverse and abundant aquatic natural resources would prevail in the waters in and around the study area.

---

[7] Ibid.

[8] A Jaccard's Index is a statistical test that shows the similarity of organisms present at compared MTSs. It shows the proportion of the number of species observed in either of two MTSs that occurred in both MTSs. The index ranges from zero to one. An index of zero means that the MTSs are completely dissimilar and have no species in common. An index of one means the MTSs have all the same species.

[9] Natural Heritage Report on Rare Species and Ecological Communities. Prepared by New York Natural Heritage Program, NYSDEC, Albany, New York, 2002.

6.9.3 Potential Impacts with the East 91st Street Converted MTS

6.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

6.9.3.2 Floodplains

The East 91st Street Converted MTS would have no effect on the elevation of the site. It would be constructed within the 100-year floodplain, and would not include any provisions for raising any portions of the site over this level.

6.9.3.3 Ecosystems

The East 91st Street Converted MTS would be a pile-supported structure and would result in a net gain of ~~43,657~~42,612 square feet of pier over the water. During the demolition of the existing MTS, the upper organic silts lying ~~beneath the structure that was above water~~under that structure would be disturbed to some degree, resulting in re-suspension of the sediment. However, the amount of re-suspended sediment is expected to be low, and the impacts, if any, highly localized. Turbidity and short-term, lowered, dissolved oxygen are possible, but not measurable, against the normal background fluctuations. Construction would involve installing piles for the foundation supports and dredging to accommodate barges. The benthic and finfish community would be temporarily disrupted during this phase of the project. It can be anticipated that the benthic invertebrates would recolonize the area within 6 to 12 months and that finfish

would return to the area immediately following completion of the construction.[10] The removal of the existing platform will also remove the existing epibenthic community; however, the new expanded platform will result in more surface area for epibenthic communities to colonize the site. This would positively affect the epibenthic communities at the East 91st Street Converted MTS.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction; flatfish (flounders) are least sensitive. Finfish eggs and larvae are more sensitive to suspended sediment, and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. In addition, larvae will be able to swim away from the impacted environments. Winter flounder eggs were found at the East 91st Street ~~Converted~~ MTS site, but construction impacts are expected to be negligible.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The proposed plan for the East 91st Street Converted MTS is for an increase in ~~43,657~~ 42,612 square feet of pier. This will result in increased shading that will block sunlight and hinder primary production. The enlarged platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[11] Epibenthic communities will have a larger surface area to colonize, and finfish should return to the area with the return of food sources.

---

[10] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

[11] Hudson River Center Site Aquatic Environmental Study Final Report, 1988. Prepared for New York City Public Development Corp. by EEA, Inc.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by EEA in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[12] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as they provide shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. This increase in shading over water will possibly lead to a slight shift in the finfish community with the addition of over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

The East 91st Street Converted MTS would not have any significant impact on the few areas of vegetation present on the site. Vegetation observed on the site were invasive weed species that were not rare, endangered or particularly important from an ecological perspective.

The peregrine falcon (*Falco peregrinus*), a federally listed endangered species, is known to occupy areas close to the site (Wards Island and the Hell Gate Railroad Bridge); however, there are no sources showing the peregrine falcon to nest on the existing MTS. Use of this site is probably limited to flyovers during hunting and migration; therefore, no significant impacts would be expected.

[12] Duffy-Anderson, J.T. & Able, K.W., 2001. "An Assessment of the Feeding Success of Young-of-the-Year Winter Flounder (*Pseudopleuronectes americanus*) Near a Municipal Pier in the Hudson River Estuary, U.S.A." Estuaries, Vol. 24, No. 3, p. 430-440.

6.10 Hazardous Materials

6.10.1 Existing Conditions

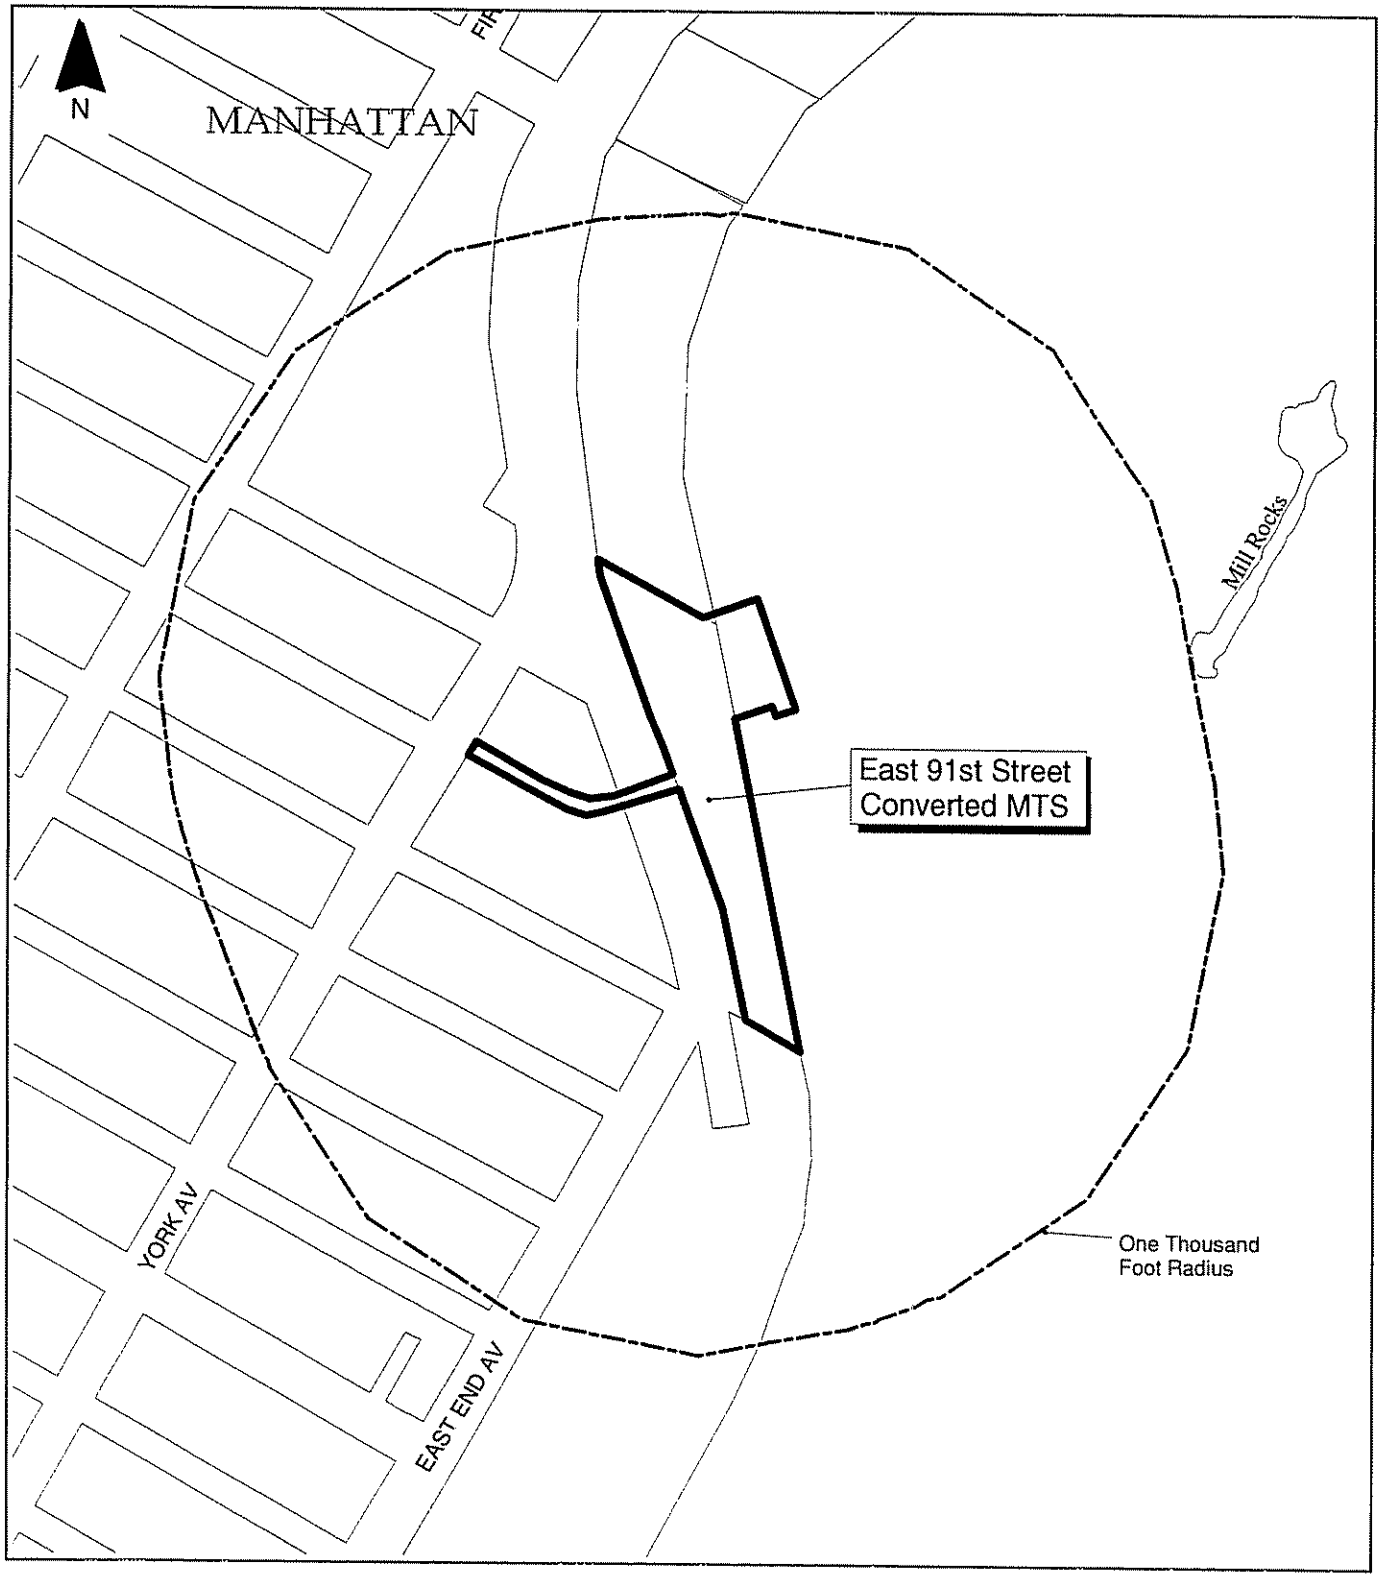
Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in ~~February~~ April, 2003 and included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps, as available, for the study area~~, if available,~~ and a Freedom of Information Law request to the FDNY for ~~UST~~ underground storage tank records. Standard ~~federal~~ Federal and ~~state~~ State environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was ~~attempted;~~ made on February 13, 2003. During the site boundaries reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains or odors. ~~however, access~~ Access to interior areas, including the fourteen-bay concrete tipping deck, toll booth, and bread room and the lower-level "vault room" was obtained on April 25, 2003.~~to the transfer station tipping deck and interior areas were not possible because of a padlocked gate at the end of the ramp on York Avenue. Therefore, site conditions are assumed based on historical and regulatory agency list reviews (2001 CEQR Technical Manual, Section 323). During the site boundaries reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors.~~ Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

6.10.1.1 Definition of Study Area

The study area includes the site and neighboring properties within a 1,000-foot radius (see Figure 6.10-1).

6.10.1.2 Delineation of Area of Concern



Areas of concern are defined as parts of the ground, groundwater, surface water or structures within the study area where the presence or likely presence of hazardous materials exists ~~and implementation~~for which modifications of the East 91st Street Converted MTS could lead to an increased exposure of people or the environment to those materials. No specific areas of concern at this site were identified ~~at this site~~ during the assessment.

6.10.2 Future No-Build Conditions

~~The existing MTS would remain standing and the site would remain as is~~Under Future No-Build Conditions, the existing East 91st Street MTS would continue as is. There would be no areas of significant concern with regard to hazardous materials.

6.10.3 Potential Impacts with the East 91st Street Converted MTS

Based on the information ~~that could be~~ obtained during this assessment, construction and/or ~~implementation~~ modification of the East 91st Street Converted MTS would not result in adverse impacts. No additional testing, other than an asbestos inspection prior to building demolition or modification would be required, ~~other than an asbestos inspection prior to building demolition or modification.~~. If any areas of concern were identified during the demolition or construction phase, an analysis would be made to determine what, if any, mitigation measures should be applied.

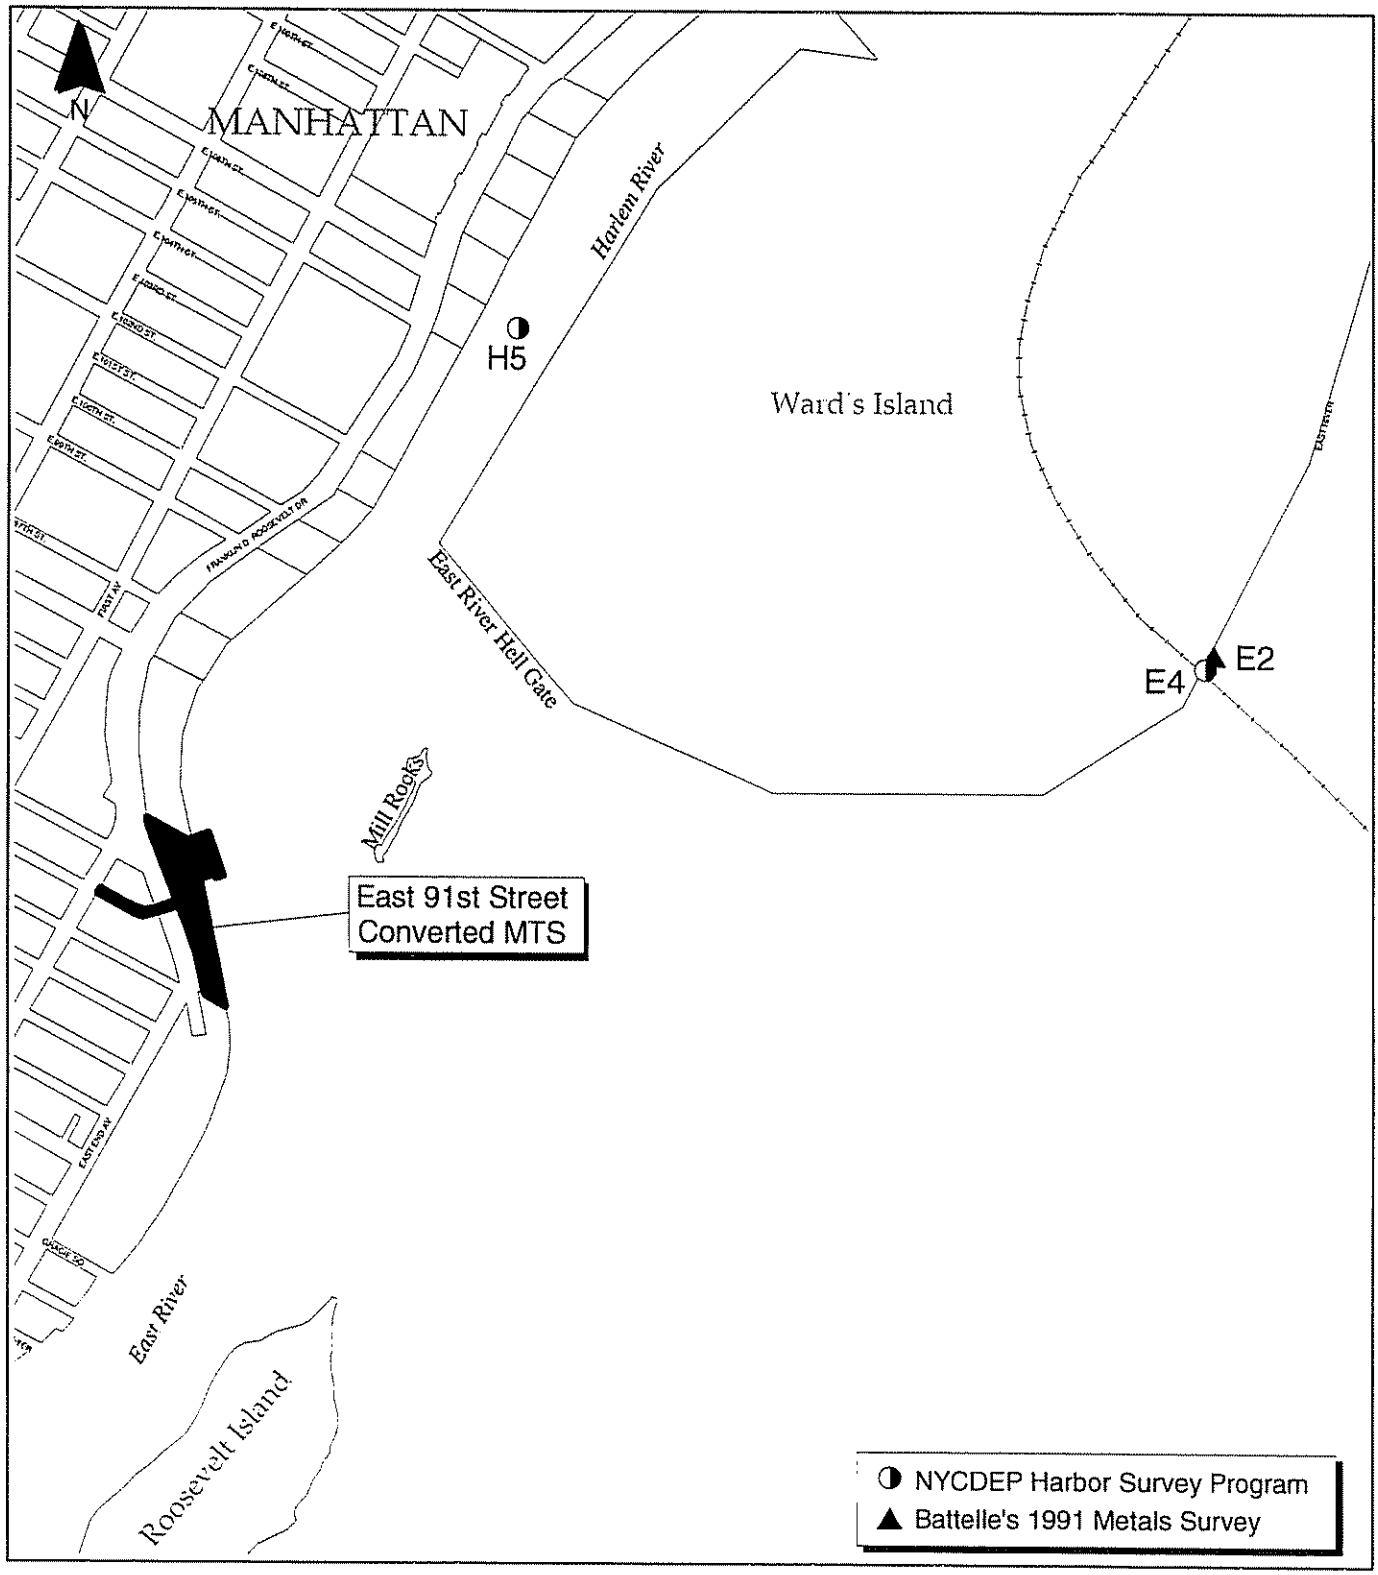
6.11 Water Quality

6.11.1 Existing Conditions

6.11.1.1 Definition of Study Area

The water quality study area encompasses the Harlem River and the East River, and includes discharges from CSOs located within ½-mile of the site.



6.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 6.11-1, are generally representative of water quality conditions in the study area:

- NYCDEP Harbor Survey Program – Stations E-4 at Hell Gate in the East River and H-5 at 106th Street in the Harlem River; and
- Battelle's 1991 Metals Survey – Station E-2 at Hell Gate.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 6.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class I," which indicates waters suitable for secondary contact recreation (i.e., fishing and boating).

As shown in Table 6.11-1, on average, NYSDEC standards and guidance values are met. For Harbor Survey Station E-4, however, the minimum surface and bottom dissolved oxygen between June 1, 2003 and September 30, 2003 did not meet the water quality standard for dissolved oxygen. For Harbor Survey Station H-5, the minimum surface and bottom dissolved oxygen between June 1, 1999 and September 30, 1999 did not meet the water quality standard for dissolved oxygen. In addition, the mercury concentration for Battelle Station E-2 did not confirm to the water quality standard for mercury.

6.11.1.3 Permitted Discharges

A review of the most recently available NYSDEC and USEPA databases indicated that there are 15 permitted discharges in the vicinity of the site. The existing discharges within a ½-mile radius are listed in Table 6.11-2 and shown in Figure 6.11-2. These discharges are all permitted by the NYSDEC.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

6.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, an estimate of existing stormwater pollutant loadings was calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% infiltration and/or storage. A runoff flow of 0.073 cfs was calculated using the impervious site area (1.22 acres), an average rainfall intensity of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 6.11-3, represent the existing loads at the site.

Table 6.11-3
Estimated Existing Pollutant Loads and Runoff Flows
East 91st Street Converted MTS Study Area

Pollutant	Concentration	Pollutant Loading (lbs/day)
Fecal Coliform MPN/100 ml	34,000	13,399[1]
BOD mg/L	11	4
Heavy Metals		
Copper µg/L	35	0.014
Lead µg/L	28	0.011
Zinc µg/L	154	0.061
Total Impervious Area (acre) = 1.22		Runoff Coefficient (C) = 1.00
Average Rainfall Intensity per Storm (inch/hour) = 0.06[2]		Runoff Volume (cfs) = 0.073

Notes:
(1) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
(2) Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

6.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to the NYCDEP CSO Abatement Program, which will reduce untreated discharges to receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from City WPCPs; and other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

6.11.3 Potential Impacts with the East 91st Street Converted MTS

All solid waste processing at the East 91st Street Converted MTS would occur within structures on the site. All process wastewater from waste handling operations in the facility, such as washdown water, would be routed to an on-site pretreatment system (e.g., oil/water separation). After treatment, the process wastewater would be discharged to the municipal sewer system and, ultimately, to the Ward's Island WPCP, where it would be treated prior to discharge to the East River and, therefore, would not adversely affect water quality.

Stormwater loads and impervious area, shown in Table 6.11-4 would be expected to increase above Existing Conditions. According to the 208 Model, however, the increased loads would have no significant impact on water quality in the adjacent surface waters.

Table 6.11-4
Impervious Area and Estimated Pollutant Loads
East 91st Street Converted MTS

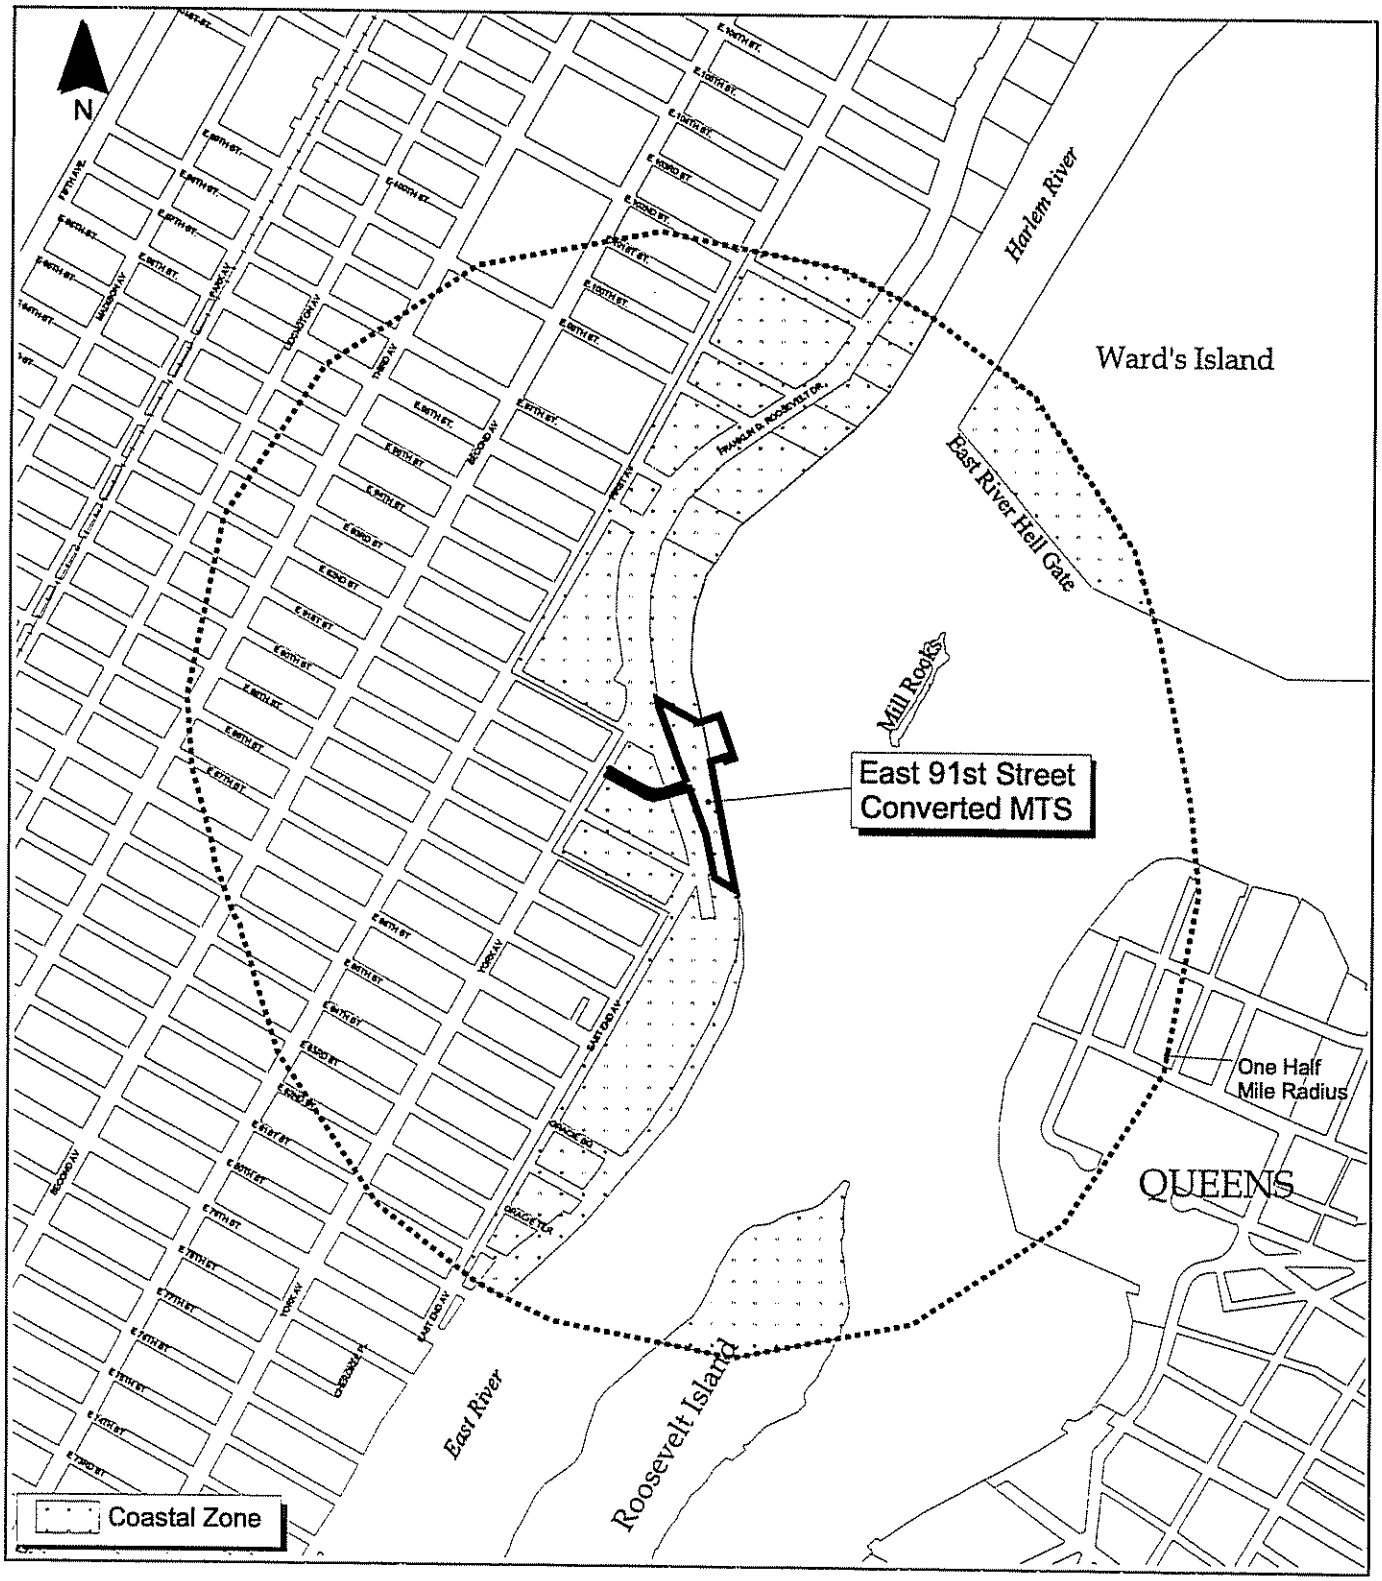
			Estimated Pollutant Loadings/Incremental Change[1]				
Conditions	**Total Impervious Area (acres)**	**Change in Impervious Area (acres)**	**Fecal Coliform[2]**	**BOD (lbs/day)**	**Copper (lbs/day)**	**Lead (lbs/day)**	**Zinc (lbs/day)**
Existing Conditions	1.22	0	13,399/NA	4/NA	0.014/NA	0.011/NA	0.061/NA
Future Build Conditions	1.78	0.56	19,595/6,196	6/2	0.020/0.006	0.016/0.005	0.089/0.028

Notes:
(1) Incremental change refers to the difference in pollutant loading between the Existing Conditions and Future Build Conditions.
(2) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable

Unimpeded operation of the East 91st Street Converted MTS may also require dredging to refurbish the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired before such activities commenced. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate

any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant long-term impacts.

6.12 Waterfront Revitalization Program



6.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of the East River, the East 91st Street Converted MTS would be within the City's coastal zone boundary (see Figure 6.12-1). According to "The New Waterfront Revitalization Program," the East 91st Street Converted MTS would be classified as a water-dependent, industrial use. It would be located within Reach 1/The East Side as indicated within the "New York City Comprehensive Waterfront Plan-Reclaiming the City's Edge" and the "Plan for the Manhattan Waterfront." It is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The East 91st Street Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These include subpolicies 1.1, 1.2, 2.1, 3.1, 4.4, 6.2, 6.3and 10.2. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. Further discussion is provided below for those policies or subpolicies needing more clarification or found to be inconsistent with a component of the East 91st Street Converted MTS. A description of waste handling operations that would occur at the East 91st Street Converted MTS is provided in Section 2.2.3.

6.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

Site delineations and study area boundaries are approximate
Base Map Source: New York City Department of City Planning

HDR URBITRAN EEA Cambridge Environmental Inc

Figure 6.12-1 Coastal Zone Boundary
East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the East 91st Street Converted MTS. As part of the East 91st Street Converted MTS, connections from the new facility to existing utilities in the vicinity (e.g., sewer and electrical connections, etc.) would be established.

Policy 2: Support water-dependent and industrial uses in New York City's coastal areas that are well-suited to their continued operation.

2.2 Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.

The East 91st Street Converted MTS would not be located within an SMIA. Its development would involve the removal of the ~~existing~~ Existing MTS and construction of a new MTS built primarily over water on pile-supported platforms. The East 91st Street Converted MTS would involve the conversion of the existing MTS from a truck-to-barge waste transfer station into a TCB MTS that would transport DSNY-managed Waste by marine transport to remote out-of-City disposal facilities. The demolition and redevelopment of the East 91st Street Converted MTS site, as described in Section 2.2.3, would largely represent the continuation of an existing industrial and water-dependent use. The East 91st Street Converted MTS would serve to maintain this use, while restoring and revitalizing existing industrial waterfront property. The redevelopment and expansion in size of the existing structure would be consistent with the previous industrial land use at the site. Although the East 91st Street Converted MTS would not encourage or facilitate the siting of any additional water-dependent uses, it would represent an expansion of an existing water-dependent use and would be compatible with existing uses. The East 91st Street Converted MTS would be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The East 91st Street Converted MTS would involve the demolition of the existing MTS. The existing vehicle access ramp, which crosses over the FDR Drive, would be removed and extended to accommodate the design of the East 91st Street Converted MTS. Waterfront construction would involve ~~three~~ four primary components: (1) the enclosed processing building, which includes the tipping floor, loading floor and pier level; (2) the outdoor gantry crane system; (3) elevated access ramp; and (4) a ~~rehabilitated bulkhead~~new and fendering system.

The East 91st Street Converted MTS would require minor dredging to improve existing water depths at and in the immediate vicinity of the site and allow for the unimpeded operation of barges and tugboats once it became operational. All dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be acquired prior to any dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 *Minimize conflicts between recreational, commercial, and ocean-going freight vessels.*

The East 91st Street Converted MTS would be located within the East River and would be expanded from its existing footprint. Once operational, it would allow for the containerization of solid waste by a TCB system and marine transport to out-of-City disposal sites. Due to the high currents at the site location, barge maneuvering would require the use of tugboats rather than DSNY personnel. Mill Rock Park, a two and a half acre island that sits in the East River, off 96th

Street, poses a navigational hazard to vessels using the waterway in the vicinity of the proposed site. An existing ferry landing (water taxi) is located at east 90th Street immediately south of the proposed site. An increase in vessel traffic would result from the operation of the proposed East 91st Street Converted MTS. However, ~~t~~These operations would be comparable to those previously conducted at the site, which did not result in conflicts with recreational, commercial or ocean-going freight. The use of tugboats and the day-to-day operation of the East 91st Street Converted MTS would not, therefore, interfere with any maritime industrial, commercial or recreational vessel activities in the area.

3.3 *Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.*

The ~~existing~~ Existing MTS managed solid waste through a truck-to-barge system where loose waste was placed in open barges. The East 91st Street Converted MTS would be a TCB MTS where waste would be transferred into containers that would be sealed and placed into flat deck barges that would transport DSNY-managed Waste to remote out-of-City disposal facilities. All containers would be loaded and sealed inside an enclosed processing building before being placed on the barges, thereby minimizing any impacts to the aquatic environment. Litter control methods, such as routine sweeping and washing of the tipping floor, would also be implemented at the facility to minimize or eliminate the potential for litter entering surface waters. Building ventilation would be maintained under negative pressure, which would maintain dust inside the building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environments. All process wastewaters would be treated on site prior to being discharged to the municipal sewer system. In addition, on-site storage of petroleum and handling of unauthorized wastes would be managed in accordance with all applicable federal, state and local regulations.

The "Plan for the Manhattan Waterfront" for this area recommends renovating the fireboat pier for commuter service, which has been subsequently developed. As part of the New York City Economic Development Corporation (NYCEDC) East River Ferry Landings Project, an expanded ferry landing (water taxi) is proposed for East 90th Street. The project would involve redevelopment of the existing pier construction of sheltered passenger areas and a floating dock for use in accessing the ferry. The waterfront plan also specifically mentioned the existing East 91st Street MTS and that it should be taken into consideration when siting a ferry at this location. The existing ferry service in the vicinity of the East 91st Street Converted MTS is not anticipated to be affected by the DSNY facility. Therefore, the East 91st Street Converted MTS would be consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs, Recognized Ecological Complexes and SCFWH information, the site would not be located within any designated areas. Although the East 91st Street Converted MTS would involve the removal and replacement of existing pilings and pier structures, it would represent an expansion of a previous use and would not be anticipated to result in any long-term effects to natural resources in the vicinity of the site. As discussed in Section 6.9.3, disturbances to surficial sediments due to construction of the East 91st Street Converted MTS and/or potential dredging would have short-term and minimal effects on the benthic community found in the immediate vicinity of the site.

4.2 Protect and restore tidal and freshwater wetlands.

A review of NYSDEC tidal and freshwater wetland and NWI maps was conducted. As discussed in Section 6.9.1, the site contains no freshwater wetlands. A majority of the East 91st Street Converted MTS would be within the East River, however, which is identified as a littoral zone, a state-designated wetland. The demolition of the existing inactive MTS and subsequent development of the East 91st Street Converted MTS would result in limited, short-term ~~impacts~~ effects upon ~~to~~ these tidal wetlands.

~~Impacts~~ Effects to littoral zones would be minimal due to previous waterfront uses at and in the immediate vicinity of the site, and permitted dredging activities that have historically occurred at the site. Minor dredging would be required to provide adequate draft for staged barges and navigational depths for tugboat maneuvering. Potential ~~impacts~~ effects upon wetlands due to dredging would be minimal and of limited duration. All dredging would be done in compliance with applicable federal, state and local regulations. ~~Mitigation for potential~~Potential ~~impacts, if required~~effects upon wetlands~~,~~ would be ~~proposed~~ addressed during the environmental review and permitting of the East 91st Street Converted MTS. DSNY, in coordination with the NYSDEC and other involved agencies, would determine the appropriate measure to address potential effects that may occur due to the East 91st Street Converted MTS and would effectively restore these wetlands and their associated value.

4.3 Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.

There are no known vulnerable fish or plant species found within the vicinity of the site. However, during a field sampling program in 2003, three non-vulnerable fish species managed under the Magnuson-Stevens Act were

collected at the proposed site. Eggs and larvae of winter flounder (*Pseudopleuronectes americanus)* and windowpane (*Scopthalmus aquosus*) and summer flounder (*Paralichthys dentatus*) larvae were identified. The habitat in the immediate vicinity of the proposed site does not represent the ideal habitat as identified in the EFH descriptions for these species. Therefore, the proposed action ~~wouldnot~~would not result in significant adverse impacts to these species.

A review of the NYSDEC Natural Heritage Report on Rare Species and Ecological Communities reports the Peregrine Falcon (*Falco peregrinus*) as a known species found in the area and as being classified as a federally endangered species. ~~As noted in Section 6.9.3,~~ Ithe East 91st Street Converted MTS would not impact these species or their habitats.

The East 91st Street Converted MTS would involve the demolition of an existing MTS. The MTS would remain as an over-water facility. Waterfront development would include an enclosed processing building, which includes the tipping floor, loading floor and pier level; an outside gantry crane system; and a new fendering ~~and bulkhead~~ system. Development would involve minor dredging; however, potential impacts to plant, fish and wildlife species would be minimized and all dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be acquired prior to any dredging activities.

In addition, all handling and containerization of solid waste would be performed inside the processing building, thereby limiting the risk of an introduction of hazardous wastes or other pollutants into the environment that could impact surrounding fish and wildlife resources. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer systems. Stormwater runoff from the East 91st Street Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The East 91st Street Converted MTS would, therefore, be consistent with this subpolicy.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The East 91st Street Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, the processing floor would be cleaned on a regular basis. All sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site disposal treatment system, which would include an oil-water separator, and then discharged to the municipal sewer system. In addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. Stormwater runoff from the East 91st Street Converted MTS would be managed in accordance with applicable regulations.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

During the development and operation of the East 91st Street Converted MTS, BMPs would be used to the extent possible to minimize any nonpoint discharges. The East 91st Street Converted MTS would comply with applicable federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be performed inside the processing building, limiting the risk of an introduction of hazardous wastes or other pollutants into the environment. In addition, litter control methods would be implemented at the facility to minimize or eliminate the potential for litter to enter surface waters.

5.3 Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.

The majority of the demolition and removal of the ~~existing~~ Existing MTS structure and foundations and construction of the East 91st Street Converted MTS would occur within the East River. During removal of the existing pile-supported

MTS, disturbances to the upper organic silts may occur, resulting in re-suspension of the sediments. The ~~alignment of the~~ existing vehicle access ramp would be ~~salvaged~~ demolish and ~~would remain; however, it would be extended over the East River~~ replaced to accommodate the new design. Minor dredging would be necessary to provide sufficient depths for barges and tugboats. Potential impacts due to dredging would be localized, however, and of short duration. All dredging would be in accordance with applicable federal, state and local regulations and removed materials would be disposed of at a permitted upland facility.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The East 91st Street Converted MTS would result in no adverse impact to the quality or quantity of surface or ground water at or in the immediate vicinity of its site. Applicable and appropriate measures would be implemented at the East 91st Street Converted MTS in accordance with federal, state and local regulations. The East 91st Street Converted MTS would be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 *Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.*

According to review of the FEMA National Flood Insurance Program maps, the ~~entire~~ majority of the East 91st Street Converted MTS site is located within the 100-year flood plain boundary (Zone A) and the ramp extends into the 500-year flood plain (Zone B). The East 91st Street Converted MTS would be located at the site of the existing MTS, but have an expanded footprint. The ~~existing~~ Existing MTS would be demolished to an elevation below the waterline to accommodate the expanded function, size and configuration of the East 91st Street

Converted MTS. The redevelopment of the site would not affect the potential for flooding or erosion. All demolition and redevelopment activities would comply with applicable building code requirements and, to the extent practicable, non-structural or structural measures would be implemented to minimize damage from flooding or erosion.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The East 91st Street Converted MTS would involve the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Waste would be transported in airtight, waterproof, sealed containers. All waste handling operations would occur inside an enclosed processing building, which would minimize the escape of litter into the surrounding water body. Sufficient container and barge capacity would be available to meet the requirements of the collection area. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the East 91st Street Converted MTS. Litter control methods would be implemented at the facility to minimize or eliminate the potential for litter entering surface waters. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility. The East 91st Street Converted MTS would not result in adverse impacts and would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

On-site storage of petroleum or hazardous materials related to the operation of the East 91st Street Converted MTS would be minimal and all storage would be in accordance with applicable federal, state and local regulations. Spill prevention and control plans would be used to prevent any hazardous materials from entering the environment.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

The East 91st Street Converted MTS would be a stand-alone, water-dependent facility on the East River. It would generally be located at the site of the existing MTS. The proposed vehicle access ramp would cross over the FDR Drive and would go over the East River Esplanade, which runs along the waterfront, adjacent to the proposed site. Access to the esplanade or the waterfront would not be impacted from the access ramp, as the ramp would be located above the esplanade and would not block access to the waterfront. Public access would generally not be compatible with the East 91st Street Converted MTS; however, its conversion would not impact existing, nor preclude any future, development of public access. Several parks are located within the study area that would allow for continued physical, visual and recreational access to the waterfront.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

Public access would not be compatible with the principal use of the site due to the industrial activities. As discussed in Section 6.5.1, there are several parks providing public access and recreation facilities that are located in the immediate vicinity of the East 91st Street Converted MTS. The East 91st Street Converted MTS would not preclude future development of public access at other locations along the East River.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

The East 91st Street Converted MTS would be an expansion of an existing water-dependent facility. It would remain compatible and consistent with adjacent properties along the waterfront and would not obstruct or impair visual access to coastal lands, waters or open space. As discussed in Section 6.7.3, the East 91st Street Converted MTS would be consistent with this subpolicy. See also response to Subpolicy 9.1.

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

Located south of the East 91st Street Converted MTS is Carl Schurz Park, which is physically separated from the site by the FDR Drive. In addition, the esplanade that runs adjacent to the existing MTS would not be affected by the new facility. Expansion and redevelopment of the existing MTS would cause no new impacts to these areas and, therefore, the East 91st Street Converted MTS would be consistent with this subpolicy.

8.5 Preserve the public interest in and the use of lands and waters held in public trust by the state and city.

The East 91st Street Converted MTS would involve the conversion of the existing MTS from a truck-to-barge waste transfer station into a TCB MTS that would transport DSNY-managed Waste by marine transport to remote out-of-city facilities. In order to allow for the efficient operation of the proposed facility, development of the facility would require development within an area approximately 42 by 272 feet, which is currently state-owned lands under water. As a result the East 91st Street Converted MTS would occupy approximately 0.25 acres of currently state-owned land.

The use of this land is required because the facility is limited in its ability to extend westward due to the presence of the FDR Drive, the esplanade and Asphalt Green. Likewise, the operational requirements of the facility limited the reorientation of barge operations along the northern or southern edges of the facility. The relocation of barge operations along the north or south portion of the facility would have resulted in additional impacts to visual quality and or scenic resources. The DSNY would apply for a River Bed ~~Easement~~ Grant from the New York State Office of General Services for that portion of the proposed facility, which would be located on state lands under water. The request for a ~~n easement~~ grant would represent the minimum amount of state-owned lands in accordance with the goals, standards and criteria presented for this subpolicy in the WRP. The granting of ~~an easement~~ grant for this small area at the East 91st Street Converted MTS would, in no way, diminish or affect other public lands under water. It would also not significantly affect public trust uses, such as recreation or public access, which are already partially limited due to previous uses and the physical characteristics of the waterbody at this site (i.e. high river velocities).

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The East 91st Street Converted MTS would be expanded from its existing footprint; however, it would not result in a significant impact to visual quality, as noted in Section 6.7.3. Views from the existing promenade, which runs adjacent to the East 91st Street site, are already obstructed to some extent by the existing facility. The East 91st Street Converted MTS would resemble the existing MTS in terms of its building typology, massing and position and elevated access, as well as adjacency to the esplanade. In addition to its close proximity to the esplanade, the proposed MTS would be in the vicinity of the Asphalt Green complex and Carl Schurz Park, where Gracie Mansion is located. The closest possible views of the MTS from Carl Schurz Park are from the northern edge of the park, near Gracie Mansion, which are no longer open to the public. The overall scale and appearance of the new facility would not likely contribute to a substantial change of views toward the waterfront from inland areas. It would involve the redevelopment of an existing water-dependent facility. Based upon the information discussed in Section 6.7.3, the East 91st Street Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The East 91st Street Converted MTS would be an expansion of an existing MTS facility and would pose no new impacts to scenic values associated with natural resources. The East 91st Street Converted MTS would, therefore, be consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

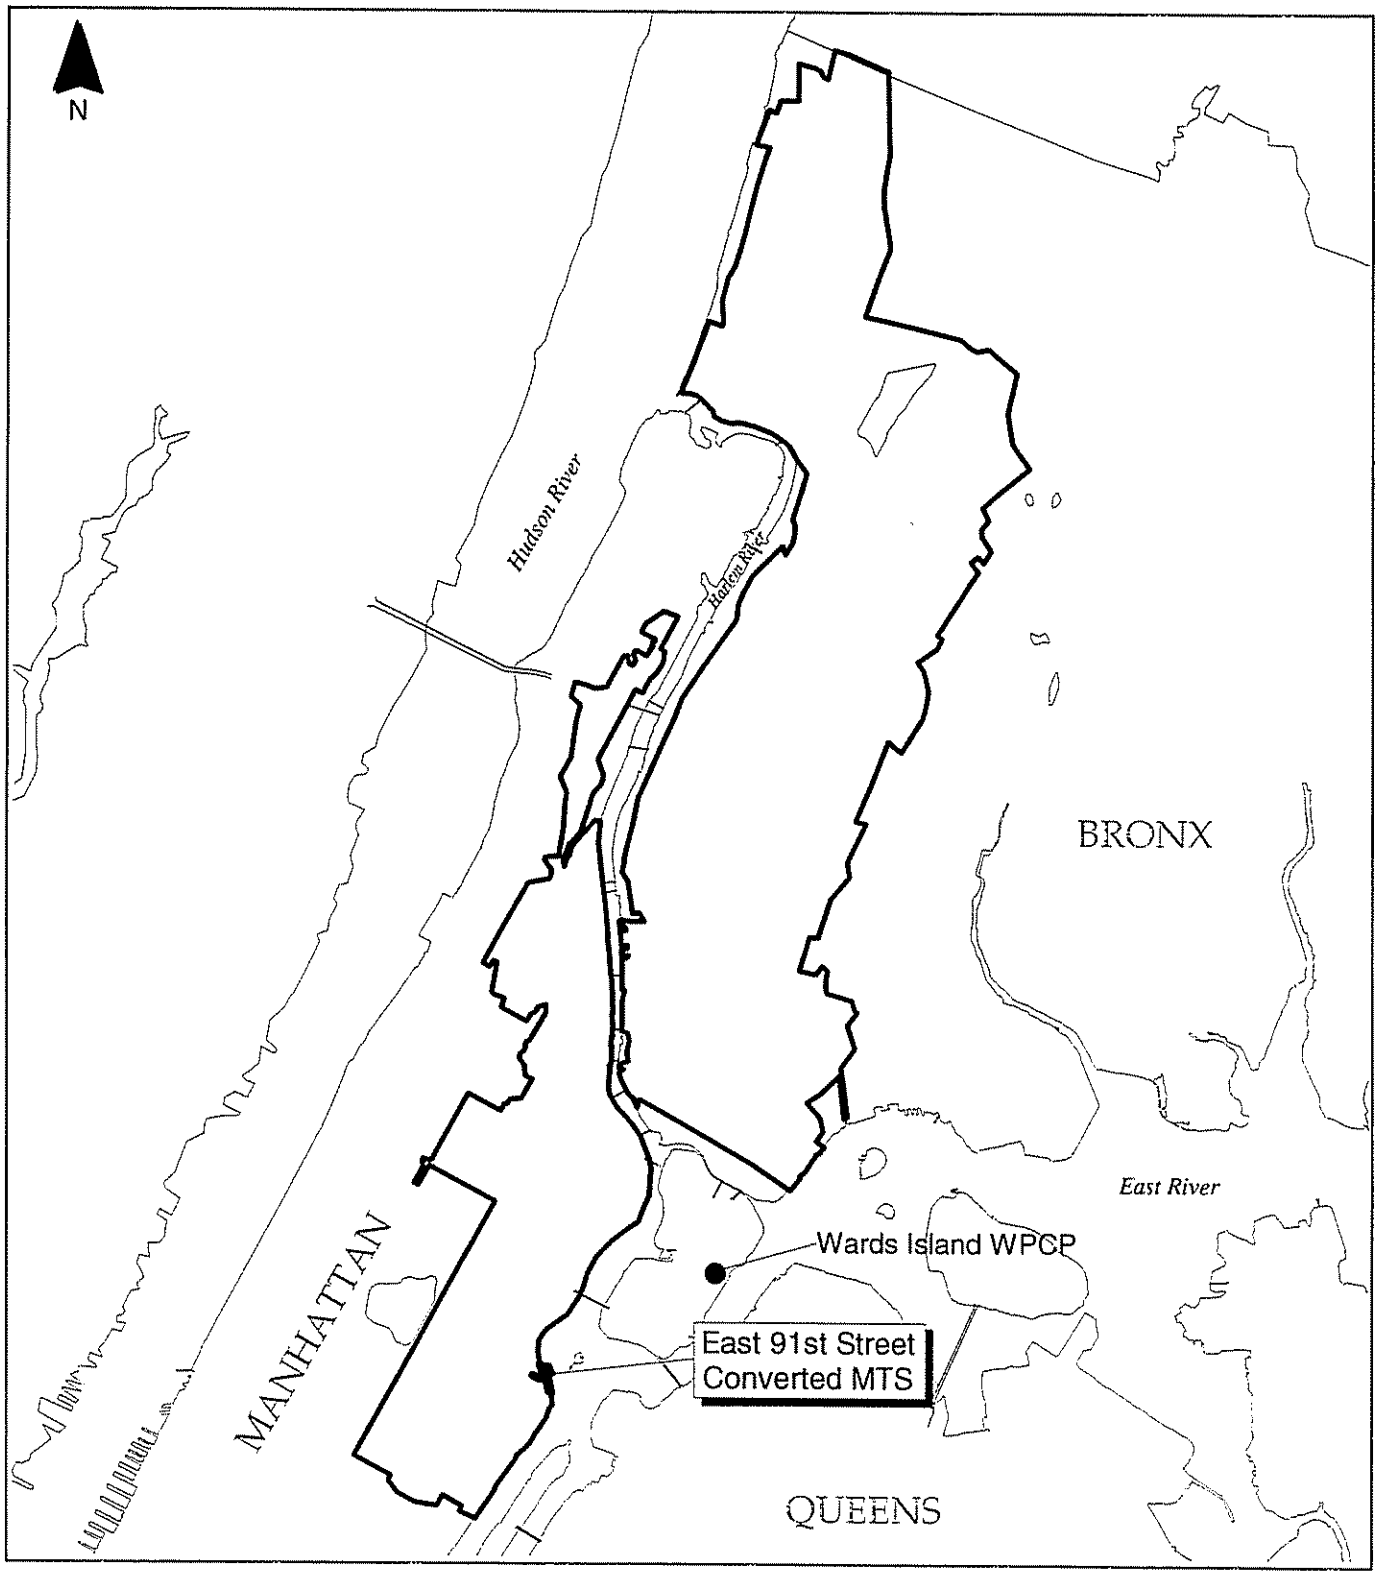
10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

According to the "Plan for the Manhattan Waterfront," the Municipal Asphalt Plant (Asphalt Green Recreational Center), listed as a City landmark on the NR, is located adjacent to the existing MTS ramp; however, as noted in Section 6.6.3, the East 91st Street Converted MTS would have no impacts on this resource. Therefore, the East 91st Street Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources have been identified on the site. Therefore, the East 91st Street Converted MTS would have no impact on such resources.

6.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



6.13.1 Existing Conditions

6.13.1.1 Water Supply

Water is supplied to the ~~existing~~ Existing East 91st Street MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. An off-site 6-inch-diameter line at East 91st Street provides potable water for both consumption and sanitary requirements. Water pressure throughout the City system is generally maitnained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual). To ensure that adequate pressure is provided on site, the potable and fire water systems are currently supplemented with a pump.

6.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Wards Island WPCP, which serves the eastern section of Manhattan generally bordered by 70th Street, 190th Street and Amsterdam Avenue/Central Park. Wards Island WPCP also serves portions of the western Bronx. The WPCP drainage area is illustrated in Figure 6.13-1. From July 2002 through June 2003, the Wards Island WPCP treated an average of 181 mgd of wastewater under dry weather flow conditions and an average flow of 193 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (see Table 6.13-1). The maximum dry weather flow during this period was 206 mgd during June 2003 and the maximum average flow was 216 mgd during June 2003. Effluent from the plant is discharged into the East River and is regulated by the NYSDEC under the SPDES. The current SPDES permit limit for flow to the Wards Island WPCP is 275 mgd. It is estimated that on-site employee water usage is about 75 gpd. This estimate is based on the current security staff of three security employees (one guard per shift, three shifts per day) using 25 gallons per person, per day (2001 CEQR Technical Manual). No other potable water is used as the facility is not currently accepting waste, and no operational personnel are assigned to the site.

Site delineations are approximate

Average Monthly Dry Weather and Average Flows
Wards Island Water Pollution Control Plant
Fiscal Year 2003

Month	Dry Weather Flow (mgd)	Average Monthly Flow[1](1) (mgd)
July 2002	175	179
August	182	191
September	172	190
October	173	196
November	173	192
December	185	195
January 2003	179	188
February	185	198
March	191	201
April	181	191
May	169	177
June	206	216
Average Effluent	**181**	**193**

Notes:
(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

A 12-inch-diameter sewer on East 91st Street serves the site. This sewer is connected to a 5.25-foot-by-4.25-foot interceptor line (combined sanitary and stormwater system) that runs north along York Avenue where waste is directed to the Wards Island WPCP. Stormwater runoff from the existing MTS parking area and ramp are routed to catch basins that discharge to the combined sewer system.

6.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each employee at the existing MTS produces approximately nine pounds of solid waste per week for a facility total of 27 pounds per week (approximately four pounds per day). The solid waste is collected by DSNY personnel and transported by truck to an appropriately licensed solid waste management facility.

6.13.1.4 Energy

Electricity to the facility is provided by Consolidated Edison of New York. A review of applicable utility plans shows electric lines along York Avenue and East 91st Street, with the ~~existing~~ Existing MTS service connected to the Consolidated Edison system at the intersection of York Avenue and East 91st Street. As the facility is currently not operating, the East 91st Street MTS utilizes a negligible amount of energy due to the low staffing levels that provide only security at the site.

6.13.2 Future No-Build Conditions

The ~~existing~~ Existing East 91st Street MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near Existing Conditions levels for security employees. Wastewater flows to the Wards Island WPCP would continue to increase and would be projected to be 194.4 mgd by 2006.

6.13.3 Potential Impacts with the East 91st Street Converted MTS

6.13.3.1 Water Supply

The East 91st Street Converted MTS would have a total of up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The East 91st Street Converted MTS would have no impact on the existing system's ability to supply water reliably. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

6.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,300 gpd for the East 91st Street Converted MTS, the small quantities of wastewater sent to the Wards Island WPCP would not significantly impact the sewage flow rate or the ability of the Wards Island WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 194.4 mgd in 2006, which would be well below the permitted capacity of 250 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

6.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the East 91st Street Converted MTS and would not significantly impact the system.

6.13.3.4 Energy

The East 91st Street Converted MTS would require an additional 5.51E+10 BTU/year of electricity to operate the facility. Natural gas heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the East 91st Street Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

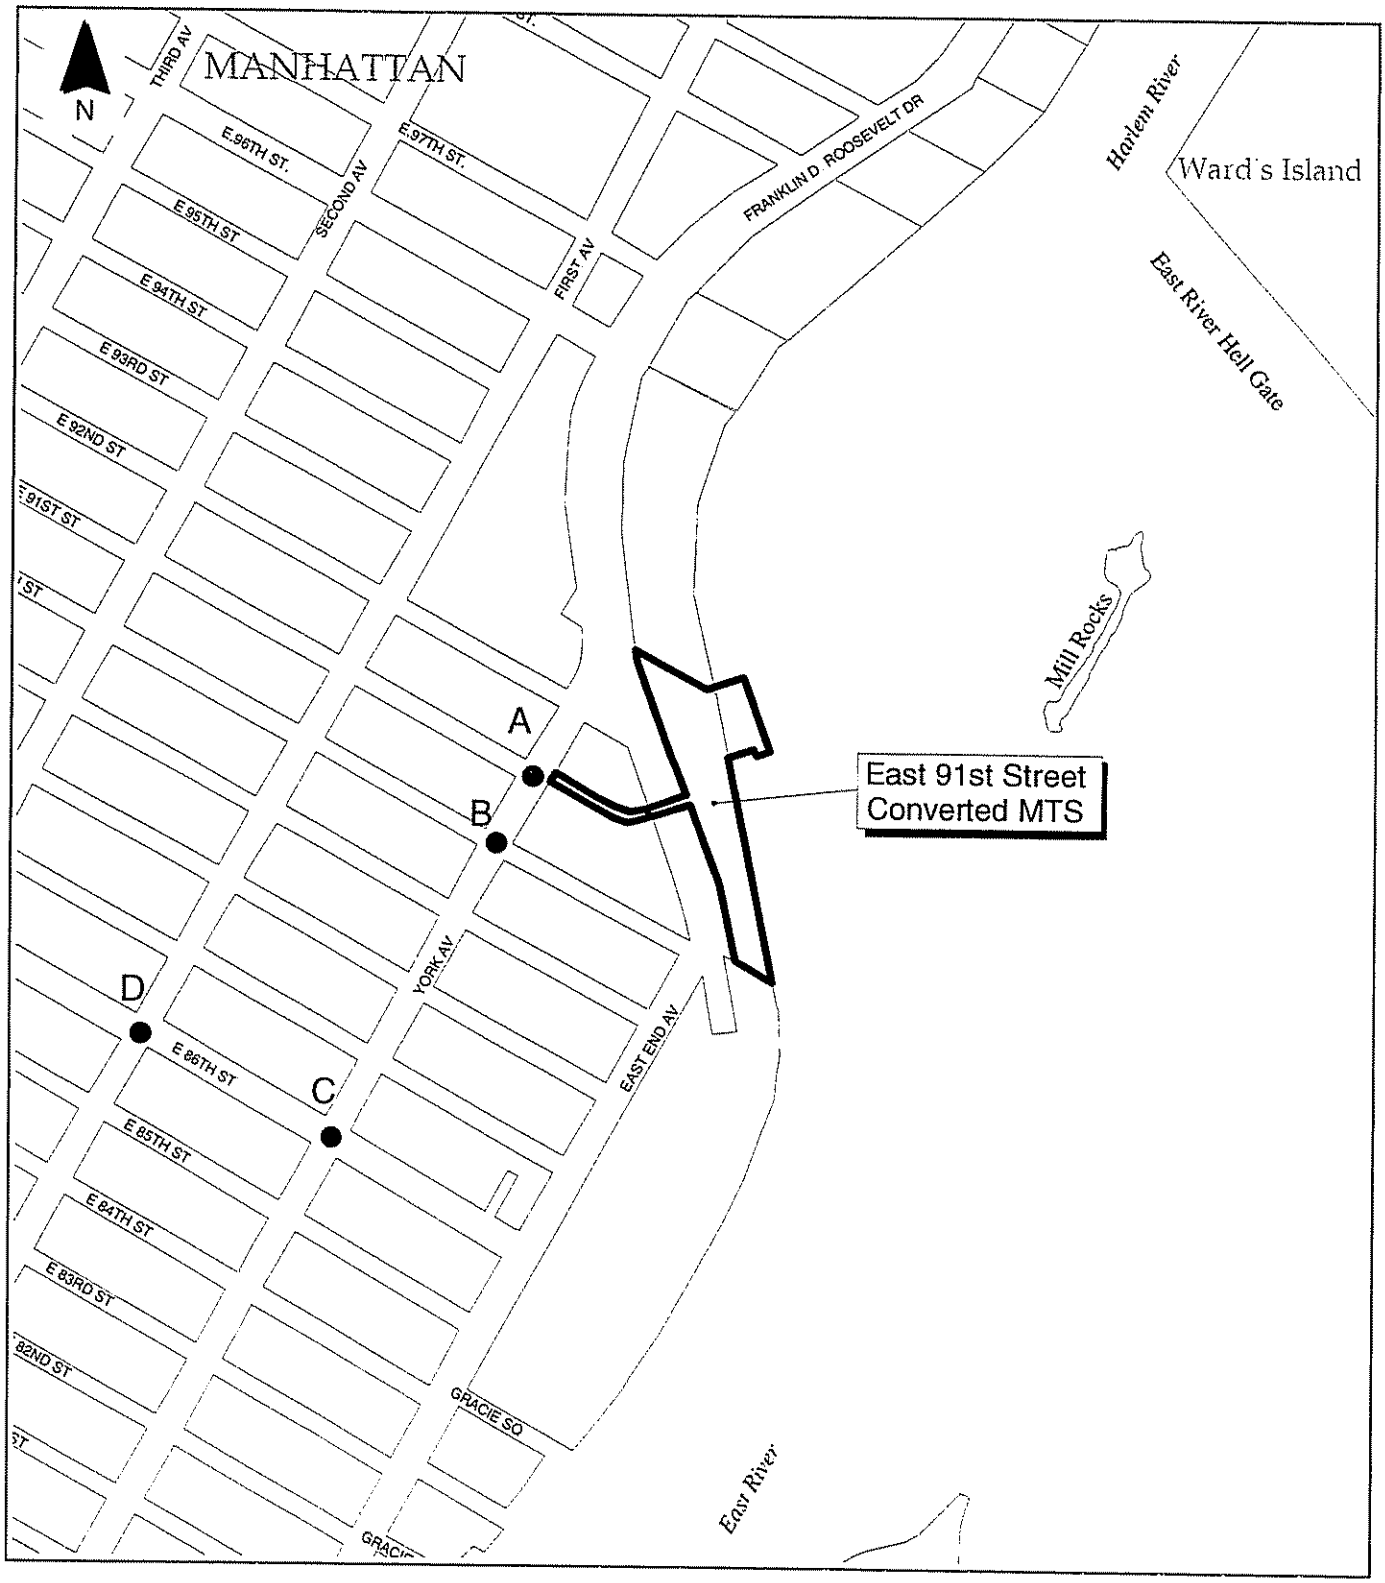
Consolidated Edison was also notified of the natural gas requirements of the East 91st Street Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts.

6.14 Traffic, Parking, Transit, and Pedestrians

6.14.1 Introduction

The East 91st Street Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

6.14.2 Existing Conditions



6.14.2.1 Definition of Study Area

The traffic analysis study area is relatively limited, existing entirely within the Upper East Side (Yorkville) neighborhood of Manhattan, and is focused primarily along the York Avenue and East 86th Street corridors. This study area is predominantly residential with ground-floor commercial uses. There are no CEQR-defined areas of concern located within the study area. Figure 6.14-1 shows the locations of the intersections selected for analysis (locations A through D). Intersections analyzed were selected using the procedures defined in Section 3.16.

All collection vehicles must access the site from York Avenue and East 91st Street. Section 6.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the East 91st Street Converted MTS.

6.14.2.2 Surface Network

One major highway, the FDR Drive, services the study area. First Avenue, Second Avenue and East 86th Street are local truck routes that provide access to and from the site. A map showing all major truck routes and local truck routes in Manhattan is provided in Section 3.16 (see Figure 3.16-4).

Site delineations and study area boundaries are approximate

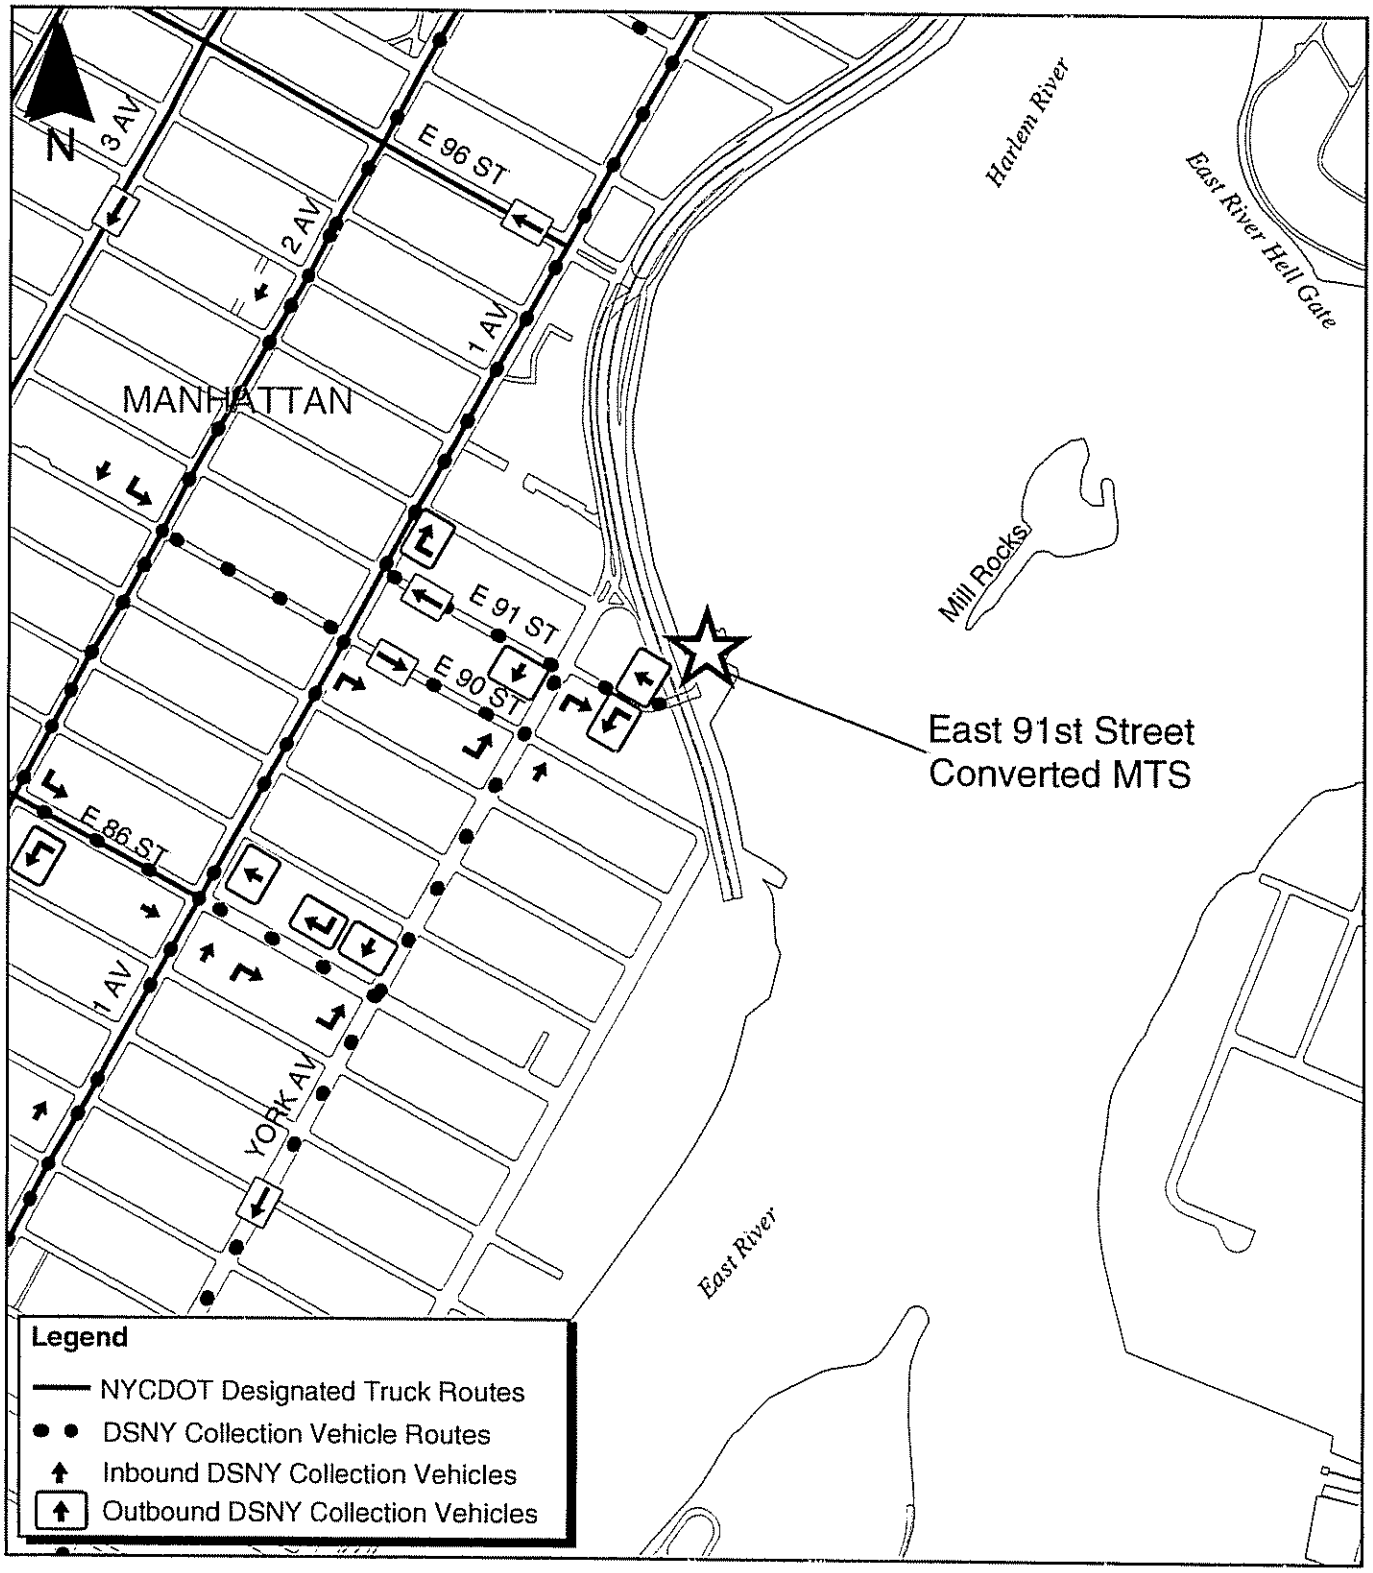
Figure 6.14-1 Traffic Analysis Study Area
East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION



First Avenue and Third Avenue are principal arterials that provide northbound access from lower Manhattan (East Village/Lower East Side) to East Harlem. Second Avenue is a principle arterial that provides southbound access from East Harlem to lower Manhattan. York Avenue and East 86th Street are minor arterials that provide access for local and commercial traffic. East 86th Street is designated as a truck route from First Avenue to Fifth Avenue. Both East 90th Street and East 91st Street are local streets.

DSNY and other agency collection vehicles traveling north to the East 91st Street Converted MTS would travel along First and Third Avenues, turn east on East 86th Street, and then north on York Avenue. All vehicles entering and exiting the Converted MTS pass through the intersection of York Avenue and East 91st Street. Vehicles traveling south to the East 91st Street MTS would follow Second Avenue to either East 90th Street or East 86th Street and turn east to York Avenue. Which street the vehicles use to access York Avenue is determined by the DSNY route for the CD from which the vehicle originates. DSNY and other agency collection vehicles returning to the north of the facility would follow East 91st Street west to First Avenue and then proceed north. Vehicles returning to the south would travel south on York Avenue, then west on 86th Street to Second Avenue, where they would continue south. Figure 6.14-2 depicts NYCDOT-designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

6.14.2.3 Existing Traffic Operations

The four intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the East 91st Street Converted MTS. All of them are on major arterials and/or collection vehicle routes. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- York Avenue and East 91st Street – Signalized Intersection (see Figure 6.14-1 – location A)
- York Avenue and East 90th Street – Signalized Intersection (see Figure 6.14-1 – location B)
- York Avenue and East 86th Street – Signalized Intersection (see Figure 6.14-1 – location C)
- First Avenue and East 86th Street – Signalized Intersection (see Figure 6.14-1 – location D)

Site delineations are approximate

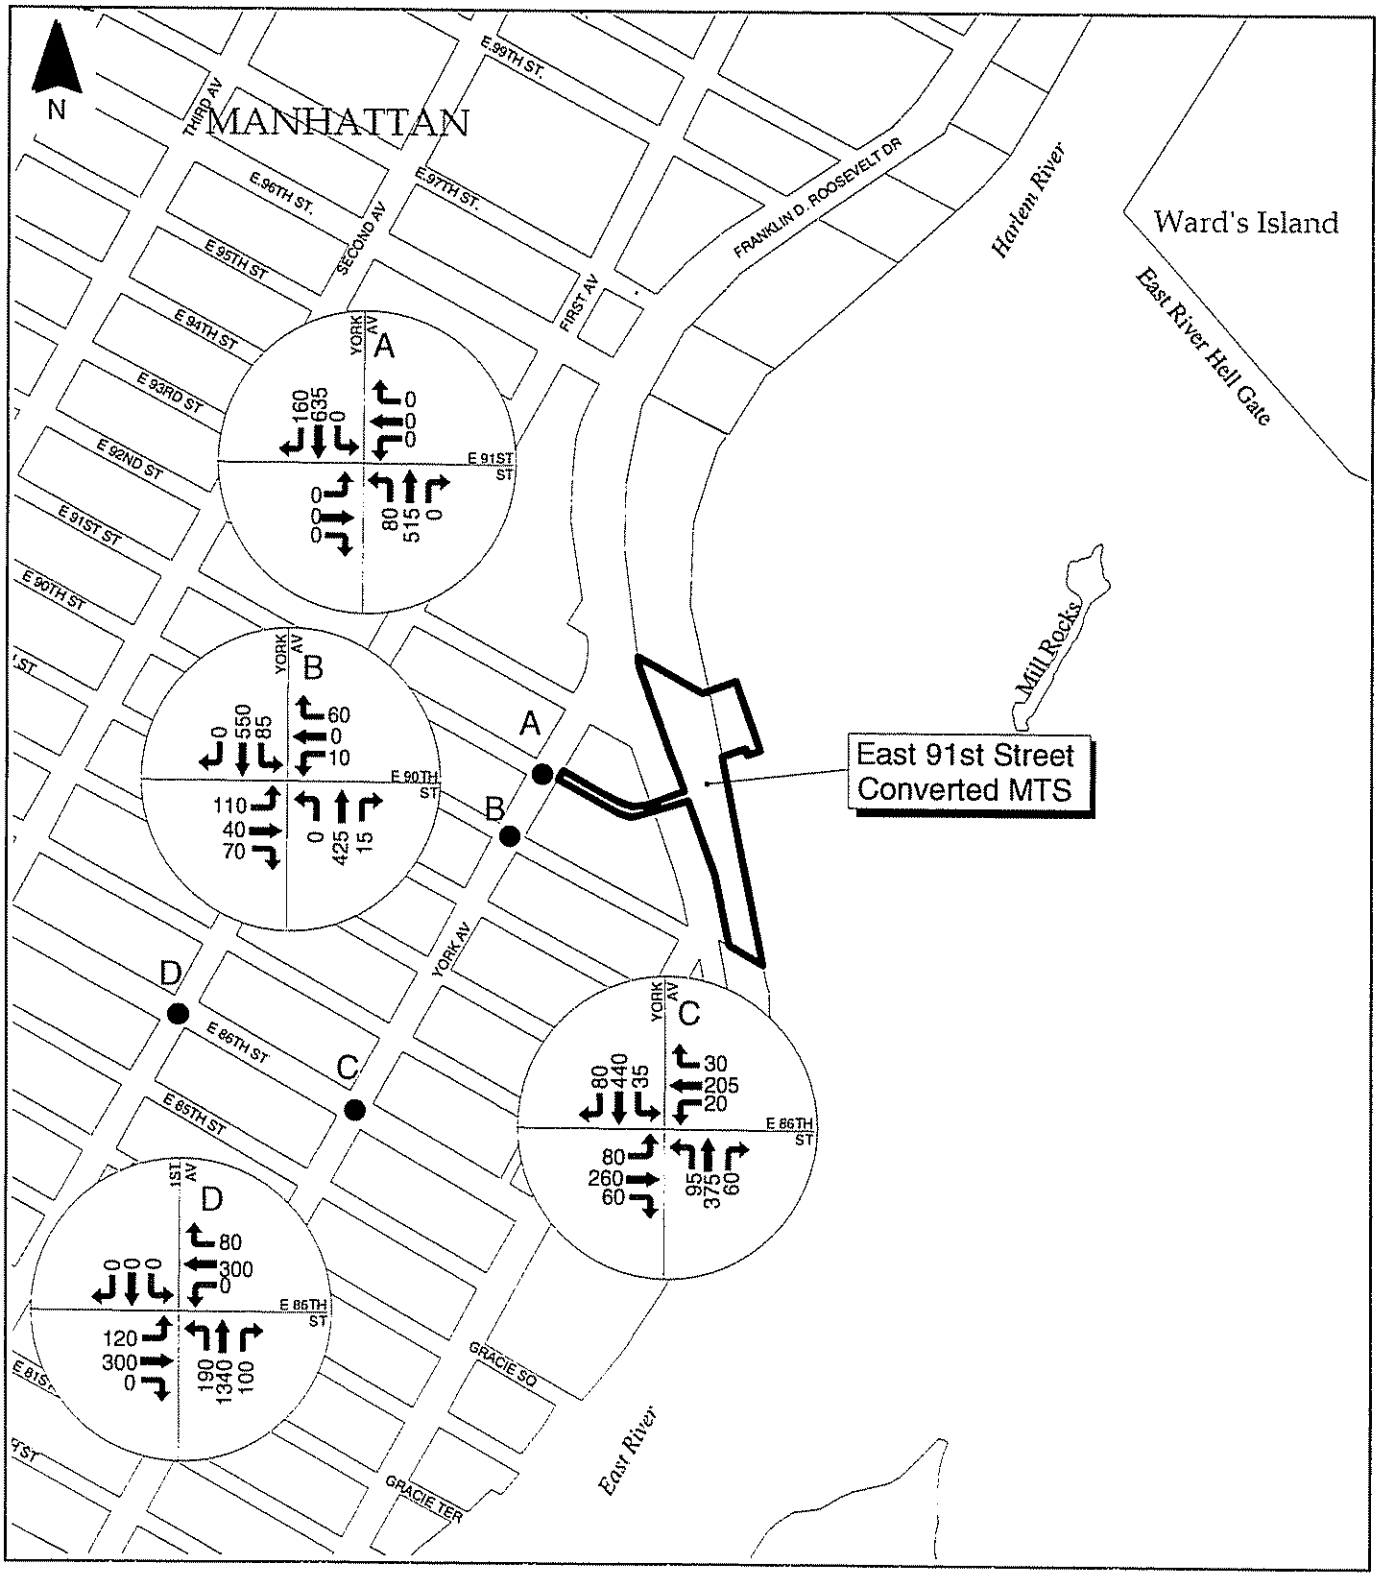
Figure 6.14-2 DSNY Collection Vehicle Routes
East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION



First Avenue is a principal arterial that provides northbound access from lower Manhattan (East Village/Lower East Side) to East Harlem. York Avenue and East 86th Street are minor arterials that provide access for local and commercial traffic. Both East 90th Street and East 91st Streets are local streets.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between February 11 and February 13, 2003, while ATR counts were conducted between February 10 and February 14, 2003. Figures 6.14-3, 6.14-4 and 6.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:30 a.m. and 8:30 a.m., the Facility peak between 9:00 a.m. and 10:00 a.m., and the PM peak between 4:00 p.m. and 5:00 p.m. Table 6.14-1 presents the v/c ratio, delay and LOS for the four intersections during the AM, Facility, and PM peaks.

Existing truck traffic through most of the intersections was moderate. The percentages of trucks increased steadily during the morning hours, remaining between 10% and 11% during mid-day hours, then decreasing to 8% or lower during the PM peak hours.

6.14.2.3.1 LOS at Signalized Intersections

Table 6.14-1 shows that the signalized intersections generally operated at an overall LOS of B or C with the following exceptions. Since the DEIS was published, the intersections of East 86th Street and York Avenue and East 90th Street and York Avenue were reanalyzed with corrected signal timing. As a result, ~~T~~the lane group with the least favorable LOS was the eastbound approach at the intersection of York Avenue and ~~,~~East ~~90th~~ 86th Street. During the AM, Facility, and PM peak hours, this approach operated at LOS D and F with delays of ~~42.0~~ 46.9, ~~38.2~~ 35.7, and ~~39.2~~ 81.2 seconds, respectively. During the PM peak hour, the northbound (defacto) left movement at the intersection of York Avenue and East 91st Street operated at LOS D with ~~41~~ 39.6 seconds of delay.

6.14.2.3.2 LOS at Unsignalized Intersections

No unsignalized intersections were analyzed.

6.14.2.4 Existing DSNY-Related Traffic

The existing DSNY-related traffic in the vicinity of the East 91st Street Converted MTS is generated by DSNY and related facilities in the general area, most notably the DSNY Manhattan CD 11 garage (East 99th Street between First and Second Avenues). Within the study area, DSNY-related traffic is primarily routed along Second Avenue and Third Avenue.

6.14.2.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The 86th Street subway station (for the Number 4, 5 and 6 lines) and the 96th Street subway station (for the Number 6 line) are located approximately ½-mile southwest and ½-mile northwest of the East 91st Street Converted MTS, respectively.

Three MTA bus lines – M15, M31 and M86 – provide service along First Avenue, Second Avenue, York Avenue and East 86th Street. There are bus stops at every study intersection except York Avenue and East 90th Street, and scheduled stops occur at various times during the day.

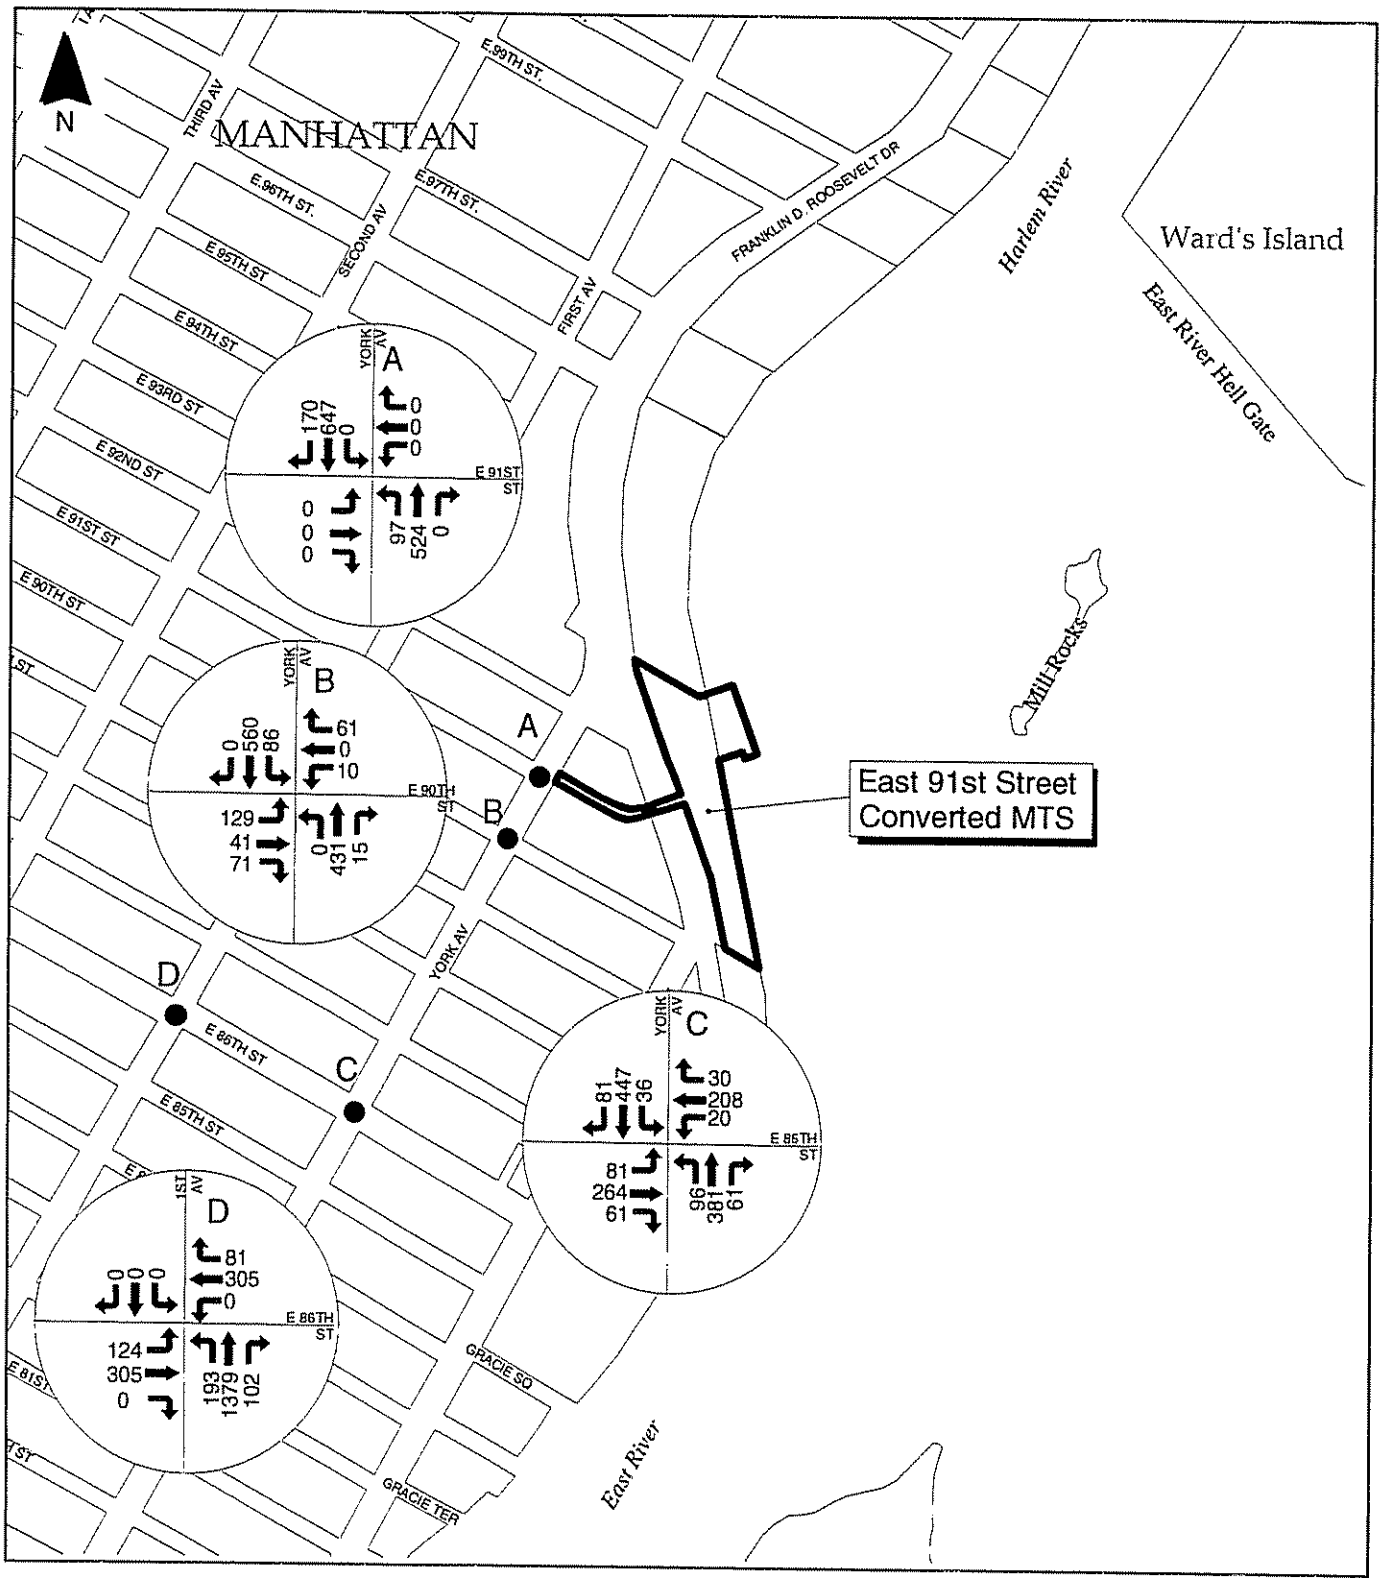
6.14.2.6 Pedestrian Activity

Pedestrian activity is generally moderate to high within the study area. Striped crosswalks and pedestrian signals are provided at all study intersections. Despite the higher-level pedestrian activity, it is not expected to affect the capacity analysis significantly.

6.14.3 Future No-Build Conditions

6.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 0.5% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. In addition, additional traffic generated by proposed developments in the study area expected to be completed by the Future No-Build year (2006) was also included. The following is a listing of the approved or in-process developments that are expected to generate significant volumes of traffic through the study area and, thus, were specifically accounted for as part of this analysis:



- 389 East 89th Street (residential and retail);
- 181 East 90th Street (residential and retail); and
- First Avenue/East 91st Street (residential, hotel and medical office building).

Figures 6.14-6, 6.14-7 and 6.14-8 depict the Future No-Build traffic volumes for the AM, Facility, and PM peaks at the intersections analyzed. Table 6.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, ~~Figure 6.14-6, Future No-Build Traffic Volumes AM Peak intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their Existing Condition LOS, with the following exceptions:~~ as shown in Table 6.14-2, the study intersections under the No-Build Condition experienced relatively small increases in delay (less than five seconds) and are projected to remain at their Existing Conditions LOS, with the following exceptions:

- During the PM peak hour, the delay of the ~~eastbound~~ northbound (defacto) ~~approach~~ left movement at the intersection of York Avenue and East ~~90th~~-91st Street increased from 39.~~2~~6 to ~~45~~80.9 seconds (LOS D to LOS F~~in both cases~~).
- ~~During the PM peak hour, the delay of the northbound (defacto) left movement at the intersection of York Avenue and East 91st Street increased from 41.6 to 86.9 seconds (LOS D to LOS F).~~

6.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

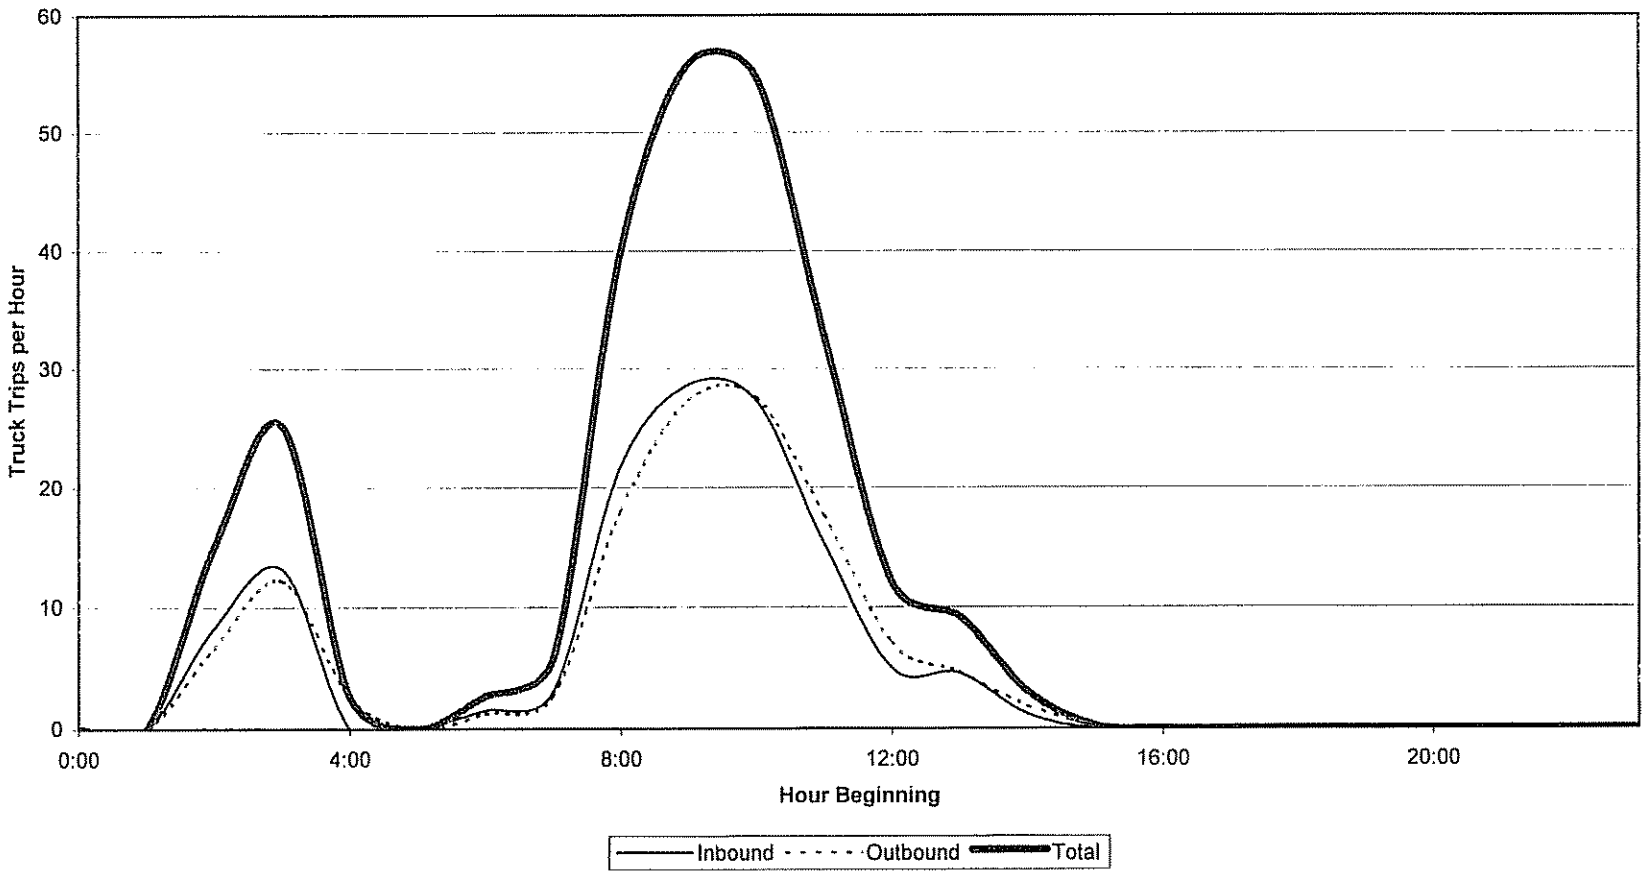
6.14.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

6.14.4 Potential Impacts with the East 91st Street Converted MTS



The East 91st Street Converted MTS would receive waste from four CDs in Manhattan — Manhattan CDs MN05, MN06, MN08 and MN11. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours.

6.14.4.1 2006 Future Build Traffic Conditions

The 2006 Future Build Traffic Conditions assume that the East 91st Street Converted MTS would generate 130 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site or the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the East 91st Street Converted MTS are shown in Figure 6.14-2.

Figure 6.14-9 presents the average peak day temporal distribution of collection vehicles for the East 91st Street Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the East 91st Street Converted MTS is expected to vary from approximately 0 to 15 truck trips per hour in the late evening/early morning, 5 to 56 truck trips per hour in the mid-morning/early afternoon, and 0 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (56) occurs at approximately 9:00 a.m.

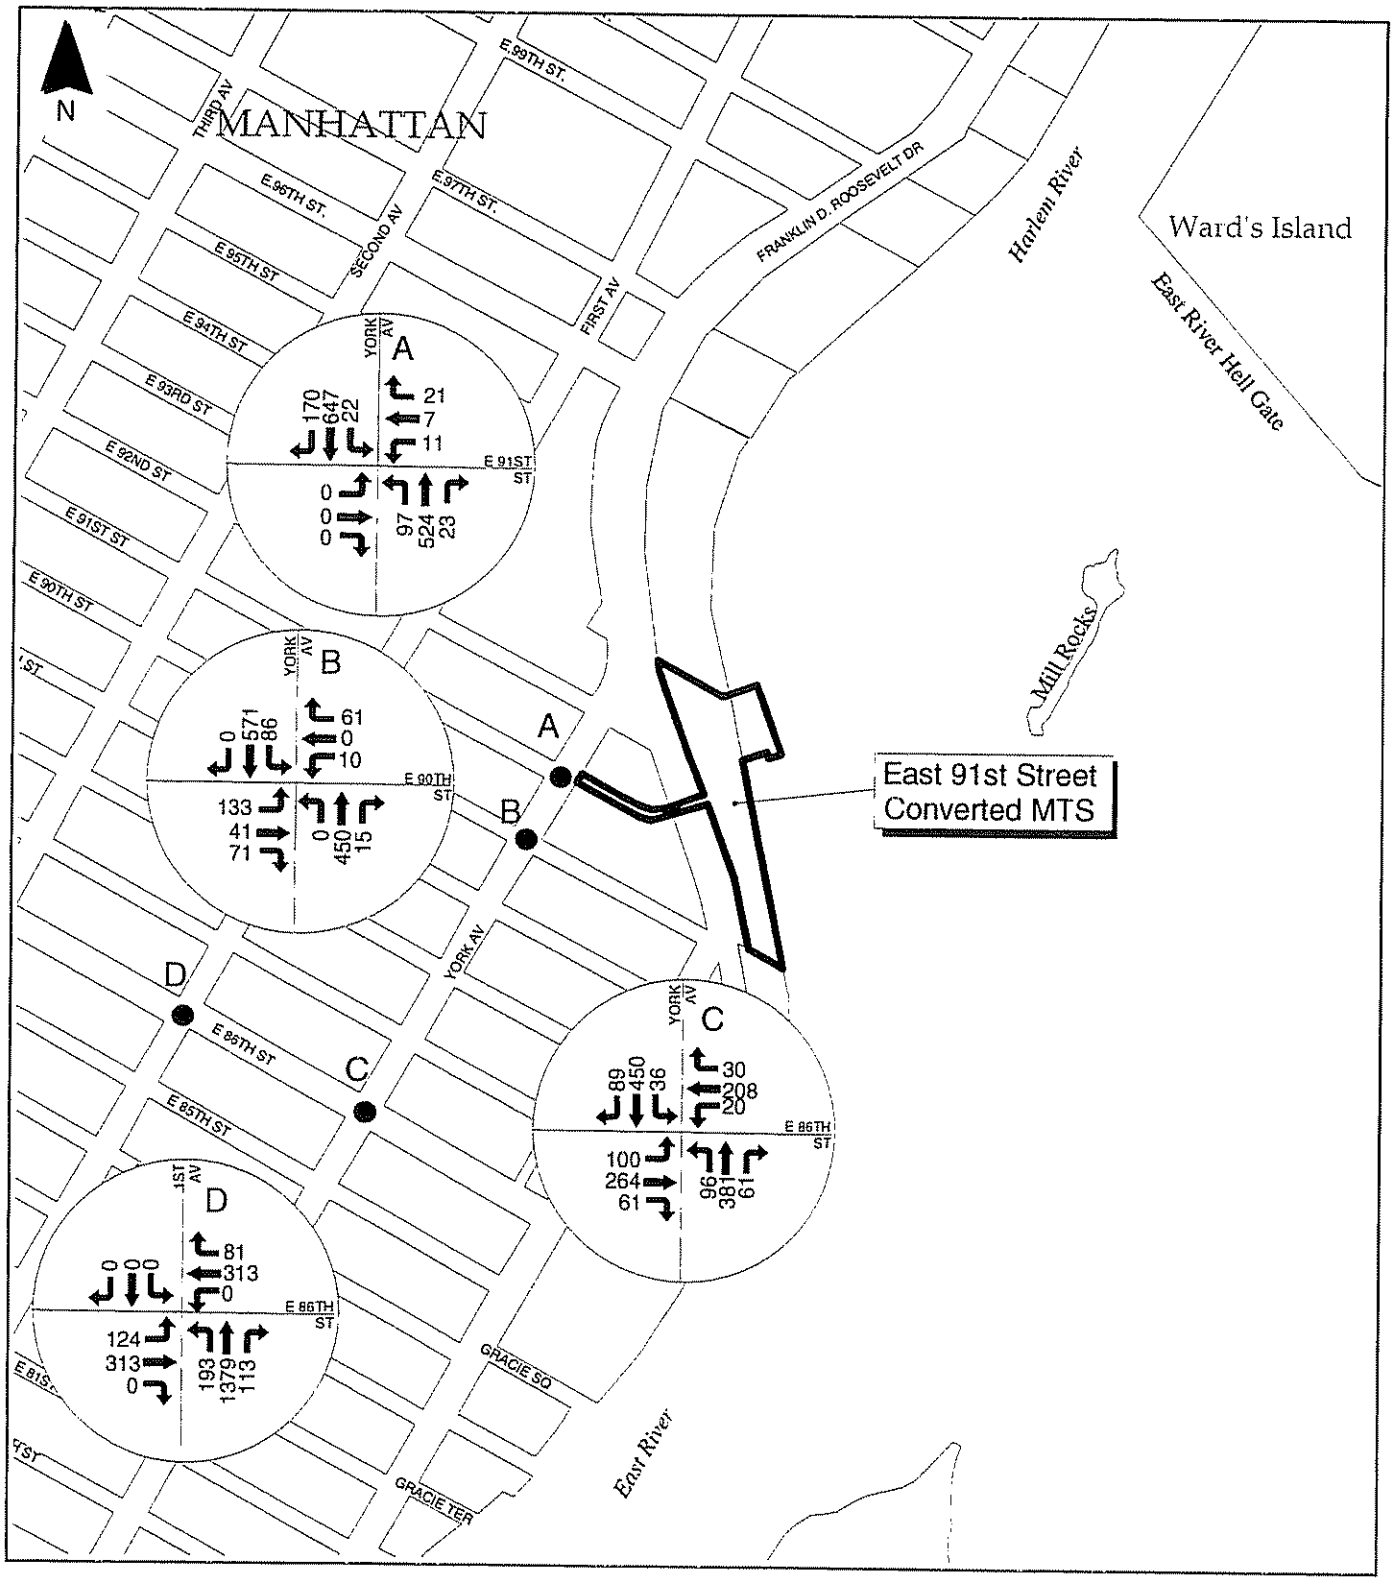


Figure 6.14-9
Truck Trips per Hour
East 91st Street Converted MTS

Figures 6.14-10, 6.14-11 and 6.14-12 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 6.14-13, 6.14-14 and 6.14-15 show the intersections analyzed with only the net increase in site-generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the East 91st Street Converted MTS. These projected net increases were routed through the intersections for the AM, Facility, and PM peak hours. The highest net increase in trucks in the ingress or egress direction was 28. The highest net increase at any one intersection was 56 trucks. Both of these net increases occurred at the intersection of York Avenue and East 91st Street.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 82% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 70% of weekday traffic volumes. Table 6.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the East 91st Street Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 6.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM Peak times associated with the East 91st Street Converted MTS. Over an average peak day, the intersections should not experience an extended increase in delay. ~~The one intersection that may experience potentially significant impacts is discussed in Section 6.14.4.2 and summarized in Table 6.14-5.~~ However, two study intersections (discussed in Section 6.14.4.2 and summarized in Table 6.14-5 are projected to experience potentially significant impacts.

Notes:
[1] HCM output is included in technical backup submitted to the NYCDOT.
DFL = defacto left
LTR = left, through and right movements
TR = through right movement
NB = northbound
SB = southbound
WB = westbound

York Avenue/East 86th Street – During the AM peak hour, a potential impact was identified on the eastbound approach when the projected delay increased from 48.0 seconds to 62.4 seconds (LOS D to LOS E). A reallocation of three seconds of green time to the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract three seconds of green time from the northbound and southbound approaches, but would reduce the delay for the eastbound approach from 62.4 seconds to 49.8 seconds. This reallocation of green time would also decrease the delay of the westbound approach by approximately three seconds, while the northbound and southbound approach delays are projected to increase by approximately two seconds.

York Avenue/East 91st Street – During the PM peak hour, a potential impact was identified on the northbound (defacto) left movement when the delay increased from ~~86.9~~ 80.9 seconds to ~~97.3~~ 90.4 seconds (LOS F in both cases). ~~An~~ reallocation of two seconds of ~~increase in~~ green time ~~of one second for~~to the northbound and southbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract ~~one~~ two seconds from the westbound approach green time, but would reduce the delay for the northbound (defacto) left movement from ~~97.3~~ 90.4 seconds to ~~86.1~~ 75.0 seconds. The reallocation of green time would also decrease the delay of both the northbound and southbound approaches ~~would decrease~~ by approximately ~~less than~~ one second. The westbound approach delay ~~would~~ is projected to increase by less than one second.

This mitigation should not generate any adverse impacts on other lane groups during other time periods.

Overall, the mitigation measure suggested would greatly enhance the intersection performance by reducing delays to LOSs similar to those under the Future No-Build Condition.

6.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

6.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

6.15 Air Quality

6.15.1 Definition of the Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the East 91st Street Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersections listed in Section 6.15.4.2.

6.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest the study area are shown in Table 6.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 6.15-1
Representative Ambient Air Quality Data
East 91st Street Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	P.S. 59	8-Hour	2,978 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	5,268 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2[(1)]	P.S. 59	Annual	71 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}	P.S. 59	Annual	34 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	88 $\mu g/m^3$	150 $\mu g/m^3$
SO_2[(1)]	P.S. 59	3-Hour	186 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	123 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	37 $\mu g/m^3$	80 $\mu g/m^3$

Notes:
Source: NYCDEP, April 2003 & USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.

6.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No Build air quality conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

6.15.4 Potential Impacts with the East 91st Street Converted MTS

6.15.4.1 On-Site Analysis

6.15.4.1.1 Sources Considered in the Analysis

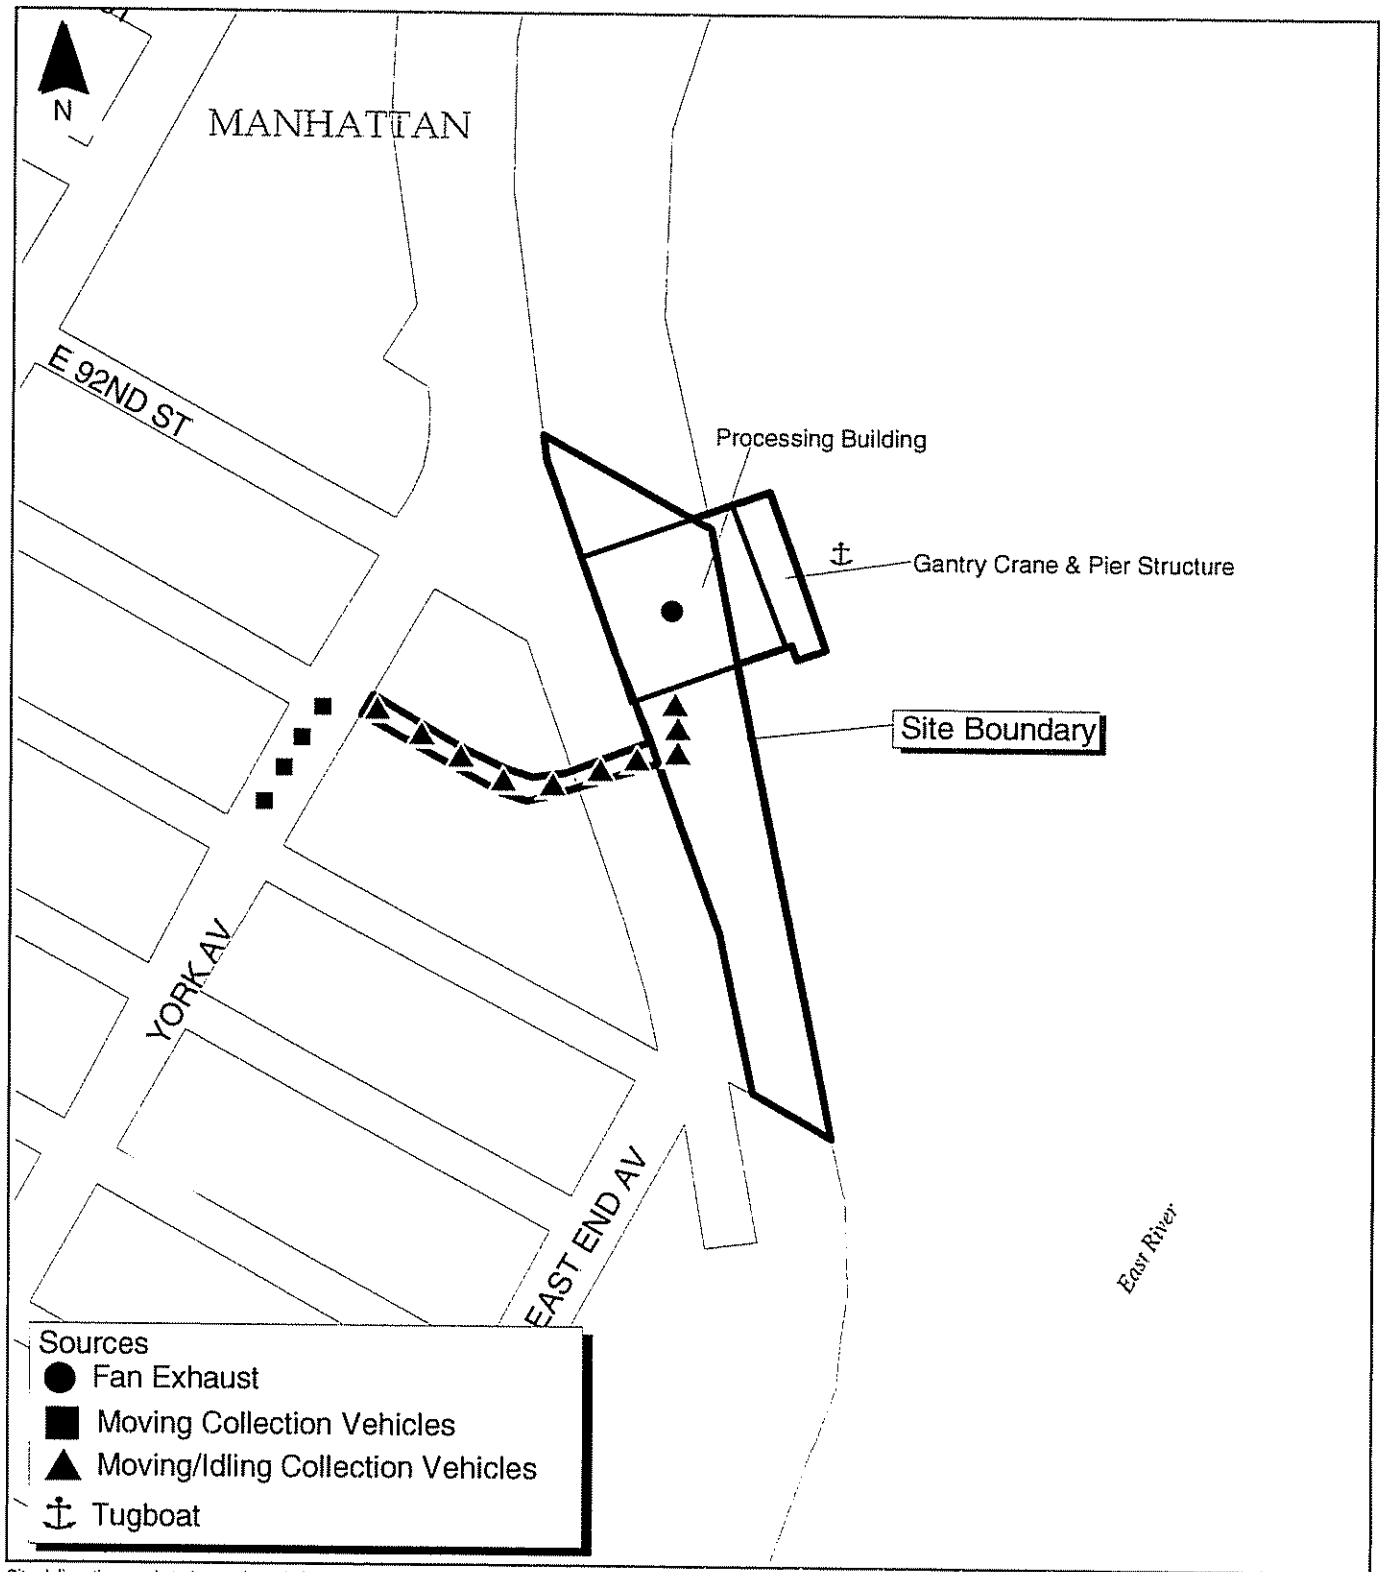
The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 6.15-2. Figure 6.15-1 shows the locations of these sources within the site.

6.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 6.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from East 91st Street Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 6.15-3, are below the STVs. The East 91st Street Converted MTS would not, therefore, significantly impact air quality in the area.

Table 6.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
East 91st Street Converted MTS

Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	46	18
Space Heaters	6	4
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3][4]	~~18~~16-in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1



Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~to be provided upon request.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (one third of 18), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

(4) The queuing collection vehicles presented in the DEIS reflected excess queuing capacity. To eliminate potential conflict at the bottom of the ramp, the number of queuing collection vehicles was revised in the FEIS.

Site delineations and study area boundaries are approximate
Base Map Source: New York City Department of City Planning
Note: These are modeled source locations used in the on-site air quality analysis and do not represent individual collection vehicles

	24-hour[6]	3	139	142	365	NA
	Annual	0.4	37	37	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP in a memorandum ~~in April 2003 background memorandum data for modeling NO_2, SO_2 and PM_{10}~~ dated February 18, 2005. Maximum background data were used unless otherwise noted.

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

6.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 6.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the East 91st Street Converted MTS are not considered to be significant.

6.15.4.2 Off-Site Analysis

6.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by facility's collection vehicles were identified using 2001 CEQR Technical Manual guidelines that are outlined in Section 3.17. Following these guidelines, the following detailed mobile source analyses were conducted for the applicable (i.e., worst-case) time periods:

- An analysis of the intersection of York Avenue and East 91st Street to determine whether East 91st Street Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 8-hour CO de minimus value or a violation of the 8-hour NAAQS;
- An analysis of the intersections of York Avenue and East 86th Street, and York Avenue and East 91st Street to determine whether East 91st Street Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 24-hour and annual $PM_{2.5}$ STVs; and
- An analysis of the intersections of York Avenue and East 86th Street, and York Avenue and East 91st Street to determine whether East 91st Street Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 6.15-2.

		Acute Non-Cancer Hazard Index Threshold[11]		**1.0E+00**	**Chronic Non-Cancer Hazard Index Threshold**[11]		**1.0E+00**	**Cancer Risk Threshold**[11]		**1.0E-06**

Notes to Table 6.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC

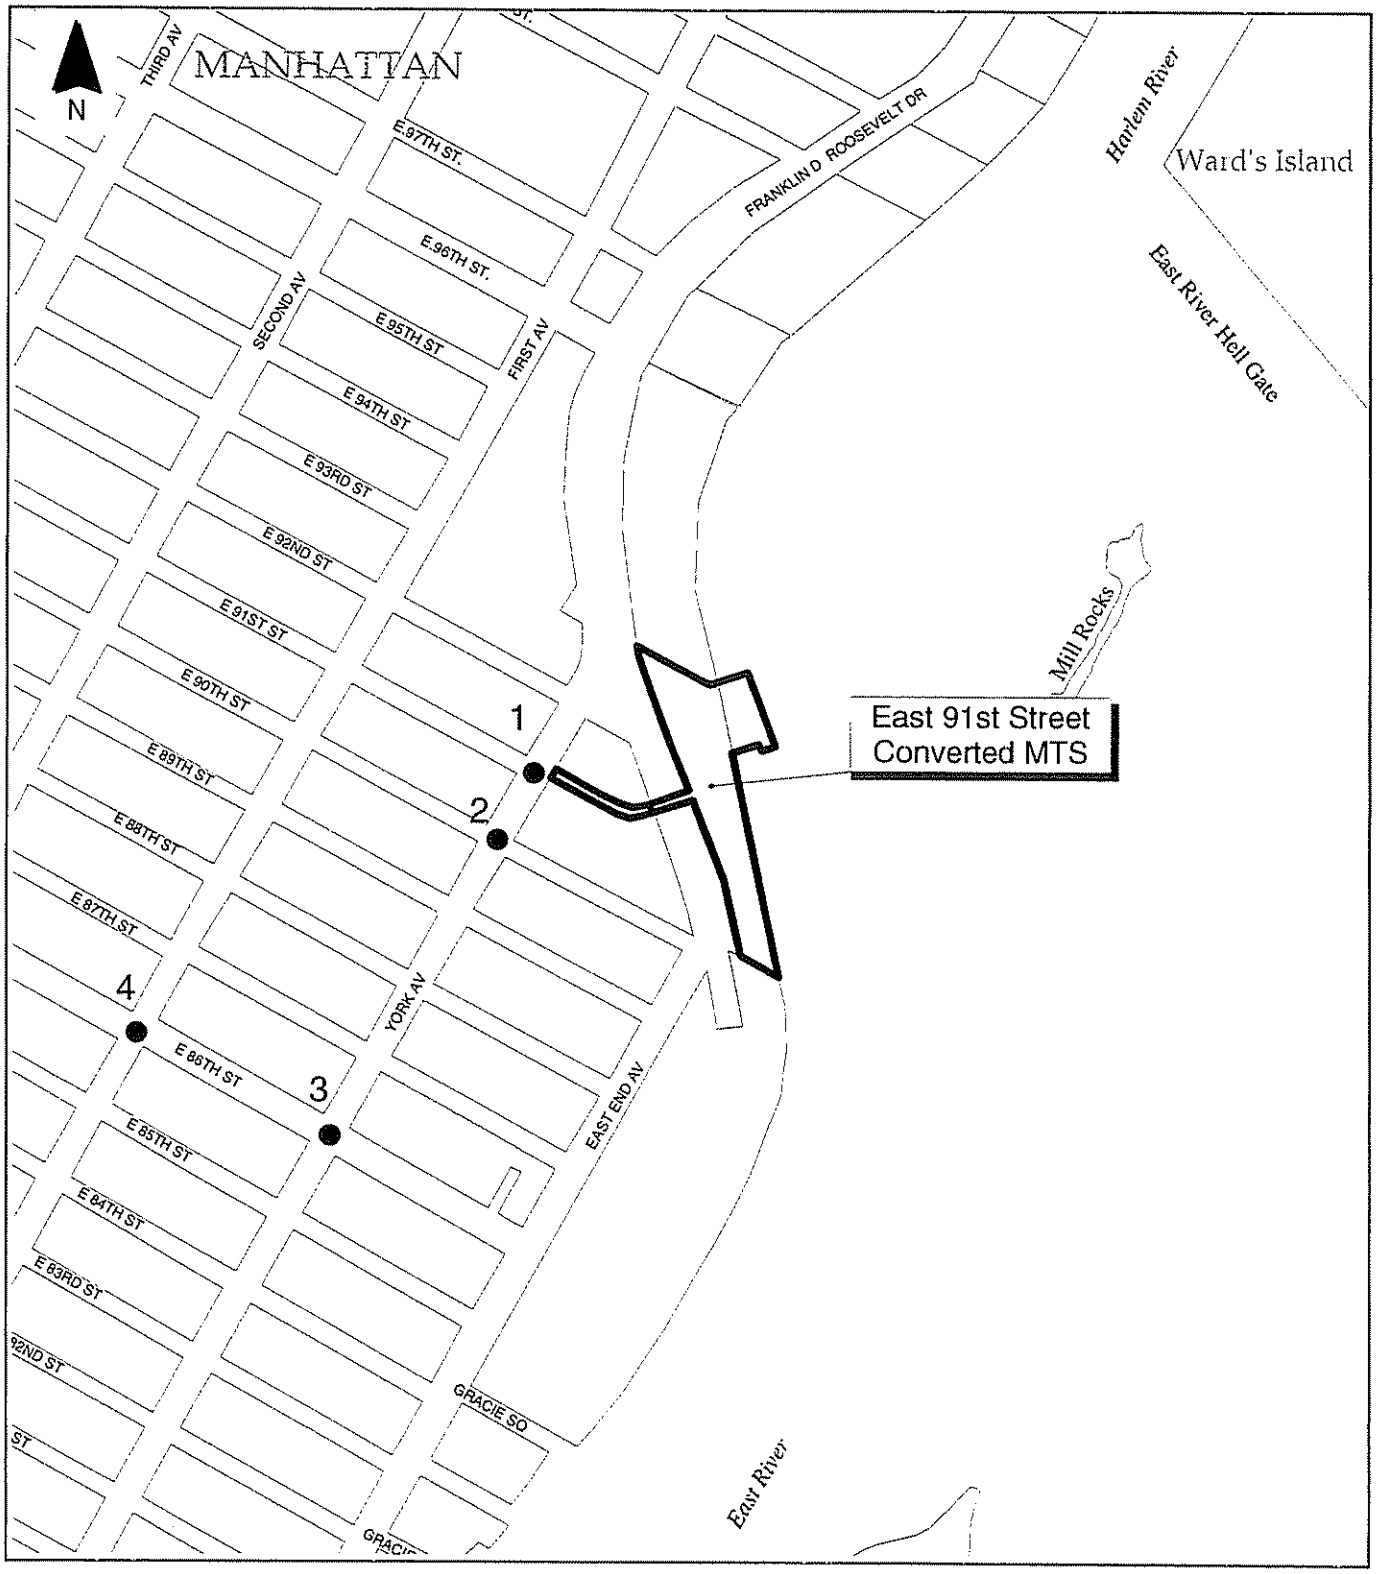
(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

6.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 6.15-5, are all within (less than) the applicable state and federal ambient air quality standards, STVs (for $PM_{2.5}$) and/or de minimus impact values (for CO). The off-site operations of the East 91st Street Converted MTS are not, therefore, considered to be significant. A conservative ratio of peak period project-induced traffic volumes to daily average project-induced volumes was used to estimate off-site annual impacts for $PM_{2.5}$. A more refined Tier II analysis will be performed to confirm the result of the annual impact for $PM_{2.5}$.

6.16 Odor

6.16.1 Existing Conditions

The existing MTS is not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptors are: ~~is the apartment building located on 90th Street east of York Avenue, approximately 360 feet from the site boundary.~~

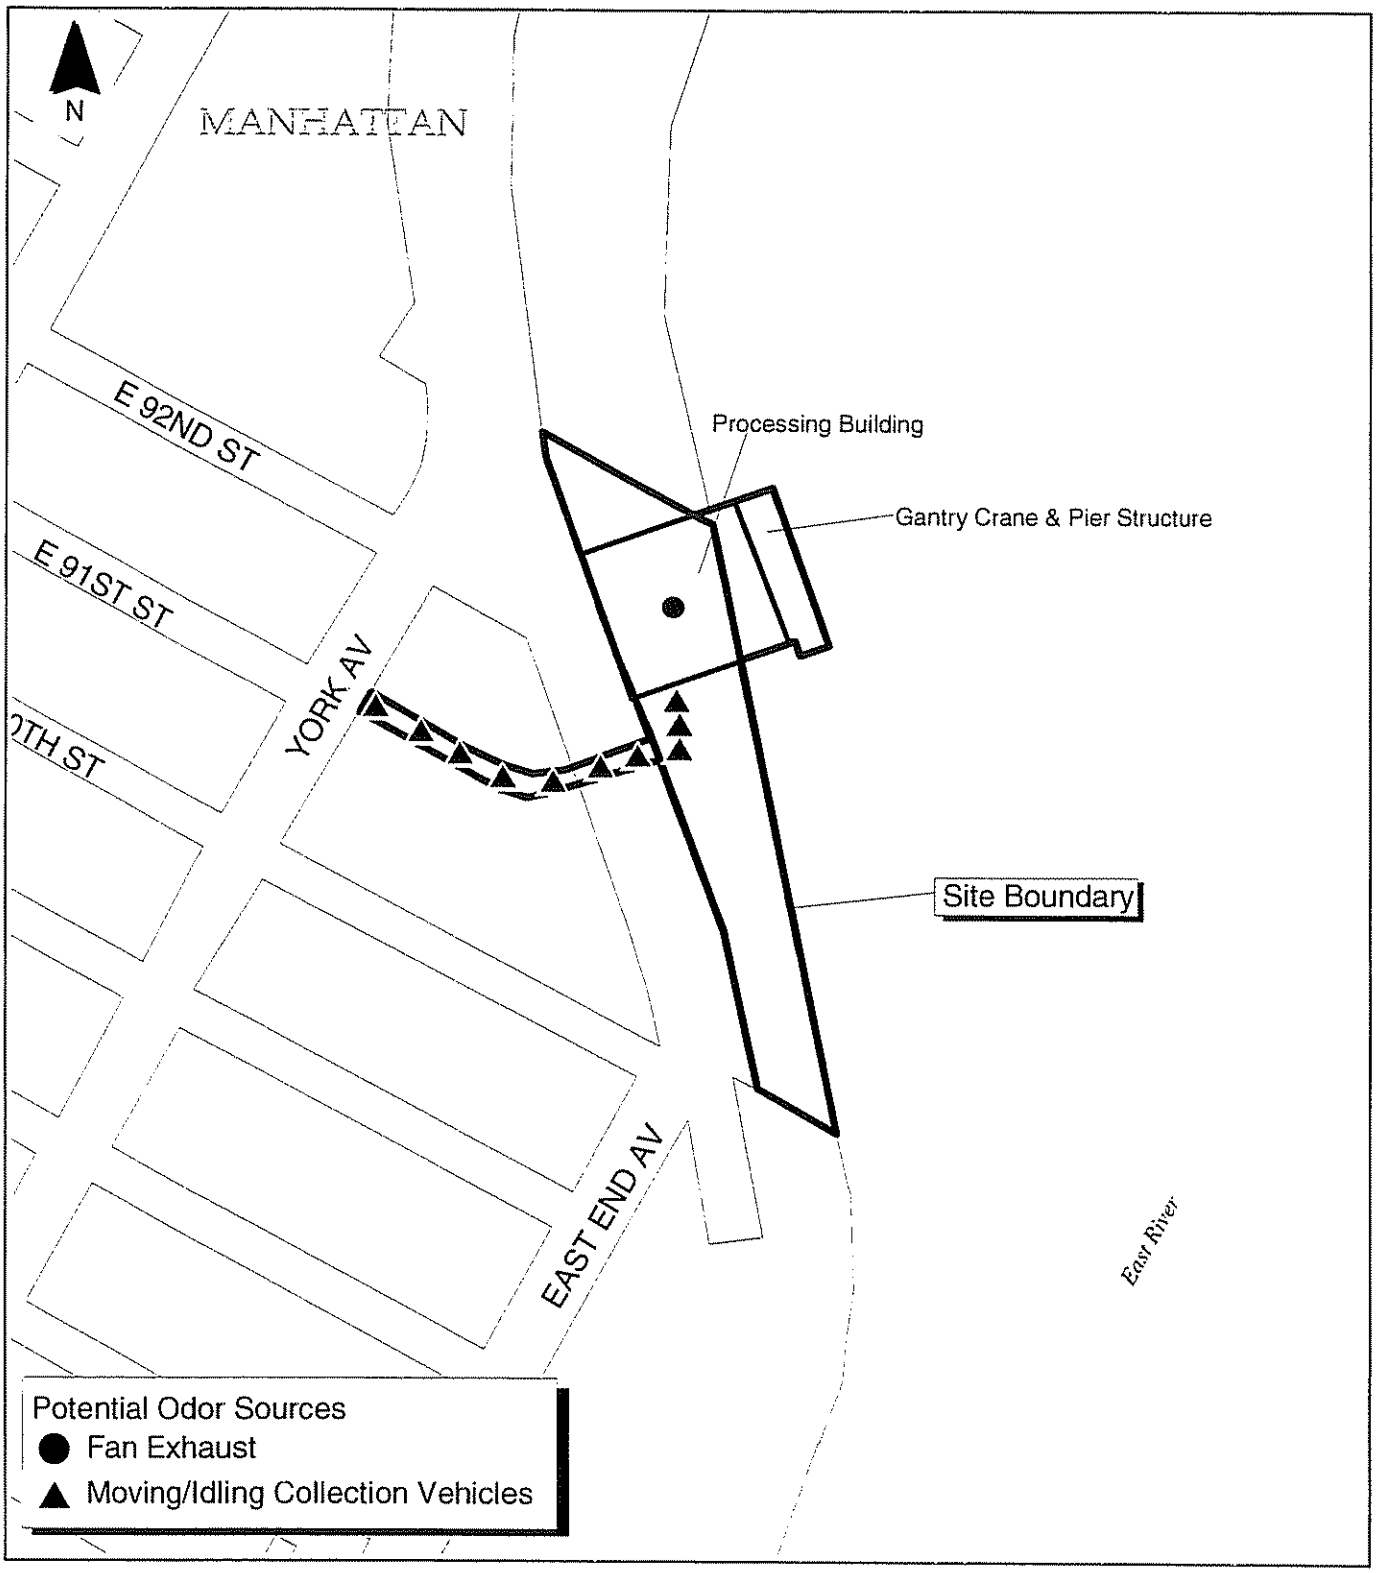
- Bobby Wagner Walk, an area that is designated as parkland and is directly abutting the East 91st Street Converted MTS property boundary.
- An apartment building on York Avenue, approximately 40 meters (131 feet) from the East 91st Street Converted MTS property boundary.
- An apartment building on East 90th Street east of York Avenue, approximately 114 meters (375 feet) from the East 91st Street Converted MTS property boundary.
- A playing field located on land abutting the East 91st Street Converted MTS truck ramp. This field is owned by Asphalt Green Aqua Center Recreation Facility (Asphalt Green).
- Asphalt Green, directly abutting the East 91st Street Converted MTS truck ramp and property boundary.
- A playground which is part of Asphalt Green on York Avenue, directly abutting the East 91st Street Converted MTS truck ramp and property boundary.

Additional residential areas exist immediately north, south and west of these noise-sensitive receptors.

6.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the East 91st Street Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.

6.16.3 Potential Impacts with the East 91st Street Converted MTS



6.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the East 91st Street Converted MTS are provided in Table 6.16-1. Figure 6.16-1 shows the locations of these sources within the site.

Table 6.16-1
Odor Sources Included in Odor Analysis
East 91st Street Converted MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving & ~~Idling~~ Queuing Collection Vehicles	~~19~~ 17

Notes:
(1) The queuing collection vehicles presented in the DEIS reflected excess queuing capacity. To eliminate potential conflict at the bottom of the ramp, the number of queuing collection vehicles was revised in this FEIS.

Site delineations and study area boundaries are approximate.

Figure 6.16-1 Potential Odor Sources

East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the East 91st Street Converted MTS.

6.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 6.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the East 91st Street Converted MTS at any nearby sensitive receptor is less than 1, so odors from the East 91st Street Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 6.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
East 91st Street Converted MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	0.92
Type of Receptor	Fence Line Receptor
Location of Receptor [2]	Site Boundary
Closest Sensitive Receptor Results[2]	~~0.13~~
~~Type of Receptor~~	~~Apartment Building~~
~~Distance to Receptor[3]~~	~~360 Feet~~
Bobby Wager Walk	0.61
Apartment Building on York Avenue	0.12
Apartment Building on East 90th Street	0.17
Asphalt Green Aqua Center Recreational Field	0.40
Asphalt Green	0.41
Asphalt Green Playground	0.16

Notes:

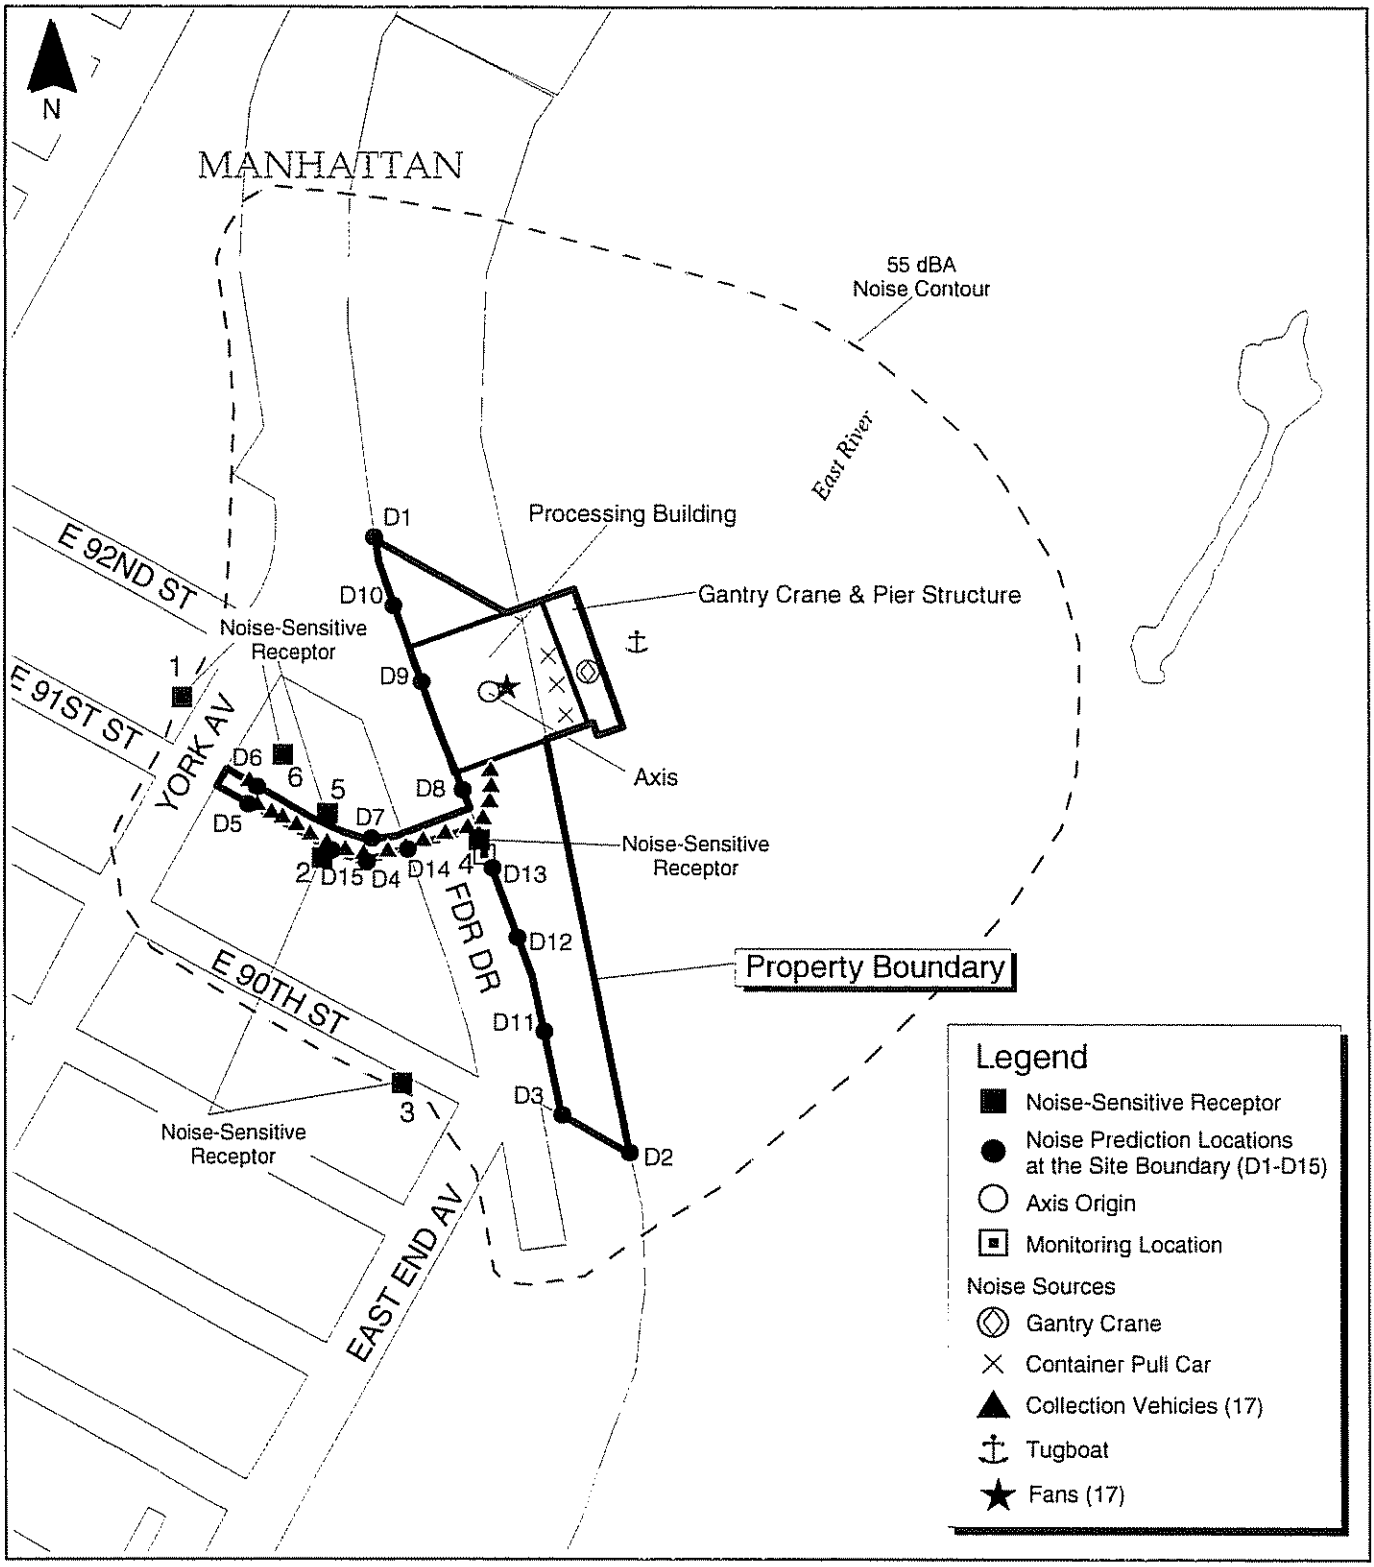
(1) Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.

(2) Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.

~~(2) Measured from the site property line.~~

6.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from East 91st Street Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.



6.17.1 Existing Conditions

6.17.1.1 Introduction

Figure 6.17-1 shows the location of the East 91st Street Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptors are:

- Bobby Wagner Walk, an area that is designated as parkland and is directly abutting the East 91st Street Converted MTS property boundary.
- An apartment building on York Avenue, approximately 40 meters (131 feet) from the East 91st Street Converted MTS property boundary.
- An apartment building on East 90th Street east of York Avenue, approximately 114 meters (375 feet) from the East 91st Street Converted MTS property boundary.
- A playing field located on land abutting the East 91st Street Converted MTS truck ramp. This field is owned by Asphalt Green Aqua Center Recreation Facility (Asphalt Green).
- Asphalt Green, directly abutting the East 91st Street Converted MTS truck ramp and property boundary.
- A playground which is part of Asphalt Green on York Avenue, directly abutting the East 91st Street Converted MTS truck ramp and property boundary.

Additional residential areas exist immediately north, south and west of these noise-sensitive receptors.

Site delineations and study area boundaries are approximate.

East 91st Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

6.17.1.2 *On-Site Noise Levels*

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptors. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[13] and the statistical metrics of L_{10}, L_{50} and L_{90}.[14] Table 6.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 5:00 p.m. and 6:00 p.m. and had an $L_{eq(1)}$ of 65.4 dBA on January 15, 2003. Although the quietest hour is typically a nighttime hour, the traffic conditions on the FDR Drive during the evening rush hour, when cars are not moving, reduces the noise level that would normally be expected next to a highway. Activities and events that contribute to the on-site noise levels are as follows:

- Traffic from the FDR Drive;
- Ferry boats loading and unloading passengers; and
- Other marine activity.

6.17.1.3 *Off-Site Noise Levels*

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if noise monitoring would be required along the East 91st Street Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required, and therefore off-site noise monitoring was conducted. Table 6.17-2 presents monitored noise levels near noise-sensitive receptors during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) based on first-level screening.

[13] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[14] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

1:00-2:00 p.m.	71.2	64.8	71.1	73.7	59.7	79.4

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour

Table 6.17-2
Existing Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor for Off-site Analysis
East 91st Street Converted MTS

~~Roadway ID~~ Location	Existing Noise Levels During Quietest Hour (dBA)[1]
East ~~91st~~-90th Street between First Avenue and York Avenue[2]	64.5
York Avenue between East 90th Street and East 91st Street[3]	62.9

Notes:
[1] A 1-hour noise level reading was measured at the closest noise-sensitive receptor during the hour expected to experience the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest).
[2] The existing noise levels were measured on July 29, 2003 between 3:00 a.m. and 4:00 a.m.
[3] The existing noise levels were measured on July 30, 2003 between 3:00 a.m. and 4:00 a.m.

6.17.2 Future No-Build Conditions

6.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

6.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 6.17-3 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 6.17-3
Off-Site Noise Traffic Volume
East 91st Street Converted MTS

Location	Hour Beginning	Existing Traffic Volume (1) (Vehicles / Hour)	Future No Build Traffic Volume (2) (Vehicles / Hour)
York Avenue between East 90th & East 91st Streets	3:00 a.m.	~~78~~ 60	~~79~~ 61
York Avenue between East 90th & East 91st Streets	10:00 a.m.	~~1084~~ 1.042	~~1100~~ 1.058
East 90th Street between First Avenue & York Avenue	~~3~~2:00 a.m.	~~24~~ 15	~~24~~ 15
East 90th Street between First Avenue & York Avenue	9:00 a.m.	~~182~~ 221	~~185~~ 224
East 91st Street between First Avenue & York Avenue	~~23~~:00 a.m.	~~33~~ 24	~~33~~ 24
East 91st Street between First Avenue & York Avenue	9:00 a.m.	~~228~~ 189	~~231~~ 192

Notes:
(1) Existing Traffic Volumes are based on corrected ATR data for this FEIS.
(2) Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

6.17.3 Potential Impacts with the East 91st Street Converted MTS

6.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the East 91st Street Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 6.17-4. The number and types of equipment assumed for this analysis was based on the East 91st Street Converted MTS's peak design capacity. As described in Section 3.19, an analysis was performed to determine if the number and type of trucks queuing on the ramp that was analyzed in the DEIS is more conservative than the greatest number of DSNY and Commercial Waste trucks expected to be queuing on the ramp based on the number of trucks that might be routed to the facility. The DEIS analysis was based on DSNY trucks queuing along the entire length of the ramp, which is more conservative than using the maximum potential number of queuing

DSNY and Commercial Waste trucks. Therefore, the results presented for the on-site analysis in this FEIS are based on DSNY trucks queuing along the entire length of the ramp.

Spectral noise levels used in the Performance Standards analysis are shown in Table 6.17-5. The number and types of equipment assumed for this analysis were based on the East 91st Street Converted MTS's peak design capacity. Shown earlier, Figure 6.17-1 indicates the East 91st Street Converted MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Hz = Hertz
K = Thousand

6.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the East 91st Street Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 56 meters (183 feet) from the property boundary in the direction of the York Avenue Apartment Building, which is approximately 40 meters (131 feet)

from the property boundary; approximately 113 meters (371 feet) from the property boundary in the direction of the Asphalt Green Recreational Field, which is directly abutting the property boundary; approximately 121 meters (397 feet) from the property boundary in the direction of the East 90th Street Apartment Building, which is approximately 114 meters (375 feet) from the property boundary; approximately 145 meters (477 feet) from the property boundary in the direction of Bobby Wagner Walk, which is directly abutting the property boundary; approximately 110 meters (363 feet) from the property boundary in the direction of Asphalt Green, which is directly abutting the property boundary; and approximately 152 meters (493 feet) from the property boundary in the direction of the Asphalt Green Playground, which is directly abutting the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (see Figure 6.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptors, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptors during the quietest hour based on monitoring data provided in Table 6.17-1 above. A detailed noise analysis was performed to calculate the East 91st Street Converted MTS-related predicted noise levels at the noise-sensitive receptors, and the predicted noise levels with both facility noise and background noise combined. The difference between this combined noise level and the existing noise level at the noise-sensitive receptor represents the predicted incremental change in noise level from the East 91st Street Converted MTS. Because this incremental change is greater than the CEQR threshold of 3 dBA, during nighttime hours or during daytime hours when the daytime background noise level is greater than 62 dBA, for the Asphalt Green Recreational Field, the Bobby Wagner Walk, and Asphalt Green receptors analyzed, there is a predicted impact that would be caused by the East 91st Street Converted MTS on-site operations based on this conservative analysis.

On-site queuing collection vehicles were further analyzed to refine the calculated noise levels from the East 91st Street Converted MTS facility truck ramp on the ~~Asphalt Green Recreational Field, Bobby Wagner Walk, and Asphalt Green~~ noise-sensitive receptors. Individual, position-specific utilization factors were assigned to each inbound collection vehicle position on the inbound side of the ramp, and to one collection vehicle position on the outbound scale based on the processing time at the East 91st Street Converted MTS. The utilization factor for each truck was estimated based on the peak hour of inbound collection vehicles, totaling 28 trucks and conservatively assuming these utilization factors would occur for 24 hours. The assumption was made that each inbound truck would be queuing on-site for approximately two minutes before proceeding one truck length further up the ramp towards the facility.

The refined analysis also includes a louver fence that will be placed on the truck ramp as a visual screen. The louver fence will be approximately nine (9) feet in height and will be constructed on top of a 3-foot high concrete base, for a total height of 12 feet. The louver fence will provide a noise reduction of approximately 7dBA for receptors adjacent to the property boundary.

Table 6.17-6 below shows the results of the CEQR analysis at the noise-sensitive receptors for the quietest background noise level with the ~~conservative~~ refined queuing analysis. ~~at the noise-sensitive receptors York Avenue Apartment Building, East 90th Street Apartment Building and the Asphalt Green Playground, and a refined queuing analysis at the Asphalt Green Recreational Field, Bobby Wagner Walk and Asphalt Green~~. The table includes the existing noise level at the noise-sensitive receptors, the East 91st Street Converted MTS-related noise levels and the combined noise level. The table also provides the difference between this combined noise level and the existing noise level at the sensitive receptors. This difference represents the predicted incremental change in noise level from the East 91st Street Converted MTS. Because this incremental change is less than the CEQR threshold of 3 dBA during nighttime hours, or during daytime hours when the daytime background noise level is greater than 62 dBA for all of the noise-sensitive receptors analyzed, there is no predicted impact that would be caused by the East 91st Street Converted MTS on-site operations.

Table 6.17-6

CEQR Analysis

Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptors

East 91st Street Converted MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
York Avenue Apartment Building	40 / 131	~~63.6~~ 63.4	~~60.9~~ 58.7	~~65.5~~ 64.7	~~1.9~~1.3	No
Asphalt Green Recreational Field[5][6]	Directly abutting truck ramp	~~69.0~~ 71.1	~~47.7~~ 66.8	~~69.0~~ 72.5	~~0.0~~ 1.4	No
East 90th Street Apartment Building[5]	114 / 375	~~64.5~~ 63.4	~~60.7~~ 61.2	~~66.0~~ 65.5	~~1.5~~ 2.1	No
Bobby Wagner Walk[6]	Directly abutting property boundary	68.0	~~57.2~~ 67.4	~~68.3~~ 70.7	~~0.3~~ 2.7	No
Asphalt Green Building [5][6]	Directly abutting truck ramp	71.1	~~48.7~~ 69.9	~~71.1~~73.6	~~0.0~~ 2.5	No
Asphalt Green Playground[5]	Directly abutting truck tramp	69.0	~~65.5~~ 56.0	~~70.6~~ 69.2	~~1.6~~ 0.2	No

Notes:

(1) Twenty-minute noise level readings measured at the noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

(2) Existing noise levels measured on ~~July 22, 2003~~August 10, 2004 at 3:00 a.m. at the York Avenue apartment building; ~~July 7, 2004~~ September 1, 2004 at 5:00 p.m. at the Asphalt Green Recreational Field and ~~Playground~~Building; ~~January 30, 2003 at 5:00 p.m.~~August 10, 2004 at 3:00 a.m. at the East 90th Street apartment building; July 8, 2004 at 5:00 p.m. at the Bobby Wagner Walk; and ~~September 1~~July 7, 2004 at 5:00 p.m. at the Asphalt Green Playground.

(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures, including the louvered fence along the ramp.

(4) According to CEQR, an increase over 65 dBA at daytime is considered an impact. However, if the existing noise level at the receptor during the daytime is 62 dBA or greater or if the analysis is for a nighttime hour, an increase over 3 dBA would be considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the East 91st Street Converted MTS with the quietest background noise levels that occur during facility operation.

(5) This noise-sensitive receptor was assumed to only be in use during daytime hours. Therefore, noise monitoring and noise analysis were only performed for the quietest daytime hour.

~~(6) These results are based on refined on-site queuing collection vehicles utilization factors.~~

6.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points representative of the East 91st Street Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (assuming tugboats are transportation facilities) (see Table 6.17-7). ~~Based on this analysis, no exceedances to the Performance Standards are predicted.~~

The NYC Zoning Resolution Performance Standards for Noise (Article IV: Manufacturing District Regulations, Section 42-21) requires that a lower standard (Maximum Permitted Sound Pressure Levels identified in 42-213 lowered by 6 dB) be met at any point at the manufacturing district boundary that adjoins a residential district. One location analyzed that is residentially zoned, though use of this property is recreational (not residential), is a point on the promenade between the FDR Drive and the East River to the north of the entrance ramp to the existing MTS. (The closest actual residence to this point is across the FDR Drive, over 400 feet away on York Avenue). Background noise levels at the point on the promenade are between 4.9 dB and 42.8 dB higher than the required standard, adjusted for residential zoning. At these levels, the theoretical exceedance at the boundary cannot be perceived and, therefore, no impact is predicted.

6.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the East 91st Street Converted MTS boundary to determine the total Leq from all indoor and outdoor sources for comparison to the current Noise Code. Based on this conservative analysis, the total Leq does exceed the current Noise Code Standard of 70 dBA at the property boundary.

dB = Decibel
K = Thousand
(1) D1 through D15 are the points on the East 91st Street Converted MTS boundary that are used in all noise analyses. D1 through D15 are all adjacent to a residential zone.

On-Site queuing collection vehicles were further analyzed to refine the calculated noise levels emitted from the East 91st Street Converted MTS facility truck ramp on the property boundary. This refined analysis is discussed in Section 6.17.3.2. In addition, the refined analysis includes a noise reduction of 7dBA at property boundary points, where applicable, that will be provided by a louver fence that has been included in the design as a visual screen. (See Section 6.17.3.2.) Table 6.17-8 below shows the results of the Current NYC Noise Code analysis with the refined queuing analysis and louver fence. Based on this analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.

6.17.3.5 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the East 91st Street Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 6.17-9.

Because the screening results presented above showed that the PCEs would double on a roadway due to DSNY and other agency collection vehicles coming to or going from the East 91st Street Converted MTS, a detailed off-site noise analysis was performed at that roadway using TNM for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime. Figure 6.17-2 depicts the locations of the roadways where a detailed off-site analysis was performed.

Table 6.17-8
Current Noise Code Analysis with
Refined On-Site Queuing Collection Vehicle Utilization Factors
East 91st Street Converted MTS

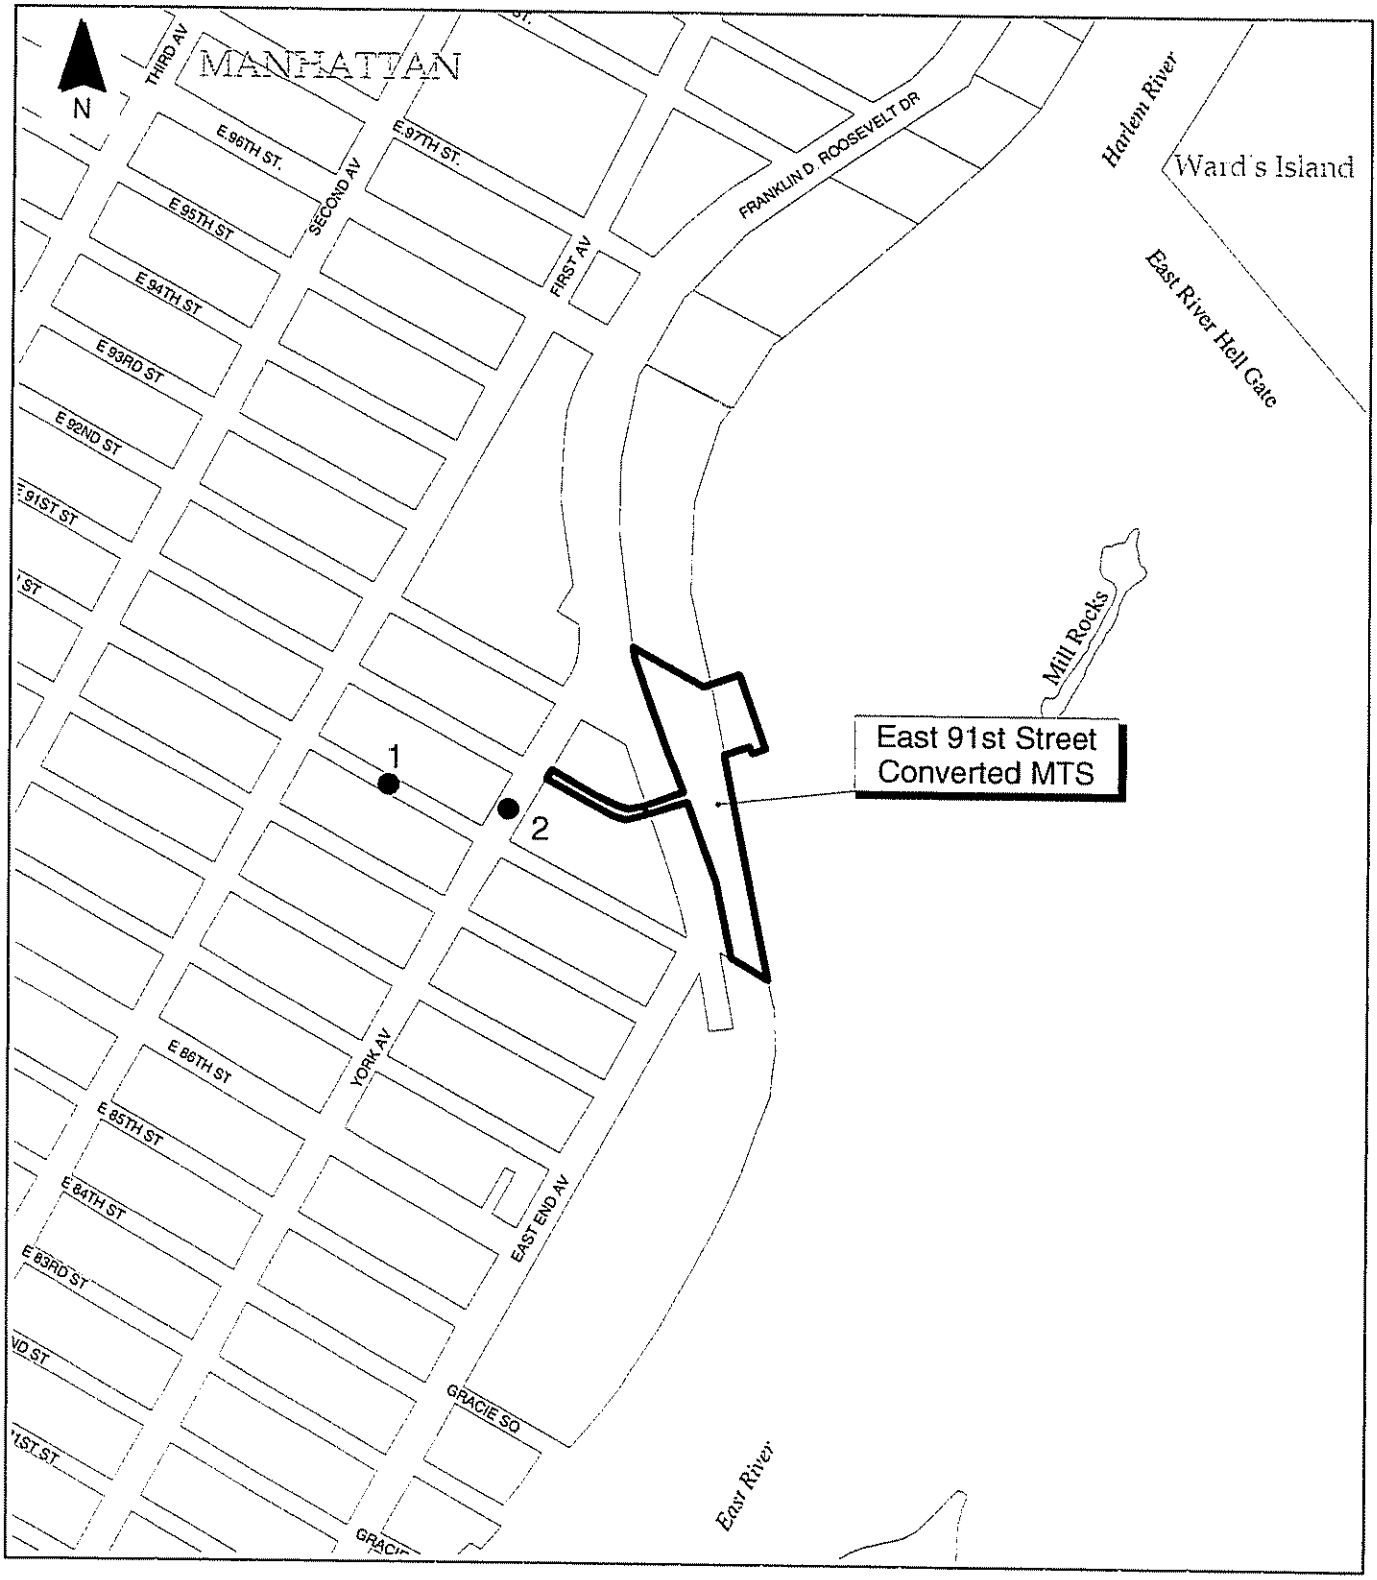
D10	59.6
D11	61.2
D12	64.7
D13	59.8
D14	60.2
D15	59.8

Notes:
(1) D1 through D15 are the points on the East 91st Street Converted MTS boundary that are used in all noise analyses.

Table 6.17-9
Off-Site Noise Screening Results
East 91st Street Converted MTS



Location	Hour Beginning	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
York Avenue between East 90th & East 91st Streets	3:00 a.m.	170	19	0	893	1,063	Yes
York Avenue between East 90th & East 91st Streets	10:00 a.m.	2,722	42	0	1,974	4,696	No
East 90th Street between First Avenue & York Avenue	3:00 a.m.	116	7	0	329	445	Yes
East 90th Street between First Avenue & York Avenue	9:00 a.m.	448	14	0	658	1,106	Yes
East 91st Street between First Avenue & York Avenue	2:00 a.m.	137	4	0	188	325	Yes
East 91st Street between First Avenue & York Avenue	9:00 a.m.	1,363	14	0	658	2,021	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include East 91st Street Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

TNM results for locations/hours that resulted in an impact based on a second-level screening are presented in Appendix E of this FDEIS. Because the incremental noise-level change, which is calculated by obtaining the difference between the TNM-predicted Future Build noise level and the TNM-predicted Future No-Build noise level, is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, an impact at these roadways would be caused by the East 91st Street Converted MTS-related collection and employee vehicles.

To determine if these TNM-predicted impacts were accurate, site-specific truck simulations were conducted at the noise-sensitive receptors. The truck simulation analysis provides a more realistic determination of DSNY and other agency collection vehicle noise impacts based on the proposed number of DSNY and other agency collection vehicles expected to travel through the roadways analyzed during the nighttime hours. Truck simulations were conducted with DSNY collection vehicles, as described in Section 3.19.7, for each roadway and hour that the first-level screening analysis resulted in a possible impact. For this procedure, two sets of noise measurements were taken — one with and one without DSNY trucks — by routing a set number of DSNY trucks during the affected nighttime hours past the noise-sensitive receptor. Table 6.17-10 below contains the results of the site-specific DSNY collection vehicle simulations, which show that only the 3:00 a.m. to 4:00 a.m. hour at the York Avenue between East 90th Street and East 91st Street location would have an impact as a result of the East 91st Street Converted MTS.

A comparison of the simulation results for the hour resulting in an impact and the TNM results for this hour for the same traffic conditions and background noise levels estimated from recordings during the simulations is provided in Appendix E of this FDEIS. Based on this comparison, it is determined that TNM over-predicted the incremental change. The over-prediction can be attributed to the default assigned noise level for each type of vehicle, which appears to be greater than the actual noise levels that would be emitted by the East 91st Street Converted MTS-related collection vehicles.

Table 6.17-10
Off-Site Noise Analysis Truck Simulation
East 91st Street Converted MTS

Location	Hour Beginning	Existing Background Noise Level (L_{eq}) (Estimated)[1] dBA	Collection Vehicles	Truck Simulation[2] Noise Level (L_{eq}) for Existing Traffic plus Collection Vehicles dBA	Impact (Noise Level Difference) dBA
York Avenue between East 90th Street and East 91st Street	2:00 a.m.[2]	63.9	12	65.7	No (1.8)
York Avenue between East 90th Street and East 91st Street	3:00 a.m.[2]	62.9	19	66.5	Yes (3.6)
East 90th Street between First Avenue and York Avenue	2:00 a.m.[3]	64.9	5	65.8	No (0.9)
East 90th Street between First Avenue and York Avenue	3:00 a.m.[3]	64.5	7	65.4	No (0.9)

Note:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Simulations performed on July 30, 2003.
(3) Simulations performed on July 29, 2003.

Because both TNM and the site-specific truck simulations predict an impact at a noise-sensitive receptor during the 3:00 a.m. to 4:00 a.m. hour for the York Avenue between East 90th Street and East 91st Street location, adjustments were made to the distribution of trucks. Only the number of trucks that can be routed through this location without causing an impact would be allowed. The remaining collection vehicles would be routed through this location during the 2:00 a.m. to 3:00 a.m. hour without causing an impact. This location was re-analyzed during these hours with the truck adjustments using the site-specific truck acoustic energy per hour, as described in Section 3.19.7.2, to confirm that off-site noise impacts would not be caused by the reduced number of collection vehicles at this location. Based on these results, with the truck adjustments, there is no predicted impact that would be caused by the East 91st Street Converted MTS collection vehicles en route to and from the facility. Table 6.17-11 shows the results of this analysis.

Table 6.17-11
Off-Site Noise Analysis using Truck Simulation Data and Adjusted Collection Vehicles
York Avenue between East 90th Street and East 91st Street
East 91st Street Converted MTS

Hour	Existing Background Noise Level (L_{eq}) (Estimated)[1] (dBA)	Adjusted Collection Vehicles	Calculated[2] Noise Level (L_{eq}) for Existing Traffic plus Adjusted Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
2:00 a.m.	63.9	~~17~~15	~~66.3~~ 66.1	No ~~(2.4)~~(2.2)
3:00 a.m.	62.9	~~14~~ 8	~~65.8~~ 64.8	No ~~(2.9)~~(1.9)

Note:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Noise levels for existing traffic plus adjusted collection vehicles were calculated utilizing the per truck acoustic energy determined from the truck simulation data for this location.

6.17.3.6 Combined On-Site and Off-Site Noise Levels

An on-site and off-site noise analysis was performed for the East 91st Street Converted MTS. Since the potential impacts of these analyses can affect the same noise-sensitive receptor, a screening analysis was conducted to determine if a combined noise analysis would be required for the operations at the East 91st Street Converted MTS. The combined analysis study area was defined by the 55 dBA isopleth contours from the on-site source and the bottom driveway

entrance to the site. The other limits for the combined analysis study area were defined by the first row of buildings along the roadway between the 55 dBA contour and the driveway entrance to the site. The results of the screening analysis show that the York Avenue apartment building is the nearest noise-sensitive receptor located within the study area that can be impacted by both on-site and off-site East 91st Street Converted MTS operations; therefore, an combined noise analysis, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on the off-site analysis discussed in Section 6.17.3.5 above. Table 6.17-12 shows the distance from the East 91st Street Converted MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, East 91st Street Converted MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted off-site noise level at the noise-sensitive receptor. The table also provides the combined on-site and off-site noise level and the difference between theise combined noise levels. This difference represents the predicted incremental change in noise level from the East 91st Street Converted MTS on-site and off-site operations at the noise-sensitive receptor. Because this incremental change is not greater than the CEQR threshold of 3 dBA during nighttime hours for the York Avenue apartment building receptor analyzed, there is no predicted impact that would be caused by the East 91st Street Converted MTS combined on-site operations and off-site operations.

Table 6.17-12
Combined On-Site and Off-Site Noise Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor with East 91st Street Converted MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters /feet)	Hour Analyzed (Hour Beginning)	Existing Noise Levels During Quietest Hour (dBA)[1]	Predicted On-Site Noise Level at Noise-Sensitive Receptor (dBA)[2]	Collection Vehicles	Predicted Off-site Noise Level at Noise-Sensitive Receptor (dBA)	Combined On-Site and Off-Site Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[3] (yes or no)
York Avenue Apartment Building between East 90th Street and East 91st Street	47 / 154	2:00 a.m.	63.9	~~44.4~~ 58.7	~~17~~ 15	~~66.3~~ 62.0	~~66.3~~ 66.8	~~2.4~~ 2.9	No
		3:00 a.m.	62.9	~~44.4~~ 58.7	~~14~~ 8	~~65.8~~ 60.3	65.8	2.9	No

Notes:

(1) Existing background noise levels were estimated from noise monitoring performed during truck simulations.

(2) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.

(3) According to CEQR, an increase over 3 dBA at nighttime is considered an impact.

6.18 Commercial Waste to the East 91st Street Converted MTS

6.18.1 Existing Conditions

No commercial waste is delivered to the East 91st Street MTS site under Existing Conditions. Commercial waste generated in Manhattan is taken directly out of the City to remote disposal locations.

6.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the East 91st Street Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

6.18.3 Potential Impacts of Sending Commercial Waste to the East 91st Street Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

6.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the East 91st Street Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 6.15, 6.16 and 6.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

6.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the East 91st Street Converted MTS were evaluated in Sections 6.14, 6.15 and 6.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 6.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 28 (inbound trip ends) per hour, which occurred during the AM peak. These 28 DSNY and other agency collection vehicles are also more than the 21 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the East 91st Street Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 28 DSNY and other collection agency vehicle inbound trip ends at the East 91st Street Converted MTS. Therefore, the addition of the 21 DSNY and other agency collection vehicles and commercial waste hauling vehicle inbound trip ends at the East 91st Street Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 28 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 28 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24 hour period. Results showed there would be no unmitigatible significant adverse environmental impacts at several of the intersections analyzed. Consequently, because the 21 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can travel through these intersections per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the East 91st Street Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 781 tons (or 71 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

This page intentionally left blank.

CHAPTER 7 ENVIRONMENTAL REVIEW: NORTH SHORE CONVERTED MTS

7.1 Introduction

The results of the environmental analyses of the North Shore Converted MTS are presented in the following sections:

7.2 Land Use, Zoning, and Public Policy
7.3 Socioeconomic Conditions
7.4 Community Facilities and Services
7.5 Open Space
7.6 Cultural Resources
7.7 Urban Design, Visual Resources, and Shadows
7.8 Neighborhood Character
7.9 Natural Resources
7.10 Hazardous Materials
7.11 Water Quality
7.12 Waterfront Revitalization Program
7.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
7.14 Traffic, Parking, Transit, and Pedestrians
7.15 Air Quality
7.16 Odor
7.17 Noise
7.18 Commercial Waste to the North Shore Converted MTS

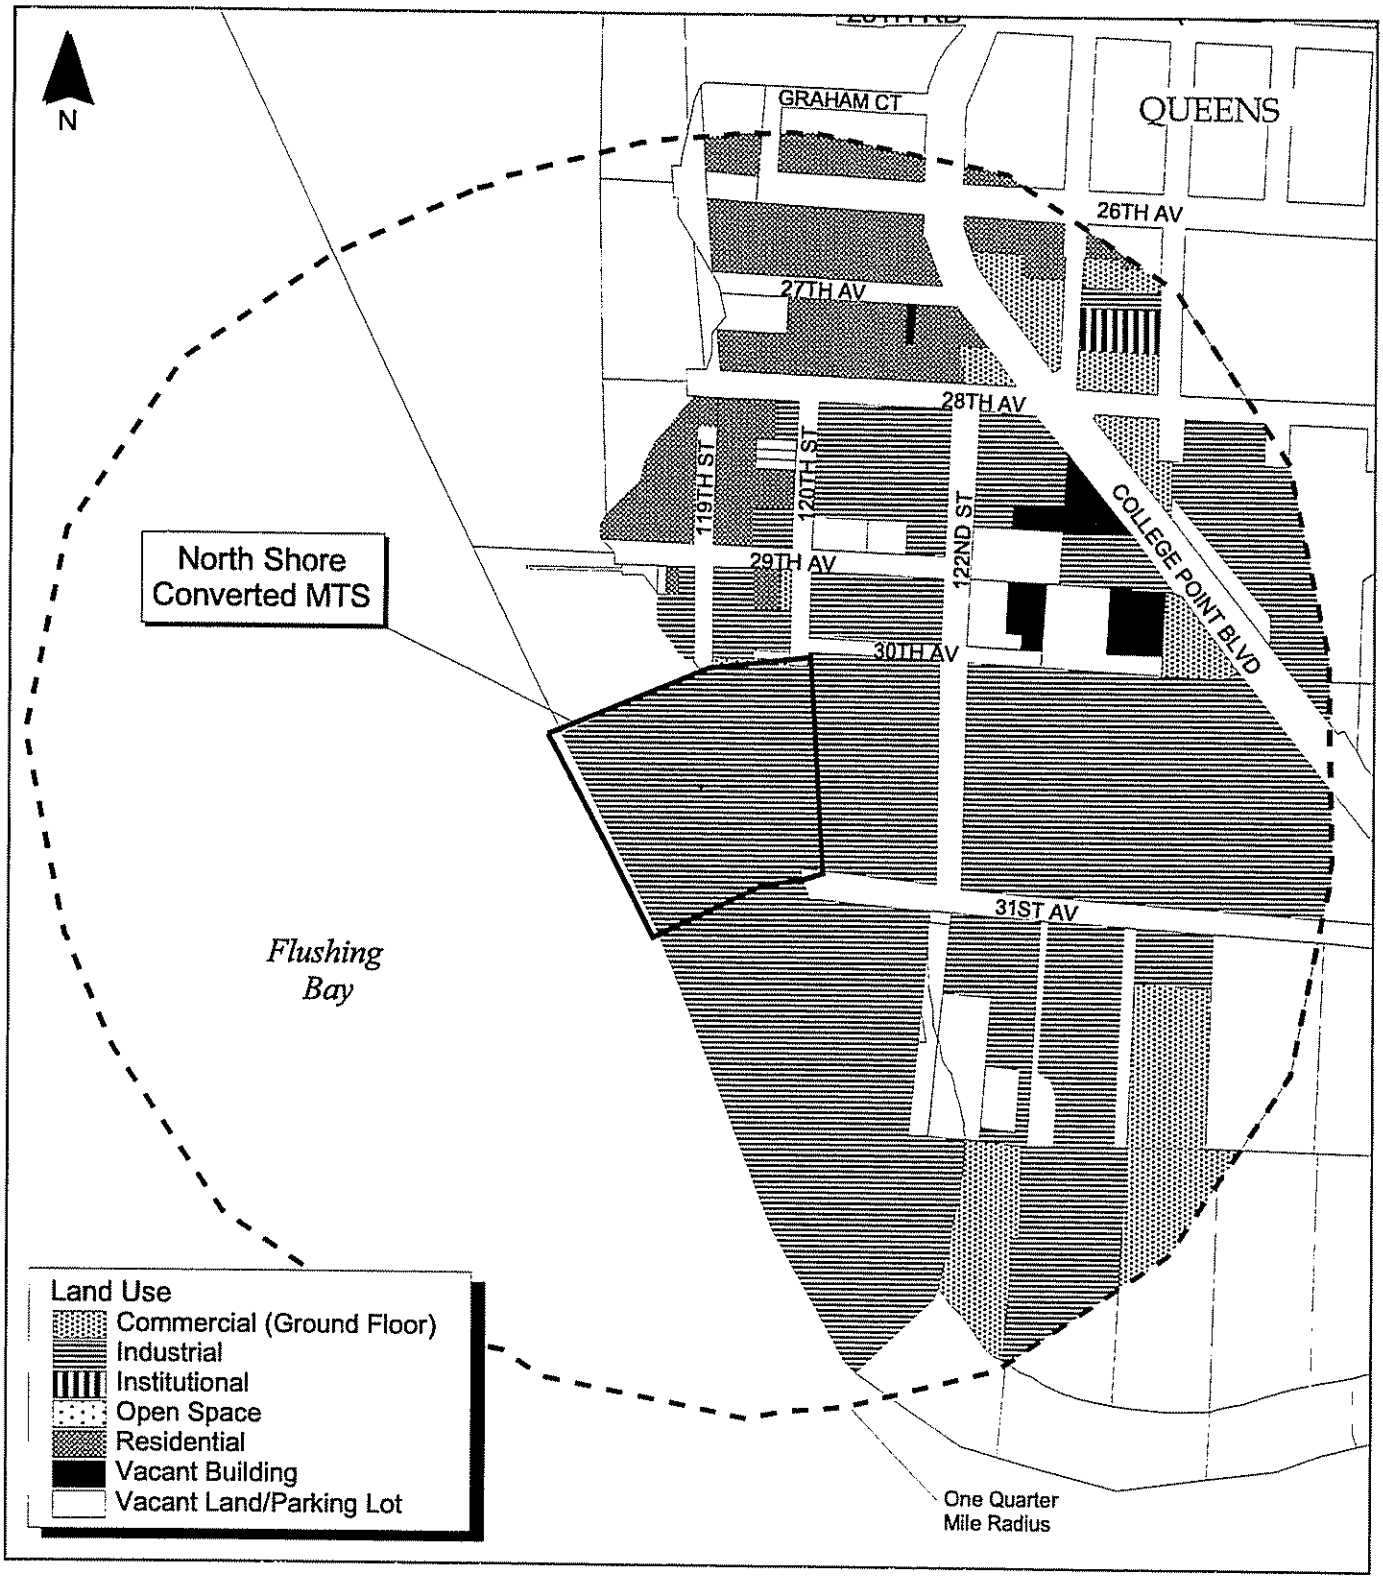
Section 2.2.4 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

7.2 Land Use, Zoning, and Public Policy

7.2.1 Existing Conditions

7.2.1.1 Definition of Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 7.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 7.2-2). Section 3.4 describes the methodology employed in these analyses, and Section 2.2.4 provides information on existing land uses and operations on the site.



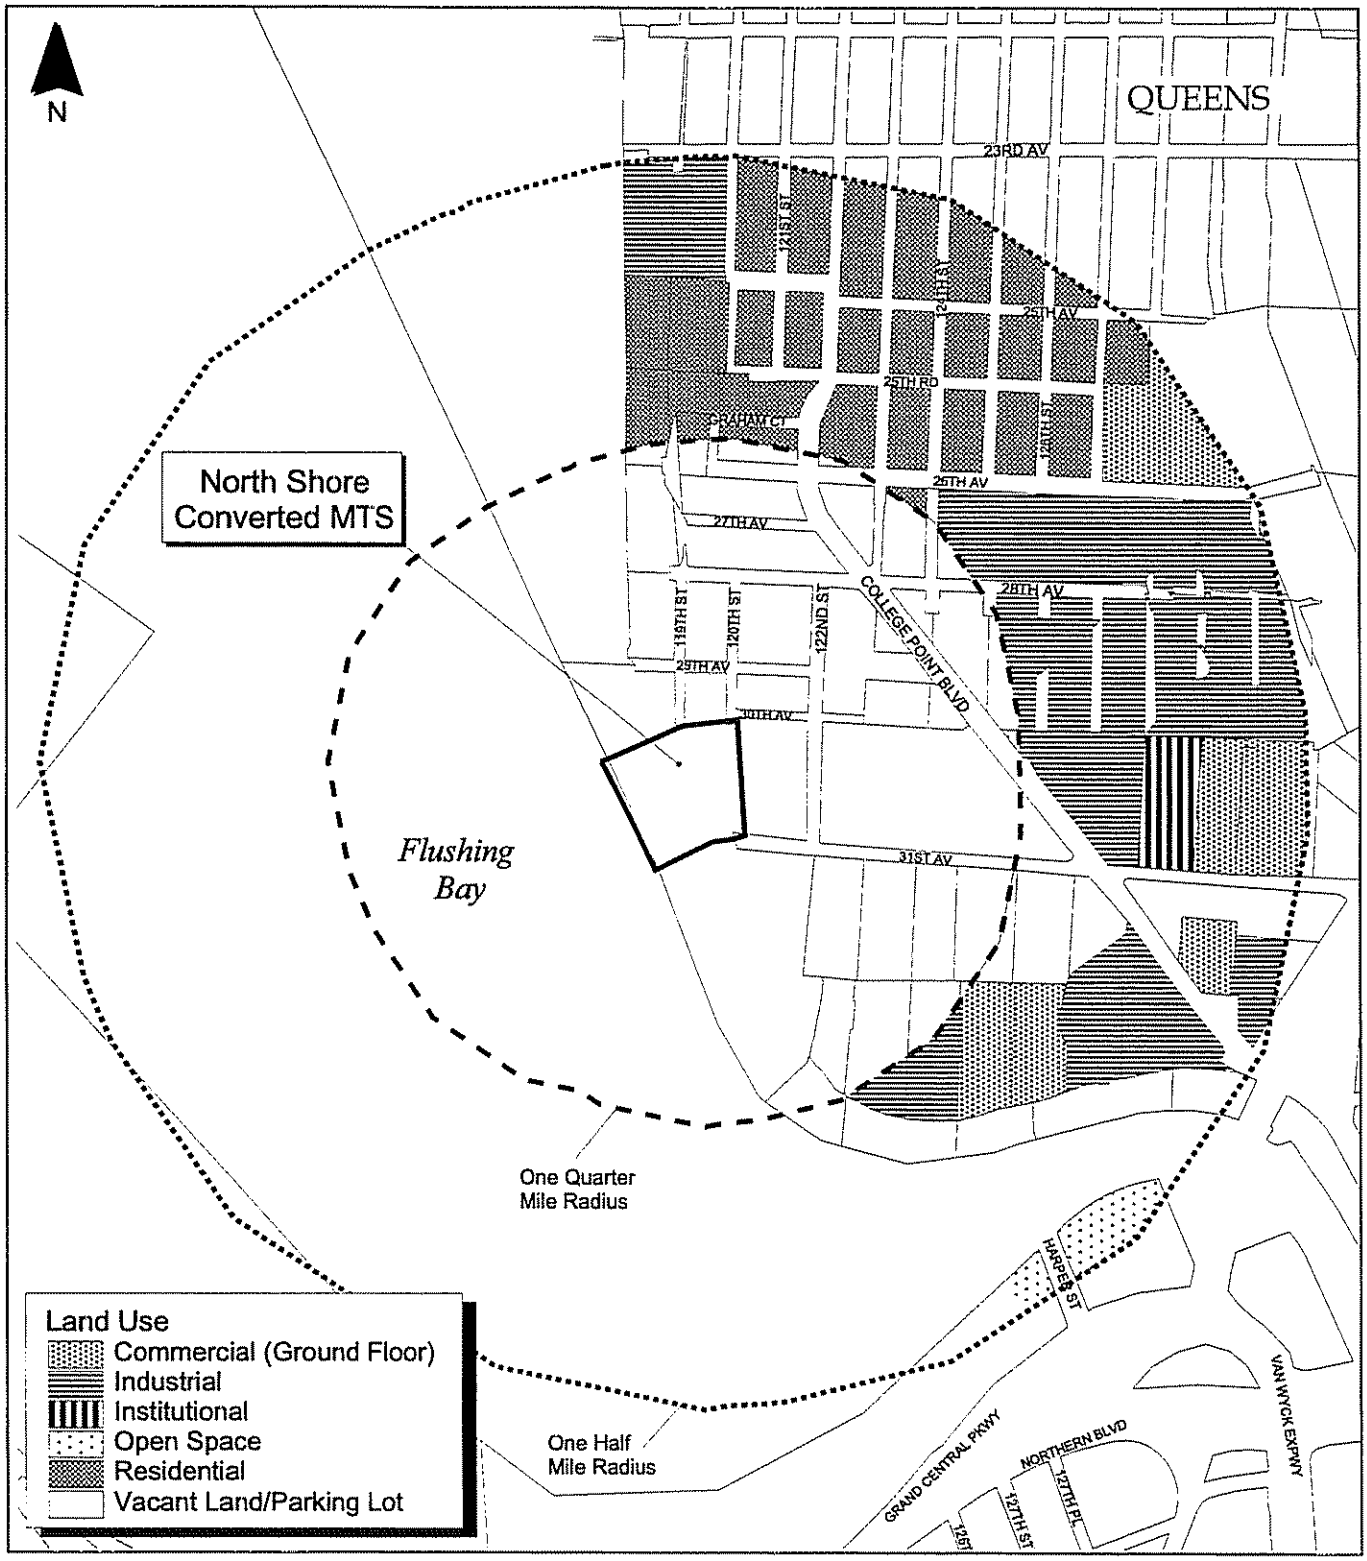
7.2.1.2 Land Use Patterns

7.2.1.2.1 General Context

The site is set on the southeast side of Flushing Bay within the mixed-use College Point peninsula and across from LaGuardia Airport. Commercial offices, manufacturing uses, warehouse storage facilities and automotive uses are the predominant land uses in the immediate vicinity south, east and northeast of the site, while residential uses are located further to the north of the site.

7.2.1.2.2 Land Uses in the Primary Study Area

The western half of the primary study area is part of Flushing Bay, while the eastern half contains a variety of land uses, mostly industrial. Industrial and manufacturing uses and their associated offices, warehouses/storage facilities and parking areas are concentrated to the south and east of the site. Commercial establishments are found throughout the primary study area, with a large number of automobile parts and service shops lining both sides of College Point Boulevard between approximately 27th and 28th Avenues and around 119th and 120th Streets, north of the site. East of and adjacent to the site is the DSNY Queens CD 7 garage, and, north of the garage, Vassilaros Coffee Roasting Company. A large Consolidated Edison facility is located on the block due east of the site and the CD garage, with storage and parking on the western end,



Site delineations and study area boundaries are approximate.

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

closest to the site. Residential uses are located north of the site from 29th Avenue to 28th Avenue west of 120th Street and north of 28th Avenue, where it is almost entirely residential between College Point Boulevard and the bay. The residential area contains single-family detached housing, two-family housing and some late 20th-century row housing. Nursing home facilities built between 1955 and 1971 are located on the western ends of the three blocks between 25th Avenue and 27th Avenue.

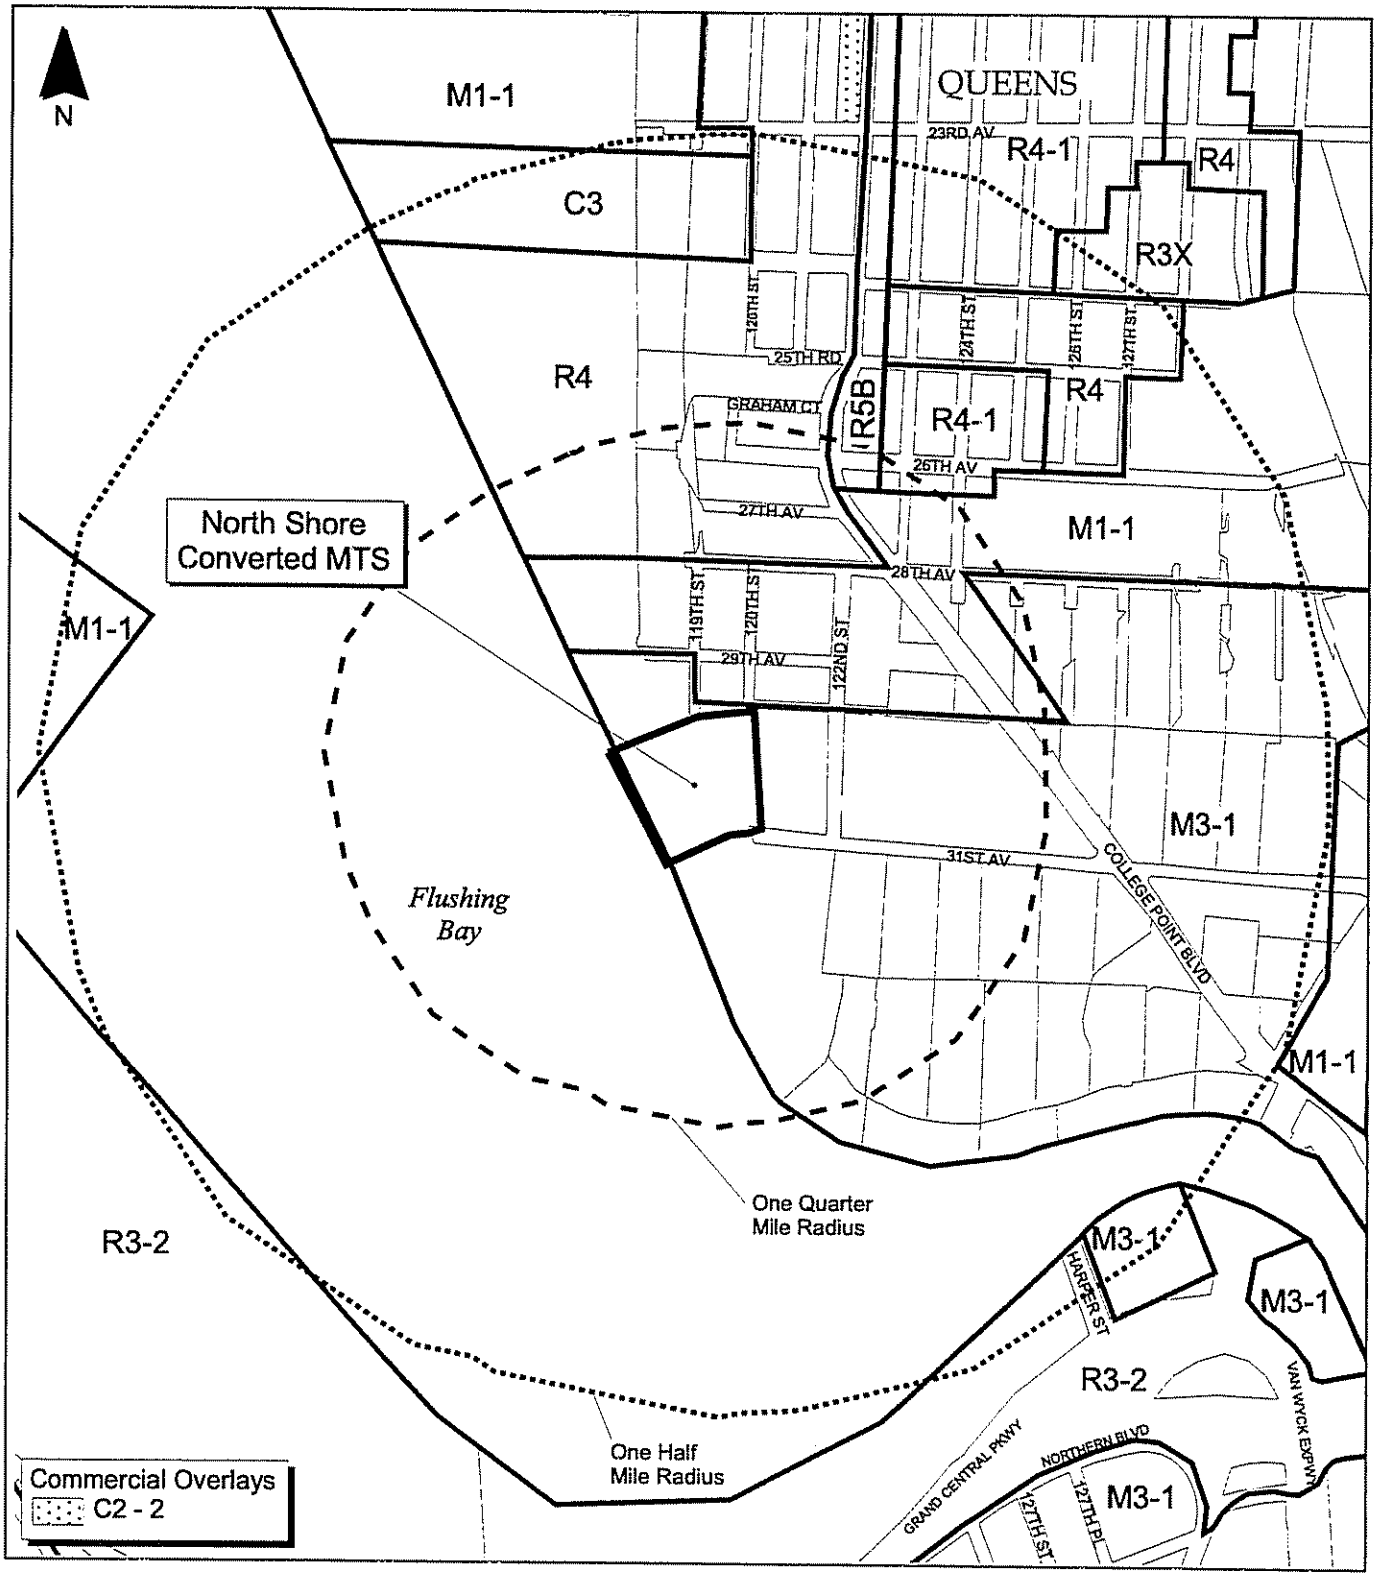
South of and adjacent to the site is the Ferrara Brothers Building Materials Company on 31st Avenue. Behind their offices is the materials storage and truck loading area. Several of the mapped streets in the area are not open to the public, but instead serve the concrete and asphalt companies located there. A Home Depot store has been recently constructed east of Ferrara Brothers near College Point Boulevard, introducing large-scale retail activity to the area.

A portion of the College Point Industrial Park to the east of the site lies in the primary study area. The park begins at College Point Boulevard and extends eastward and southward from about 26th Avenue to about 31st Avenue. Warehouses, busing facilities and storage/parking areas are located within that portion of the park within the study area, while the remainder of the park features such prominent businesses as The New York Times printing facility.

7.2.1.2.3 Land Uses in the Secondary Study Area

The northern portion of the secondary study area is almost exclusively residential, with the exception of major industrial uses in the area between 120th Street and the shore. Enterprises uses such as Sunrise Oil and an active boat yard and parking are found there. The northern residential portion of the study area east of 119th Street contains more multi-family apartment housing than in the residential areas nearer to the site. Machine shops and small manufacturers are scattered throughout. Public School No. 29, built in 1928, is located just outside the study area, on the south side of 23rd Avenue between 125th and 126th Streets. As mentioned, a new Home Depot is situated west of College Point Boulevard, south of 31st Avenue. Except for the Full Gospel New York Church at 130-30 31st Avenue, industrial uses, including the City's impound lot south of 28th Avenue, characterize most of the remaining secondary study area east of College Point Boulevard. Large manufacturers, such as The New York Times printing facility, are located to the east on the perimeter of the secondary study area.

Southeast of the site, the secondary study area consists of large privately owned lots of industrial waterfront and warehouses, as well as the former Metropolis nightclub at the southern end of Street. Most of these properties are accessible only via private drives. The secondary study area also includes the southern shore of Flushing Bay, where the City Bureau of Highways' Queens asphalt plant is located, as is the Flushing Meadows Corona Park, which extends south of the bay. The study area extends westward across the bay to include a small portion of the eastern edge of LaGuardia Airport.



7.2.1.3 Zoning On and Near the Site

7.2.1.3.1 Zoning Within the Primary Study Area

The site is in an M3-1 zoning district that extends north to about 30th Avenue, west and south to the bay, and east beyond College Point Boulevard. (See Figure 7.2-3 and Table 3.4-1: Zoning District Characteristics.) Bordering the M3-1 zone to the north is an M1-1 zone that extends from the bay to beyond the eastern edge of the secondary study area. North of this M1-1 zoning district are portions of larger R4, R5B and R4-1 zoning districts.

7.2.1.3.2 Zoning Within the Secondary Study Area

The secondary study area is primarily zoned M3-1 east and southeast of the site. North and northeast of the site, the secondary study area is primarily zoned for residential uses, buffered by an M1-1 zone that cuts diagonally through the study area. The C3 zone at the northern edge of the study area encompasses the commercial waterfront between 23rd and 25th Avenues and 120th Street.

Site delineations and study area boundaries are approximate.
Base Map Source: New York City Department of City Planning

HDR HydroQual URBITRAN DD EEA Cambridge Environmental Inc

Figure 7.2-3 Zoning

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

7.2.1.4 Plans and Policies

The FY 2004 CDNS for CD 7 does not provide physical planning recommendations that may be relevant specifically to the site or the primary and secondary study areas.

NYCDCP's Comprehensive Waterfront Plan for Reach 10 (Flushing Bay to Nassau County) recommends that "street-end" access to the waterfront that is compatible with industrial uses be provided at several points along the College Point industrial waterfront. Other recommendations pertaining to the study area include a recommendation to rezone a 2.5-acre vacant M1 site between 25th and 23rd Avenues to C3 to permit such water-dependent uses as a marina and restaurant or residential development. (See Section 7.5 for details on NYCDPR park plans and Section 7.12 for a review of consistency with the Waterfront Revitalization Program.)

7.2.2 Future No-Build Conditions

It is reasonable to anticipate that the Future No-Build Conditions in the primary and secondary study areas generally will resemble the Existing Conditions. The site will remain DSNY property, the existing MTS will remain standing and the associated DSNY salt storage and garage facilities will continue to be fully operational.

7.2.3 Potential Impacts with the North Shore Converted MTS

7.2.3.1 Land Use and Zoning

The North Shore Converted MTS would include containerization functions and would replace the existing, non-operating MTS. The North Shore Converted MTS would not be a substantial new use, however, since it would be a reactivation of former waste handling activities at the site. It would be unlikely to encourage or discourage similar development or other typical development in the area and would be unlikely to affect the residential area to the north. Because the general area is zoned for industrial uses, the North Shore Converted MTS would not likely affect surrounding zoning patterns.

7.2.3.2 Consistency with Public Plans and Policies

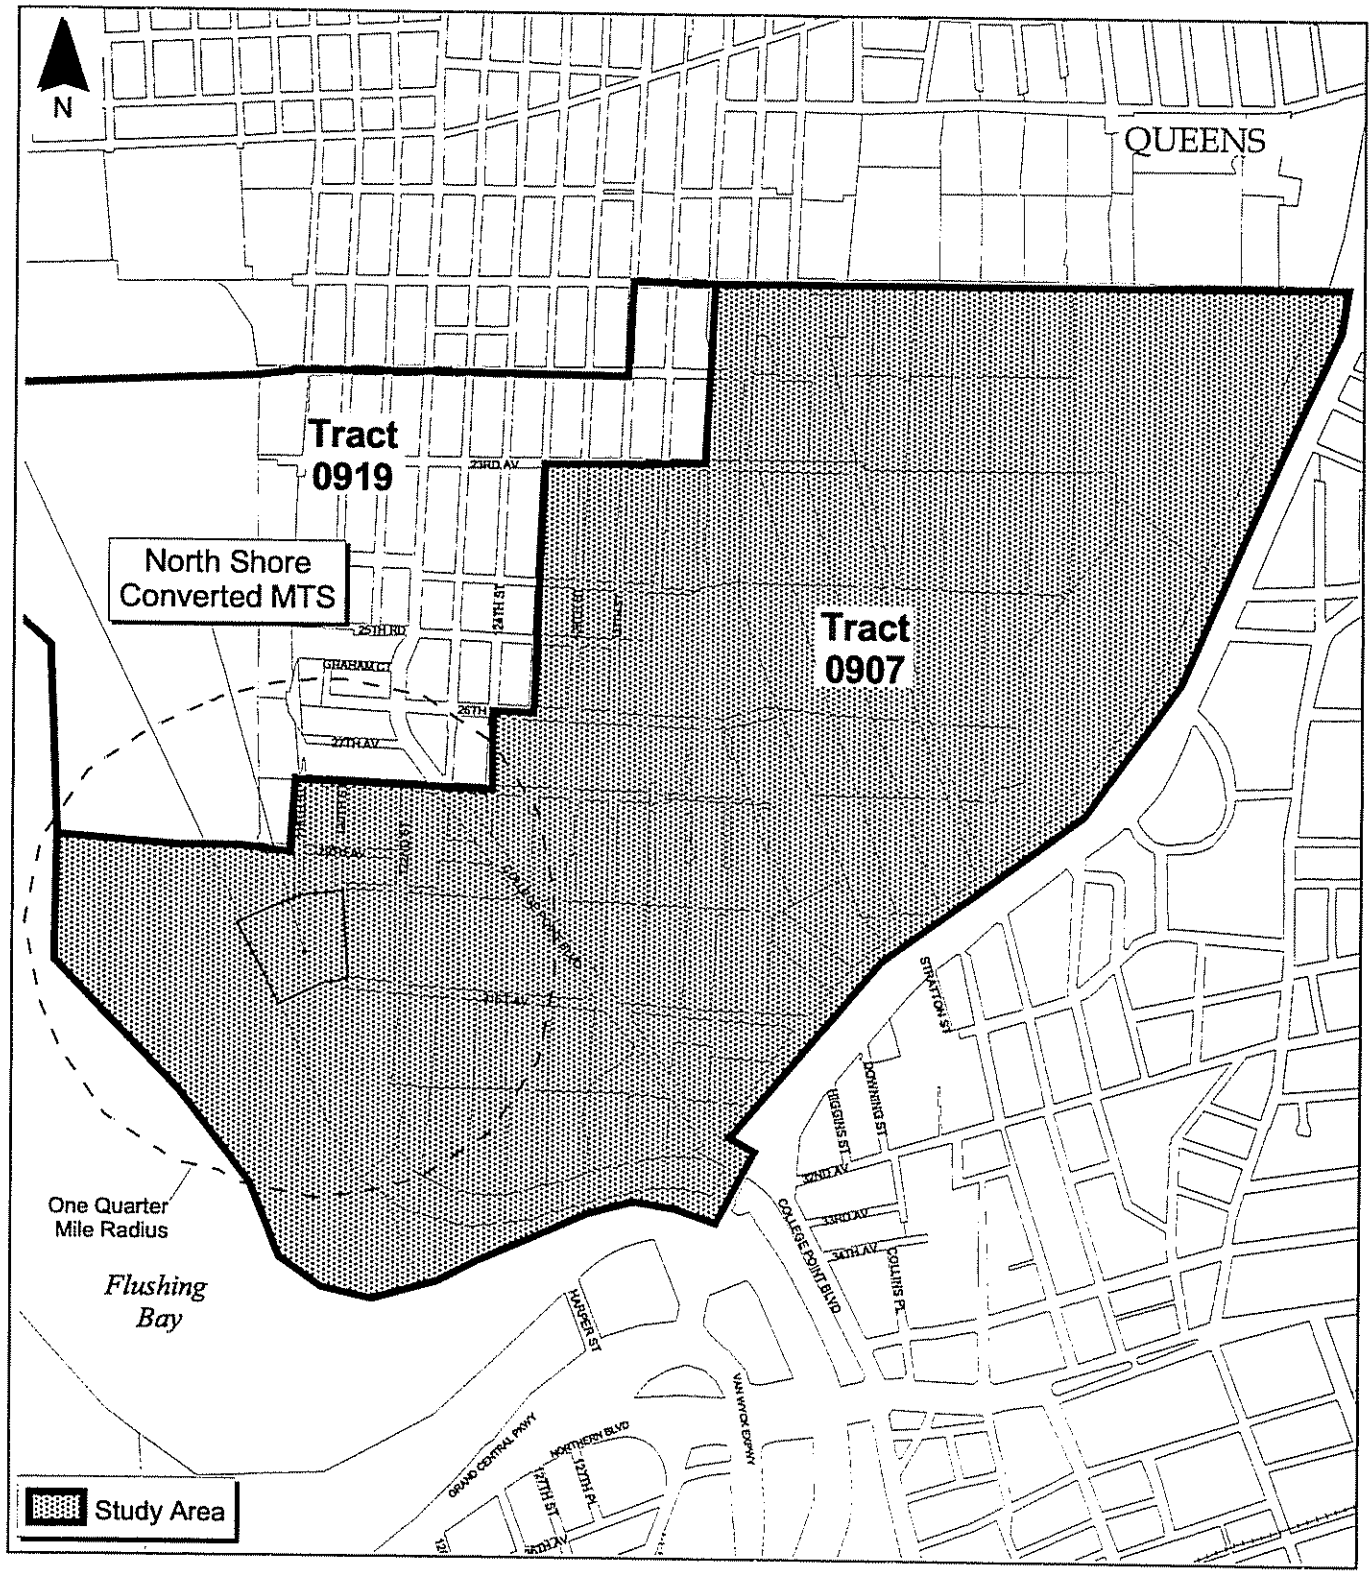
There are no recommendations or objectives stated in relevant plans and policies that specifically relate to the site, study area or the North Shore Converted MTS, so the new facility would be consistent with public plans and policies.

7.3 Socioeconomic Conditions

7.3.1 Existing Conditions

7.3.1.1 Definition of the Study Areas

Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area is comprised of Census Tract 907 (see Figure 7.3-1). Queens Census Tract 907 extends east from Flushing Bay in Queens to the Whitestone Expressway, as far south as approximately 32nd Avenue and as far north as approximately 20th Avenue. For comparison purposes, both 1990 and 2000 Census data were also gathered at the borough and City levels. The study area used for the assessment of potential impacts on economic conditions extends as far north as approximately 23rd Avenue and as far east as approximately the intersection of the Whitestone Expressway and College Point Avenue.



Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

7.3.1.2 Demographic Characteristics

7.3.1.2.1 Population

The total 2000 study area population was 1,243 persons (see Table 7.3-1). In terms of total population growth from 1990 to 2000, the study area experienced a smaller percentage increase (7%) than did the borough during the same period (14%), but its population grew almost as rapidly as the City's as a whole (9%).

The age-sex distribution was approximately the same as the population distribution of the borough and the City. The study area contained approximately the same percentage of children and teenagers as the borough or City; approximately 26% of the study area population was under the age of 20, compared to 25% for Queens and 27% for the City.

Site delineations and study area boundaries are approximate

Figure 7.3-1 Census Tracts

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

7.3.1.2.5 Housing

The housing stock of the study area is considerably newer than the borough and City. About half of the housing units (49%) in the study area were constructed between 1960 and 1980 and the remainder were largely built before 1960, while the majority of housing units in both Queens (71%) and the City (67%) were built before 1960. As of 2000, there were 448 housing units in the study area with a vacancy rate of about 1%, lower than the borough (4%) and the City (6%). In contrast to these two larger areas, the study area was occupied by a considerably higher percentage of owners than renters. Only 38% of the housing units were renter-occupied, in contrast to the borough (55%) and the City (66%).

The 2000 median value of housing units in the study area ($235,800) was greater than in Queens ($212,600) or the City ($211,900). The study area's median monthly rent ($784) was slightly higher than in the borough ($775) or the City ($705). The turnover in the study area (32%) from 1995 until 2000 was lower than that of the borough (42%) or the City (43%).

From 1990 to 2000, a total of 31 housing units were added in the study area, representing a 7% increase, slightly less than the borough (9%) and equivalent to the City (also 7%).

7.3.1.2.6 Education

Among people aged three and older, there was a slightly lower rate of school enrollment (21%) than in either the borough (27%) or the City (29%). Of those enrolled in school within the study area in 2000, 71% were enrolled in elementary school or high school and 25% were enrolled in college or beyond. In Queens, 61% were enrolled in elementary school or high school and 28% in college or beyond, while 62% of the City's enrolled population was in elementary or high school and 27% in college or beyond.

The number of persons enrolled in school from 1990 to 2000 within the study area remained relatively the same, in contrast to the 25% increase in Queens and the 18% increase in the City.

The study area had a lower educational attainment level than either the borough or the City. While half of the study area population aged 25 and over had some college degree compared to Queens (47%) and the City (48%), a smaller percentage of study area residents graduated college

(13%) compared to the borough (24%) and the City (27%). Similarly, the study area had a slightly higher percentage of people with only high school diplomas (29%) compared to the borough (28%) and the City (24%).

Despite the lower educational levels, from 1990 to 2000 the study area witnessed rising levels of educational attainment. The number of college graduates increased 48%; the same trend was evident in the borough and the City, which experienced increases of 32% and 29%, respectively.

7.3.1.2.7 Income and Poverty

In 2000, the median household income and median family income ($45,956) for the study area were the same. They were only a little different than the reported numbers in Queens ($42,439 and $48,608, respectively), while greater than those of the City ($38,293 and $41,887, respectively). Forty-four percent of households in the study area had incomes of $50,000 and above, compared with 43% in the borough and 40% in the City.

Within the study area, the percentage of families living below the poverty level (12%) was the same as that of Queens but less than that of the City (19%). The percentage of families living below the poverty level with children under the age of 18 (17%) was the same for Queens and considerably less than the City (26%).

A smaller percentage of persons in the study area under the age of 18 were living below the poverty level in 2000 (18%) than in Queens (19%) or the City (30%). The 2000 Census also reported that about 9% of persons 65 years or older were living below the poverty level in the study area, less than Queens (13%) and half the proportion of the City (18%).

From 1990 to 2000, the total number of people living below the poverty level in the study area increased dramatically, from 5 to 155, while the borough of Queens experienced an increase of 53%, more than twice that of the City (21%).

7.3.1.3 Economic Conditions

The study area contains a mix of offices, automotive repair shops, light industrial uses and some warehouse storage facilities. Industrial uses include a Consolidated Edison facility, the Ferrara Brothers Building Materials Company, Sunrise Oil and other manufacturing uses. Nearby commercial enterprises are primarily associated with automobile parts and service.

A portion of the 578-acre College Point Industrial Park is located within ½-mile of the site. It currently houses active warehouses, light industry, bus facilities, storage/parking areas and Consolidated Edison facilities between College Point Boulevard and Linden Place.

7.3.2 Future No-Build Conditions

7.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Queens CD 7 will remain about the same as current conditions.[2]

7.3.2.2 Economic Conditions

No significant changes to socioeconomic conditions within the study area are expected. Stable industrial and commercial uses are expected to continue to shape the character of the area around the site. The NYCEDC will continue to market sites within the College Point Industrial Park, although no significant new construction is expected to occur within the study area.

The near-term economic health of industrial areas such as the study area may be supported by recently established City programs available through the IDA. These programs, such as the Industrial Incentive Program and the Small Industry Incentive Program, provide businesses with tax incentives for capital renovation and expansion projects. However, no significant changes are anticipated through 2006.

---

[2] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

Regional projections indicate that employment in Queens CD 7 will remain about 11% of the borough total.[3]

7.3.3 Potential Impacts with the North Shore Converted MTS

The North Shore Converted MTS represents the reactivation of solid waste transfer operations with added containerization operations. No significant direct or indirect impacts are anticipated related to socioeconomic conditions.

7.3.3.1 Residential Impacts

No residential uses would be displaced or indirectly affected as a result of the North Shore Converted MTS, and land use and neighborhood character analyses predict no adverse impacts.

7.3.3.2 Direct Business and Institutional Impacts

The North Shore Converted MTS would not result in direct displacement of any businesses or institutional uses.

7.3.3.3 Indirect Business and Institutional Impacts

The businesses adjacent to and near the site are industrial, automotive, office or storage-related uses that would not be significantly affected by the North Shore Converted MTS.

7.3.3.4 Employment Impacts

The North Shore Converted MTS is expected to generate a total of approximately 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

---

[3] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

7.4 Community Facilities and Services

7.4.1 Existing Conditions

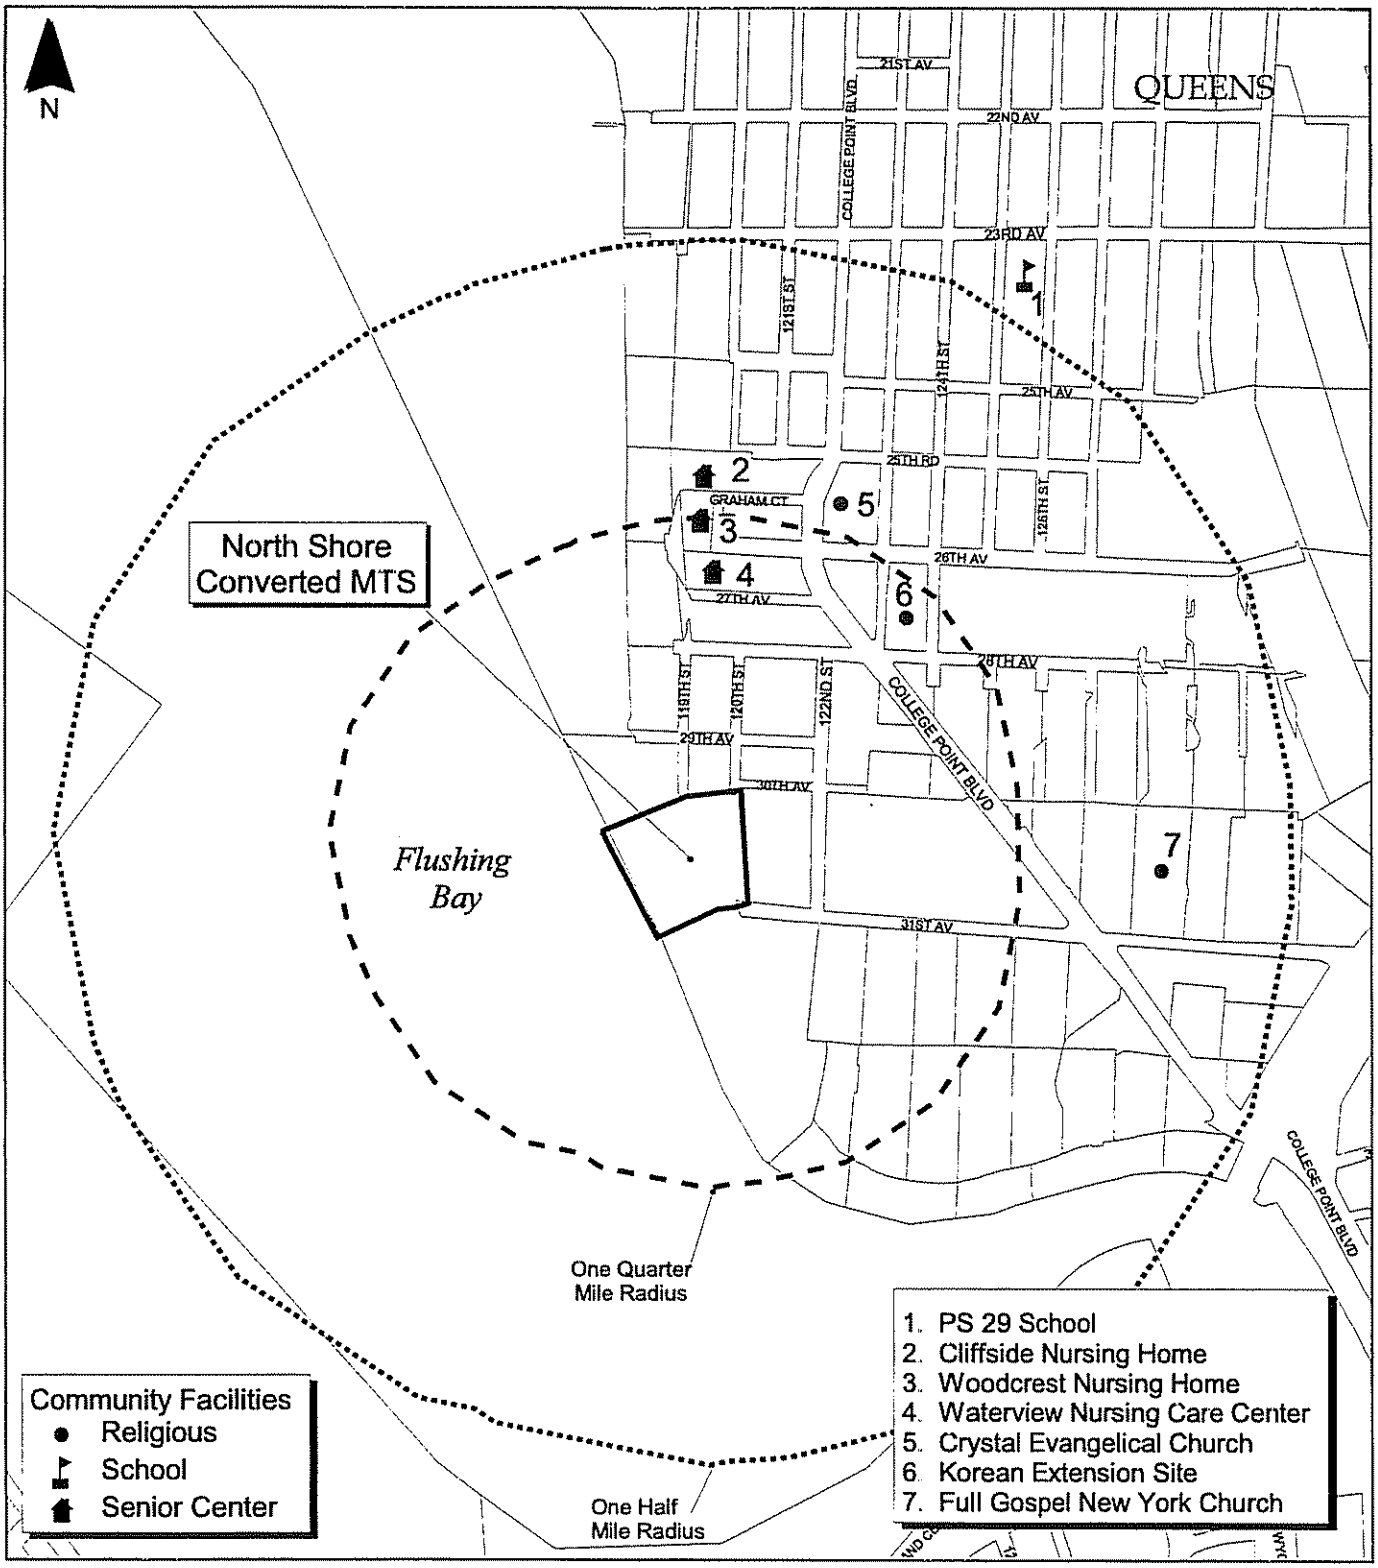
7.4.1.1 Definition of the Study Areas

The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼- and ½-mile from the site.

7.4.1.2 Summary of Community Facilities and Services

Consistent with the industrial nature of the primary and secondary study areas, very few community facilities are present. Community facilities within and serving the area are listed in Table 7.4-1 and locations are shown on Figure 7.4-1.

7.4.2 Future No-Build Conditions



There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

7.4.3 Potential Impacts with the North Shore Converted MTS

The North Shore Converted MTS would not create any significant new demand on services and community facilities. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the North Shore Converted MTS (Appendix A).

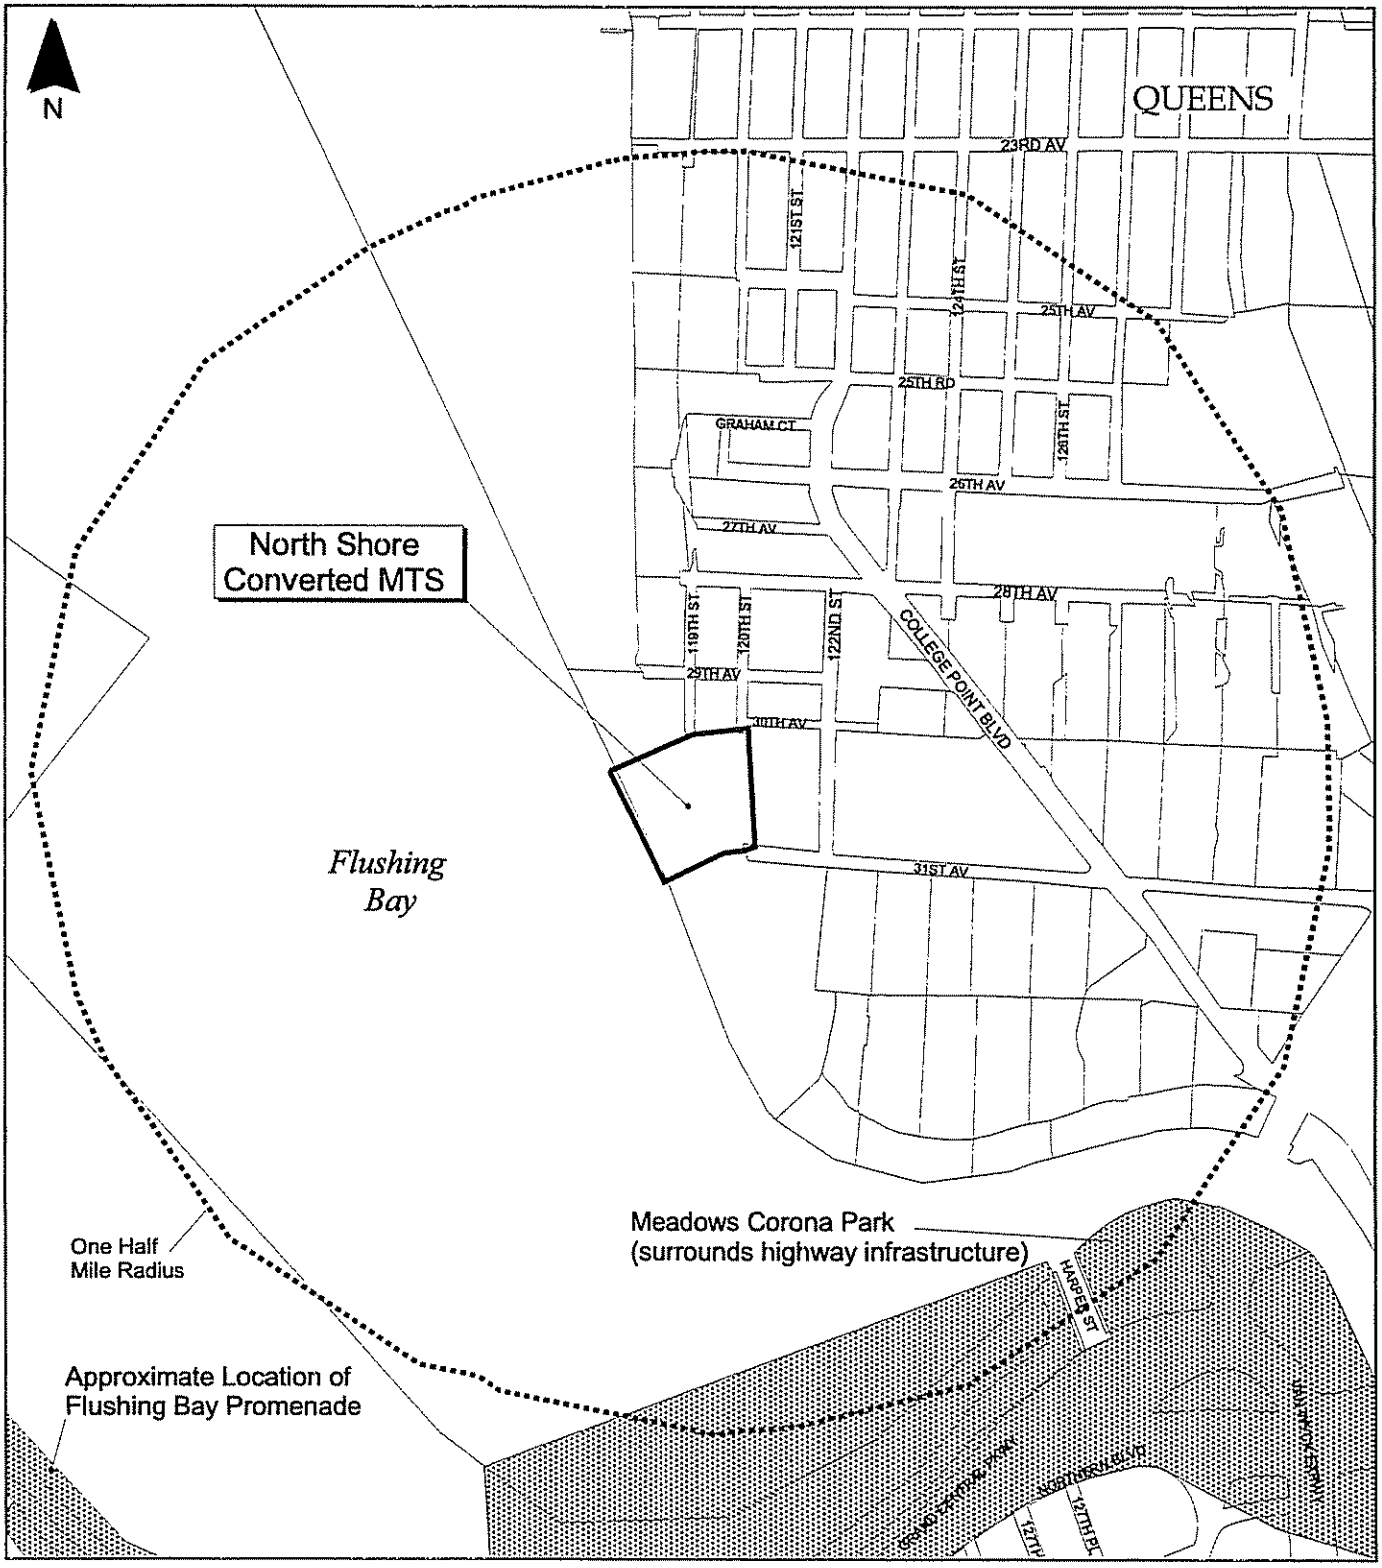
7.5 Open Space

7.5.1 Existing Conditions

7.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

7.5.1.2 Summary of Open Space in the Study Area



A small portion of Flushing Meadows Corona Park, a large regional open space resource, is located within the study area (Table 7.5-1 and Figure 7.5-1.)

Table 7.5-1
Public Parks and Open Spaces

Name	Address	Acreage
Flushing Meadows Corona Park	Flushing Meadows Corona Park, north of Grand Central Parkway	1,258

7.5.2 Future No-Build Conditions

The various park improvements planned for Flushing Meadows Corona Park will be located outside the study area. The improvements planned or under construction include a pool and ice skating facilities, statue, playground and three soccer fields. The only portion of the park that would likely afford views of the site is the Flushing Bay Promenade, which is along the Southern shore of Flushing Bay.

Site delineations and study area boundaries are approximate.

Figure 7.5-1 Open Space/Parkland

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

7.5.3 Potential Impacts with the North Shore Converted MTS

The North Shore Converted MTS would have no effect on any open space resources within the study area. It would neither physically change or eliminate any open space or reduce its utilization or aesthetic value, nor introduce a substantial new user population that would create or exacerbate over-utilization of open space resources. In particular, the North Shore Converted MTS would not affect views from the Flushing Bay Promenade because its appearance and placement would be similar to those of the existing MTS.

7.6 Cultural Resources

7.6.1 Existing Conditions

7.6.1.1 Definition of the Study Area

The cultural resources study area is defined as the area within ½-mile of the site.

7.6.1.2 Development History of the Area

Flushing Bay and its creek form the western boundary of College Point, which had practically been an island until much of the marshland was filled in the 19th century. The College Point neighborhood was established in 1854 by Conrad Poppenhausen, owner of a hard-rubber factory, to accommodate his workers. Streets, houses, businesses and schools were developed under Poppenhausen's guidance. The area grew rapidly in the 1880s and 1890s, attracting a largely German population. Breweries, silk mills and paint works were established. Beer halls and amusement parks, especially Point View Island, made the area popular for outings, steamboat excursions and political clubs. The resorts declined during the Prohibition era and were replaced eventually by aircraft and aviation parts factories built by Sikorsky Aircraft, the LWF Company and the EDO Corporation to support the nearby LaGuardia Airport. LaGuardia Airport, located on the south side of Flushing Bay, opened in 1939 as the first viable commercial airport serving the City.

7.6.1.3 Cultural Resources on the Site

There are no elements of architectural or archaeological significance on the site.

7.6.1.4 Historic Resources Within the Study Area

There are no state, national or local historic districts or individually designated properties within the study area.

7.6.2 Future No-Build Conditions

There are no elements of potential historic significance slated for review. Because of the nature of architectural and archaeological resources, and the fact that there is no reason to anticipate the designation of such resources in this area in the near future, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

7.6.3 Potential Impacts with the North Shore Converted MTS

The North Shore Converted MTS would have no effect on any known cultural resources. Based upon its review, SHPO has stated that the North Shore Converted MTS would have no impact upon cultural resources in, or be eligible for inclusion in, the State and National Registers of Historic Places. The LPC has stated that the site contains no architectural or archaeological significance (see Appendix A).

7.7 Urban Design, Visual Resources, and Shadows

7.7.1 Existing Conditions

7.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (see Figure 7.8-1). The site has been developed in a manner consistent with adjacent properties and the overall study area. It is a non-sensitive industrial area in terms of urban design and visual quality assessment. There are no sensitive view corridors, publicly accessible open areas or points of waterfront access that might be affected by development of the North Shore Converted MTS.

7.7.1.2 Description of the Site

Much of the space on the site and in the surrounding area is devoted to parking for employees and for storage of trucks and other vehicles associated with the existing uses (see Figure 7.7-1). A curved ramp extending from 31st Street leads to the existing MTS (see Figure 7.7-2). The design of the existing MTS is typical of similar facilities with a height of approximately 50 feet and a shell constructed of prefabricated steel. There are lights mounted on the exterior walls of the facility and light poles throughout the site.

In addition to the existing MTS building, there is the foundation of a former salt shed, within which salt is still stored in the northern portion of the site and that still contains salt piles. The base walls are constructed of unpainted, prefabricated concrete panels.

The shoreline near the existing MTS is overgrown with scrub and grasses and a few trees next to the access ramp. Otherwise, the site is entirely paved and has no vegetative landscaping.

7.7.1.3 Urban Design and Visual Resources of the Study Area

The area surrounding the site is characterized by mid- to late-20th-century brick and prefabricated concrete or steel industrial buildings, which generally do not exceed two stories in height and are generally not built to the lot lines. The block forms, large lots and street patterns

Figure 7.7-1 : View of MTS from 31st Avenue.

Figure 7.7-2 : View from the site at 31st Avenue, with salt piles and parking area visible over the ramp.

Figure 7.7-1 and 7.7-2
Urban Design and Visual Quality
North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

are suited to truck circulation with certain streets fully dedicated to truck use. Alteration of fairly large lots to suit industry needs has kept the development pattern of the area suitable for manufacturing.

Although there are some properties within the area that are undeveloped, all property appears to be utilized. Un-built areas, for example, tend to serve as parking areas for trucks and equipment associated with the industrial uses. There is no recreational open space. There are no undisturbed natural features in the area and the lack of landscaping reflects the purely functionalist fashion in which the area has developed.

DSNY's Queen CD 7 garage, which contains administrative offices, is adjacent to the eastern side of the site. The southern portion of the building, the administrative section, is two stories tall and the remainder of the building, extending north and facing the shore, is one story tall and has eight garage bays. A one-story portion of the building with five garage bays extends east from the administrative section and faces south. The building is unpainted and is faced in textured, prefabricated concrete and blocks views of the existing MTS from 31st Avenue, approaching the site from the east. A view corridor exists from the Consolidated Edison building on 31st Avenue and 125th Street to the site, but since it is in a purely industrial area, it is not considered sensitive (see Figure 7.7-3).

Flushing Bay developed as a working waterfront, but non-water-dependent industries are inland around the site. The Consolidated Edison building at 125th Street and 31st Avenue (east of the site) is 10 stories tall and has exterior walls that are mostly glass. Various one-story, mid-20th century manufacturing and garage-type buildings are visible to the north of the site. Beyond these buildings are semi-detached, two-story white clapboard houses with chimneys in a repeating facade pattern.

Ferrara Brothers Building Materials Company has offices and materials storage and loading facilities on the property adjacent to the southern edge of the site (see Figure 7.7-4). The office building on 31st Avenue is a two-story building faced in brick and dark steel siding. The areas used for storing and loading building materials, such as sand and mixes, are behind (south of) the offices. The loading facilities are painted orange, like the trucks used in the operation, and are clearly industrial in nature.

This page intentionally left blank.

Figure 7.7-3 : View north from the site at 31st Avenue.

Figure 7.7-4 : Ferrara Brothers Building Materials Corporation viewed from 31st Avenue, facing south.

This page intentionally left blank.

7.7.2 Future No-Build Conditions

There are no plans for the site or surrounding environs; therefore, the anticipated Future No-Build Conditions are fundamentally the same as Existing Conditions. The site will remain DSNY property, the existing MTS will remain standing and the DSNY salt pile storage and garage facility will continue to be utilized.

7.7.3 Potential Impacts with the North Shore Converted MTS

The North Shore Converted MTS would not significantly affect the urban design or visual quality of the site or study area. Because it would be constructed on a site that is already arranged to handle waste transfer operations, no impacts on urban design of the area would result. Likewise, the North Shore Converted MTS would be similar in appearance to the existing MTS. With it and the associated barges being set amid DSNY and other industrial uses, the North Shore Converted MTS would result in no impact to visual quality.

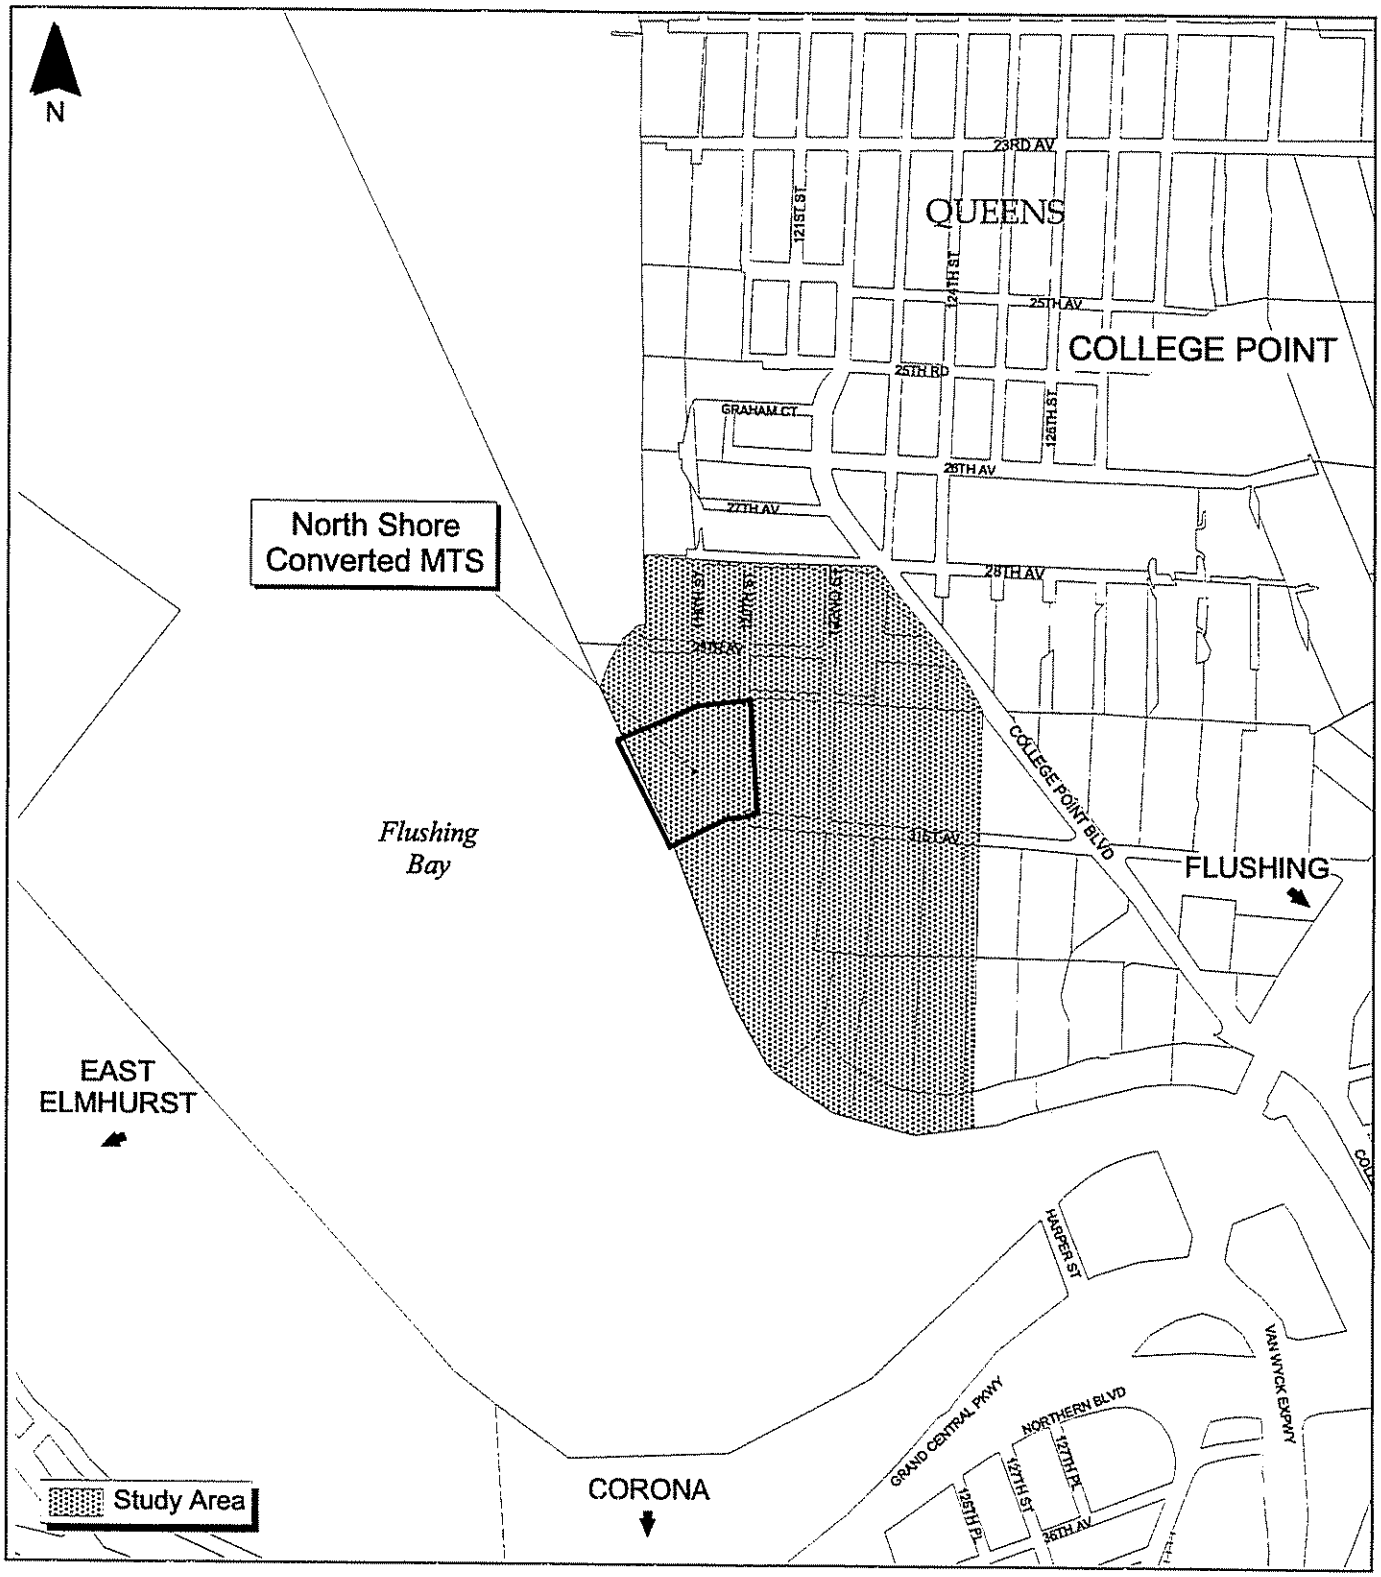
According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.)

A survey was conducted within this 430-foot area and found that there were no parks, publicly accessible open spaces, historic resources or important natural features; therefore, no assessment of shadows was deemed necessary and no shadow impact is expected as a result of the proposed project.

7.8 Neighborhood Character

7.8.1 Existing Conditions

7.8.1.1 Definition of the Study Area



The site is located on the industrial portion of the Flushing Bay waterfront in the College Point neighborhood. The neighborhood character study area is defined by physical landscape elements that distinctly mark the edge of a specific neighborhood, visually insulate the site and study area or physically obstruct pedestrian and vehicular access to it from outlying areas. In this case, the study area is defined by predominantly industrial activities and related visual quality.

The triangular study area is bounded by 28th Avenue to the north, College Point Boulevard to the northeast, and, to the east, the continuation of 124th Street extending south to the shoreline (see Figure 7.8-1).

7.8.1.2 Description of Neighborhood Character

Industrial uses, such as the existing MTS and concrete production facilities, characterize most of the land use pattern in the neighborhood study area, with warehouses and vacant lots and vacant buildings in the northern portion. There is, however, a distinctly residential area north of 29th Avenue between 120th Street and the shore, which is a continuation of the residential development pattern that characterizes the area north of the study area. These residential uses are buffered from the site itself by small-lot manufacturing uses and automotive repair shops on the blocks north of and adjacent to the site, similar to the uses that line 120th Street. Located amid the industrial uses south of the Ferrara Brothers Building Materials Company is the former Metropolis nightclub, which is near the waterfront.

The site and the other industrial uses in the study area are destination points and there is limited through-access for automobiles. In fact, several mapped roads exclusively serve private industrial uses. There is through-access for automobiles and pedestrians between the residential northern portion of the study area and the site, but it appears that when it was in operation, the site had been accessed exclusively by DSNY employees in automobiles and collection trucks.

Site delineations are approximate

HDR URBITRAN EEA Cambridge Environmental Inc HYDROQUAL DD

Figure 7.8-1 Neighborhood Location

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The residential character of the northern portion of the study area is most similar to the neighborhood north of the study area, both in type of land use and in visual quality. These two residential blocks are divided into small lots with trees and residential landscapes. They are generally well maintained and are not congruent with the overall industrial character of the rest of the study area.

The visual quality in the remainder of the study area is generally not aesthetically pleasing, but it is consistent with the industrial nature of the area. There are no community facilities or public open spaces within the neighborhood character study area. Additionally, while the houses and industrial uses along the shore have waterfront access, there is no public waterfront access in the study area and there are no views that would be considered visually sensitive. While the residences north of the site and the entrance to the offices of the Ferrara Brothers property south of the site are landscaped, there are no particularly sensitive elements of overall landscape design within the study area.

7.8.2 Future No-Build Conditions

There are no known plans for development of the site or the study area that would potentially lead to changes in neighborhood character. The Future No-Build Conditions are, therefore, expected to be the same as Existing Conditions.

7.8.3 Potential Impacts with the North Shore Converted MTS

No change to the industrial neighborhood character would be expected with the reactivation of the site to handle waste transfer activities. The fairly isolated neighborhood, characterized by industrial uses, including the DSNY garage (and related activities) that would continue under Future No-Build Conditions, would not be noticeably affected by the construction and operation of the North Shore Converted MTS.

7.9 Natural Resources

7.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities typical of this area of Queens. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from implementation of the North Shore Converted MTS.

7.9.1.1 Definition of Study Area

The study area includes the site and the waterfront section that is bounded by Flushing Bay to the west (see Figure 2.2.4-1). The upland sections of the study area are occupied with a salt storage shed and a parking area. This part of the study area and surrounding neighborhood ~~are~~ is completely developed, and, therefore, ~~have~~ has very limited terrestrial natural resources. Such resources that do exist will be discussed in following sections. Because Future Build Conditions would include dredging of bottom sediments and construction of a new MTS, a description of aquatic communities is included.

7.9.1.2 Geology

Boring data from the City of New York Public Works drawing titled Record of Borings, made at the Proposed Site for the North Shore Marine Loading Station, dated November 18, 1952, indicates that the following geologic strata were encountered within or immediately adjacent to the footprint of the proposed structure.

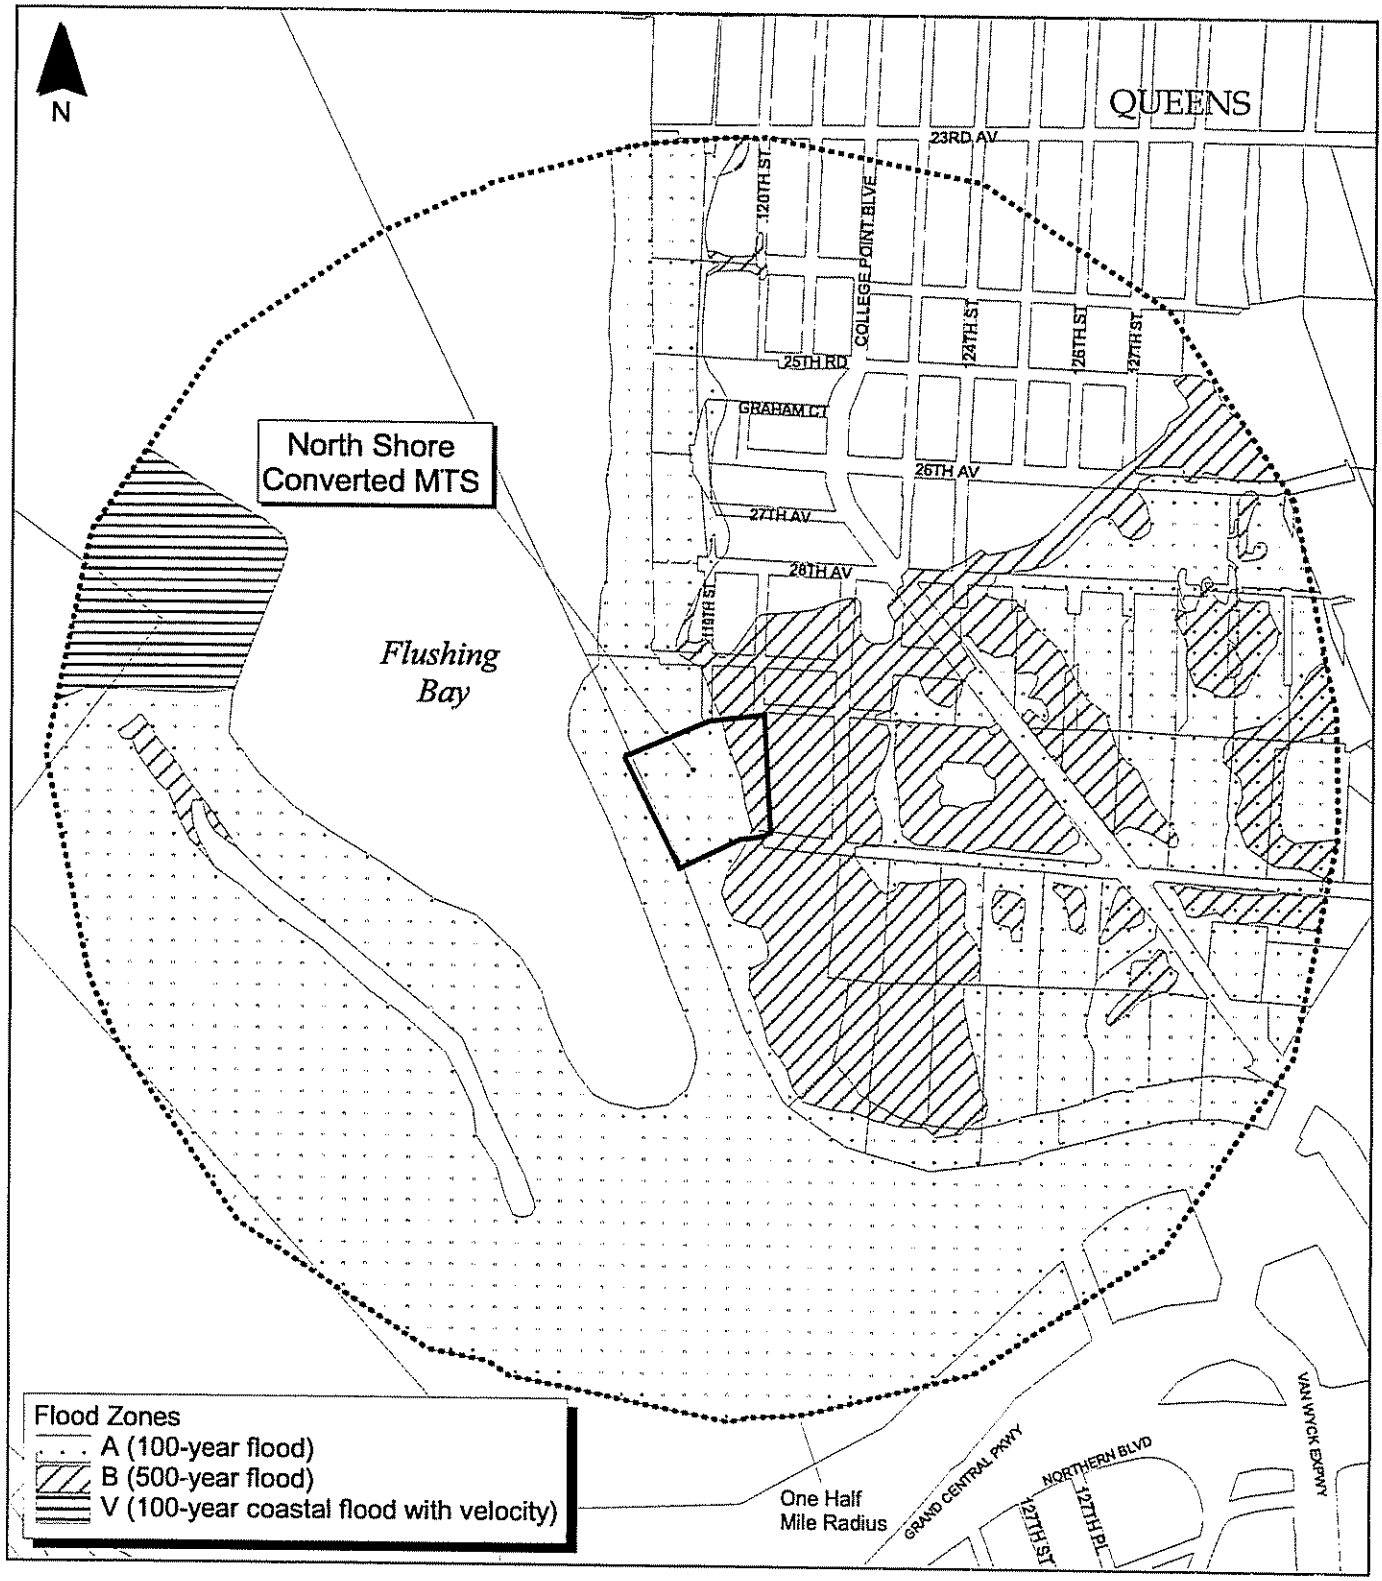
In the land-based borings, an uncontrolled fill stratum was encountered near the surface and ranged in thickness from 2 to 5 feet below ground surface. The uncontrolled fill consisted of silt with miscellaneous aggregate including deleterious materials. Very soft, dark gray to black organic soil was encountered in the borings within Flushing Bay. This organic soil stratum contained shells and thin sand and clay lenses and ranged in thickness from 2 feet at the shoreline to 32 feet under the footprint of proposed structure. All borings terminated in a dense to very

dense, silty sand to silty sand with gravel stratum. This layer was found immediately beneath the fill on land and beneath the organic soil in the water borings. Although the borings did not fully penetrate the silty sand stratum, the stratum was penetrated 18 to 47 feet.

Surface sediment collected from the site in 2003 was composed of 97.5% silt and clay, 2.2% sand and 0.4% gravel, with approximately 63,417 mg/kg TOC.[4] Sediment was found to be somewhat degraded due to contaminants in the sample material. The three metals found in the highest concentrations were lead (166.67 mg/kg), chromium (110.17 mg/kg) and barium (98.83 mg/Kg).

Historically, the banks of Flushing Bay were comprised of extensive intertidal marshes covering more than 100 acres. The sediments under and around the site are silty muds, while extensive filling and hardening of the upland areas has taken place and the geology has little, if any, resemblance to its former state.

7.9.1.3 Floodplains



The existing MTS and salt shed are within the 100-year coastal floodplain (see Figure 7.9-1). Flushing Bay is the only surface water body on or adjacent to the study area. Other than Flushing Bay, a NYSDEC-designated littoral zone, no other wetlands are in the study area (see Figure 7.9-2).

7.9.1.4 Ecosystems

Flushing Bay is a shallow, highly impacted water body that has been greatly altered by human activities over the past century. Almost the entire shoreline is hardened and the hydrodynamics of Flushing Bay have been changed by the creation of LaGuardia Airport, which led to extensive filling and placement of jetties and groins.

Figure 7.9-2 Wetlands

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Much of the upland area on and around the site consists of fill material placed over an intertidal marsh. The original marsh was extensive, covering more than 100 acres that reached as far north as 20th Avenue. The existing MTS was built on pilings over the water with a short causeway that connects it with the shore.

At present, there is little vegetation of significance on the site because most of the surface is covered by buildings, roadways or other hard surfaces. ~~Vegetative cover on the site, which was confined to the shoreline near the existing MTS, was too sparse to be mapped. There were two small patches of *Spartina* sp. and a small fringe of this species along the shoreline, but the cover was very sparse. Various opportunistic plant species are present on the site.~~ Vegetative cover on the site was limited to the shoreline near the existing MTS. Several isolated patches of intertidal maresh vegetation consisting of smooth cordgrass (*Spartina alterniflora*) were present off the southeastern corner of the MTS, as well as to the north of the MTS ramp. One patch of high marsh, consisting of common reed (*Phragmites australis*) was also noted immediately south of the ramp. The tidal wetlands fringing Flushing Bay were delineated and surveyed on April 21, 2004, and the individual patches of wetland vegetation were identified and mapped in February 2005. The stem density within these isolated tidal wetland patches was noted as sparse. Various opportunistic plant species are present on the upland portion of the site, including mugwort (*Artemesia vulgaris*), Queen Anne's lace (*Daucus carota*), poor-man's pepper (*Lepidium virginicum*) and seaside goldenrod (*Solidago semper virens*). Saplings of tree-of-heaven (*Ailanthus altissima*) were observed in the vicinity of the ramp to the existing MTS.

The sediment under and around the existing MTS are silty muds, typical of the soft depositional types found in quiescent areas in Flushing Bay. Flushing Creek contains a large CSO that contributes substantial organic loading to lower Flushing Bay waters. The bay itself is known for highly enriched sediments that contribute to odor problems during warm weather.

A field program that took place in 2003 was designed to fully characterize the marine biological resources of the study area. The program includes monthly sampling for finfish eggs and larvae and water quality, and quarterly sampling for adult finfish, benthic invertebrates and sessile colonizing organisms. Results of the program will be discussed in the following paragraphs.

A total of 126 adult finfish, representing eight species were collected in 2003.[5] The most abundant species were Atlantic silverside (*Menidia menidia*) and Atlantic herring (*Clupea harengus*). Two adult species with EFH listing were collected at the North Shore Converted MTS: Atlantic herring and winter flounder (*Pleuronectes americanus*). The most abundant finfish eggs collected at this facility were cunner (*Tautogolabrus adspersus*) and Atlantic menhaden (*Brevoortia tyrannus*). The most abundant finfish larvae were herring spp. (*Clupea* spp.), Atlantic menhaden, anchovy spp. (*Anchoa* spp.), winter flounder and goby spp. (*Gobiosoma* spp.). A Shannon-Weaver Index[6] indicated that finfish larvae was most diverse at the North Shore Converted MTS.

The most abundant megainvertebrate species collected at the North Shore Converted MTS were sevenspine bay shrimp (*Crangon septemspinosa*) and grass shrimp (*Palaeomonetes vulgaris*). The dominant benthic invertebrates collected were pollution tolerant worms: *Streblospio benedicti*, Oligochaeta and *Haploscoloplos* sp. *S. benedicti* was by far the most abundant, having approximately 15,500 individuals per square meter of sediment. The most abundant epibenthic colonizers collected from the North Shore Converted MTS were *Corophium insidiosum* (amphipod), *Microdeutopus* sp. (amphipod), *Balanus* sp. (barnacle), *Polydora* sp. (polychaete worm), and hydrozoa, mud and algal film.

NYSDEC Breeding Bird Atlas records list the horned lark (*Eremophila alpestris*) as a species with a probable breeding status near the study area. The state legal status of the horned lark is Protected-Special Concern, which includes those species that are not yet recognized as endangered or threatened but for which documented concern exists for their continued welfare in New York, and that are federally-protected wild birds. The peregrine falcon (*Falco peregrinus*), a federally-listed endangered species, was not listed as present for this site in the recent response from the USF&WS.

---

[5] Ibid.

[6] The Shannon-Weaver Index is a measure of community diversity. If an individual of the community is selected at random, the index gives a measure of the uncertainty that the selected individual will be of a particular species. The higher the index, the more diverse the community.

7.9.2 Future No-Build Conditions

If the North Shore Converted MTS were not to be built, the study area would remain as is. The limited aquatic and terrestrial natural resources would remain and the study area would continue to be an ecologically unproductive and stressed urban area.

7.9.3 Potential Impacts with the North Shore Converted MTS

7.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

7.9.3.2 Floodplains

Implementation of the North Shore Converted MTS would have no effect on the elevation of the site. It would be constructed within the 100-year floodplain, and would not include any provisions for raising any portions of the site over this level.

7.9.3.3 Ecosystems

The North Shore Converted MTS would be a pile-supported structure and would result in a net gain of ~~46,402~~ 46,159 square feet ~~of structure~~ over the water. During the demolition of the existing MTS, the upper organic silts lying beneath the structure that was above water would be disturbed to some degree, resulting in re-suspension of the sediment. However, the amount of re-suspended sediment is expected to be low, and the impacts, if any, highly localized. Turbidity and short-term, lowered dissolved oxygen are possible, but not measurable, against the normal background fluctuations. Construction would involve installing piles for the foundation supports and dredging to accommodate the deeper draft of the coastal barges. The benthic and finfish community would be temporarily disrupted during this phase of the project. It can be anticipated

that the benthic invertebrates would recolonize the area within 6 to 12 months and that finfish would return to the area immediately following completion of the construction.[7] Given the relatively small size of the project, minimal overall impact to the benthic community is expected at the North Shore Converted MTS. The removal of the existing platform will also remove the existing epibenthic community; however, the new expanded platform will result in more surface area for epibenthic communities to colonize the site. This would positively affect the epibenthic communities at the North Shore Converted MTS.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction; flatfish (flounders) are least sensitive. Herring catch was much higher at the North Shore Converted MTS than flounder catch, so it can be assumed that this site will experience herring avoidance during construction activities. Finfish eggs and larvae are more sensitive to suspended sediment and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. In addition, larvae will be able to swim away from the impacted environments.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The proposed plan for the North Shore Converted MTS is for an increase in ~~46,402~~ 46,159 square feet of pier. This will result in increased shading that will block sunlight and hinder primary production. The enlarged platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[8] Epibenthic communities will have a larger surface area to colonize, and finfish should return to the area with the return of food sources.

---

[7] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

[8] Hudson River Center Site Aquatic Environmental Study Final Report, 1988. Prepared for New York City Public Development Corp. by EEA, Inc.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by EEA in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[9] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as it provides shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. However, because the increase in shading over water is very small, there are not expected to be significant deleterious results. There is a possibility of a slight shift in the finfish community with the addition of over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

The North Shore Converted MTS would not have any significant impact on the few areas of vegetation present on the site. ~~Vegetation observed on the site were invasive weed species that are not rare, endangered or particularly important from an ecological perspective. The sparse *Spartina* sp. patches are not expected to be negatively impacted.~~Vegetation observed on the upland portions of the site consisted of various non-native and "invasive weed species."~~.~~ There would be a slight loss of wetland vegetation from the site. It was estimated that a total of approximately 0.051 acres or 2,237.8 square feet of tidal wetland vegetation situated off the southeast corner of the site would be lost or replaced by deep water pockets of unvegetated littoral zone as a result of the N~~n~~orth Shore Converted MTS and/or the proposed dredging. This includes approximately 224 square feet of high marsh covered by the invasive common reed, and approximately 2,015 square feet of sparsely vegetated intertidal marsh patches covered by smooth cordgrass. This loss would be mitigated by additional plantings of intertidal march and high marsh vegetation to the north of the MTS ramp or off-site. Preliminary site investigations indicate that limited suitable habitat exists to the north of the on-site stone pier; however,

[9] Duffy-Anderson, J.T. & Able, K.W., 2001. "An Assessment of the Feeding Success of Young-of-the-Year Winter Flounder (*Pseudopleuronectes americanus*) Near a Municipal Pier in the Hudson River Estuary, U.S.A."

wetland mitigation plans would be developed and finalized in accordance with guidance received from the NYSDEC. The relatively small (totaling 178 square feet), isolated intertidal marsh patches located to the north of the existing ramp will not be directly impacted by project construction, and are not likely to be indirectly impacted due to shading from the new facility because of their distance from the proposed limit of construction.

The horned lark, a species of special concern, is listed by the NYSDEC as having probable breeding status in the area surrounding the site. However, this bird is only found in open areas with bare ground or short grass.[10] This bird, therefore, would not be found breeding on or using the site and any plans for the site would not impact the bird.

Estuaries, Vol. 24, No. 3, p. 430-440.

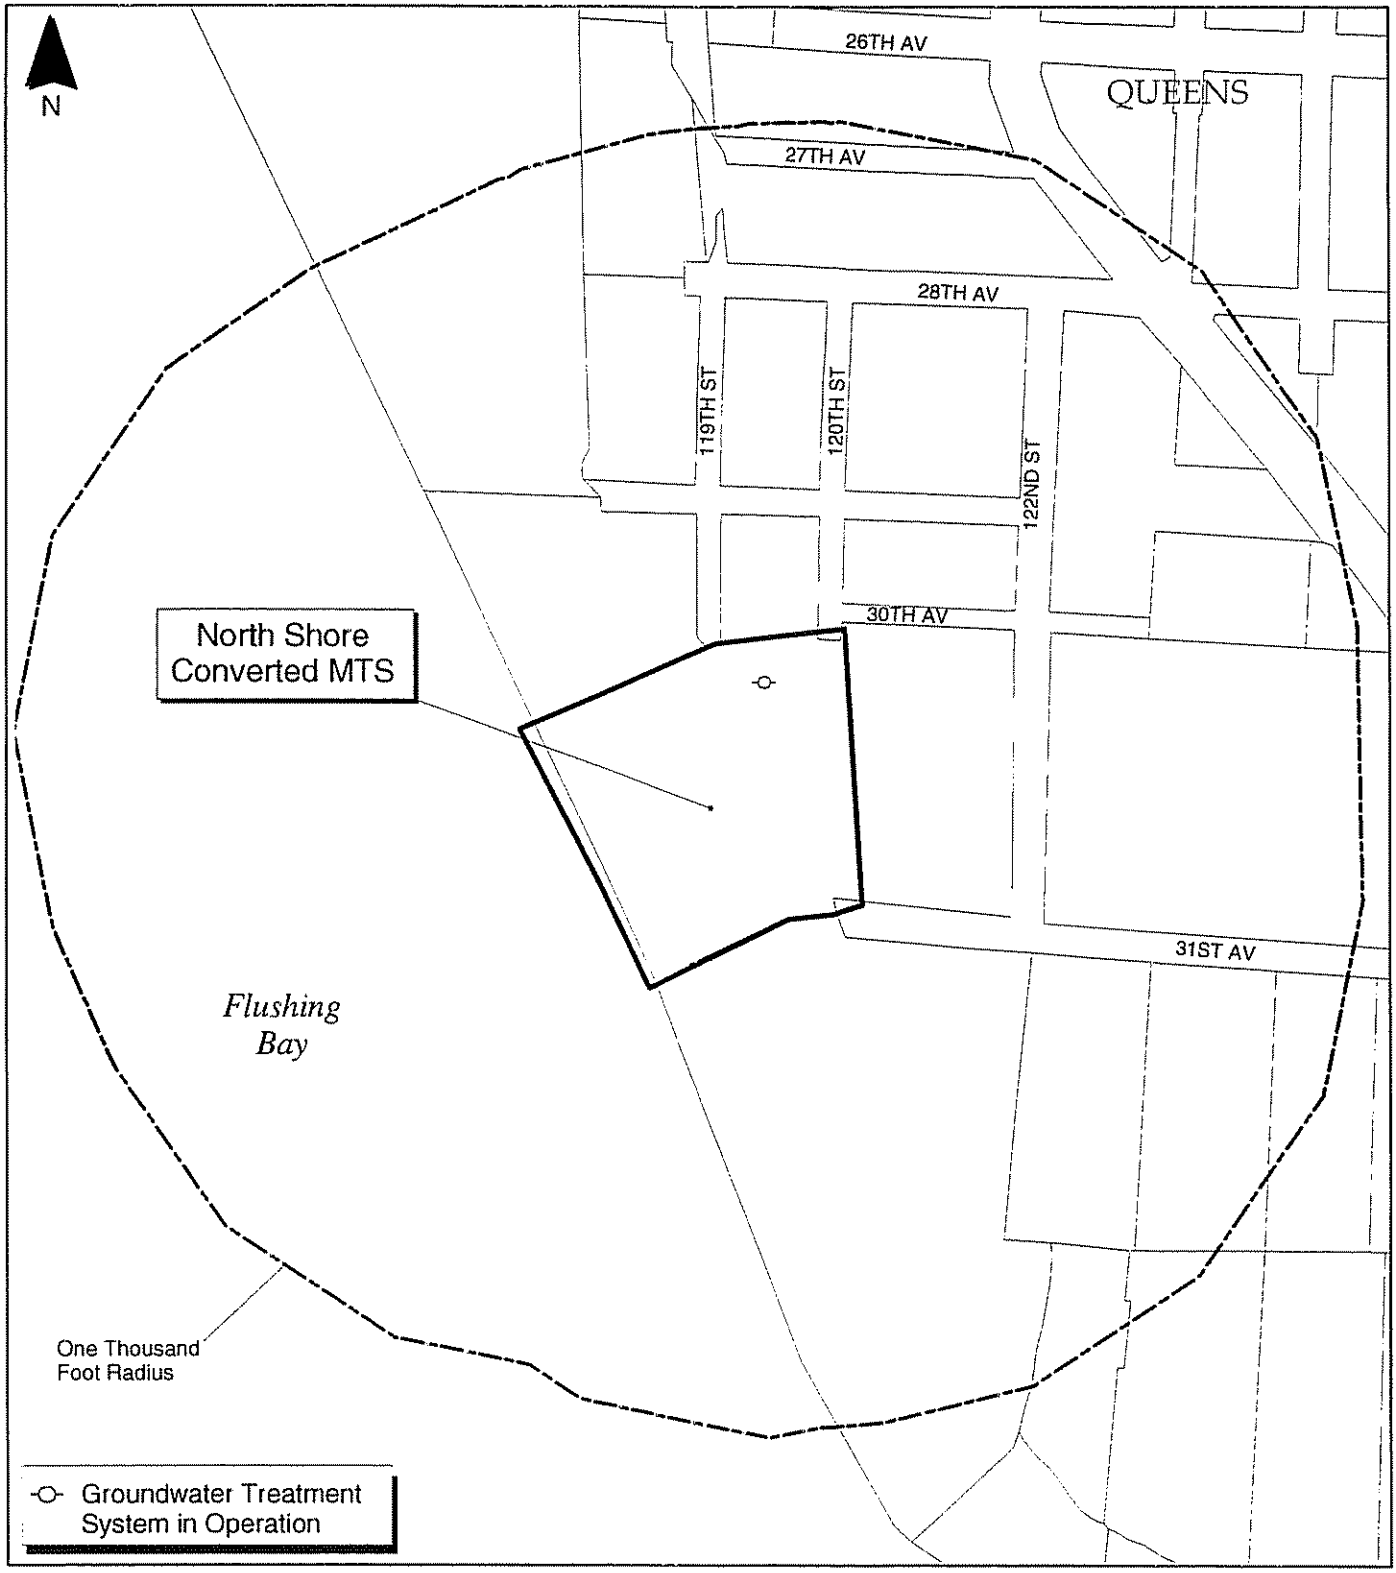
7.10 Hazardous Materials



7.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in April 1999 and updated in February 2003. It included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the FDNY for UST records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted, most recently in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors. Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

7.10.1.1 Definition of Study Area

The study area includes the site and neighboring properties within a 1,000-foot radius (see Figure 7.10-1).

Site delineations and study area boundaries are approximate

HDR URBITRAN EEA Cambridge Environmental Inc

Figure 7.10-1 Hazardous Material Sites

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

7.10.1.2 Delineation of Area of Concern

After review of the applicable databases and an on-site inspection, there is only one area of concern of note. During the reconnaissance of the study area, there was an apparent groundwater remedial system in the parking lot that serves the adjacent DSNY garage. The parking lot would be incorporated into the North Shore Converted MTS. The remedial system was operational in February 2003 and was likely associated with NYSDEC Spill No. 9508111, when, according to regulatory database information, the discovery in 1995 of free petroleum product beneath the DSNY garage led to the installation of a ground water recovery system. As of November 2001, the recovery system was not working effectively and NYSDEC asked for improvement or another approach.

7.10.2 Future No-Build Conditions

The existing MTS would remain standing as is, and operation of the ground water recovery system would continue. The system would require modification or improvement to meet the operational guidelines established by NYSDEC.

7.10.3 Potential Impacts with the North Shore Converted MTS

Implementation of the North Shore Converted MTS may interfere with the ground water recovery system. If so, the system would require modification to retain or improve its operational capability.

In the event that contaminated soils are encountered during construction, the soil would be excavated and disposed of in a manner that is consistent with the levels of contamination as specified in New York State regulations. The necessary and appropriate health and safety measures would be employed during construction to mitigate and minimize any exposure risk to workers or the general public related to the possible subsurface contamination.

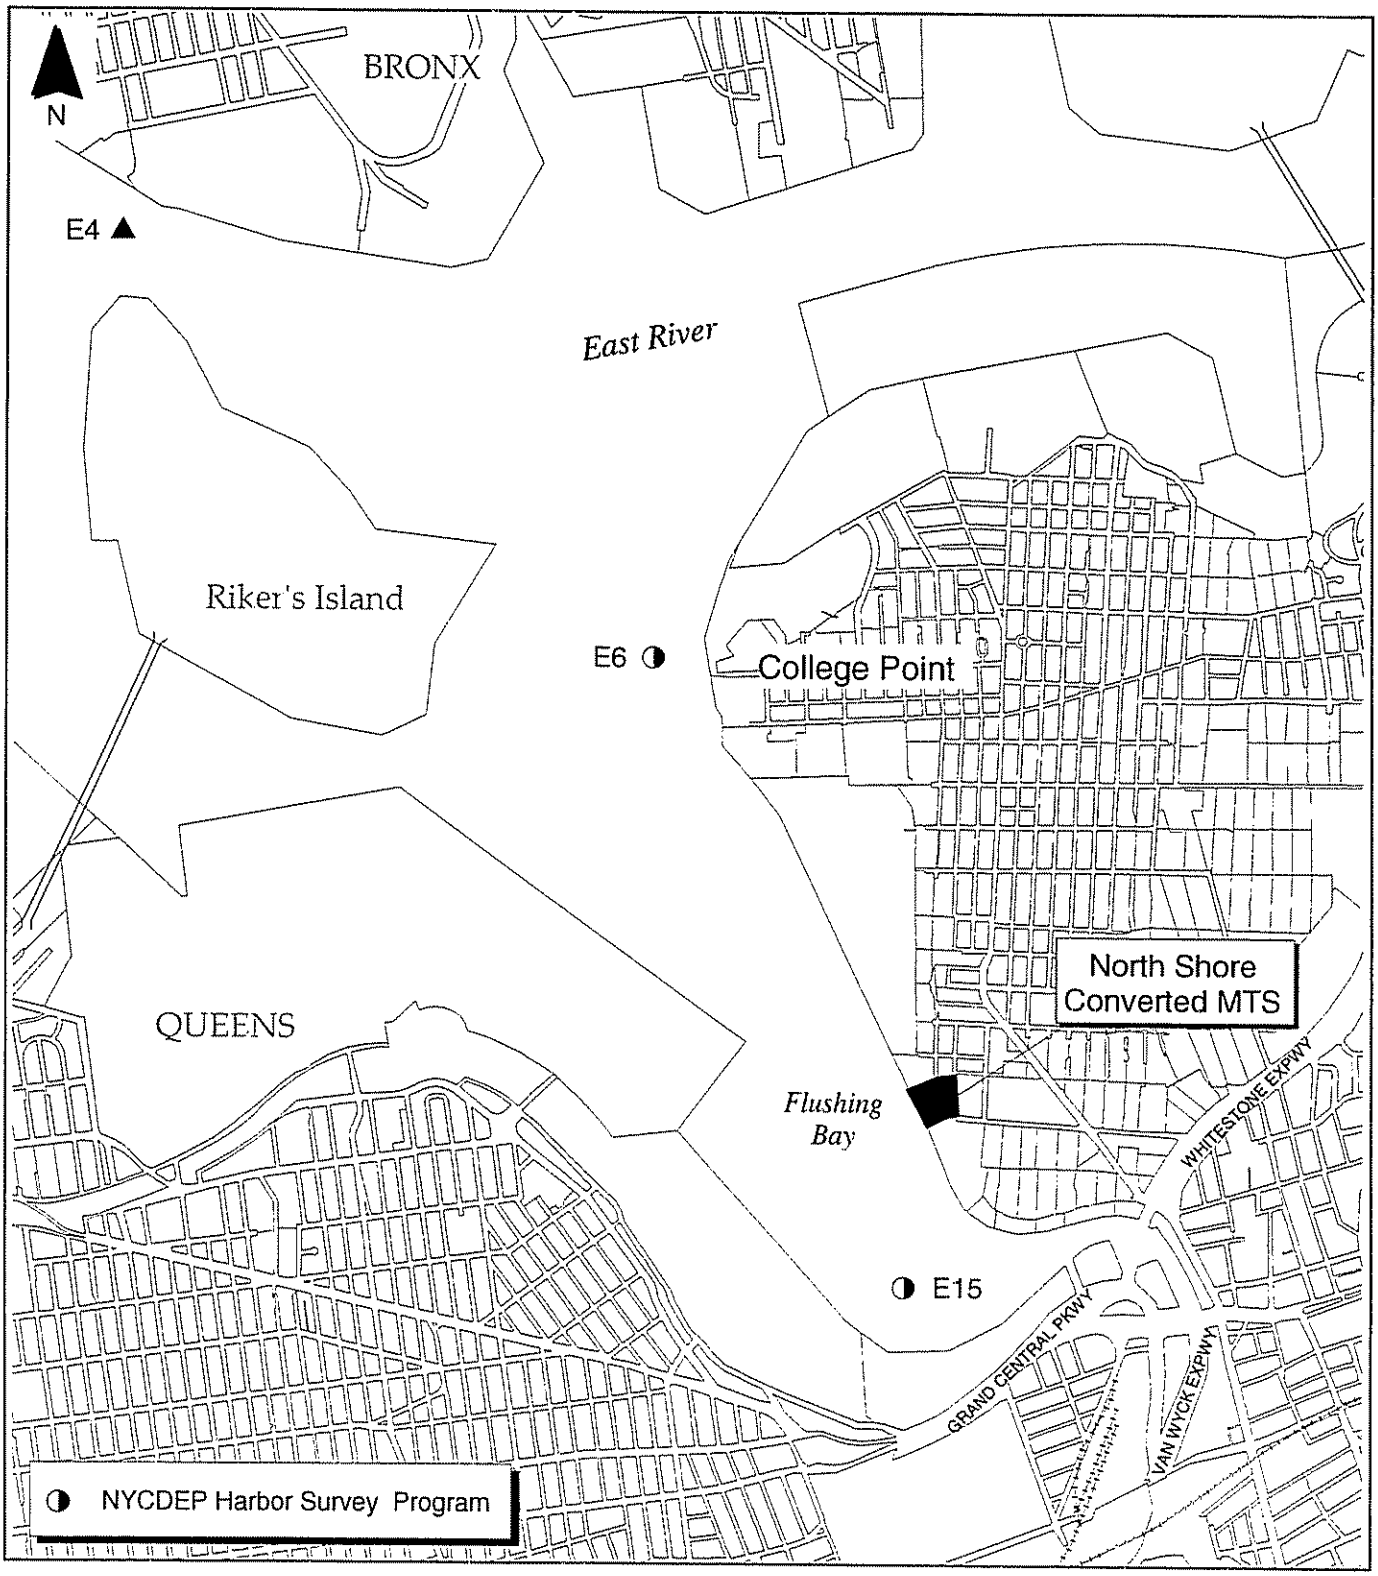
7.11 Water Quality

7.11.1 Existing Conditions

7.11.1.1 Definition of the Study Area

The water quality study area encompasses Flushing Bay and the East River, and includes discharges from CSOs and point sources within ½-mile of the site.

7.11.1.2 Water Quality



The water quality data for the following monitoring stations, shown in Figure 7.11-1, are generally representative of water quality conditions in the study area:

- NYCDEP Harbor Survey Program – Stations E-6 off of College Point in the East River and E-15 in Flushing Bay; and
- Battelle's 1991 Metals Survey – Stations E-4T and E-4B[11] in the East River off of Hunts Point.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 7.11-1. These standards and guidance values for the waters in the vicinity of the site correspond to "Class I," which indicates waters suitable for secondary contact recreation (i.e., fishing and boating).

As shown in Table 7.11-1, the data indicate that, on average, NYSDEC standards and guidance values are met. For NYCDEP Harbor Survey Station E-6, however, the minimum surface and bottom dissolved oxygen between June 1, 2003 and September 30, 2003 did not meet the water quality standards for dissolved oxygen. In addition, the mercury concentration for Battelle Stations E-4T and E-4B did not conform to the water quality standard for mercury.

[11] Stations E-4T and E-4B are located at the same longitude and latitude. Station E-4T is located at the surface of the East River. Station E-4B is located at the bottom of the East River.

7.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, estimates of stormwater pollutant loadings were calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and/or infiltration. A runoff flow of 0.514 cfs was calculated using the impervious site area (8.56 acres), an average rainfall intensity of 0.06 inches/hour and a runoff coefficient set equal to 1. The resulting stormwater loads, shown in Table 7.11-3, represent the existing loads at the site.

Site delineations and study area boundaries are approximate.

Table 7.11-3
Estimated Existing Pollutant Loads and Runoff Flows
North Shore Converted MTS Study Area

Pollutant	Concentration	Pollutant Loading (lbs/day)
Fecal Coliform MPN/100 ml	34,000	94,186[1]
BOD mg/L	11	31
Heavy Metals		
Copper µg/L	35	0.097
Lead µg/L	28	0.078
Zinc µg/L	154	0.427
Total Impervious Area (acre) = 8.56		Runoff Coefficient (C) = 1.00
Average Rainfall Intensity per Storm (inches/hour) = 0.06[2]		Runoff Flow (cfs) = 0.514

Notes:
(1) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
(2) Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

7.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to ongoing water quality improvement programs, such as the NYCDEP CSO Abatement Program, which will reduce untreated discharges to receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from City WPCPs; and other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

7.11.3 Potential Impacts with the North Shore Converted MTS

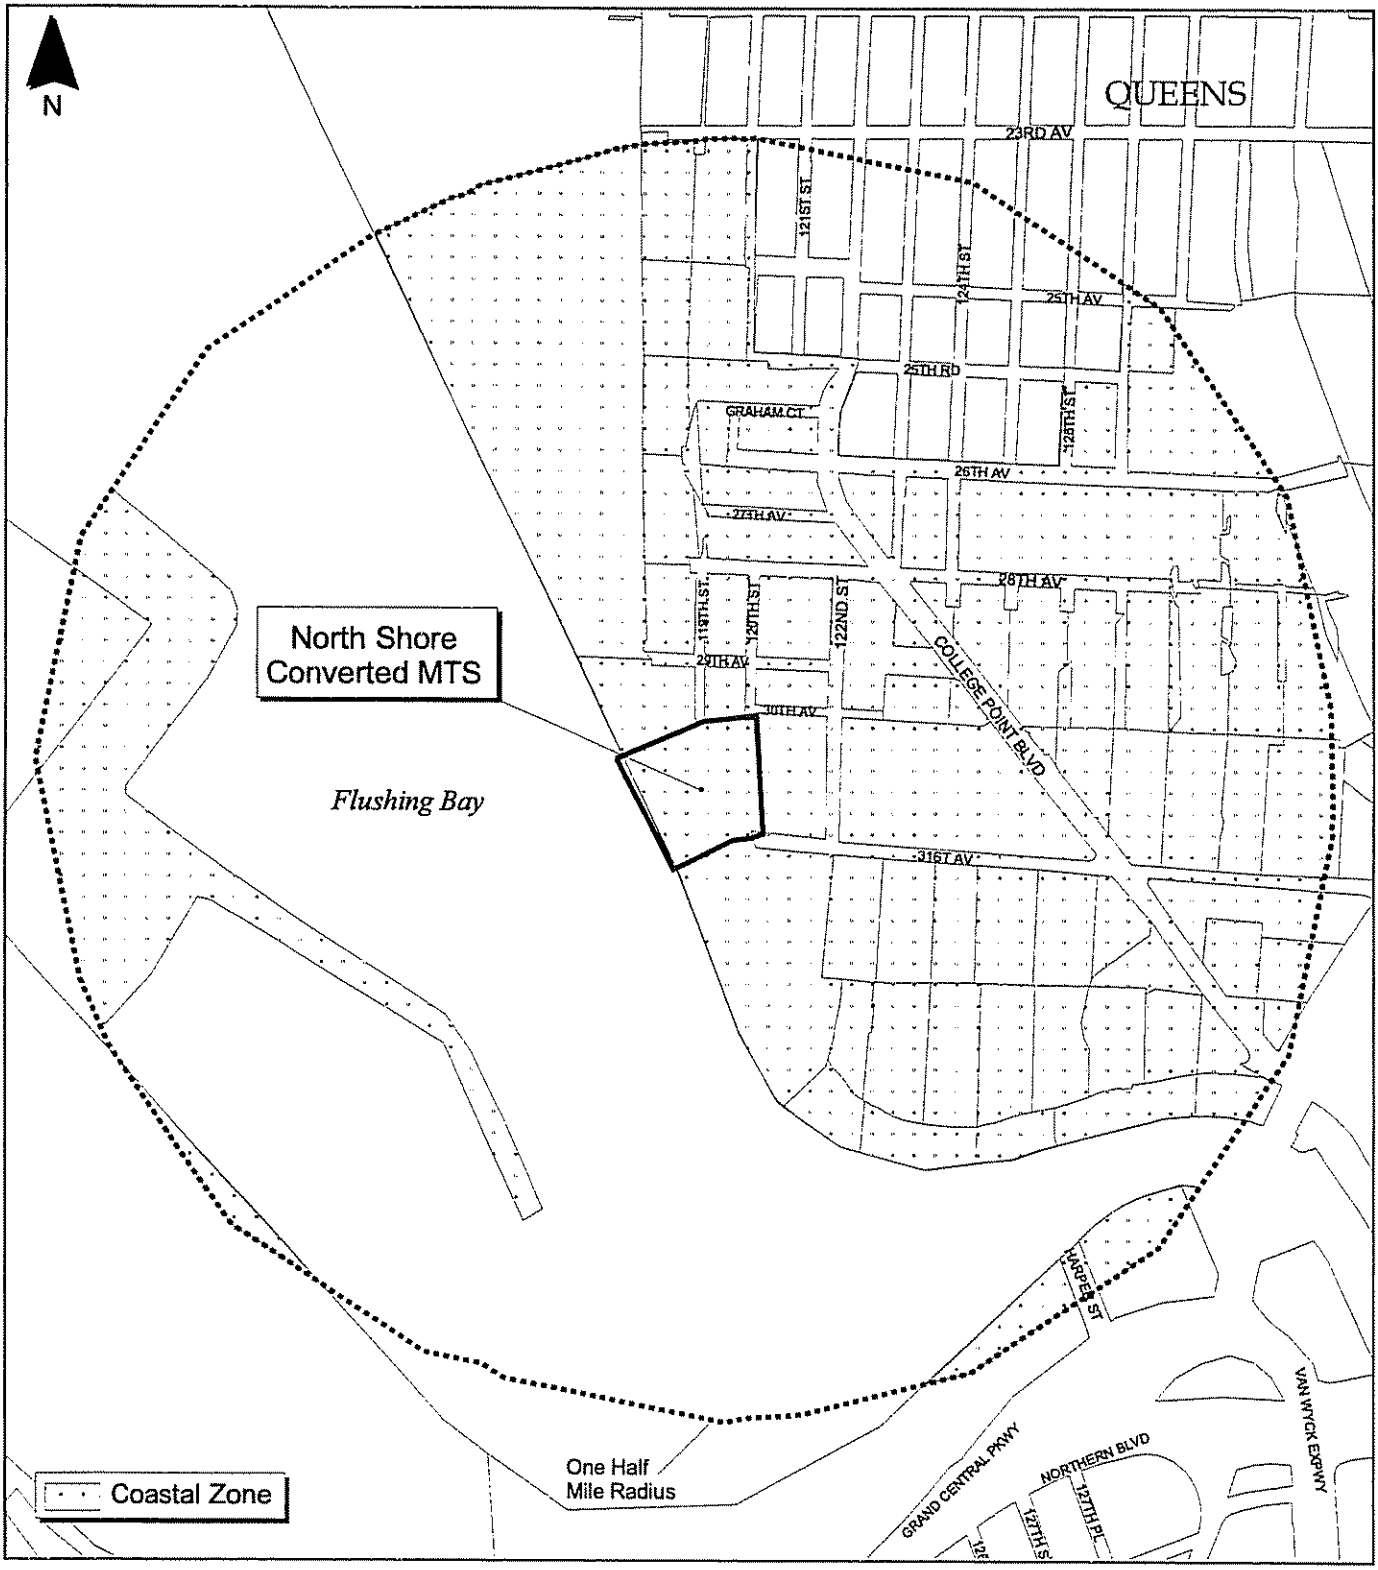
With the development and operation of the North Shore Converted MTS, conditions would be similar to Future No-Build Conditions. All solid waste processing would occur within structures on the site. All process wastewater from waste handling operations in the facility, such as washdown water, would be routed to an on-site pretreatment system (e.g., oil/water separation). After treatment, the process wastewater would be discharged to the municipal sewer system and, ultimately, to the Tallman Island WPCP, where it would be treated prior to discharge to the East River and, therefore, would not adversely affect water quality.

Stormwater loads and impervious area, shown in Table 7.11-4, would be expected to increase above Existing Conditions. According to the 208 Model, however, the increased loads would have no significant impact on water quality in the adjacent surface waters.

The North Shore Converted MTS may also require dredging activities to construct the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired prior to any proposed dredging activities. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant adverse long-term impacts.

Table 7.11-4
Impervious Area and Estimated Pollutant Loads
North Shore Converted MTS

			Estimated Pollutant Loadings/Incremental Change[1]				
Conditions	Total Impervious Area (acres)	Change in Impervious Area (acres)	Fecal Coliform[2]	BOD (lbs/day)	Copper (lbs/day)	Lead (lbs/day)	Zinc (lbs/day)
Existing Conditions	8.56	0.0	94,186/NA	31/NA	0.097/NA	0.078/NA	0.427/NA
Future Build Conditions	9.45	0.89	103,932/9,746	34/3	0.107/0.010	0.086/0.008	0.471/0.044



Notes:
(1) Incremental change refers to the difference in pollutant loading between the Existing Conditions and Future Build Conditions.
(2) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable

7.12 Waterfront Revitalization Program

7.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of Flushing Bay, the North Shore Converted MTS would be within the City's coastal zone boundary (see Figure 7.12-1). According to "The New Waterfront Revitalization Program," the North Shore Converted MTS would be classified as a water-dependent, industrial use. It would be located within Reach 10 Queens North Shore as indicated within the "New York City Comprehensive Waterfront Plan - Reclaiming the City's Edge" and the "Plan for the Queens Waterfront." It is not currently located within an NYCDCP-designated SNWA or SMIA. The North Shore Converted MTS is subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The North Shore Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.1, 3.1, 4.4, 6.2, 6.3, 8.1, 8.5, 9.2 and 10.2. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. In instances where a component of the North Shore Converted MTS required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below. A description of waste handling operations that would occur at the North Shore Converted MTS is provided in Section 2.2.4.

Site delineations are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

7.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the new North Shore Converted MTS. As part of the North Shore Converted MTS, connections from the new facility to existing utilities in the vicinity (e.g., sewer and electrical connections, etc.) would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.2 Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.

The existing North Shore MTS is not currently located within a designated SMIA. Its development would involve the demolition of the existing MTS and the construction of a new MTS at and north of the existing MTS site. The positioning of the proposed Converted MTS would allow for barge access and would minimize the amount of dredging that needs to be done at the site. In addition, there is a required design slope needed for the access ramp in order for trucks to access the site. The North Shore Converted MTS would involve the conversion of the existing facility from a truck-to-barge waste transfer station into a TCB MTS station that would transport DSNY-managed Waste to remote out-of-City disposal facilities by marine transport.

The demolition and subsequent site redevelopment, as described in Section 2.2.4, would help to restore and revitalize industrial waterfront property and would be compatible with existing and neighboring heavy industrial and maritime uses. Waterfront development would be comprised of four primary components: (1) an enclosed over-water processing building which would include a tipping floor, loading floor and pier level; (2) an elevated access ramp to the processing building; (3) a gantry crane, outside of the processing building; and (4) a ~~rehabilitated bulkhead and~~ new fendering system. A gantry crane would be used in the loading and unloading of DSNY barges at the facility. The North Shore Converted MTS would be consistent with existing land uses in the vicinity of its site and with the "Plan for the Queens Waterfront," which recommends the continued industrial use of the area. Although it would not encourage or facilitate the siting of any additional water-dependent uses, the North Shore Converted MTS would represent an expansion and revitalization of an existing water-dependent use and would be compatible with surrounding uses. The North Shore Converted MTS would, therefore, be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The North Shore Converted MTS would involve the demolition of the existing MTS structure and the subsequent development of a new MTS at the site. The North Shore Converted MTS would allow for the truck delivery of waste to the facility where waste would be placed in sealed containers, loaded onto DSNY barges and transported to out-of-City disposal facilities.

Waterfront development would be comprised of four primary components: (1) an enclosed over-water processing building which would include a tipping floor, loading floor and pier level; (2) an elevated access ramp to the processing building; (3) an outdoor gantry crane; and (4) a ~~rehabilitated bulkhead and~~ new

fendering system. A gantry crane would be used in the loading and unloading of DSNY barges at the facility. The pilings that support the existing MTS would be removed as part of the demolition activities and new pilings would be installed. In addition, the North Shore Converted MTS would require dredging to construct the new pier structure and improve existing water depths at and in the immediate vicinity of the site to allow for the unimpeded operations of barges and tugboats once the North Shore Converted MTS became operational. All required dredging would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

Development of the North Shore Converted MTS would involve the revitalization of an existing waterfront use and would not interfere with any maritime industrial, commercial or recreational vessel activities in the vicinity of its site. Activities within Flushing Bay resulting from the North Shore Converted MTS would be limited to barge loading along the pier level and the periodic swapping of loaded barges. Approximately ~~four or five~~three barges would be filled on a daily basis at the North Shore Converted MTS. These swapping activities would be in close proximity to the new MTS structure and comparable in nature to previous barge activities at the existing MTS; therefore, no adverse impacts upon other uses within the water body would be anticipated. The North Shore Converted MTS would, therefore, be consistent with this subpolicy.

3.3 *Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.*

The existing MTS managed solid waste through a truck-to-barge system where loose waste was placed in open barges. The North Shore Converted MTS would be a TCB MTS where waste would be transferred into containers that would be sealed and placed onto flat deck barges that would transport DSNY-managed Waste to out-of-City disposal locations and, therefore, would be protective of the aquatic environment and surrounding land and water uses. All solid waste handling would occur within an enclosed processing building. All waste would be placed in sealed containers before leaving the building for loading on barges.

Building ventilation would be maintained under negative pressure, which would maintain dust inside the enclosed processing building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environment. Litter control methods, such as routine sweeping and washing of the tipping floor, would be implemented to minimize or eliminate the potential for litter entering surface waters. All process wastewaters generated on site (e.g., washdown waters, etc.) would be treated prior to their discharge to the municipal sewer system. In addition, on-site storage of petroleum products and hazardous materials related to the operation of the North Shore Converted MTS would be done in accordance with applicable federal, state and local regulations. The North Shore Converted MTS would be protective of the surrounding environment and, therefore, consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York City coastal area.

4.1 *Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.*

Based upon a review of SNWAs, as described in "The New Waterfront Revitalization Program," as well as Recognized Ecological Complexes and SCFWH information, the North Shore Converted MTS is not within a designated area. The North Shore Converted MTS would represent an expansion in size of a previous use and would not be anticipated to result in any long-term impacts to natural resources in the vicinity of this site. The North Shore Converted MTS would, therefore, be consistent with this subpolicy.

4.2 Protect and restore tidal and freshwater wetlands.

A review of NYSDEC tidal and freshwater wetland maps was conducted to determine the presence of wetlands within the site. As noted in Section 7.9.1, the North Shore Converted MTS would be located within Flushing Bay, a NYSDEC-designated littoral zone. In addition, a wetland delineation was performed on February 4, 2005, and indicated the presence of intertidal and high marsh areas consisting of *Spartina alterniflora* and *Phragmites australis* respectively. No freshwater wetlands exist on the site. The North Shore Converted MTS would involve the demolition of the existing MTS structure and development of a new MTS at and in the vicinity of the existing facility. These activities and anticipated dredging would result in limited, short-term ~~impact~~ effects upon ~~to~~ these tidal wetlands.

Dredging activities associated with the development of the North Shore Converted MTS are not anticipated to have significant ~~impacts~~ effects on wetlands in the vicinity of the site, primarily due to previous and ongoing activities and previous dredging that has historically occurred at the existing MTS. ~~Mitigation for potential~~Potential ~~impacts~~ effects upon wetlands would be ~~proposed~~ addressed during the environmental review and permitting of the North Shore Converted MTS. ~~This mitigation, if required,~~ DSNY in coordination with NYSDEC and other involved agencies would determine the appropriate measures to address potential ~~impacts~~ effects that may occur due to the North Shore Converted MTS and would effectively restore these wetlands and their associated value. The North Shore Converted MTS would, therefore, be consistent with this subpolicy.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

The NYSDEC Breeding Bird Atlas identified the horned lark (*Eremophila alpestris*), a designated species of Special Concern, as having probable breeding status in the area surrounding the site. However, as discussed in Section 7.9.3, this bird is only found in open areas with bare ground or short grass; therefore, the over-water North Shore Converted MTS would not be anticipated to interfere with this species.

The pilings that support the existing MTS would be removed as part of the demolition, and new pilings would be installed to support the North Shore Converted MTS. In addition, dredging would be required to construct the pier structure for the North Shore Converted MTS and to improve existing water depths at and in the immediate vicinity of the site to allow for unimpeded operations of barges and tugboats once it became operational. As stated in Section 7.9.3, modifications to the site would pose little, if any, adverse ecological impacts or loss of habitat to rare or endangered species due to the disturbed nature of the site. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer system. Stormwater runoff from the North Shore Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. Further, the North Shore Converted MTS would not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The North Shore Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, sanitary and process wastewaters (e.g. floor washdown waters, etc.) would be conveyed to an on-site treatment system, which would consist of oil/water separators, etc., discharging eventually to the municipal sewer system. In addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. Stormwater runoff from the North Shore Converted MTS would be managed in accordance with all applicable federal, state and local regulations.

In addition, the majority of activity associated with the North Shore Converted MTS would be conducted within an enclosed processing building. Only sealed, air- and watertight containers would be transferred to barges outside of the processing building by gantry cranes installed at the pier level. Inside the facility, several measures would be taken to minimize the potential for environmental degradation as a result of the facility. Building ventilation would be maintained under negative pressure, which would keep dust inside the enclosed processing building. Litter control methods such as routine sweeping and washing of the tipping floor would be implemented to minimize or eliminate the potential for litter entering surface waters. The North Shore Converted MTS would be consistent with this subpolicy.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

BMPs would be used to the extent possible during all phases of construction, including demolition of the existing MTS structure and operation of the North Shore Converted MTS, in order to minimize any nonpoint discharges. The MTS

would comply with federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be conducted within an enclosed processing building. During construction, non-structural (such as silt curtains) and, if necessary, structural, measures would be used to minimize nonpoint source pollution.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

As part of the North Shore Converted MTS, the pilings that support the existing MTS would be removed and new pilings would be installed to support the new building. In addition, dredging would be required to construct the pier structure for the North Shore Converted MTS and to improve existing water depths at and in the immediate vicinity of the site to allow for the unimpeded operation of barges and tugboats. Any dredging done as part of the construction of the new MTS would result in temporary impacts and would be conducted in a manner to minimize siltation and erosion and other short-term impacts to water quality. All dredged materials would be disposed of at a permitted upland facility in accordance with applicable federal, state and local regulations. Non-structural (such as silt curtains) and, if necessary, structural, measures would be employed to minimize siltation and potential adverse impacts to tidal wetlands in the vicinity. Therefore, the North Shore Converted MTS would be consistent with this subpolicy.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The North Shore Converted MTS would have no impact on the quality or quantity of surface or ground waters. Sanitary and process wastewaters (e.g. floor washdown waters, etc.) would be conveyed to an on-site treatment system and

would then discharge to the municipal sewer system. Stormwater runoff from the North Shore Converted MTS would be managed in accordance with all applicable federal, state and local regulations. No surface or ground waters in the vicinity of the site constitute a primary or sole source of water supply. The North Shore Converted MTS would be consistent with this policy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to a review of the FEMA National Flood Insurance Program maps, the site is located entirely within the 100-year floodplain boundary (Zone A). As part of the North Shore Converted MTS, the existing MTS would be demolished and a new MTS constructed at and north of the site. The pilings that support the existing MTS would be removed as part of the demolition and new pilings would be installed to support the new building. To the extent practicable, non-structural (such as silt curtains) and, if necessary, structural, measures would be used to minimize impacts due to flooding and erosion during the demolition of the existing MTS and subsequent construction of the new, expanded processing building. Construction of the new North Shore Converted MTS would not affect the potential for flooding or erosion. All structures would comply with applicable building code requirements.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The North Shore Converted MTS would not involve the storage, treatment or disposal of hazardous waste, but would facilitate the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours of tipping. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the North Shore Converted MTS. The majority of North Shore Converted MTS activities would occur within an enclosed processing building. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility. Only sealed, air- and watertight containers would be used outside of the facility.

On-site storage of petroleum or hazardous materials related to the operation of the North Shore Converted MTS would be minimal and all storage would be in accordance with applicable federal, state and local regulations. The North Shore Converted MTS would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.

Due to the existing, heavy industrial uses at and in the immediate vicinity of the North Shore Converted MTS, public access would not be compatible with the principal use of the site. Therefore, this subpolicy is not applicable.

8.2 Incorporate public access into new public and private development where compatible with proposed land use and coastal location.

The North Shore Converted MTS would be a stand-alone, water-dependent, industrial facility fronting Flushing Bay. Public access would not be compatible with the North Shore Converted MTS; however, its development would not preclude any future development of public access at other locations along the Flushing Bay waterfront.

8.3 Provide visual access to coastal lands, waters and open space where physically practical.

Development of a new North Shore Converted MTS site would represent an expansion of an existing waterfront use that is currently inactive and would not impair visual access to coastal lands, waters or open space. Also see response to Subpolicy 9.1.

8.4 Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

Only one significant, mapped park, Flushing Meadows-Corona Park, was identified approximately ½-mile south of the site. The North Shore Converted MTS, however, would have no effect on this or any other open space resource within the study area. Therefore, it would be consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The new MTS structure would have no significant impact on the site, the urban design or visual quality of the surrounding area or the existing (non-sensitive) view corridors, as noted in Section 7.7.3. Based on the information presented in that section, the North Shore Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The North Shore Converted MTS would involve the expansion of an existing use and would pose no impact to scenic values associated with natural resources. Therefore, this subpolicy is not applicable.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological, and cultural legacy of the New York City coastal area.

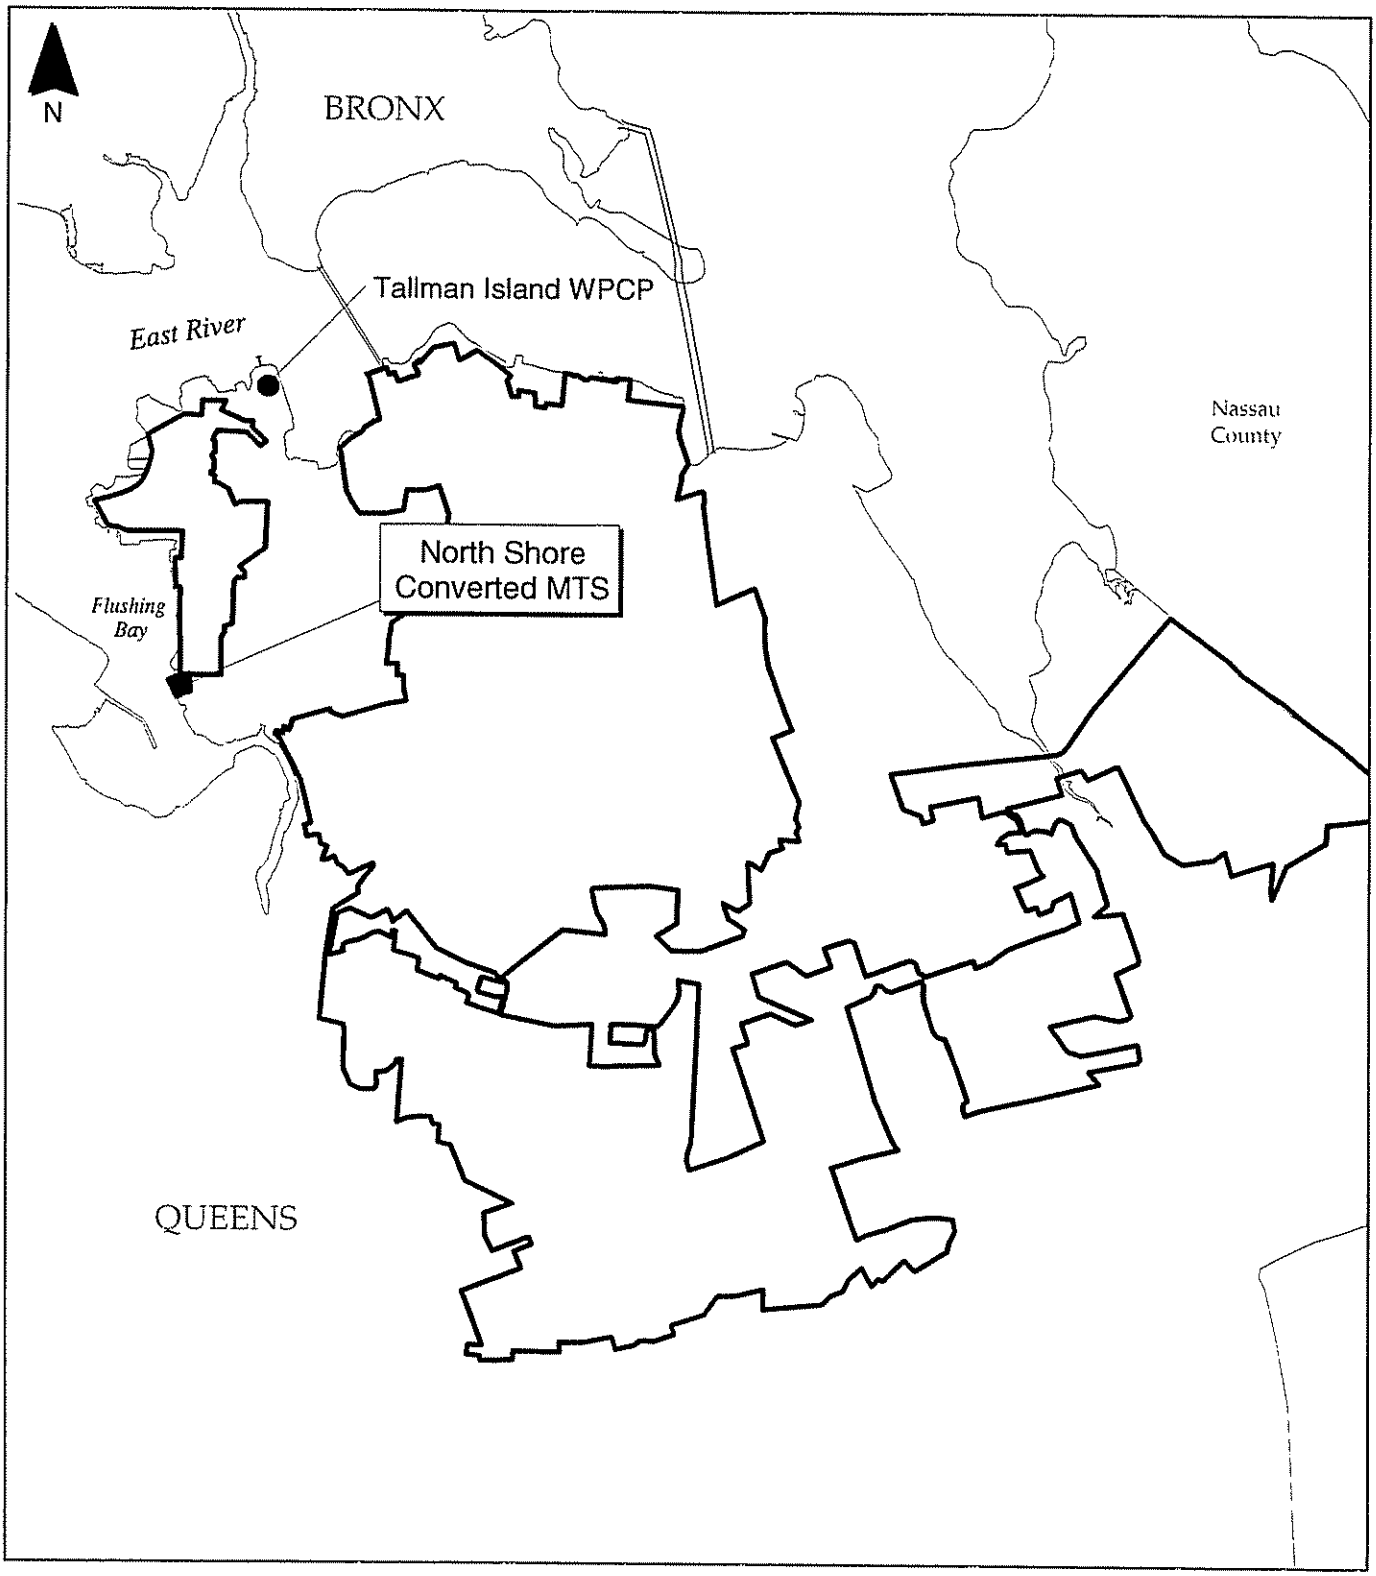
10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

The North Shore Converted MTS will have no effect on any cultural resources on or near the site, as noted in Section 7.6.3. Based on the information presented in that section, the North Shore Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site or in the study area. This subpolicy is, therefore, not applicable.

7.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



7.13.1 Existing Conditions

7.13.1.1 Water Supply

Water is supplied to the North Shore MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. An off-site 8-inch-diameter pipe along 122nd Street north of 30th Avenue provides potable water to the facility for both process and sanitary requirements. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

7.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps showed that the site is served by the Tallman Island WPCP, which serves portions of Queens. The WPCP drainage area is illustrated in Figure 7.13-1. From July 2002 through June 2003, the WPCP treated an average of 54 mgd of wastewater under dry weather flow conditions and an average flow of 58 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 7.13-1). The maximum dry weather flow during this period was 58 mgd during September 2002 and June 2003 and the maximum average flow was 65 mgd during June 2003. Effluent from the plant is discharged into the East River, and is regulated by the NYSDEC under the SPDES. The current SPDES permit limit for flow to the Tallman Island WPCP is 80 mgd. It is estimated that current on-site employee water usage at the MTS is about 75 gpd. This estimate is based on three security employees (one guard per shift, three shifts per day) using 25 gallons per person per day (2001 CEQR Technical Manual). As the facility is currently not accepting waste, no other potable water is used and no operational staff are currently assigned to the site.

Site delineations are approximate

Figure 7.13-1 Existing WPCP Drainage Area

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Table 7.13-1
Average Monthly Dry Weather and Average Flows
Tallman Island WPCP
Fiscal Year 2003

Month	Dry Weather Flow (mgd)	Average Monthly Flow[1](1) (mgd)
July 2002	47	47
August	49	52
September	58	63
October	55	62
November	56	63
December	54	57
January 2003	52	55
February	54	58
March	56	60
April	52	56
May	51	55
June	58	65
Average Effluent	**54**	**58**

Notes:
(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

Wastewaters generated at the existing North Shore MTS are currently routed to a 12-inch sanitary sewer line flowing from west to east along 29th Avenue. Stormwater runoff flows into a 24-inch storm sewer line running from 31st Avenue to College Point Boulevard. Wastewater is discharged to the municipal sewer system from the site via a pump station on 122nd Street.

7.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each employee at the existing MTS produces approximately nine pounds of solid waste per week for a facility total of 27 pounds per week (approximately four pounds per day). The solid waste is collected by DSNY personnel and is transported by truck to an appropriately licensed solid waste management facility.

7.13.1.4 Energy

Based on a review of applicable utility service plans, Consolidated Edison of New York supplies electricity to the facility via lines running along 31st Avenue. The existing North Shore MTS utilizes a negligible amount of energy due to the low staffing levels providing only security for the facility. There is currently no gas supplied directly to the facility.

7.13.2 Future No-Build Conditions

The existing North Shore MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near the Existing Conditions levels for security employees. Wastewater flows to the Tallman Island WPCP would continue to increase and would be projected to be 58.9 mgd by 2006.

7.13.3 Potential Impacts with the North Shore Converted MTS

7.13.3.1 Water Supply

The North Shore Converted MTS would have a total of up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The North Shore Converted MTS would have no impact on the existing system's ability to supply water reliably. According to NYCDEP, the water pressure in the distribution lines in the area is about 45 psi. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

7.13.3.2 *Sanitary Sewage*

Based on the estimated water usage of 3,300 gpd for the North Shore Converted MTS, the small quantities of wastewater sent to the Tallman Island WPCP would not significantly impact the sewage flow rate or the ability of the Tallman Island WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 58.9 mgd in 2006, which would be well below the permitted capacity of 70 mgd. In addition, the new wastewater flows due to the Proposed Action would not result in a significant increase in combined sewer overflows (CSO).

7.13.3.3 *Solid Waste*

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the North Shore Converted MTS and would not significantly impact the system.

7.13.3.4 *Energy*

The North Shore Converted MTS would require an additional 5.51E+10 BTU/year of electricity to operate the facility. Natural gas heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the North Shore Converted MTS and has stated that all demands generated by the facility could be met without any impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

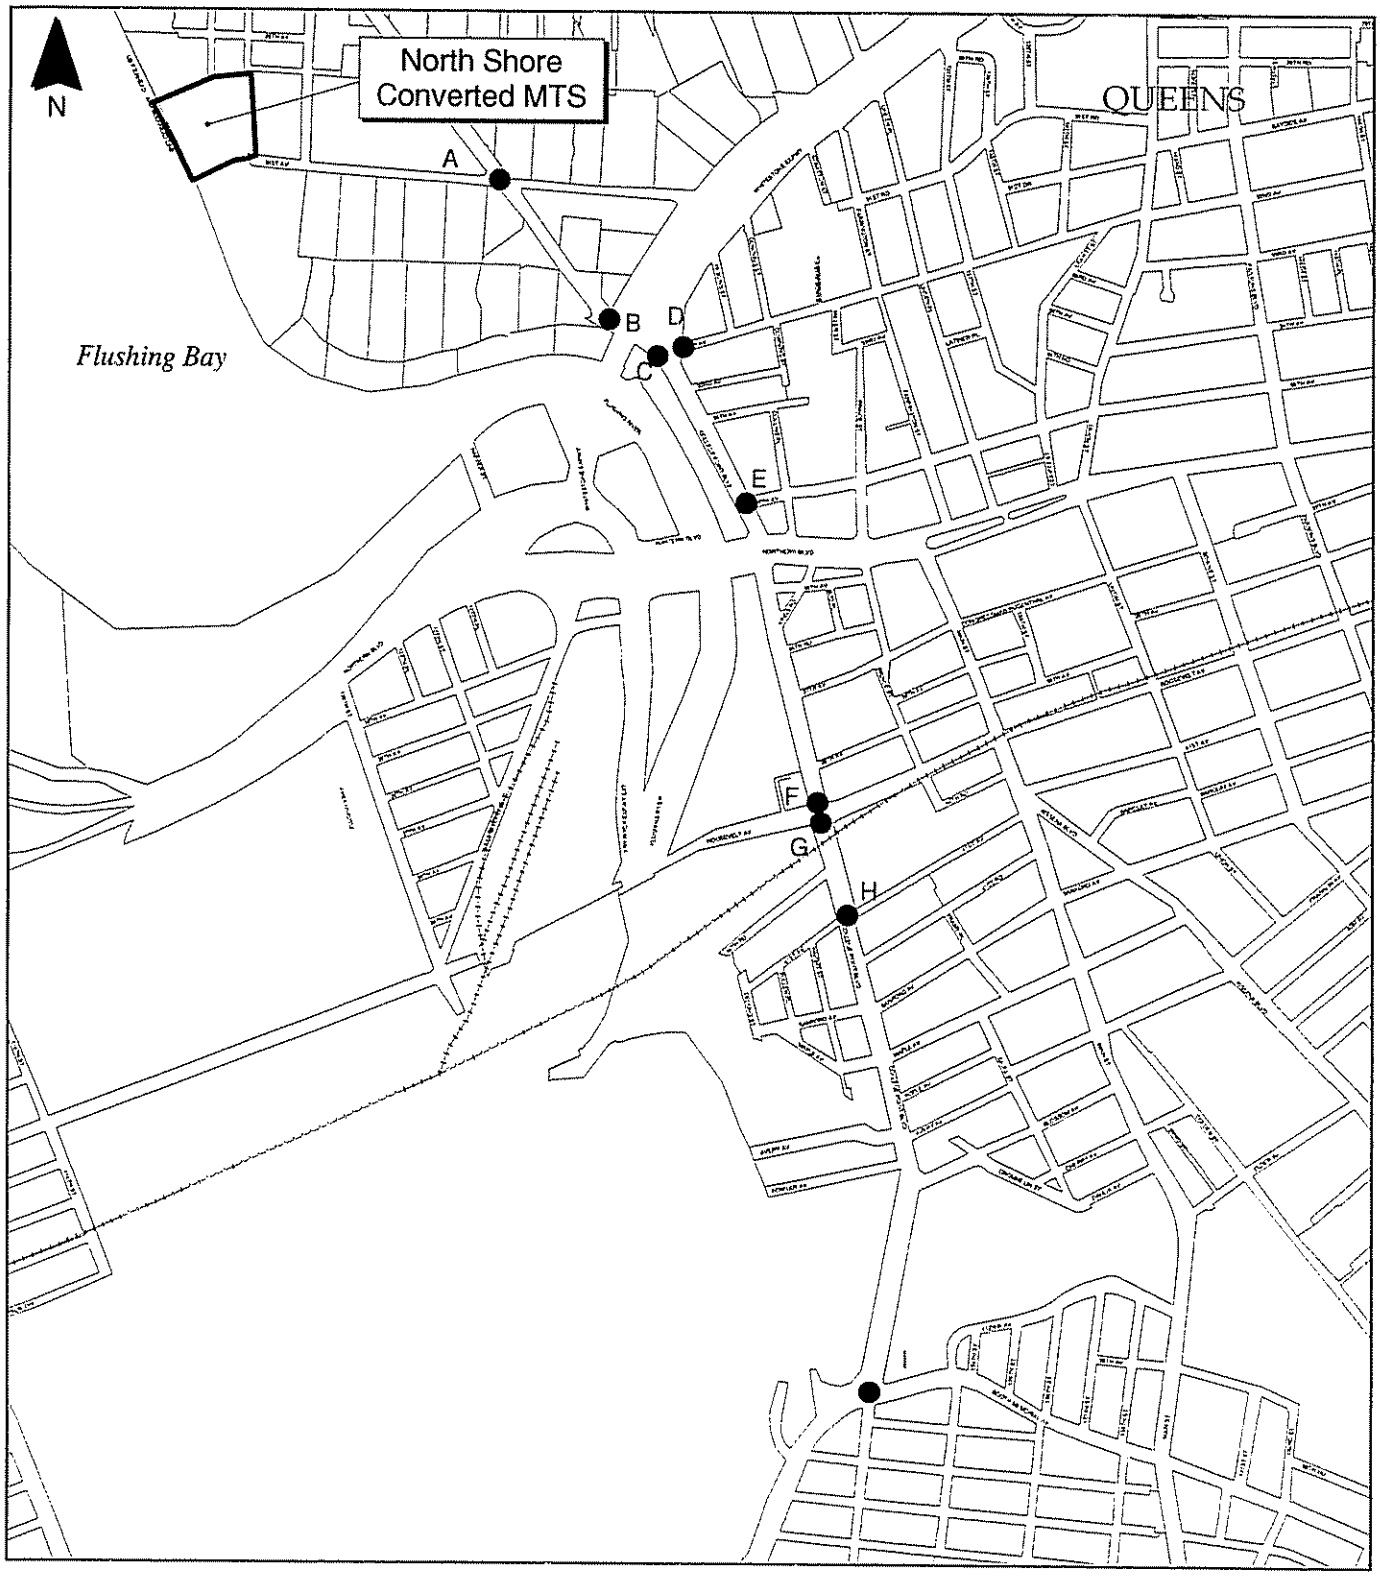
Consolidated Edison was also notified of the natural gas requirements of the North Shore Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impact on the utility.

7.14 Traffic, Parking, Transit, and Pedestrians

7.14.1 Introduction

The North Shore Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

7.14-2 Existing Conditions



7.14.2.1 Definition of Study Area

The traffic analysis study area is broad, covering portions of the College Point, Flushing and Queensboro Hill sections of Queens. It includes the corridor along College Point Boulevard that is bounded by 31st Avenue on the north and Booth Memorial Avenue on the south. Commercial, industrial and residential areas are included in the traffic study area. There are no CEQR-defined areas of concern located within the study area. Figure 7.14-1 shows the locations of the intersections selected for analysis (locations A through I). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points more than ½-mile away in conjunction with local truck routes. Section 7.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the North Shore Converted MTS.

7.14.2.2 Surface Network

Two major highways service the traffic analysis study area — the predominantly east-west LIE and the predominantly north-south Van Wyck Expressway. College Point Boulevard and the Whitestone Expressway Service Roads are local truck routes that provide access from the south and east of the site. A map showing all major truck routes and local truck routes in Queens is provided in Section 3.16 (see Figure 3.16-5).

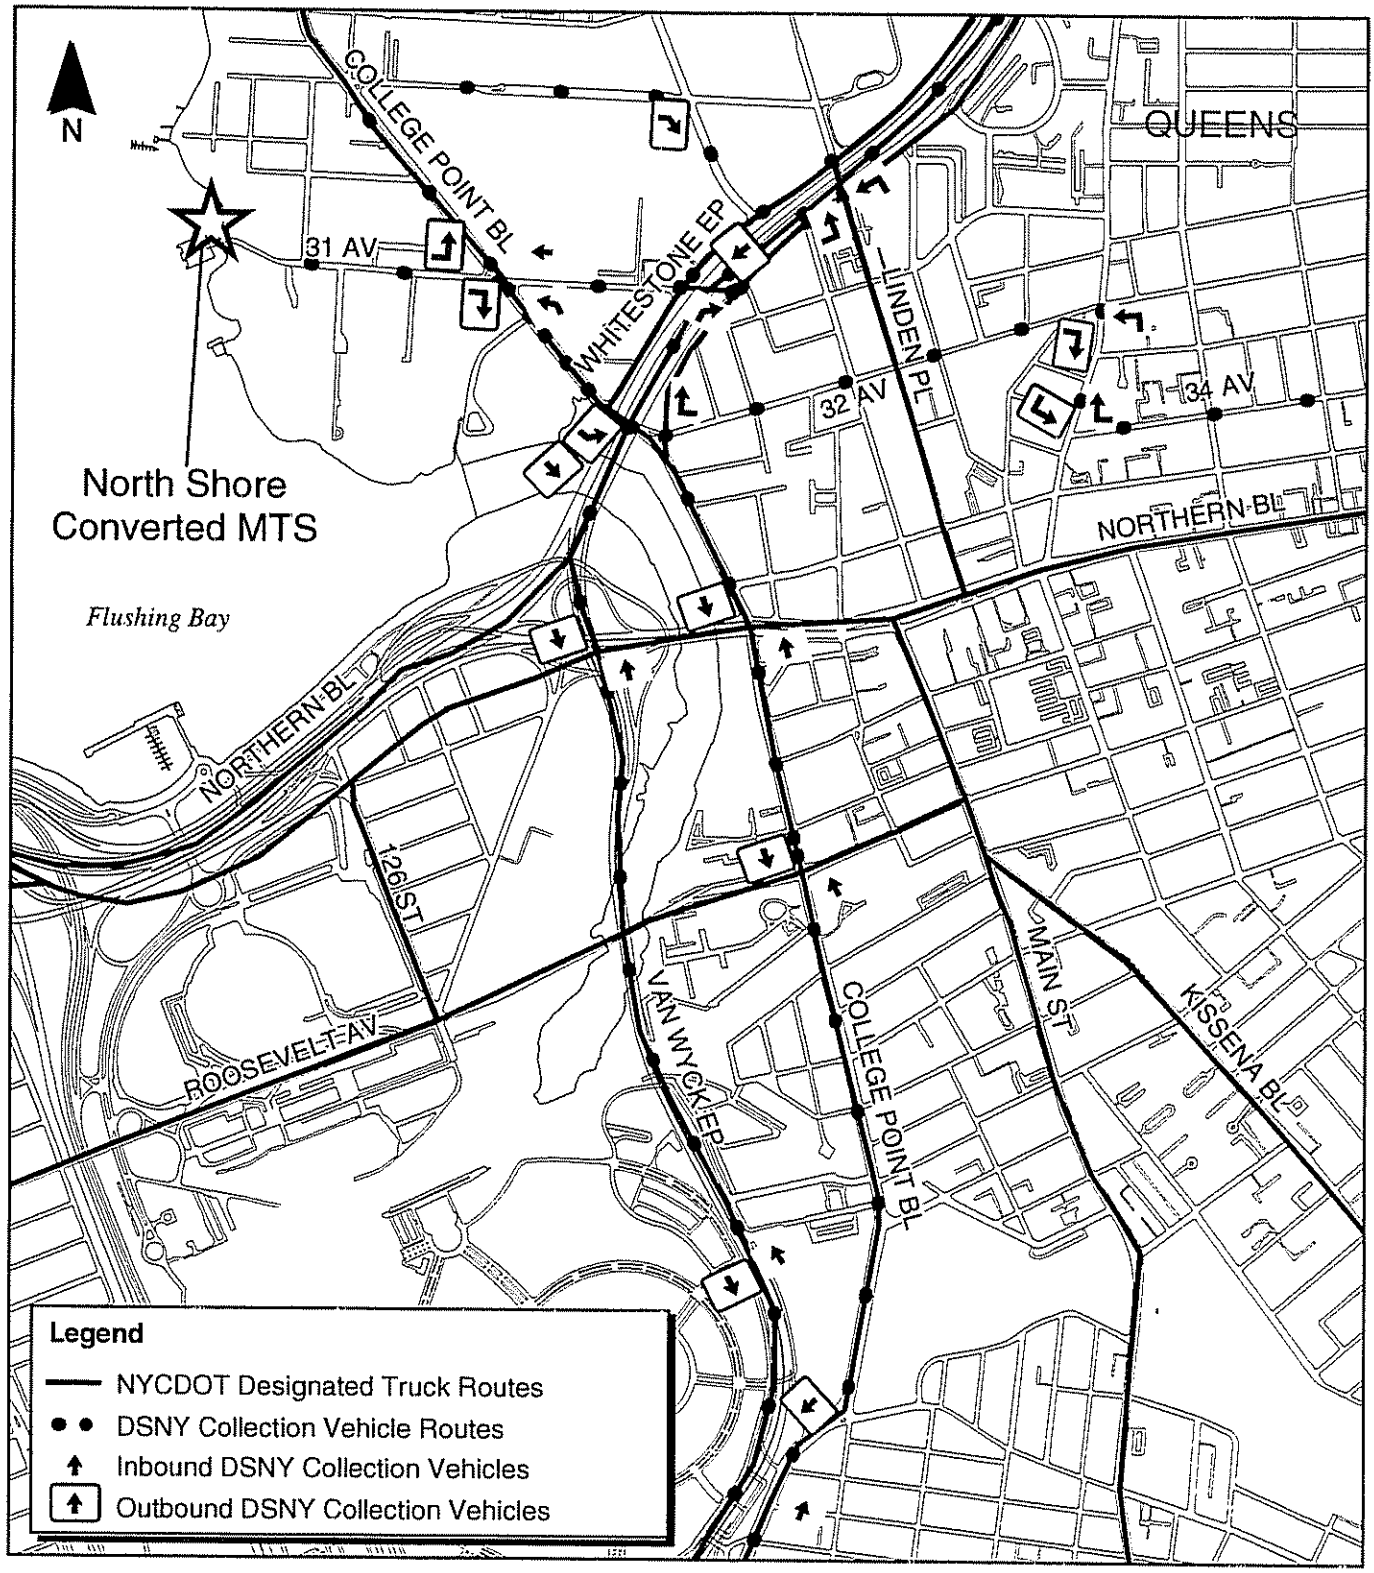
Figure 7.14-1 Traffic Analysis Study Area
North Shore Converted MTS



CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

31st Avenue, 32nd Avenue, 35th Avenue and 41st Avenue generally serve as collector roads for local traffic and provide access for local and industrial traffic to and from the arterial of College Point Boulevard. College Point Boulevard provides access to and from the LIE. The Whitestone Expressway Service Roads are arterials that provide access to and from the Whitestone Expressway. Roosevelt Avenue and Booth Memorial Avenue are east-west arterials that cross College Point Boulevard.

Most DSNY and other agency collection vehicles making deliveries to the North Shore MTS use either the Van Wyck Expressway or LIE to travel toward the North Shore Converted MTS. These vehicles exit the Van Wyck Expressway or LIE onto College Point Boulevard and proceed north towards the facility. Vehicles from one CD travel north on the Van Wyck Expressway to the Linden Place exit. These vehicles exit onto the Whitestone Expressway Service Road (northbound) and turn northwest on Linden Place. From Linden Place, the vehicles turn onto the Whitestone Expressway Service Road (southbound) and then turn west on 31st Avenue. Although this exit is located closer to the facility, the NYCDOT has requested that limited traffic be routed through the intersection of Linden Place and the Whitestone Expressway Service Roads due to exiting congestion at this intersection. All vehicles traveling to and from the North Shore Converted MTS converge at the intersection of 31st Avenue and College Point Boulevard. Inbound vehicles travel west along 31st Avenue to the facility. Figure 7.14-2 depicts NYCDOT designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

Exiting DSNY and other agency collection vehicles return east along 31st Avenue and turn south onto College Point Boulevard to return to the Van Wyck Expressway or LIE, except for the vehicles that use the Linden Place exit. These vehicles turn north onto College Point Boulevard, east on 28th Avenue south onto Ulmer Street. From Ulmer Street, the vehicles turn onto the Whitestone Expressway Service Road (southbound) and enter onto the Van Wyck Expressway.

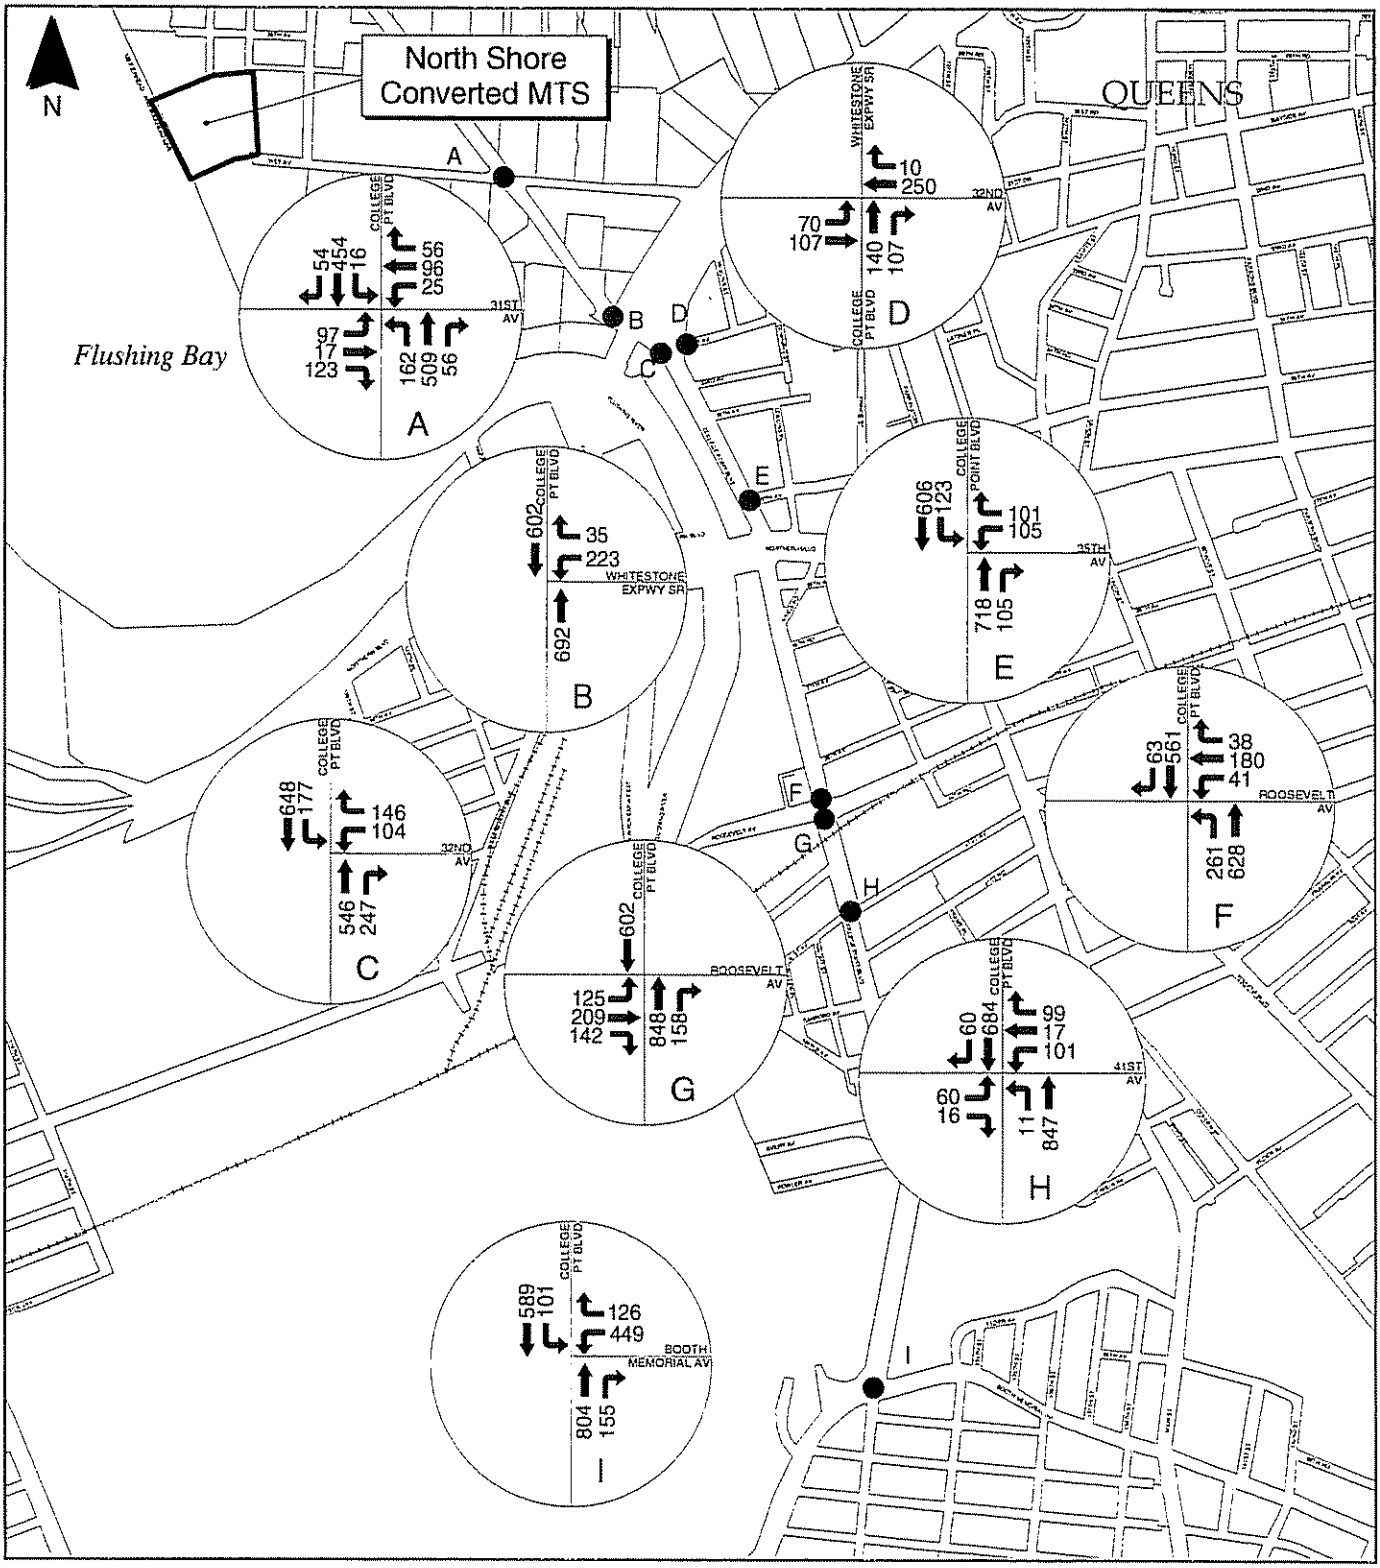
7.14.2.3 Existing Traffic Operations

The nine intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the North Shore Converted MTS. All of them are on major arterials and/ or collection vehicle routes. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- College Point Boulevard and 31st Avenue – Signalized Intersection (see Figure 7.14-1 – location A)
- College Point Boulevard and Whitestone Expressway Service Road (Westbound) – Signalized Intersection (see Figure 7.14-1 – location B)
- College Point Boulevard and 32nd Avenue – Signalized Intersection (see Figure 7.14-1 – location C)
- Whitestone Expressway Service Road (Eastbound) and 32nd Avenue – Signalized Intersection (see Figure 7.14-1 – location D)
- College Point Boulevard and 35th Avenue – Signalized Intersection (see Figure 7.14-1 – location E)
- College Point Boulevard and Roosevelt Avenue (Westbound) – Signalized Intersection (see Figure 7.14-1 – location F)
- College Point Boulevard and Roosevelt Avenue (Eastbound) – Signalized Intersection (see Figure 7.14-1 – location G)
- College Point Boulevard and 41st Avenue – Signalized Intersection (see Figure 7.14-1 – location H)
- College Point Boulevard and Booth Memorial Avenue – Signalized Intersection (see Figure 7.14-1 – location I)

31st Avenue, 32nd Avenue, 35th Avenue and 41st Avenue generally serve as collector roads for local traffic and provide access for local and industrial traffic to and from the arterial of College Point Boulevard. College Point Boulevard provides access to and from the LIE. The Whitestone Expressway Service Roads are arterials that provide access to and from the Whitestone Expressway. Roosevelt Avenue and Booth Memorial Avenue are east-west arterials that cross College Point Boulevard.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between November 14, 2002 and November 21, 2002, while ATR counts were conducted between November 18, 2002 and November 24, 2002. Figures 7.14-3, 7.14-4 and 7.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:30 a.m. and 8:30 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 4:30 p.m. and 5:30 p.m. Table 7.14-1 presents the v/c ratio, delay and LOS for the nine intersections during the AM, Facility, and PM peaks.



Existing truck traffic through most of the intersections was relatively high. The percentages of trucks increases steadily during the morning hours, remains between 20% and 35% during midday hours, then decreases to 10% or lower during the PM peak hours.

7.14.2.3.1 LOS at Signalized Intersections

Table 7.14-1 shows that the existing signalized intersections generally operated at an overall LOS of B or C with the following exceptions. The lane group with the least favorable LOS was the southbound defacto left movement at the intersection of College Point Boulevard and Booth Memorial Avenue. During the PM peak hour, this movement operated at LOS E with a delay of 61.9 seconds. Several other lane groups at various intersections operated at a LOS of D during various peak hours.

7.14.2.3.2 LOS at Unsignalized Intersections

No unsignalized intersections were analyzed.

7.14.2.4 Existing DSNY-Related Traffic

Under Queens' interim export, Tully Environmental, a commercial vendor located close to the North Shore Converted MTS, accepts waste originating from CDs in Queens. Queens CDs delivering to Tully Environmental are QN7, QN12 and E-Z Pack loads from QN2, QN7 and QN14. Additionally, duel bin school trucks, basket trucks, SHBLK, street dirt, lot clearing (LC) and other City department (OCD) loads from all Queens CDs are delivered to Tully Environmental. Existing DSNY-related traffic in the traffic study area is located on College Point Boulevard, 35th Street and Roosevelt Avenue.

7.14.2.5 Public Transportation

Public transportation in the study area consists predominantly of bus trips. The Q48 runs east-west along Roosevelt Avenue and the Q58 and Q65 run north-south along College Point Boulevard. Bus stops are located at some of the study area intersections analyzed, and scheduled stops occur at various times during the day.

7.14.2.6 Pedestrian Activity

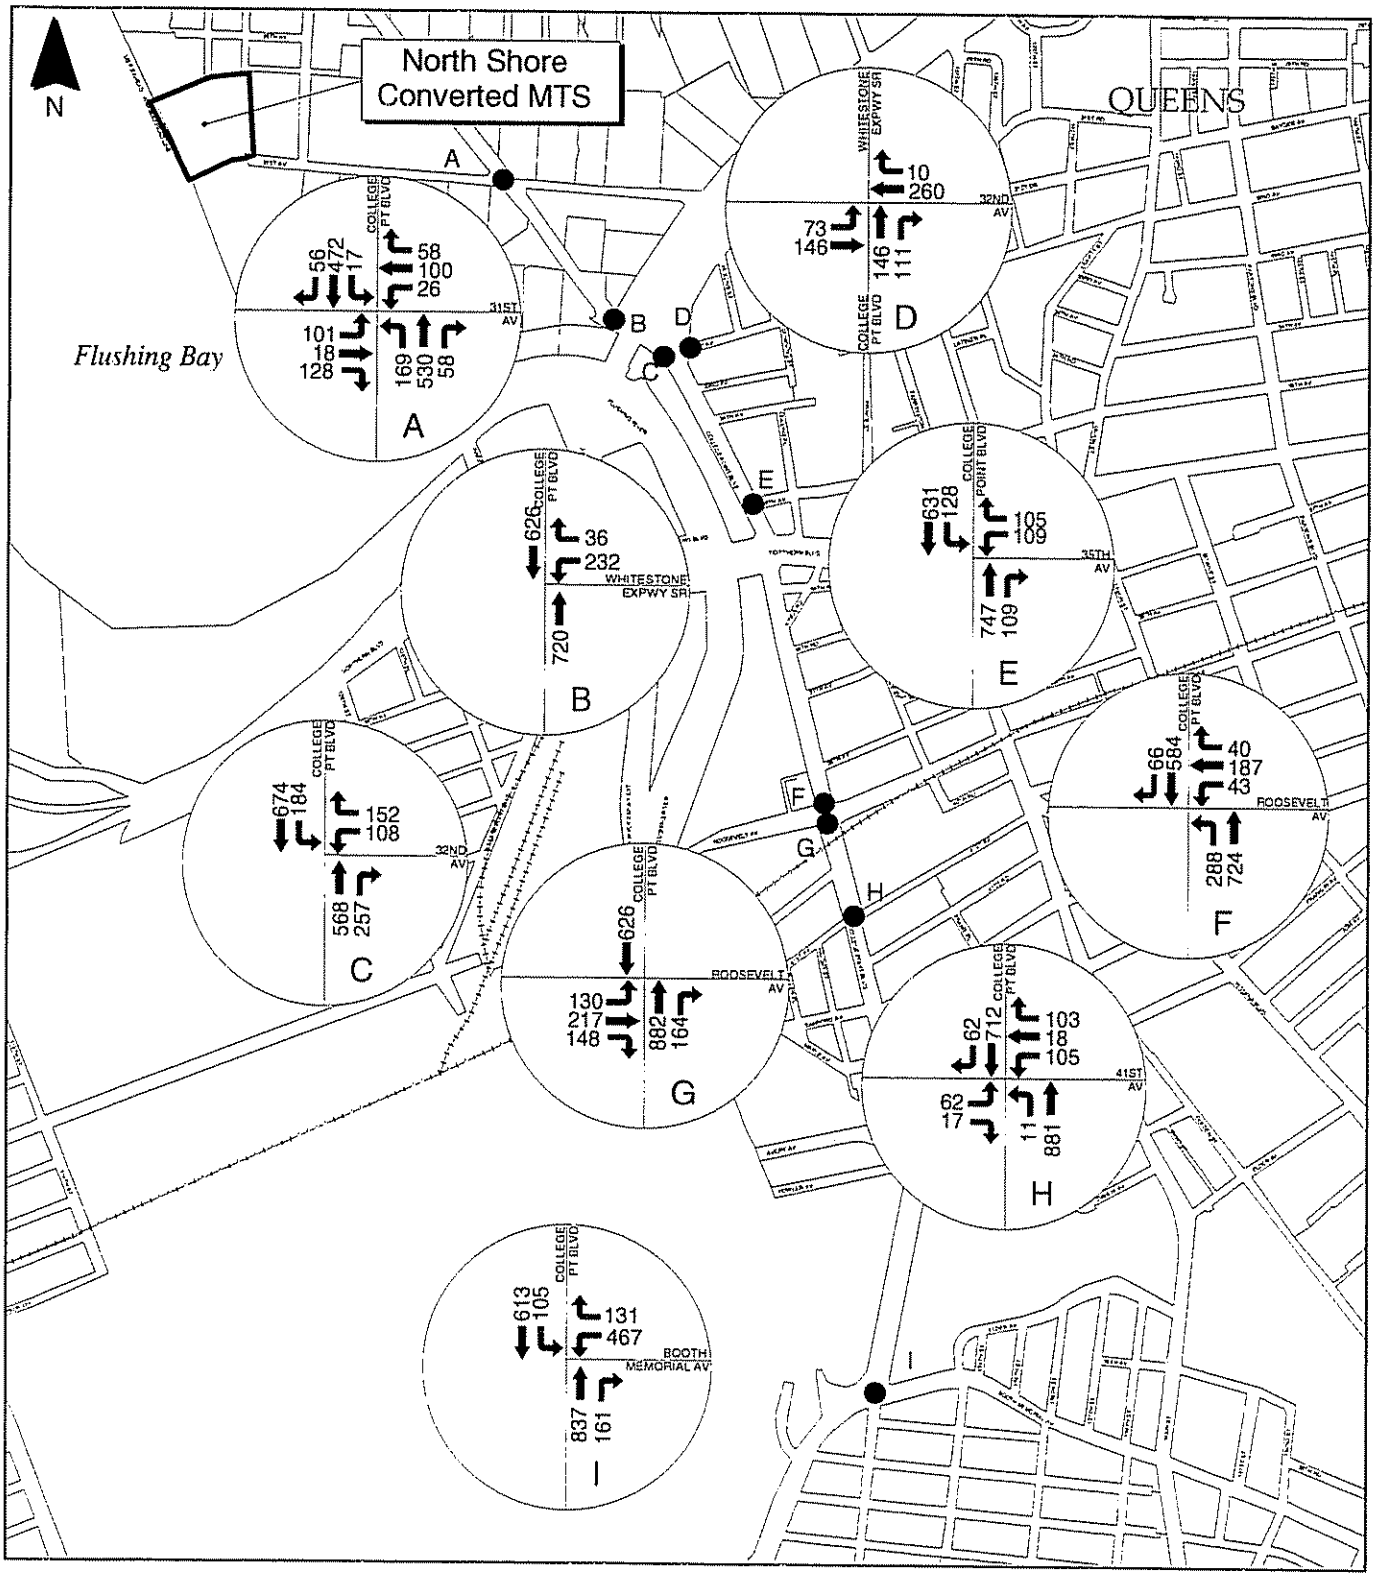
Light pedestrian activity occurs along College Point Boulevard in the center section of the study area where restaurants and commercial and residential areas produce and attract pedestrians throughout the day. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.

7.14.3 Future No-Build Conditions

7.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 100 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes in the study area.

Figures 7.14-6, 7.14-7 and 7.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 7.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, signalized intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their Existing Condition LOS, with the following exceptions:



- During the AM peak hour, the overall LOS of the College Point Boulevard and 32nd Avenue intersection and the College Point Boulevard and Booth Memorial Avenue intersection deteriorated from B to C.
- During the PM peak hour, the overall LOS of the College Point Boulevard and Roosevelt Avenue (Westbound) intersection deteriorated from C to D.

7.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

7.14.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

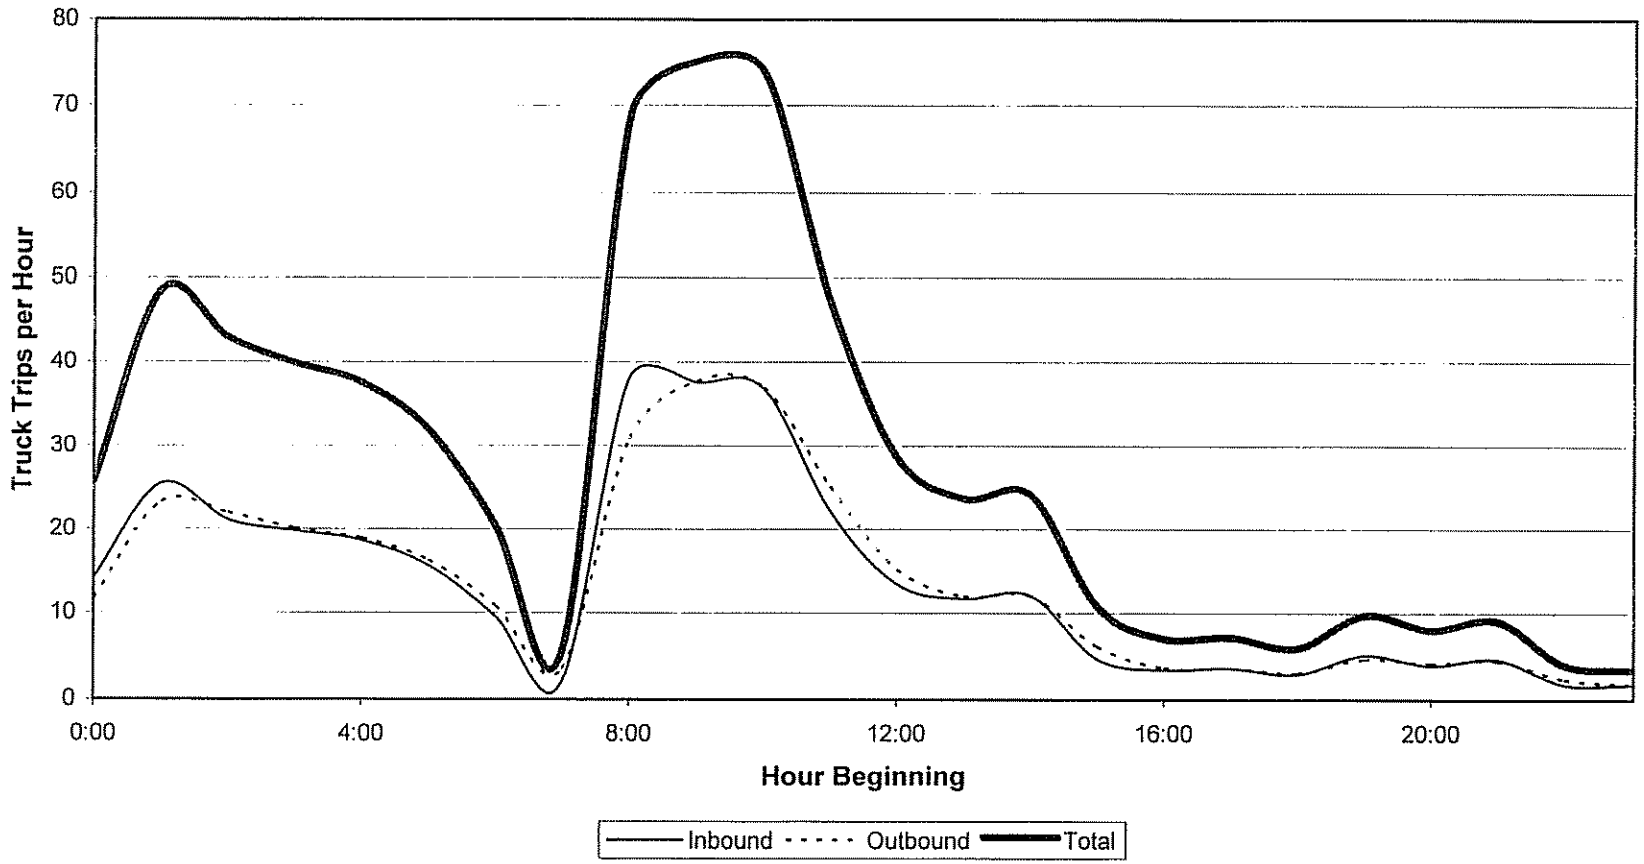
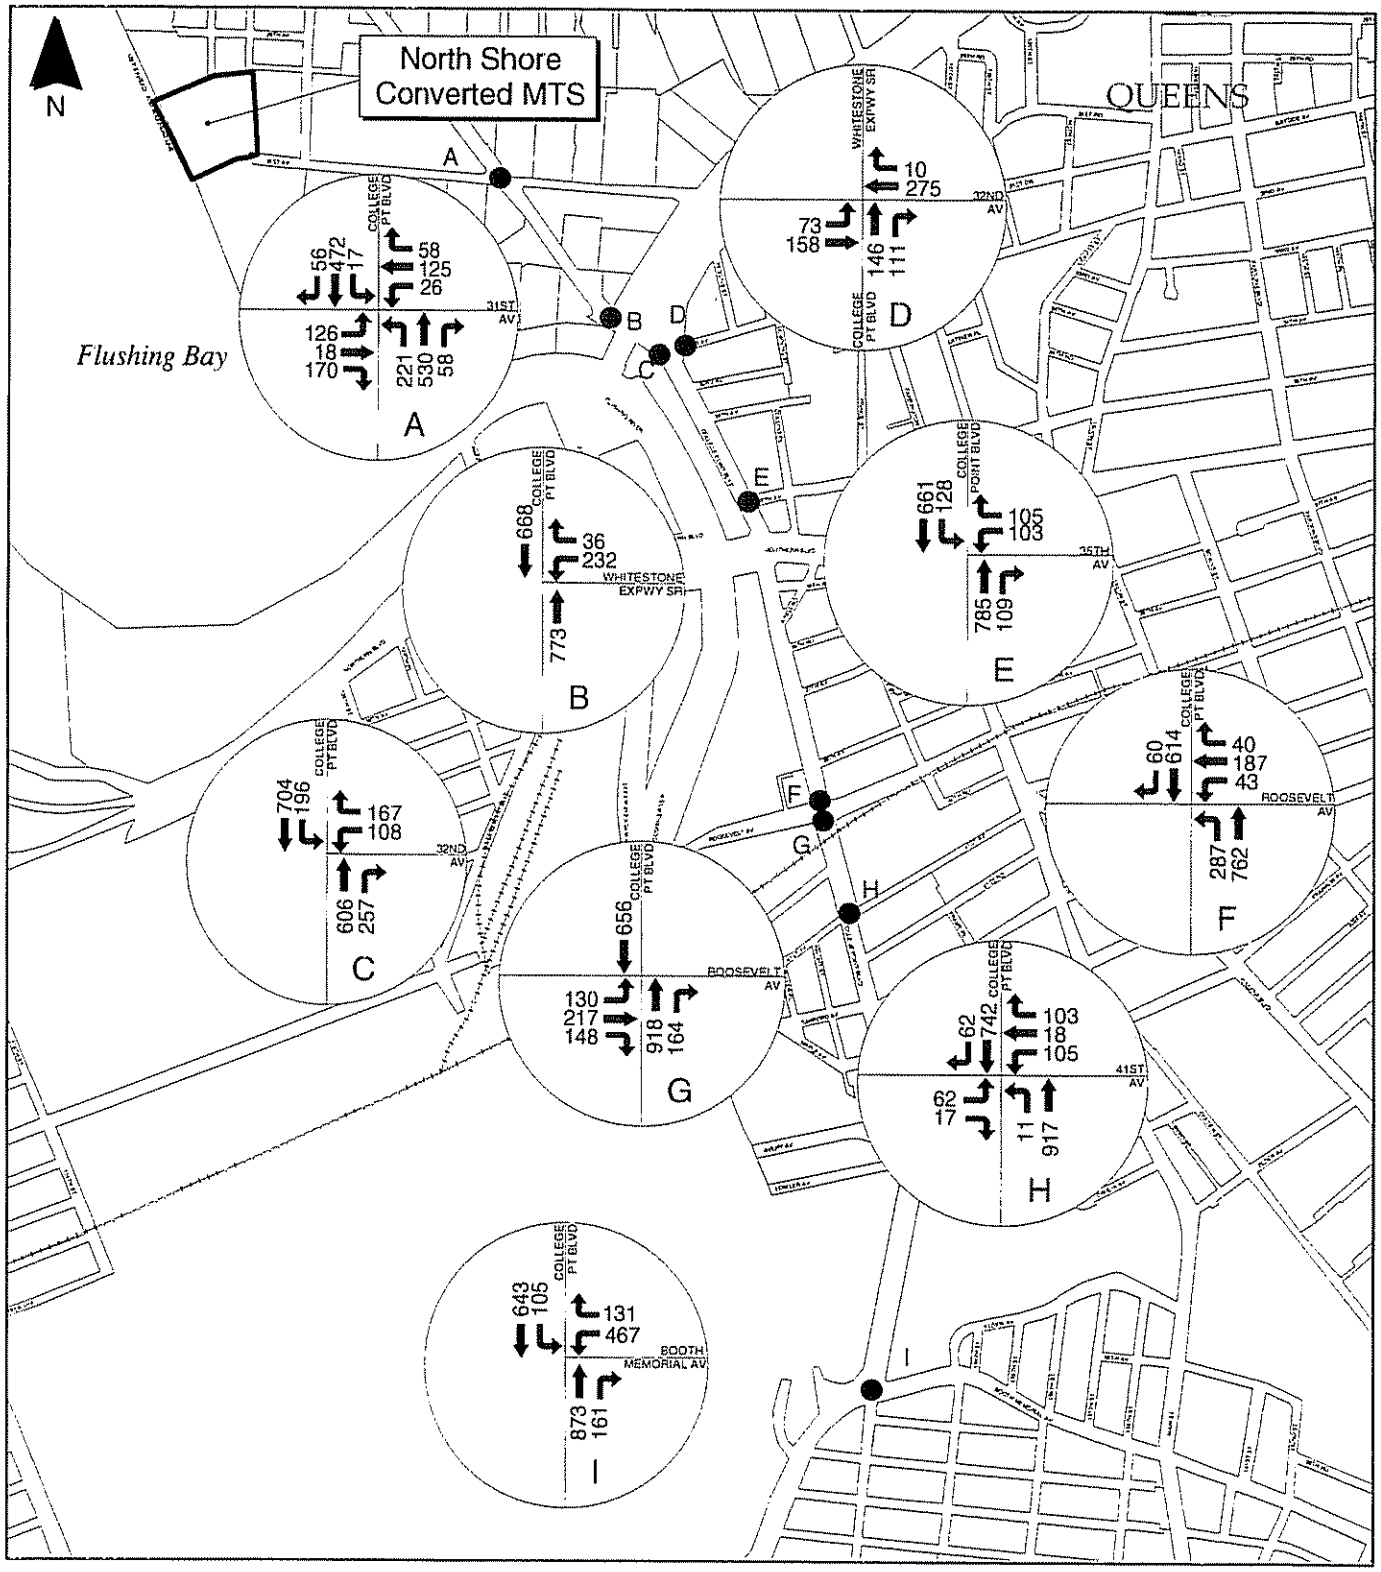
7.14.4 Potential Impacts with the North Shore Converted MTS



The North Shore Converted MTS would receive waste from nine CDs in Queens — QN 7 through QN 15. Additionally, the waste collected from Queens AFF and SHBLK operations would be delivered to the North Shore Converted MTS. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Additionally, employee trips to and from the site may result in traffic impacts during the AM peak hour.



7.14.4.1 2006 Future Build Traffic Conditions

The 2006 Future Build Traffic Conditions assume that the North Shore Converted MTS would generate 329 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site of the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the North Shore Converted MTS are shown in Figure 7.14-2.

Figure 7.14-9 presents the average peak day temporal distribution of collection vehicles for the North Shore Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the North Shore Converted MTS is expected to vary between approximately 1 to 25 truck trips per hour in the late evening/early morning, 10 to 38 truck trips per hour in the mid-morning/early afternoon, and 1 to 5 truck trips per hour in the late afternoon /early evening. The peak hourly number of collection vehicle truck trips (38) occurs at approximately 10:00 a.m. Figures 7.14-10, 7.14-11 and 7.14-12 depict the Future Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Figures 7.14-1~~1~~3, 7.14-14 and 7.14-15 depict the net future traffic volumes added to the Future No-Build Conditions to generate Future Build Conditions for AM, Facility, and PM peaks at the intersections analyzed.

Employee trips generated as a result of the North Shore Converted MTS are expected to be about 44 per shift (22 coming in and 22 leaving). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Therefore, during shift changes, employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m.

Because only the AM peak (7:30 a.m. – 8:30 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the North Shore Converted MTS during the shift change (44) were considered as part of the net increase in site-generated traffic. Figures 7.14-10, 7.14-11 and 7.14-12 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 7.14-13, 7.14-14 and 7.14-15 show the intersections analyzed with only the net increase in site-generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the North Shore Converted MTS. These projected net increases were routed through the intersections for each of the three peak hours. The highest net increase in trucks in the ingress or egress direction was 38. The highest net increase at any one intersection was 76 trucks. Both of these net increases occurred at the intersection of College Point Boulevard and 31st Avenue.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 86% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 64% of weekday traffic volumes. Table 7.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the North Shore Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 7.14-3
Weekday and Weekend Traffic
North Shore Converted MTS

DSNY and Other Agency Collection Vehicle Traffic		Background Traffic NB and SB on College Point Boulevard [1]	
Average Peak Day Trucks/Day	Saturday Trucks/Day	Weekday Average Vehicles/Day	Weekend Average Vehicles/Day
329	282	20,661	13,306

Note:
[1] NB and SB traffic data collected from ATR counts taken on College Point Boulevard between 31st Avenue and Whitestone Expressway Service Road from September 11 to 16, 2003.

Table 7.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the North Shore Converted MTS. Over an average peak day, the intersections should not experience an extended increase in delay. The two intersections that may experience potentially significant impacts are discussed in Section 7.14.4.2 and summarized in Table 7.14-5.

7.14.4.2 Impacts and Mitigation

Two of the nine intersections may experience impacts great enough to be considered significant during only one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines require mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below; their effectiveness is summarized in Table 7.14-5.

College Point Boulevard/31st Avenue – During the AM peak hour, a potential impact was identified on the eastbound left-turn/through/right turn lane group when the delay increased from 32.2 seconds to 37.8 seconds (LOS C deteriorated to LOS D). An increase in green time of one second for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract one second from the northbound and southbound approach green time. The southbound approach delay would increase by less than one second, the northbound approach delay would increase less than four seconds and the westbound approach delay would decrease by less than one second, compared to Future No-Build Conditions. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

LTR = left, through and right movements
DFL = defacto left
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
L = left movement
TR = through right movement
T = through movement
LR = left right movement

College Point Boulevard/Booth Memorial Avenue – During the AM peak hour, a potential impact was identified on the southbound defacto left lane group (LOS D) when the delay increased from 38.9 seconds to 45.1 seconds. An increase in the green time of one second for the southbound and northbound approaches should eliminate the delay increase. This mitigation measure decreases the westbound approach green time by one second. The westbound approach delay time would increase by approximately one second and the northbound and southbound approach delay times would decrease by less than one second compared to Future No-Build Conditions. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

In addition to the two intersections that may experience impacts, the 31st Avenue and site entrance/exit intersection may also require low-cost and easily implemented mitigation. Even though traffic operations at this intersection should not affect traffic significantly along 31st Avenue, some improvements near the intersection would need to be considered, such as restricting parking along 31st Avenue within the vicinity of the intersection to improve site distance at the site entrance/exit. In addition, a stop sign at the site exit would be beneficial. This mitigation should not generate any adverse impacts on other lane groups during any time periods.

Overall, the mitigation measures suggested would greatly enhance the intersection performance by reducing delays to LOSs similar to those under the Future No-Build Condition.

7.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

7.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

7.15 Air Quality

7.15.1 Definition of the Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the North Shore Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersections listed in Section 7.15.4.2.

7.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 7.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 7.15-1
Representative Ambient Air Quality Data
North Shore Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[1]	Queens College – 14439 Gravett Road	8-Hour	2,998 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	15,345 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	College Point Post Office	Annual	56 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}[2]	Greenpoint	Annual	23 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	51 $\mu g/m^3$	150 $\mu g/m^3$
SO_2[1]	Queens College – 14439 Gravett Road	3-Hour	134 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	103 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	18 $\mu g/m^3$	80 $\mu g/m^3$

Note:
Source: NYCDEP, April 2003 and USEPA Air data – Monitor Values Report (http://oaspub.epa.gov/airdata)
[1] Values are the highest pollutant levels recorded during the 2003 calendar year.
[2] Values are the highest pollutant levels recorded during the 1999 calendar year.

7.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build air quality conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effect may be offset by increases in regional traffic volumes.

7.15.4 Potential Impacts with the North Shore Converted MTS

7.15.4.1 On-Site Analysis

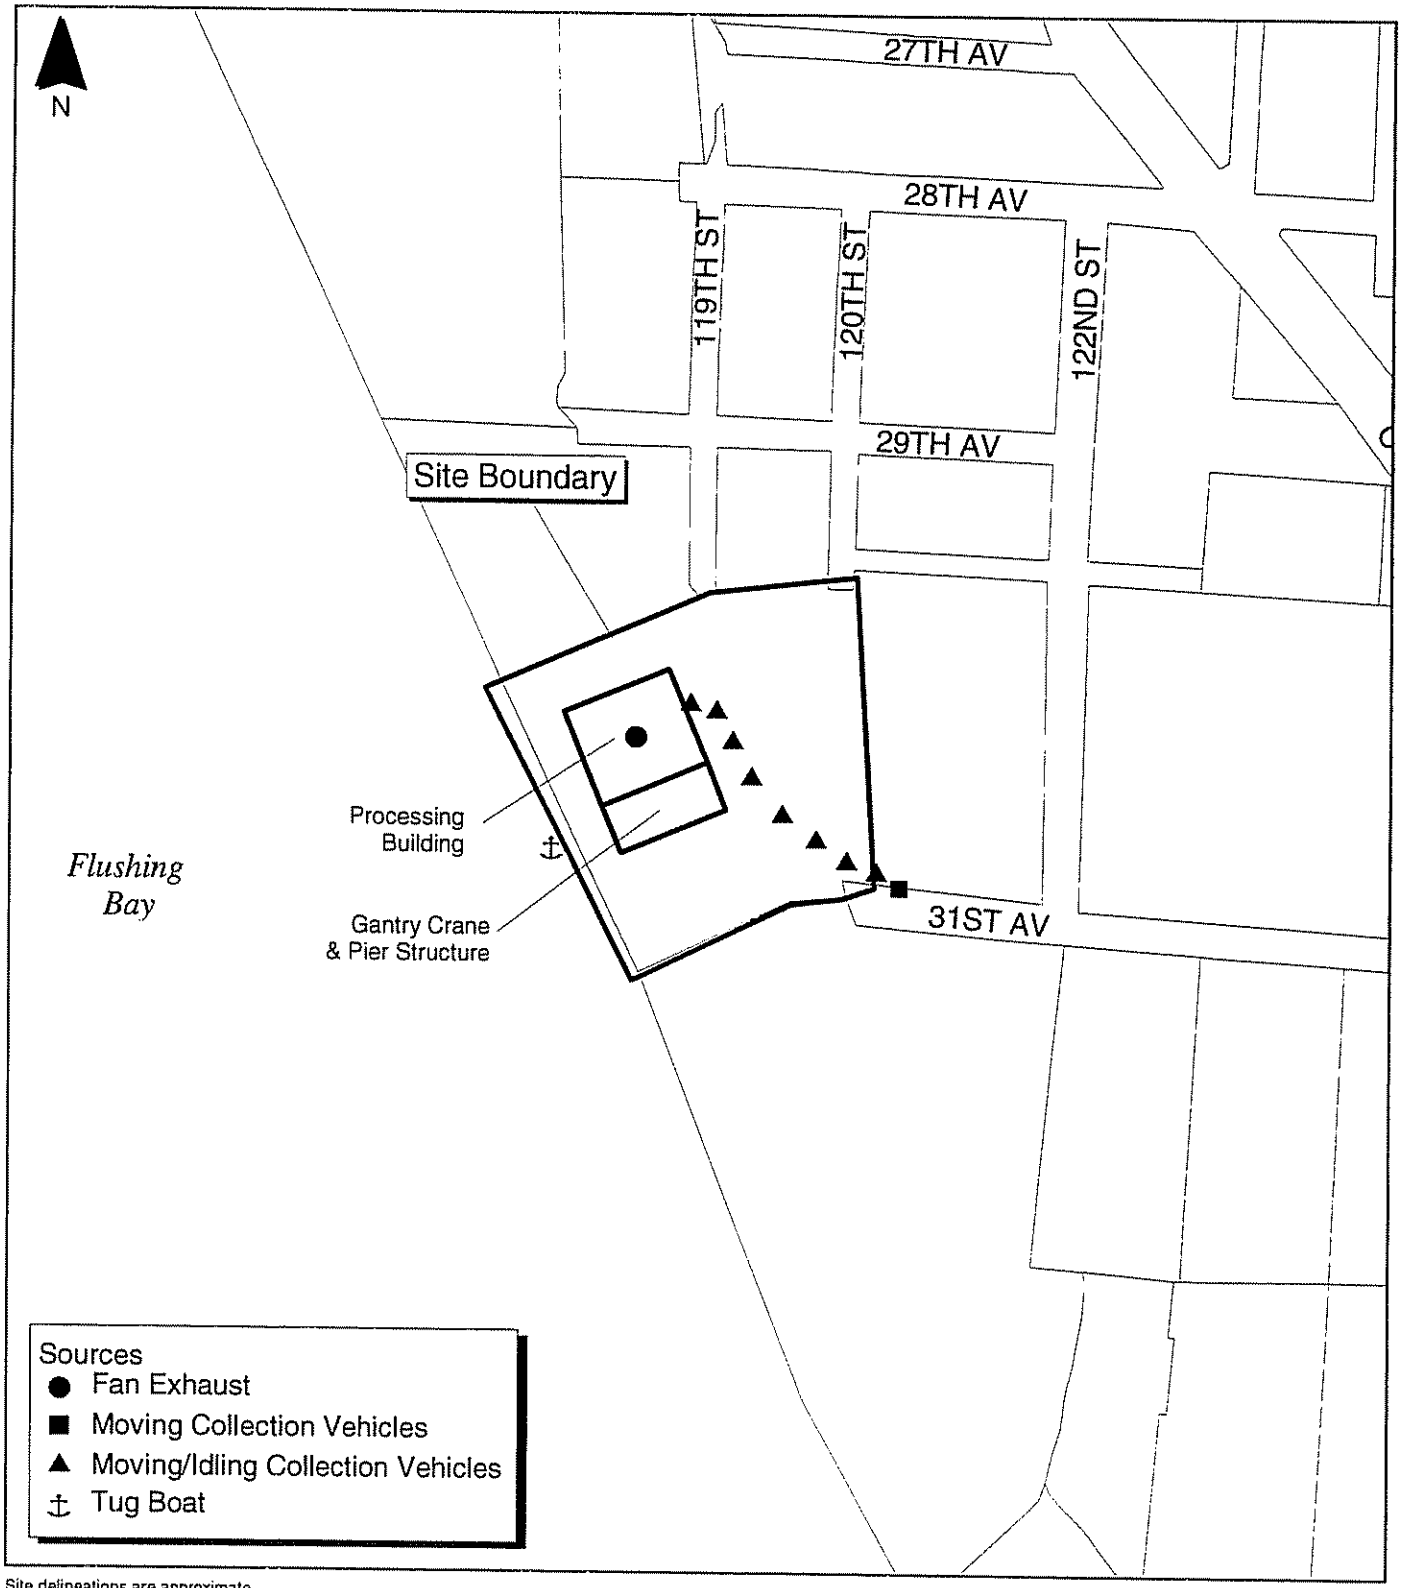
7.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 7.15-2. Figure 7.15-1 shows the locations of these sources within the site.

7.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 7.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from project-generated vehicles at any of the receptor locations considered, which are also presented in Table 7.15-3, are below the STVs. The North Shore Converted MTS would not, therefore, significantly impact air quality in the area.

Table 7.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
North Shore Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	46	18
Space Heaters	6	4
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3]	21 in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~to be provided upon request.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (one third of 21), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

Site delineations are approximate
Base Map Source: New York City Department of City Planning
Note: These are modeled source locations used in the on-site air quality analysis and do not represent individual collection vehicles

	Annual Neighborhood Average	~~0.020~~0.021[5]	NA	NA	NA	0.1
Sulfur Dioxide (SO_2), $\mu g/m^3$	3-hour[6]	36	186	222	1,300	NA
	24-hour[6]	3	107	110	365	NA
	Annual	0.3	18	18	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~ memorandum dated February 18, 2005.

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

7.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 7.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the North Shore Converted MTS are not considered to be significant.

7.15.4.2 Off-Site Analysis

7.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines that are outlined in Section 3.17. Following these guidelines, the following detailed mobile source analyses were conducted for the applicable (i.e., worst-case) time periods:

- An analysis of the intersections of College Point Boulevard at 31st Avenue, College Point Boulevard at Booth Memorial Avenue, and College Point Boulevard at 32nd Avenue and Whitestone Expressway Service Road, to determine whether North Shore Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 8-hour CO de minimus value or a violation of the 8-hour NAAQS;
- An analysis of the intersections of College Point Boulevard at 31st Avenue, College Point Boulevard at Booth Memorial Avenue, and College Point Boulevard at 32nd Avenue and Whitestone Expressway Service Road, to determine whether North Shore Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and
- An analysis of the intersections of College Point Boulevard at 31st Avenue, College Point Boulevard at Booth Memorial Avenue, and College Point Boulevard at 32nd Avenue and Whitestone Expressway Service Road, to determine whether North Shore Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 7.15-2.

Notes to Table 7.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC.

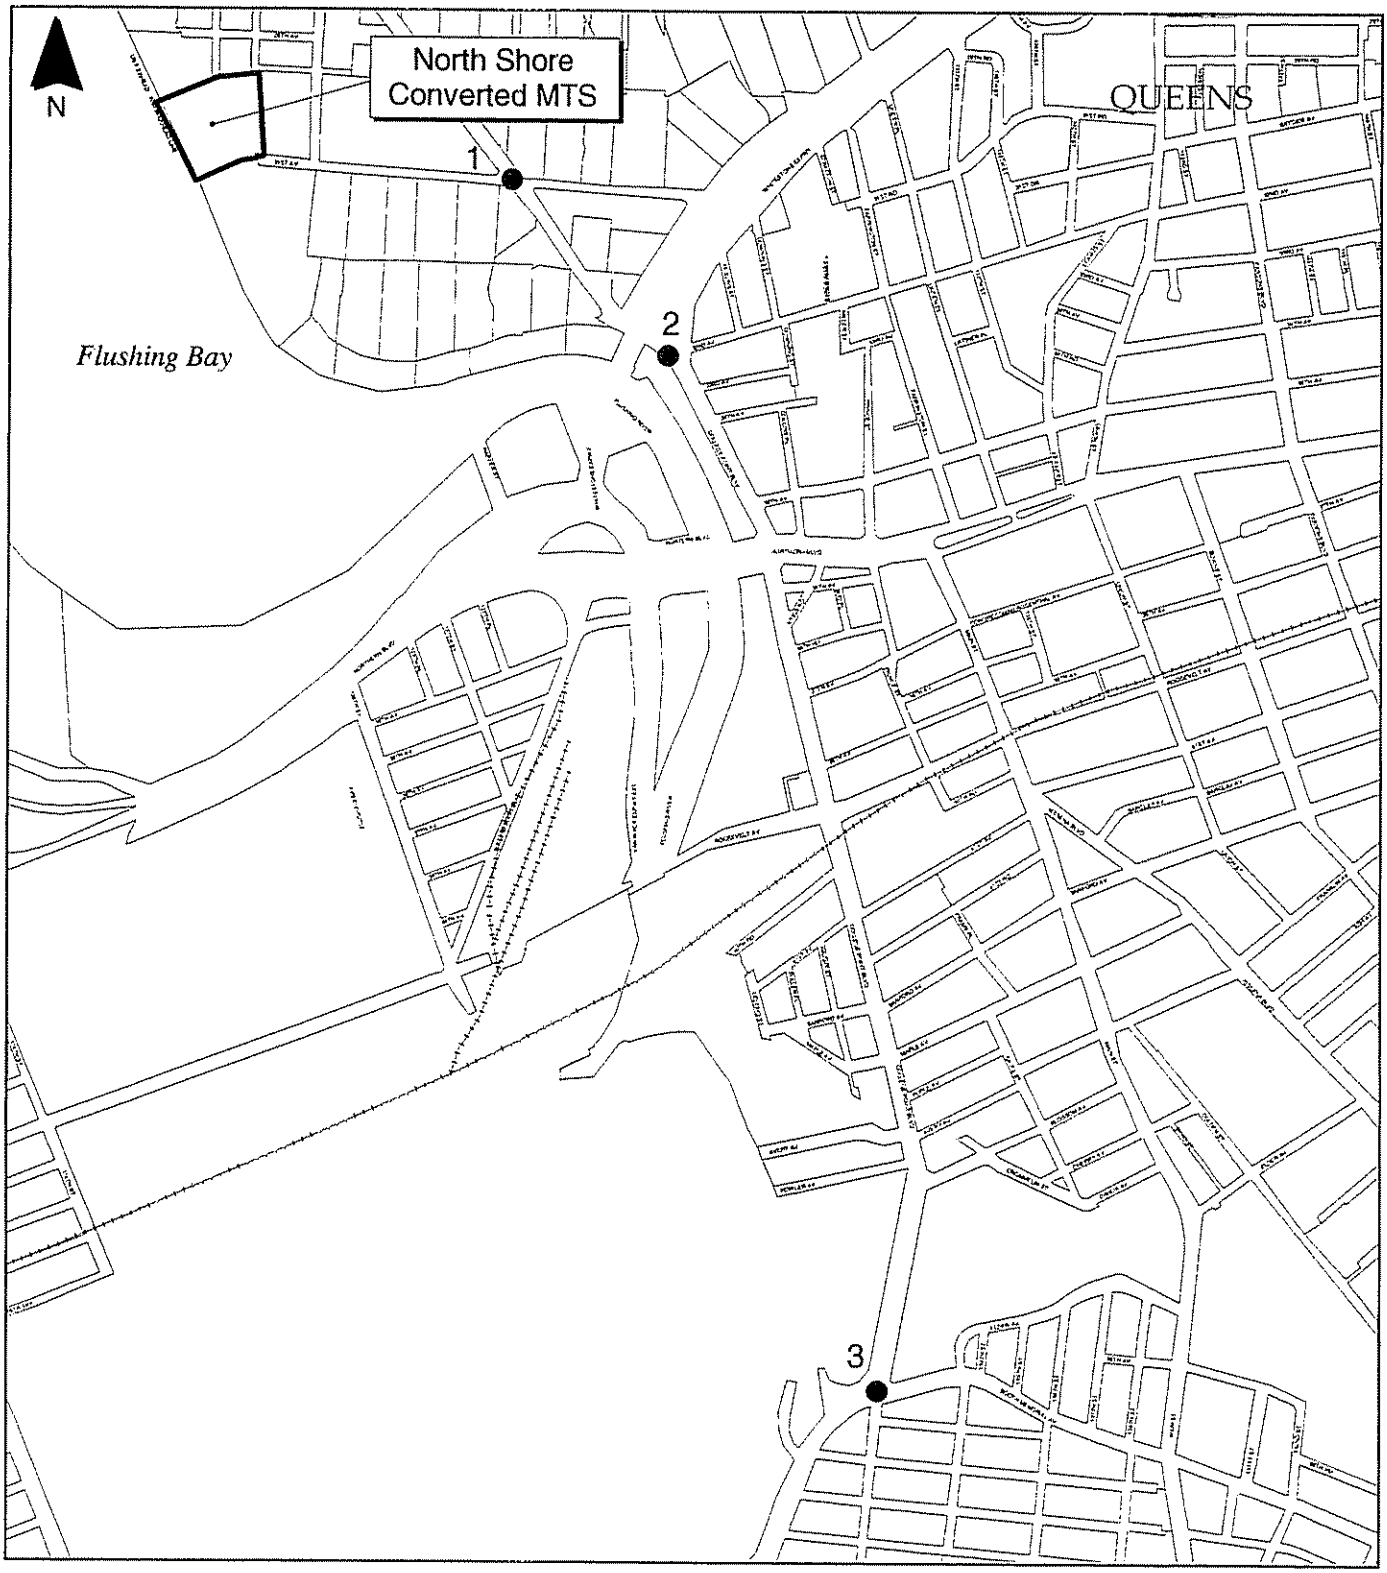
(3) Estimated by dividing the maximum 1-hr concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

7.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 7.15-5, are all within (less than) the applicable state and federal ambient air quality standards, STVs (for $PM_{2.5}$) and/or de minimus impact values (for CO). A Tier II analysis of the intersections at College Point Boulevard at 31st Avenue was necessary to determine the off-site annual impacts for $PM_{2.5}$. The results of this Tier II analysis are within the applicable annual STVs for $PM_{2.5}$. The off-site operations of the North Shore Converted MTS are not, therefore, considered to be significant.

Notes for Table 7.15-5:

(1) CO and PM_{10} concentrations are the maximum concentrations estimated using the AM, Facility, and PM peak traffic information plus background concentration (8-hr CO = 2.75 ppm; 24-hr PM_{10} = 57 $\mu g/m^3$; Annual PM_{10} = 23 $\mu g/m^3$).

(2) The maximum incremental concentrations of the on-site emissions at the intersection considered.

(3) The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced [or Future Build] traffic only) estimated by taking the difference between the maximum $PM_{2.5}$ concentrations for the Future No-Build and Future Build scenarios at any receptor three meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.

(4) The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced [or Future Build] traffic only) estimated by taking the difference between the maximum $PM_{2.5}$ concentrations for the Future No-Build and Future Build scenarios at any receptor 15 meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.

(5) Results determined by performing a TIER II analysis and averaging concentrations over the entire receptor network.

ppm = parts per million

$\mu g/m^3$ = microgram per cubic meter

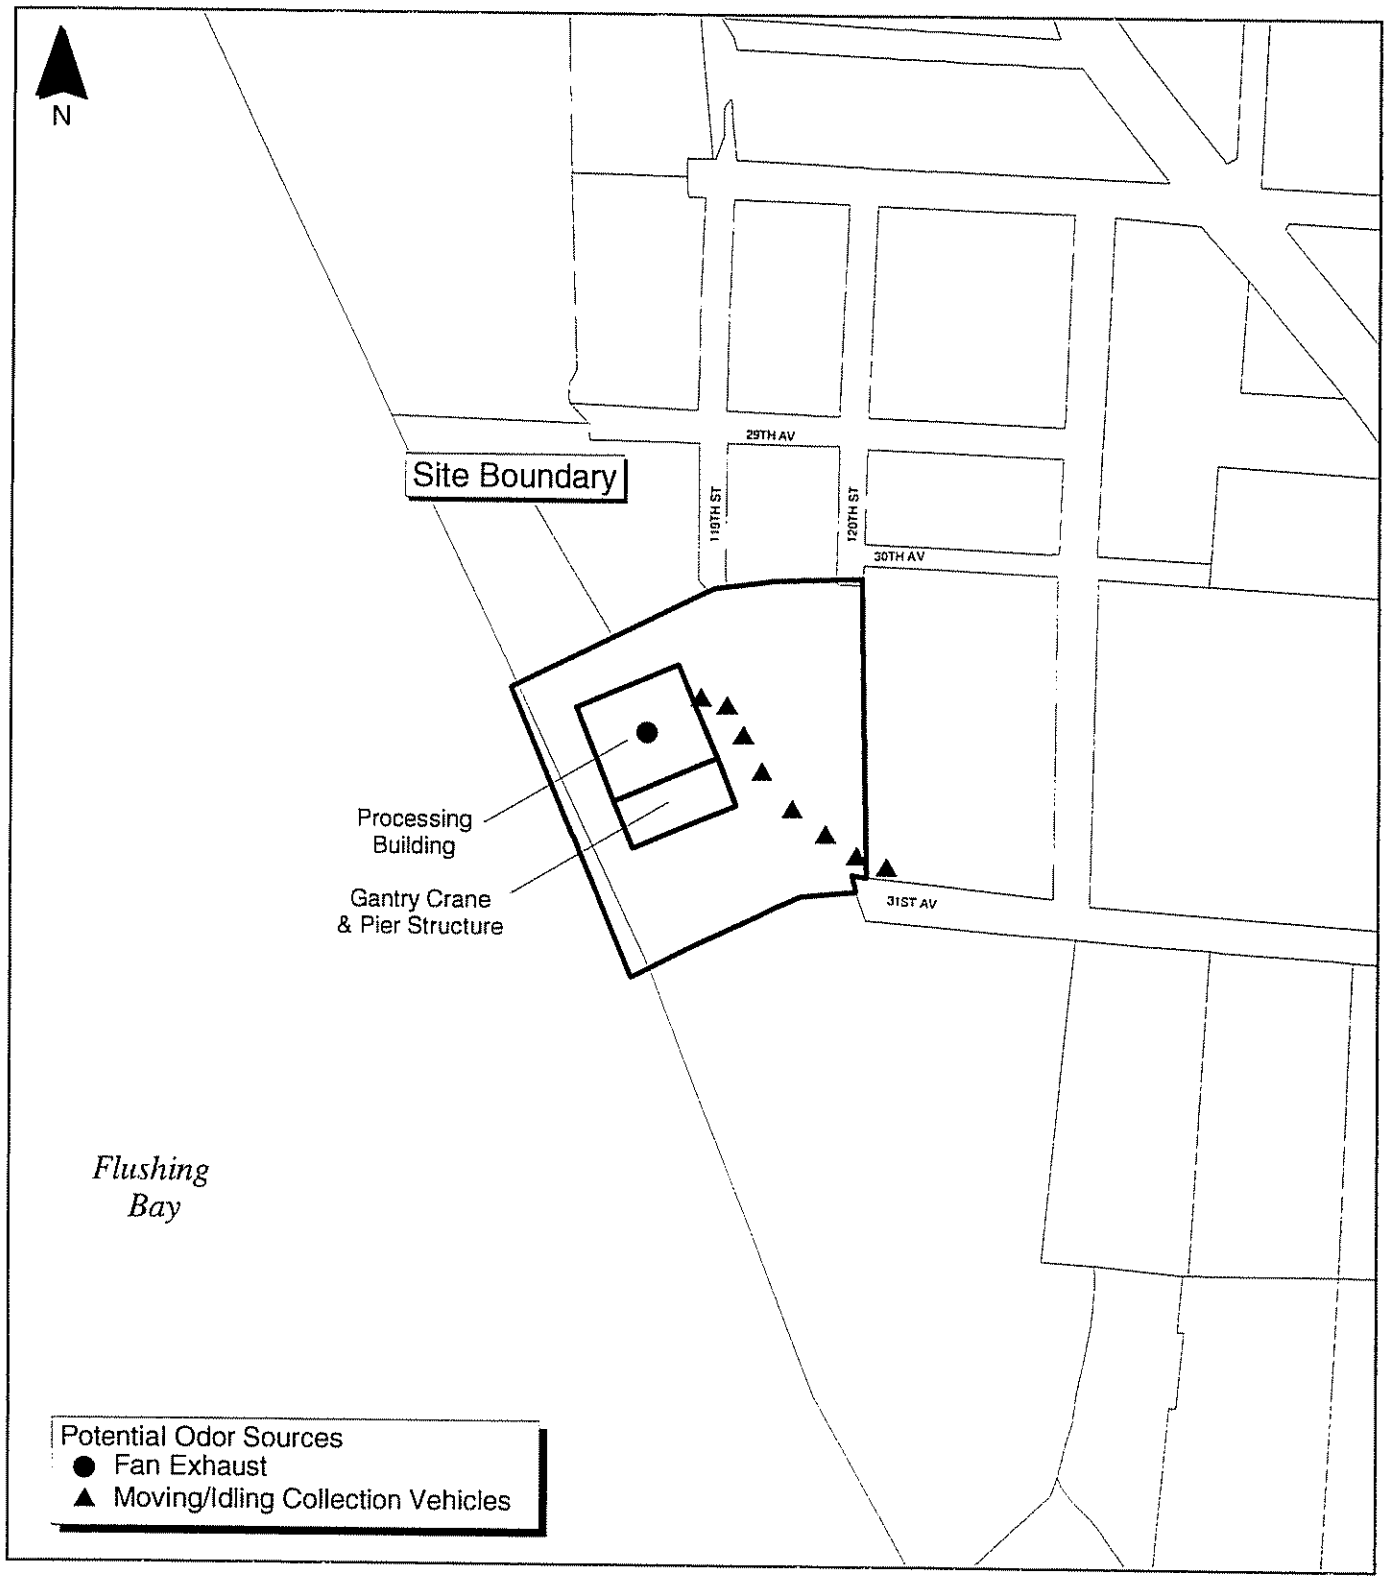
7.16 Odor

7.16.1 Existing Conditions

The existing MTS is not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is a residential house on 29th Avenue west of 119th Street, approximately ~~280~~ 301 feet from the site boundary.

7.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the North Shore Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



7.16.3 Potential Impacts with the North Shore Converted MTS

7.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the North Shore Converted MTS are provided in Table 7.16-1. Figure 7.16-1 shows the locations of these sources within the site.

Table 7.16-1
Odor Sources Included in Odor Analysis
North Shore Converted MTS

Figure 7.16-1 Potential Odor Sources

North Shore Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the North Shore Converted MTS.

7.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 7.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the North Shore Converted MTS at any nearby sensitive receptor is less than 1, so odors from the North Shore Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 7.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
North Shore Converted MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	~~0.42~~0.47
Type of Receptor	Discrete Receptor
Location of Receptor	Over Water
Closest Sensitive Receptor Result[2]	~~0.06~~0.086
Type of Receptor	Residential House
Distance to Receptor[2]	280 Feet

Notes:

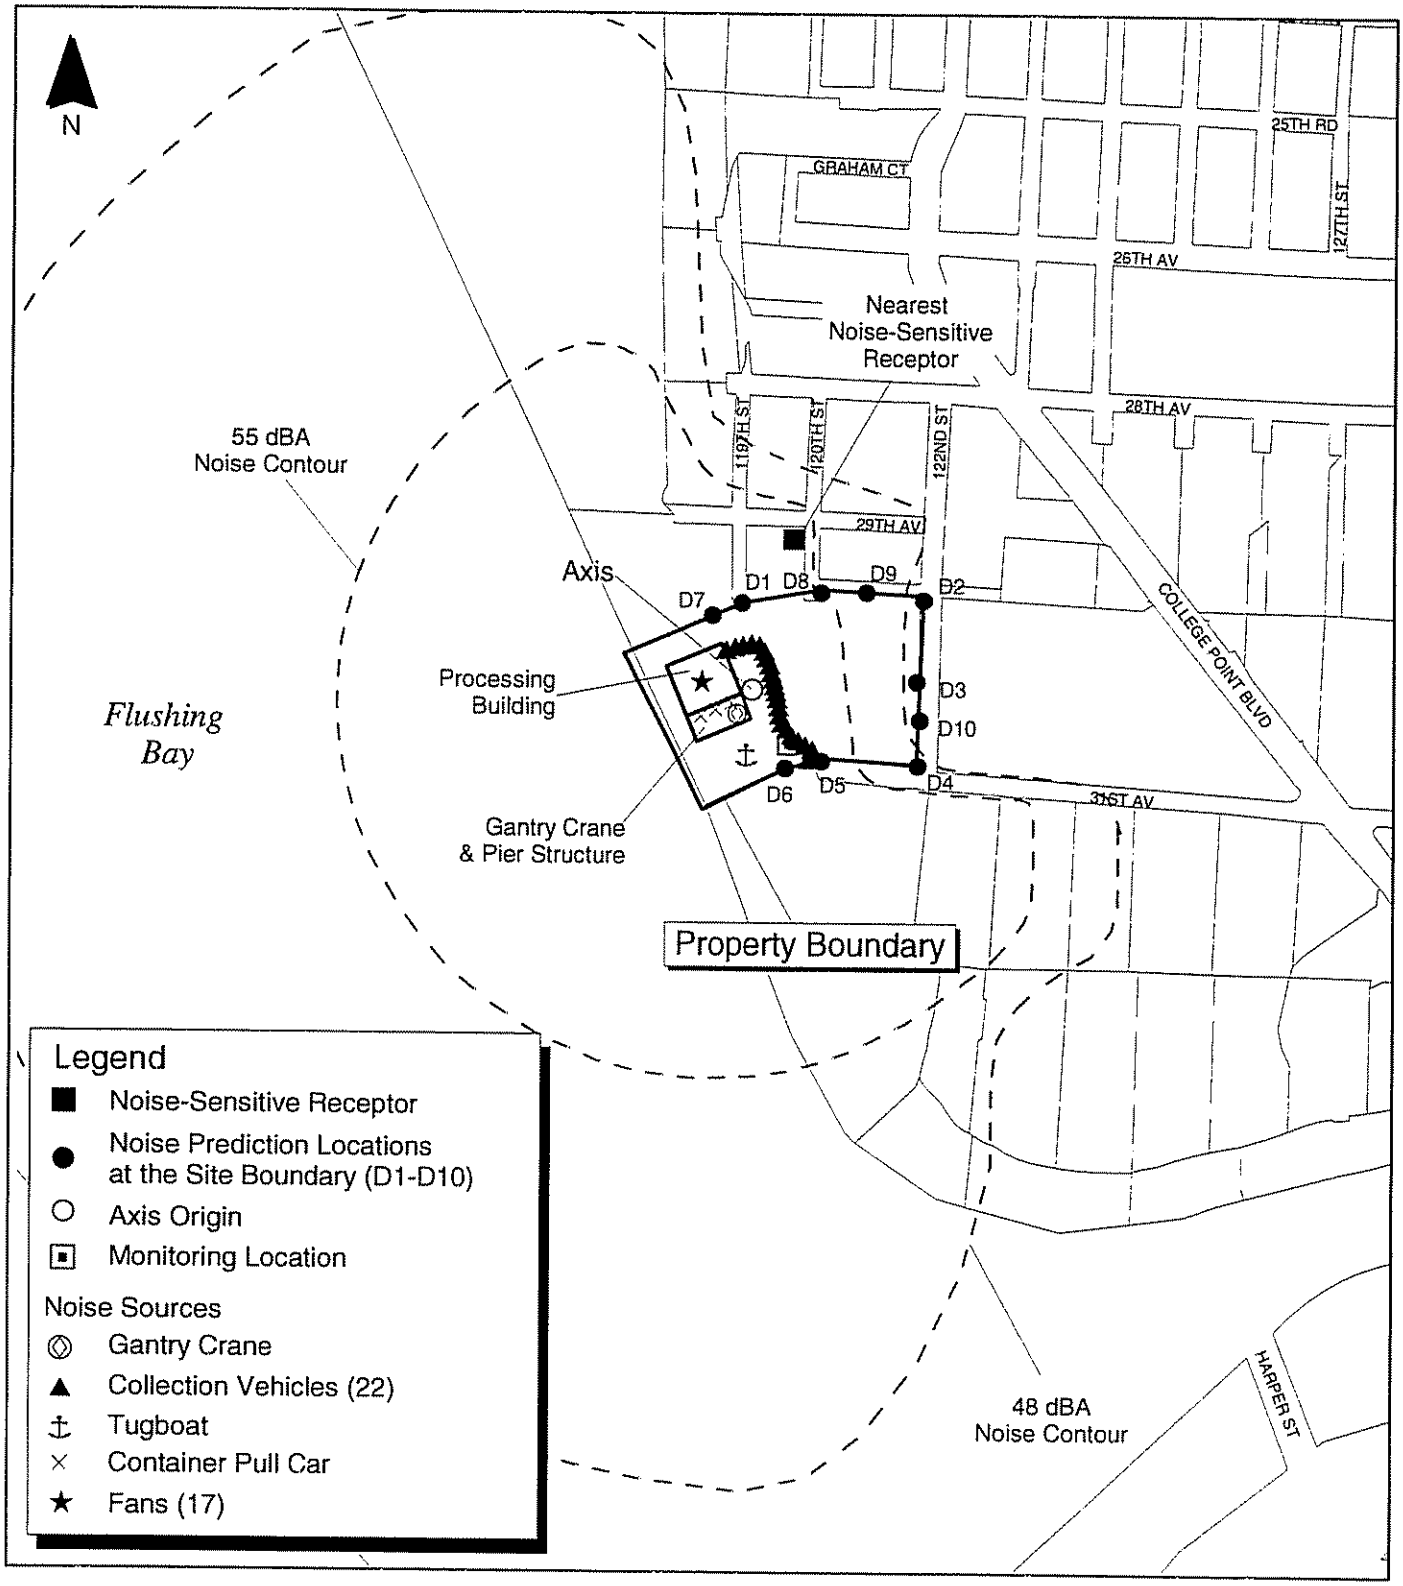
(1) Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.

(2) Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.

7.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from North Shore Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

7.17.1 Existing Conditions



7.17.1.1 Introduction

Figure 7.17-1 shows the location of the North Shore Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is a residential house on 29th Avenue west of 119th Street, approximately 92 meters (301 feet) from the North Shore Converted MTS property line. Additional residential areas exist immediately west and north of these residences.

7.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptor. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[12] and the statistical metrics of L_{10}, L_{50} and L_{90}.[13] Table 7.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 11:00 p.m. and 12:00 a.m. and had an $L_{eq(1)}$ of 57.0 dBA on January 9, 2003. Activities and events that contribute to the on-site noise levels are as follows:

[12] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[13] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

2:00-3:00 p.m.	65.8	57.7	61.2	69.5	54.8	85.8

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

- Airplanes, including jets, that arrive and depart from LaGuardia Airport regularly;
- A DSNY salt shed that is used during the winter; and
- An active DSNY garage that is used regularly.

7.17.1.3 Off-Site Noise Levels

Existing off-site noise sources consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if noise monitoring would be required along the North Shore Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required and, therefore, off-site noise monitoring was conducted. Table 7.17-2 presents monitored noise levels near noise-sensitive receptors during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) based on first-level screening.

Table 7.17-2
Existing Noise Levels (Leq) at the Nearest Noise-Sensitive Receptor for Off-Site Analysis
North Shore Converted MTS

Roadway ID	Existing Noise Levels During Quietest Hour (dBA)[1]
College Point Boulevard North of Roosevelt Avenue [2]	64.9
College Point Boulevard South of Sanford Avenue [3]	66.0

Notes:
(1) A 1-hour noise level reading was measured at the closest noise-sensitive receptor during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest).
(2) The existing noise level was measured on August 13, 2003 between 2:00 a.m. and 3:00 a.m.
(3) The existing noise level was measured on August 12, 2003 between 3:00 a.m. and 4:00 a.m.

7.17.2 Future No-Build Conditions

7.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build conditions are expected to be the same as Existing Conditions.

7.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 7.17-3 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 7.17-3
Off-Site Noise Traffic Volume
North Shore Converted MTS

Location	Hour Beginning	Existing Traffic Volume [1] (Vehicles / Hour)	Future No-Build Traffic Volume [2] (Vehicles / Hour)
College Point Boulevard North of Roosevelt Avenue	3:00 a.m.	111	116
College Point Boulevard North of Roosevelt Avenue	9:00 a.m.	1265	1317
College Point Boulevard South of Sanford Avenue	3:00 a.m.	144	150
College Point Boulevard South of Sanford Avenue	9:00 a.m.	1378	1434
College Point Boulevard between 58th and 57th Avenues	3:00 a.m.	299	311

Notes:
[1] Existing Traffic Volumes are based on ATR data.
[2] Future No-Build Traffic Volumes are based on CEQR Annual Traffic Growth Rates.

7.17.3 Potential Impacts with the North Shore Converted MTS

7.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the North Shore Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 7.17-4. The number and types of equipment assumed for this analysis were based on the North Shore Converted MTS's peak design capacity. As described in Section 3.19, an analysis was performed to determine if the number and type of trucks queuing on the ramp that was analyzed in the DEIS is more conservative than the greatest number of DSNY and Commercial Waste trucks expected to be queuing on the ramp based on the number of trucks that might be routed to the facility. The DEIS analysis was based on DSNY trucks queuing along the entire length of the ramp. For the North Shore Converted MTS, the analysis of the greatest number of DSNY and Commercial Waste trucks that will be expected to be queuing on the ramp (based on the number of trucks routed to the facility) is more conservative. Therefore, the results presented for the on-site analysis in this FEIS are based on the greatest number of DSNY and Commercial Waste trucks that are expected to be queuing on the ramp.

Spectral noise levels used in the Performance Standards analysis are shown in Table 7.17-5. The number and types of equipment assumed for this analysis were based on the North Shore Converted MTS's peak design capacity. Shown earlier, Figure 7.17-1 indicates the North Shore Converted MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 7.17-4
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
North Shore Converted MTS

Equipment Name (quantity) [1]	Reference Sound Pressure Noise Level at 50 feet (dBA) [2]

Harbor Tug Boat (1) [5]	69
Exhaust Fans (17)	76 [3]
Inbound Moving/Queuing DSNY Collection Vehicles (see Table 7.17-4(a))	67
Inbound Moving/Queuing Commercial Waste Collection Vehicles (see Table 7.17-4(a))	71.3
Outbound Moving/Queuing Collection Vehicle (1)	67 or 71.3 [6]

Notes:

(1) Instantaneous maximum number of pieces of equipment on site at any given time

(2) Noise level representative of each piece of equipment.

(3) Noise level representative of a total of 17 exhaust fans.

(4) Noise level will be specified for gantry crane in DSNY's plans and specification for construction of the Converted MTS's.

(5) Noise level will be specified for the harbor tug boat in DSNY's plans and specification for construction of the Converted MTS's.

(6) For each hour, the type of truck assumed to be queuing on the outbound scale varied depending on the type of trucks entering the facility. If both DSNY and Commercial Waste trucks enter the facility, the outbound truck was assumed to be a Commercial Waste truck, to be conservative. However, if only DSNY trucks enter the facility, the outbound truck was assumed to be a DSNY truck. Similarly, if only Commercial Waste trucks enter the facility, the outbound truck was assumed to be a Commercial Waste truck. If a Commercial Waste truck was assumed, 71.3 dBA was used as a noise level. If a DSNY truck was assumed, 67 dBA was used as a noise level.

K = Thousand

7.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the North Shore Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 104 meters (340 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is 92 meters (301 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on-site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the

screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (see Figure 7.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 7.17-1 above. A detailed noise analysis was performed to calculate the ~~Table 7.17-6 below identifies the existing background noise level during the quietest hour. The table shows the distance from the North Shore Converted MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor,~~ North Shore Converted MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both North Shore Converted MTS noise and background noise combined. ~~The table also provides the~~ The difference between this combined noise level and the existing noise level at the noise-sensitive receptor. ~~This difference~~ represents the predicted incremental change in noise level from the North Shore Converted MTS. ~~Because this incremental change is not greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, there is no predicted impact that would be caused by the North Shore Converted MTS on-site operations.~~ According to CEQR, an increase of 3 dBA or more at nighttime is considered an impact. In addition, if the daytime background noise level is 62 dBA or more, an increase of 3 dBA or more is considered an impact. Because this incremental change is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor for the quietest nighttime hour, there is a predicted impact that would be caused by the North Shore Converted MTS on-site operations based on this conservative analysis.

On-site queuing collection vehicles were further analyzed to refine the calculated noise levels from the North Shore Converted MTS facility truck ramp on the noise sensitive receptors. Individual, position-specific utilization factors were assigned to each inbound collection vehicle position on the inbound side of the ramp, and to one collection vehicle position on the outbound scale based on the processing time at the North Shore Converted MTS. The utilization factor for each truck was calculated on a 24-hour basis, for each hour, based on the actual number of inbound collection vehicles. The assumption was made that each inbound truck would be queuing on-site for approximately two minutes before proceeding one truck length further up the

ramp towards the facility. The actual number of DSNY and Commercial collection vehicles used in the hourly analysis is shown in Table 7.17-4(a). A restriction on the number of relayed DSNY collection vehicles delivering waste between 1:00 a.m. and 5:00 a.m.; and commercial waste hauling vehicles at certain hours between 8:00 p.m. and 8:00 a.m. will mitigate predicted on-site impacts at nearby noise sensitive receptors.

Table 7.17-6 below shows the results of the CEQR analysis with a refined hourly analysis at the Residential House. An analysis could not be performed for the hours of 7:00 a.m. to 5:00 p.m. due to construction activities adjacent to the noise-sensitive receptor. The Table includes the existing noise level at the noise-sensitive receptor, the North Shore Converted MTS-related noise levels and the combined noise level. The table also provides the difference between this combined noise level and the existing noise level at the sensitive receptor. This difference represents the predicted incremental change in noise level from the North Shore Converted MTS. Because this incremental change is less than the CEQR threshold of 3 dBA during nighttime hours, or during daytime hours when the daytime background noise level is greater than 62 dBA, there is no predicted impact that would be caused by the North Shore Converted MTS on-site operations.

7.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points along the North Shore Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (assuming ~~tugboats~~ both are transportation facilities) (see Table 7.17-7). Based on this analysis, no exceedances to the Performance Standards are predicted.

Table 7.17-6

Existing and Predicted Noise Levels (L_{eq}) at the Residential House Noise-Sensitive Receptor
North Shore Converted MTS

Hour Beginning[1]	Existing Noise Levels During Quietest Hour (dBA) [2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA) [3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Level (dBA)	Impact (yes or no) [4]
12:00 AM	52.3	51.8	55.1	2.8	No
1:00 AM	53	52.7	55.9	2.9	No
2:00 AM	48.1	47.6	50.9	2.8	No
3:00 AM	50.1	49.8	52.9	2.8	No
4:00 AM	49.7	49.2	52.5	2.8	No
5:00 AM	51.8	50.8	54.4	2.6	No
6:00 AM	62.2	52.1	62.6	0.4	No
5:00 PM	62.3	50.8	62.6	0.3	No
6:00 PM	63.5	49.8	63.7	0.2	No
7:00 PM	60.7	49.2	61.0	0.3	No
8:00 PM	61	60.8	63.9	2.9	No
9:00 PM	60.9	60.3	63.6	2.7	No
10:00 PM	59.4	59.1	62.3	2.9	No
11:00 PM	55.5	50.8	56.8	1.3	No

Notes:

(1) Existing noise levels could not be measured between 7:00a.m. and 5:00 p.m. due to construction activities adjacent to the noise-sensitive receptor.

(2) Twenty-minute noise level readings measured at the residential house receptor on March 14-15, 2005.

(3) Predicted noise level calculations at the noise-sensitive receptor include on-site and off-site shielding from structures including a louver fence.

(4) According to CEQR, an increase over 65 dBA at daytime is considered an impact. However, if the existing noise level at the receptor during the daytime is 62 dBA or greater or if the analysis is for a nighttime hour, an increase over 3 dBA would be considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the North Shore Converted MTS with the quietest background noise levels that occur during facility operation.

(1) D1 through D10 are the points on the North Shore Converted MTS boundary that are used in all noise analyses.

7.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the North Shore Converted MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. The overall noise predictions were based on the refined queuing analysis as well as a louver fence that will be placed on the truck ramp. The louver fence will be approximately 9 feet in height and will be constructed on top of a 3-foot high concrete base, for a total height of 12 feet. The louver fence will provide a noise reduction of approximately 7dBA for receptors adjacent to the property boundary. ~~This is~~Results are shown in Table 7.17-8. Based on this analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 7.17-8
Current Noise Code Analysis
North Shore Converted MTS

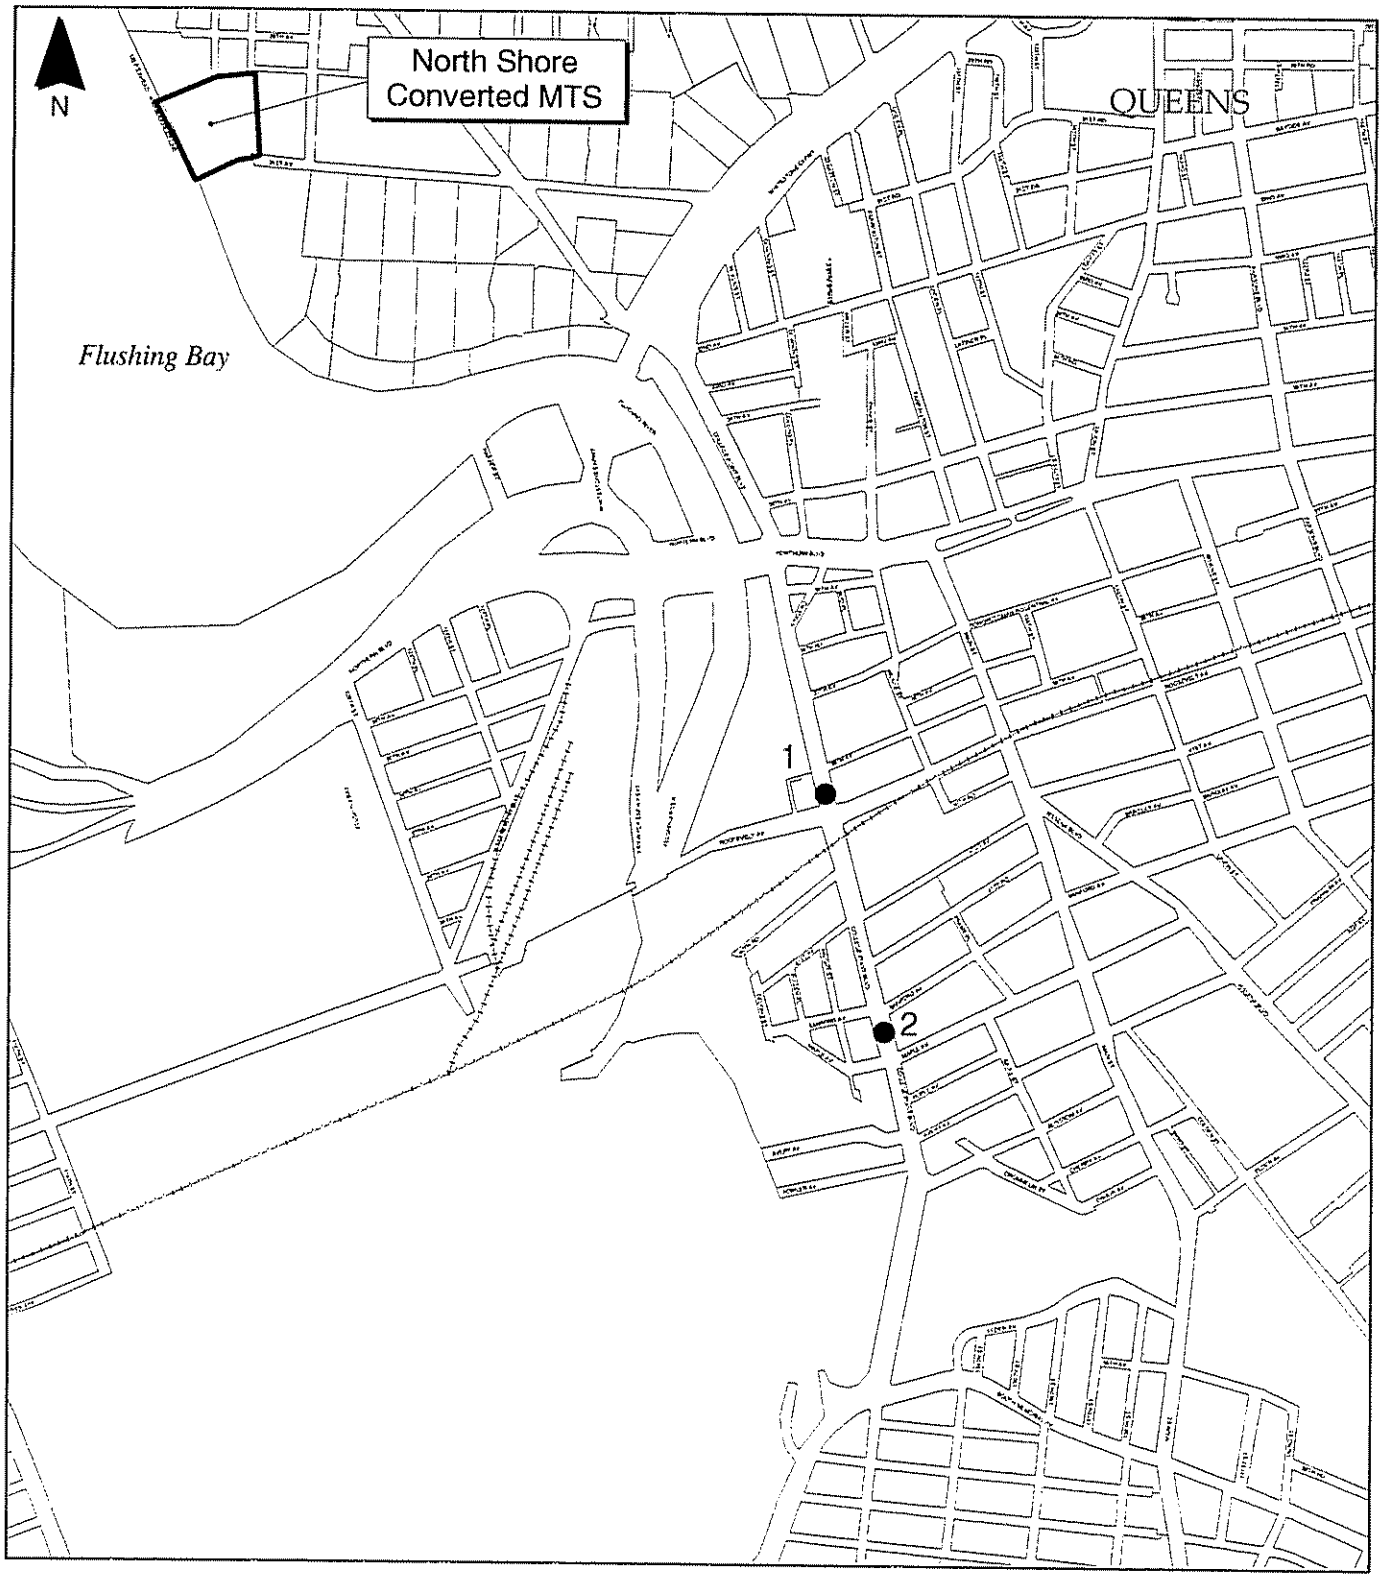
Notes:
[1] D1 through D10 are points on the North Shore Converted MTS boundary that are used in all noise analysis.

7.17.3.5 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the North Shore Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 7.17-9.

Because the screening results presented above showed that the PCEs would double on a roadway due to DSNY and other agency collection vehicles ~~coming~~ traveling to or ~~going~~ departing from the North Shore Converted MTS, a detailed off-site noise analysis was performed at that roadway using TNM for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime. Figure 7.17-2 depicts the locations of the roadway where detailed off-site noise analysis was performed.

Table 7.17-9
Off-Site Noise Screening Results
North Shore Converted MTS



Location	Hour Beginning	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
College Point Boulevard North of Roosevelt Avenue	3:00 a.m.	305	26	0	1,222	1,527	Yes
College Point Boulevard North of Roosevelt Avenue	9:00 a.m.	4,078	43	0	2,021	6,099	No
College Point Boulevard South of Sanford Avenue	3:00 a.m.	220	26	0	1,222	1,442	Yes
College Point Boulevard South of Sanford Avenue	9:00 a.m.	5,049	46	0	2,162	7,211	No
College Point Boulevard between 58th and 57th Avenues	3:00 a.m.	2,075	26	0	1,222	3,298	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include North Shore Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

Site delineations are approximate

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

TNM results for locations/hours that resulted in an impact based on second-level screening are presented in Appendix E of this FDEIS. Because the incremental noise-level change, which is calculated by obtaining the difference between the TNM-predicted Future Build noise level and the TNM-predicted Future No-Build noise level, is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, an impact at these roadways would be caused by the North Shore Converted MTS-related collection and employee vehicles.

To determine if these TNM-predicted impacts were accurate, site-specific truck simulations were conducted at the noise sensitive receptors. The truck simulation analysis provides a more realistic determination of DSNY and other agency collection vehicle noise impacts based on the proposed number of DSNY and other agency collection vehicles expected to travel through the roadways analyzed during the nighttime hours. Truck simulations were conducted with DSNY collection vehicles, as described in Section 3.19.7.2, for each roadway and hour that the first-level screening analysis resulted in a possible impact. For this procedure, two sets of noise measurements were taken – one with and one without DSNY trucks – by routing a set number of DSNY trucks during the affected nighttime hours past the noise-sensitive receptor. Tables 7.17-10 and 7.17-11 contain the results of the site-specific DSNY collection vehicle simulations, which show a possible impact at College Point Boulevard, north of Roosevelt, during the hours of 1:00 a.m. to 3:00 a.m., and at College Point Boulevard, south of Sanford Avenue, during the hours of 3:00 a.m. to 5:00 a.m.

A comparison of the simulation results for the hours resulting in an impact and the TNM results for these hours for the same traffic conditions and background noise levels estimated from recordings during the simulations is provided in Appendix E of this FDEIS. Based on this comparison, it is determined that TNM over-predicted the incremental change. The over-prediction can be attributed to the default assigned noise level for each type of vehicle, which appears to be greater than the actual noise levels that would be emitted by the North Shore Converted MTS-related collection vehicles.

Table 7.17-10
Off-Site Noise Analysis Truck Simulation
College Point Boulevard – North of Roosevelt Avenue
North Shore Converted MTS

Hour Beginning	Existing Background Noise Level[1] (L_{eq}) (Estimated) (dBA)	Collection Vehicles	Truck Simulation[2] Noise Level (L_{eq}) for Existing Traffic plus Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
12:00 a.m.	65.5	11	67.5	No (2)
1:00 a.m.	65.7	31	69.3	Yes (3.6)
2:00 a.m.	64.9	22	68.0	Yes (3.1)
3:00 a.m.	67.0	26	69.4	No (2.4)
4:00 a.m.	67.7	24	69.5	No (1.8)
5:00 a.m.	68.2	21	69.6	No (1.4)

Notes:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Simulations performed on August 13, 2003.

Table 7.17-11
Off-Site Noise Analysis Truck Simulation
College Point Boulevard – South of Sanford Avenue
North Shore Converted MTS

Hour Beginning	Existing Background Noise Level[1] (L_{eq}) (Estimated) (dBA)	Collection Vehicles	Truck Simulation[2] Noise Level (L_{eq}) for Existing Traffic plus Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
1:00 a.m.	69.9	31	72.2	No (2.3)
2:00 a.m.	71.0	22	72.3	No (1.3)
3:00 a.m.	66.0	26	69.9	Yes (3.9)
4:00 a.m.	67.3	24	70.5	Yes (3.2)
5:00 a.m.	70.8	21	71.9	No (1.1)

Notes:

(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.

(2) Simulations performed on August 12, 2003.

Because both TNM and the site-specific truck simulations predict an impact at a noise-sensitive receptor from 1:00 a.m. to 3:00 a.m. for the College Point Boulevard – North of Roosevelt Avenue location, and from 3:00 a.m. to 5:00 a.m. for the College Point Boulevard – South of Sanford Avenue location, adjustments were made to the truck routes to the North Shore Converted MTS. During these hours, ~~North Shore Converted MTS related~~DSNY collection vehicles en route to the North Shore Converted MTS from Queens CD 9 would be routed further on the Van Wyck Expressway to Exit 14, Linden Place, rather than the originally proposed route of the Van Wyck Expressway or LIE to College Point Boulevard, thus avoiding the locations predicted to have an impact. However, during these hours, ~~North Shore Converted MTS related~~DSNY collection vehicles leaving the MTS would continue to be routed along College Point Boulevard to either the LIE or Van Wyck Expressway.

Both locations were re-analyzed with the truck adjustments during these hours using the site-specific truck acoustic energy per hour as described in Section 3.19.7.2 to confirm that off-site noise impacts would not be caused by the reduced number of collection vehicles at these locations. Based on these results, with the re-routed ~~North Shore Converted MTS related~~DSNY collection vehicles, there is no predicted impact that would be caused by the ~~North Shore Converted MTS~~DSNY collection vehicles en route to and from the facility. Tables 7.17-12 and 7.17-13 show the results of this analysis.

7.17.3.6 Combined On-Site and Off-Site Noise Levels

On- and off-site noise analyses were performed for the North Shore Converted MTS, however the potential impacts of these analyses did not affect the same noise-sensitive receptor~~s~~. Therefore, a combined noise analysis was not performed.

Table 7.17-12
Off-Site Noise Analysis using Truck Simulation Data and Adjusted Collection Vehicles
College Point Boulevard – North of Roosevelt Avenue
North Shore Converted MTS

Hour	Existing Background Noise Level[1] (L_{eq}) (Estimated) (dBA)	Adjusted Collection Vehicles based on Linden Exit	Calculated[2] Noise Level (L_{eq}) for Existing Traffic plus Adjusted Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
1:00 a.m.	65.7	14	67.7	No (2.0)
2:00 a.m.	64.9	8	66.3	No (1.4)
3:00 a.m.	67.0	12	68.3	No (1.3)
4:00 a.m.	67.7	11	68.6	No (0.9)

Notes:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Noise levels for existing traffic plus adjusted collection vehicles were calculated utilizing the per truck acoustic energy determined from the truck simulation data for this location.

Table 7.17-13
Off-Site Noise Analysis using Truck Simulation Data and Adjusted Collection Vehicles
College Point Boulevard – South of Sanford Avenue
North Shore Converted MTS

Hour	Existing Background Noise Level[1] (L_{eq}) (Estimated) (dBA)	Adjusted Collection Vehicles based on Linden Exit	Calculated[2] Noise Level (L_{eq}) for Existing Traffic plus Adjusted Collection Vehicles (dBA)	Impact (Noise Level Difference) (dBA)
1:00 a.m.	69.9	14	71.1	No (1.2)
2:00 a.m.	71.0	8	71.5	No (0.5)
3:00 a.m.	66.0	12	68.2	No (2.2)
4:00 a.m.	67.3	11	69.1	No (1.8)

Notes:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Noise levels for existing traffic plus adjusted collection vehicles were calculated utilizing the per truck acoustic energy determined from the truck simulation data for this location.

7.18 Commercial Waste to the North Shore Converted MTS

7.18.1 Existing Conditions

No commercial waste is delivered to the North Shore MTS site under Existing Conditions. Commercial waste generated in Queens is delivered to privately owned and operated transfer stations in the City, or taken directly out of the City to remote disposal locations.

7.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the North Shore Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

7.18.3 Potential Impacts of Sending Commercial Waste to the North Shore Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

7.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the North Shore Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 7.15, 7.16 and 7.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

7.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the North Shore Converted MTS were evaluated in Sections 7.14, 7.15 and 7.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 7.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 39 (inbound trip ends) per hour, which occurred during the AM peak. These 39 DSNY and other agency collection vehicles are also more than the 26 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the North Shore Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 39 DSNY and other collection agency vehicle trip ends at the North Shore Converted MTS. Therefore, the addition of the 26 DSNY and other agency collection vehicles and commercial waste hauling vehicle inbound trip ends at the North Shore Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 39 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 39 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24-hour period. Results showed there would be no unmitigatible significant adverse environmental impacts at several analyzed intersections. Consequently, because the 26 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can travel through these intersections per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

For the intersection of College Point Boulevard and 31st Avenue, a Tier II analysis was required. The estimated actual hourly distribution over 24 hours included the estimated 26 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that could potentially be processed at the North Shore Converted MTS, and no unmitigatible significant adverse environmental impacts were identified.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the North Shore Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 1,000 tons (or 95 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

This page intentionally left blank.

CHAPTER 8 ENVIRONMENTAL REVIEW: 52ND STREET BARGE STAGING AREA

8.1 Introduction

The results of the environmental analyses of the 52nd Street Barge Staging Area are presented in the following sections:

8.2 Land Use, Zoning, and Public Policy
8.3 Socioeconomic Conditions
8.4 Community Facilities and Services
8.5 Open Space
8.6 Cultural Resources
8.7 Urban Design, Visual Resources, and Shadows
8.8 Neighborhood Character
8.9 Natural Resources
8.10 Hazardous Materials
8.11 Water Quality
8.12 Waterfront Revitalization Program
8.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
8.14 Traffic, Parking, Transit, and Pedestrians
8.15 Air Quality
8.16 Odor
8.17 Noise

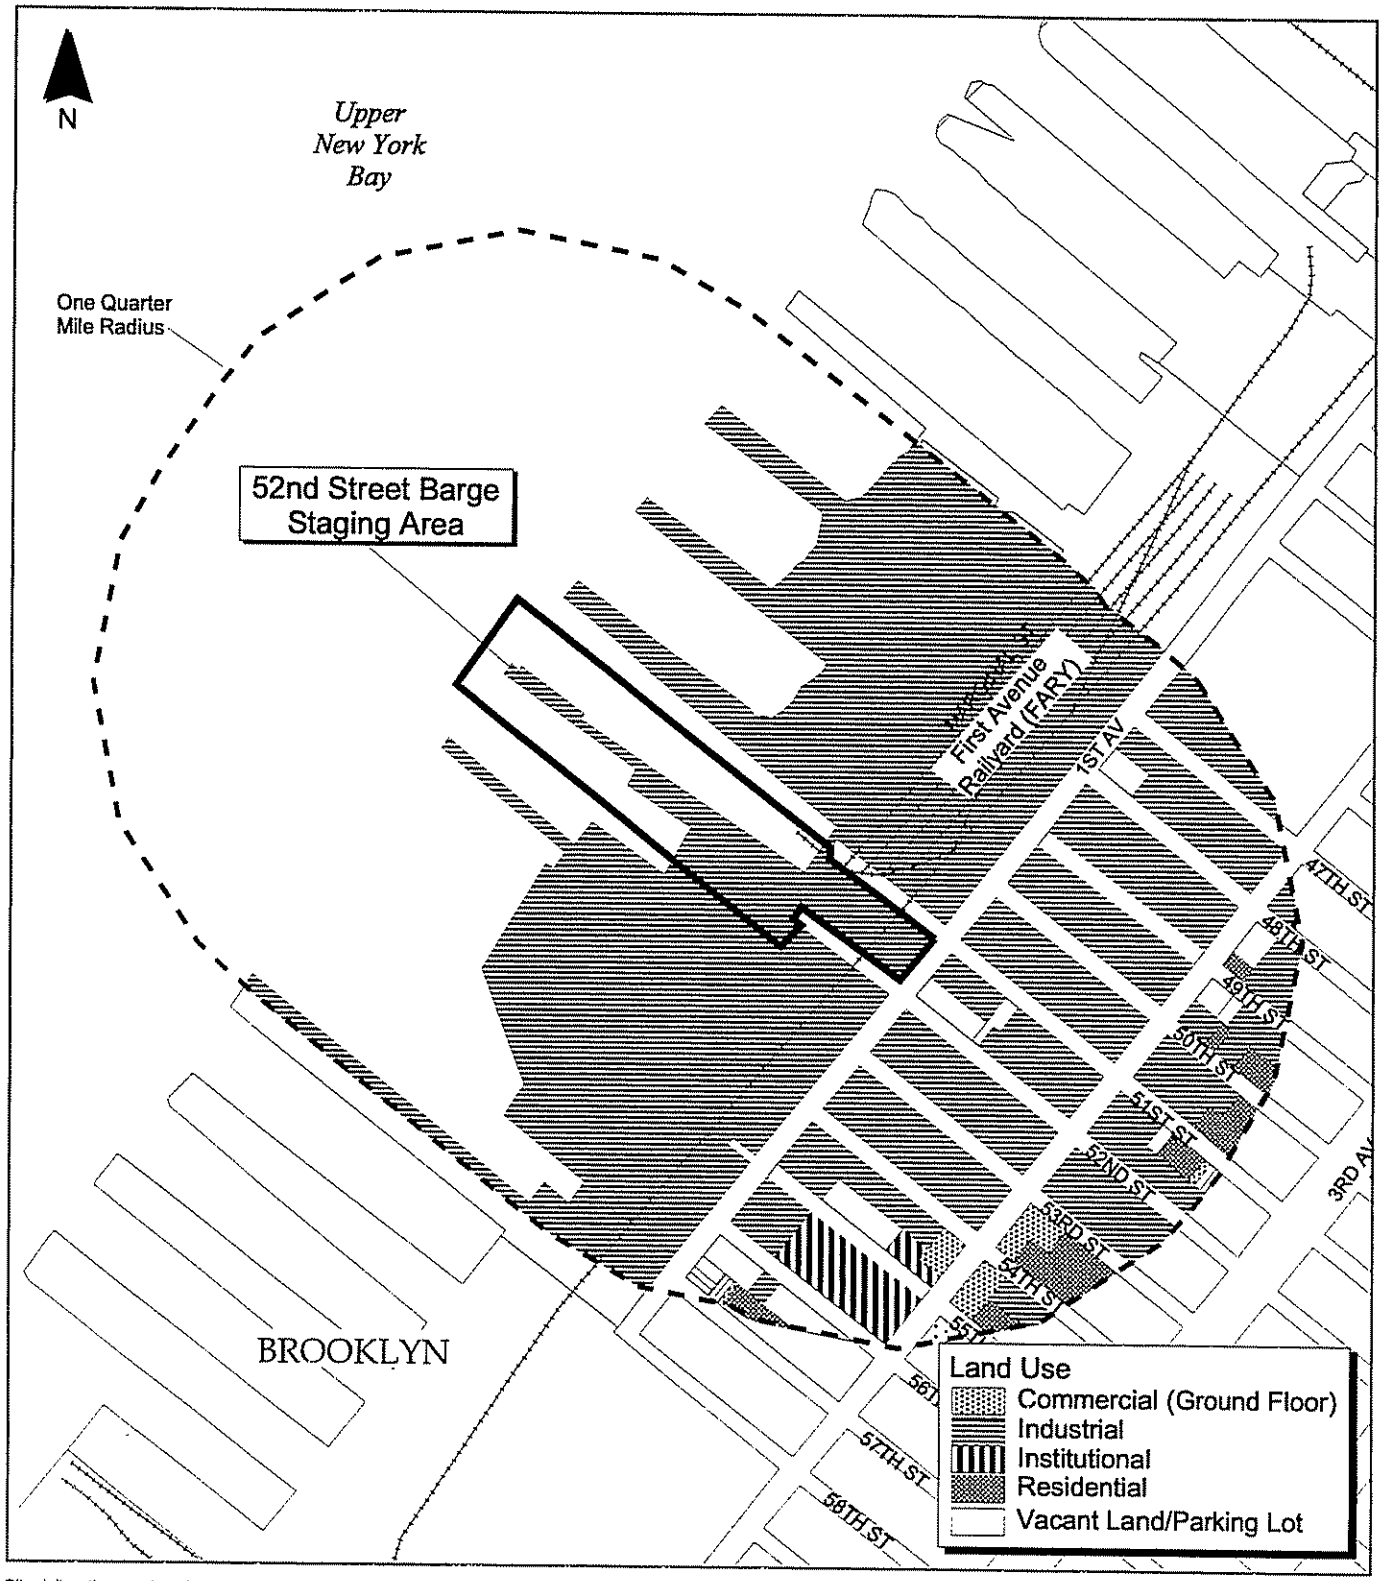
Section 2.2.5 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

8.2 Land Use, Zoning, and Public Policy

8.2.1 Existing Conditions

8.2.1.1 Definition of the Study Area

For the land use, zoning, and public policy analyses, the primary study area is defined as the area within ¼-mile of the site (see Figure 8.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 8.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.2.5 provides information on existing land uses and operations on the site.



8.2.1.2 Land Use Patterns

8.2.1.2.1 General Context

The site is home to an existing DSNY vehicle maintenance facility, sand/salt storage location and parking lot for employees. Access is provided via First Avenue and both 51st and 52nd Streets; an unused spur railroad track (part of the First Avenue Rail Yard) crosses the site west of First Avenue; and the elevated Gowanus Expressway traverses the area above Third Avenue. It is located within the Sunset Park section of the industrial Brooklyn waterfront, just south of Bush Terminal and north of the Brooklyn Army Terminal (BAT). The waterfront and general area west of Third Avenue are predominantly industrial and generally characterized by large-scale industrial lofts.

8.2.1.2.2 Land Uses in the Primary Study Area

Land uses along First Avenue are characterized by light industrial activity, warehousing and some commercial space. A series of five- to six-story warehouses are located between First Avenue and the waterfront, north of 51st Street. These structures include loading piers and parking areas for both trucks and cars.

Site delineations and study area boundaries are approximate
Base Map Source: New York City Department of City Planning
This figure illustrates predominant land uses by lot in the primary study area.

Figure 8.2-2 Land Use in the Secondary Study Area

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

Between First and Second Avenues there are warehouses, factories, automotive repair shops, parking lots and several vacant sites. The First Avenue Rail Yard north of 51st Street includes several unused railroad spurs that run parallel to First Avenue. South of the site is the Brooklyn Wholesale Meat Market, consisting of three buildings at 5600 First Avenue, between 55th and 56th Streets. Individual meat and poultry wholesalers occupy two of the buildings and a processor and distributor of frozen meals leases the third.

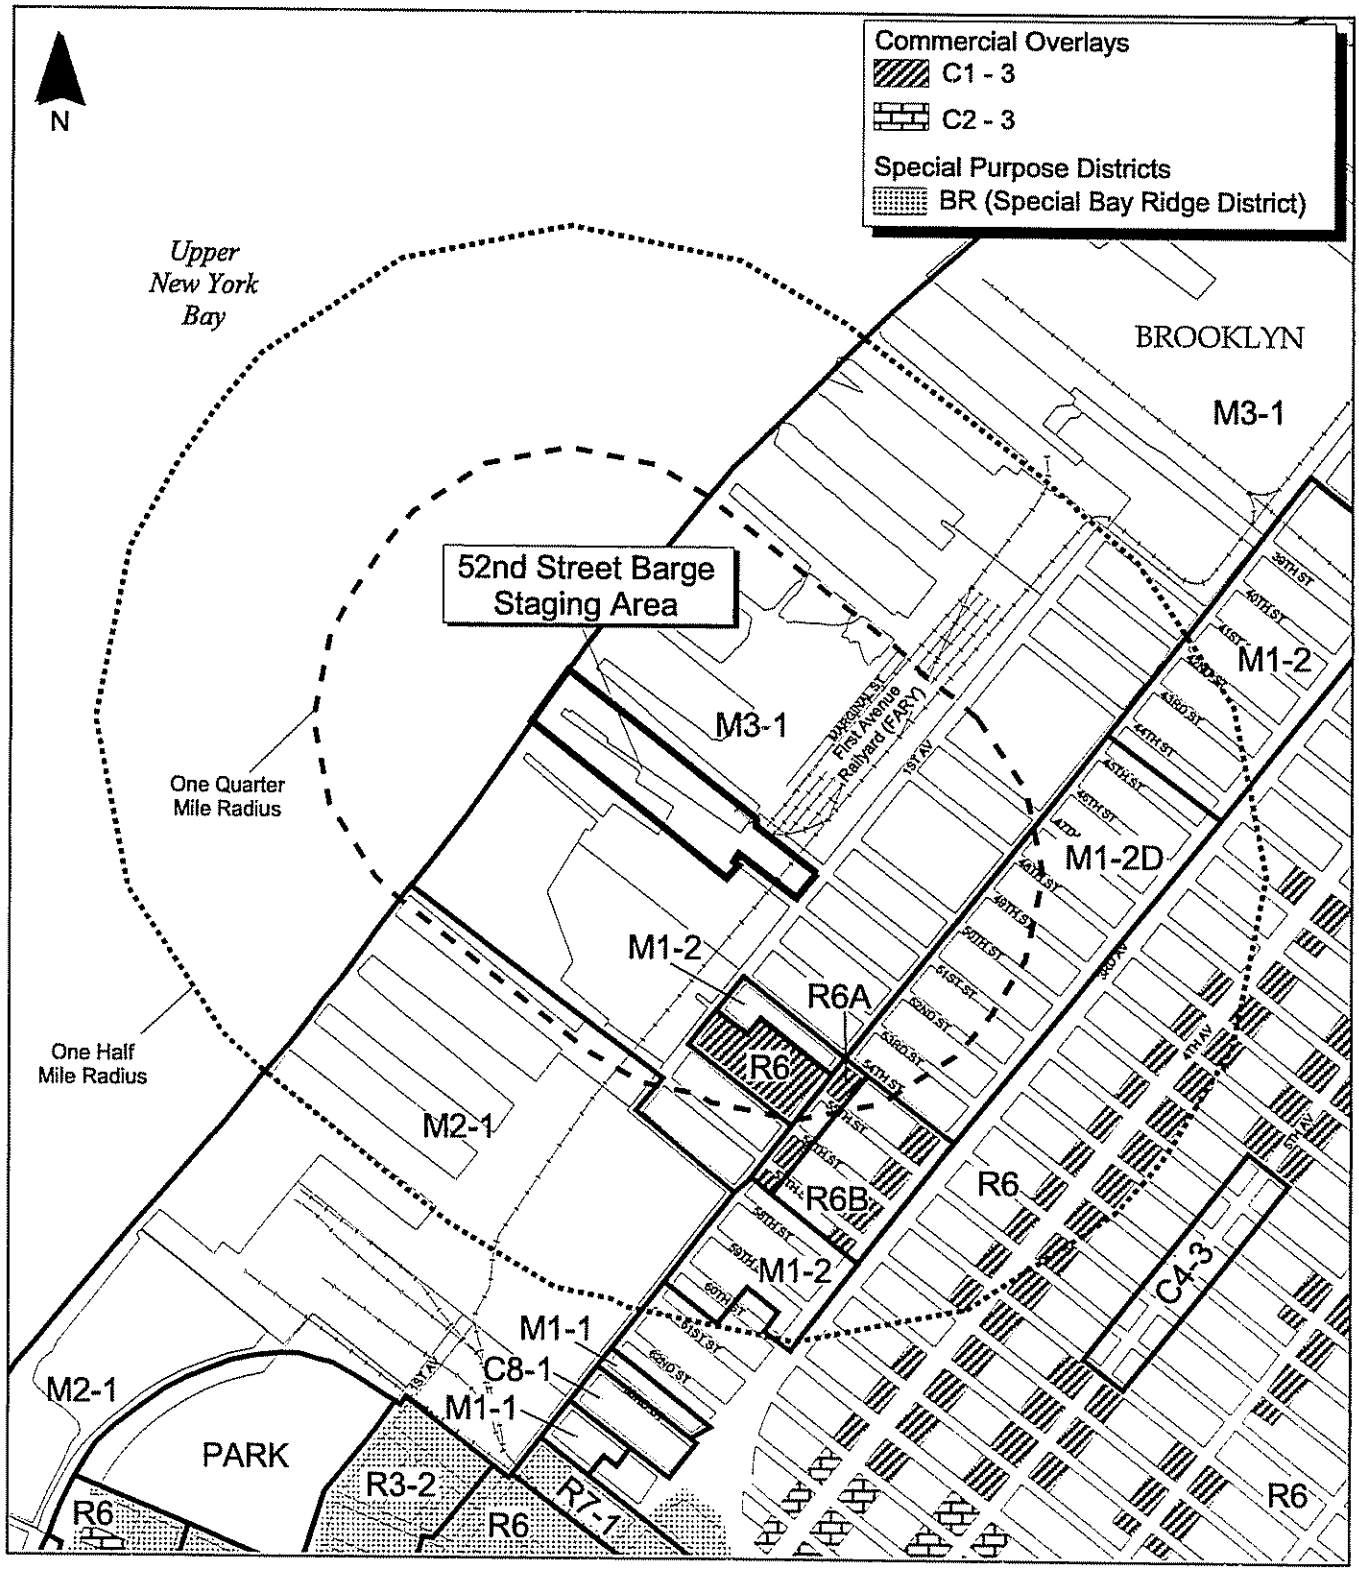
Residential uses in the primary study area consist of two- and three-story single- and multi-family attached structures east of Second Avenue.

Likewise, community facilities within the primary study area are generally located east and southeast of the site. The Lutheran Medical Center, including its associated mental health clinic, the Augustana Lutheran elder care facility and five-story parking structure, as well as the Martin Luther King Playground, are located on Second Avenue at 55th and 56th Streets.

8.2.1.2.3 Land Uses in the Secondary Study Area

The general land use pattern found in the primary study area continues in the secondary study area. Industrial uses housed in large industrial loft buildings are located on the blocks nearest the waterfront, while a mix of residential, commercial and lighter industrial activities characterize the blocks east of Second Avenue. Rows of single-family attached homes and two- and three-story row houses line most of the blocks, along with isolated storefronts and auto repair shops, between Second and Third Avenues and 42nd and 46th Streets. The blocks also feature street trees, which become more prominent further east.

Third Avenue is dominated by the elevated Gowanus Expressway/BQE/I-287, which physically separates the areas east and west of Third Avenue. Third Avenue is itself a major arterial, functioning as a service road to the expressway above. The area directly below, dividing the expressway structure, is utilized for public metered parking.



East of Third Avenue, the blocks are solidly residential, with a mix of single- and multi-family structures. Most blocks contain rows of attached brick row houses with driveways, as well as small-scale commercial storefronts at the corners. Isolated auto services (including inspection, repair, painting, etc.) tend to be located midblocks on the avenues, approximately one or two per block.

Fourth Avenue, which carries the area's only subway lines (N and R trains), has local stations at 45th Street and 53rd Street and an express station at 59th Street. As such, it is the primary commercial strip serving the Sunset Park neighborhood. Local commercial businesses, chain restaurants and banks use ground floor space along Fourth Avenue, with apartments in second, third and fourth stories above. Churches and schools, including St. Michael's Church and P.S. 1, are also located along Fourth Avenue.

8.2.1.3 Zoning On and Near the Site

8.2.1.3.1 Zoning Within the Primary Study Area

The site and most of the primary study area lie within a large M3-1 zone, which extends southward from the shoreline to Second Avenue and east from 57th Street, and to the northeast beyond the secondary study area. East of Second Avenue (between 44th and 54th Streets) is a mixed-use M1-2D zoning district and a small M1-2 zoning district on 54th Street west of Second Avenue. Immediately south of this light industrial district is an R6 district that encompasses Lutheran Medical Center. Small portions of R6A and R6B districts – allowing medium contextual residential development – are situated at the southeastern edge of the area, along Second Avenue and to the east. (See Figure 8.2-3 and Table 3.4-1: Zoning District Characteristics.)

HDR URBITRAN EEA Cambridge Environmental Inc

Figure 8.2-3 Zoning

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

8.2.1.3.2 Zoning Within the Secondary Study Area

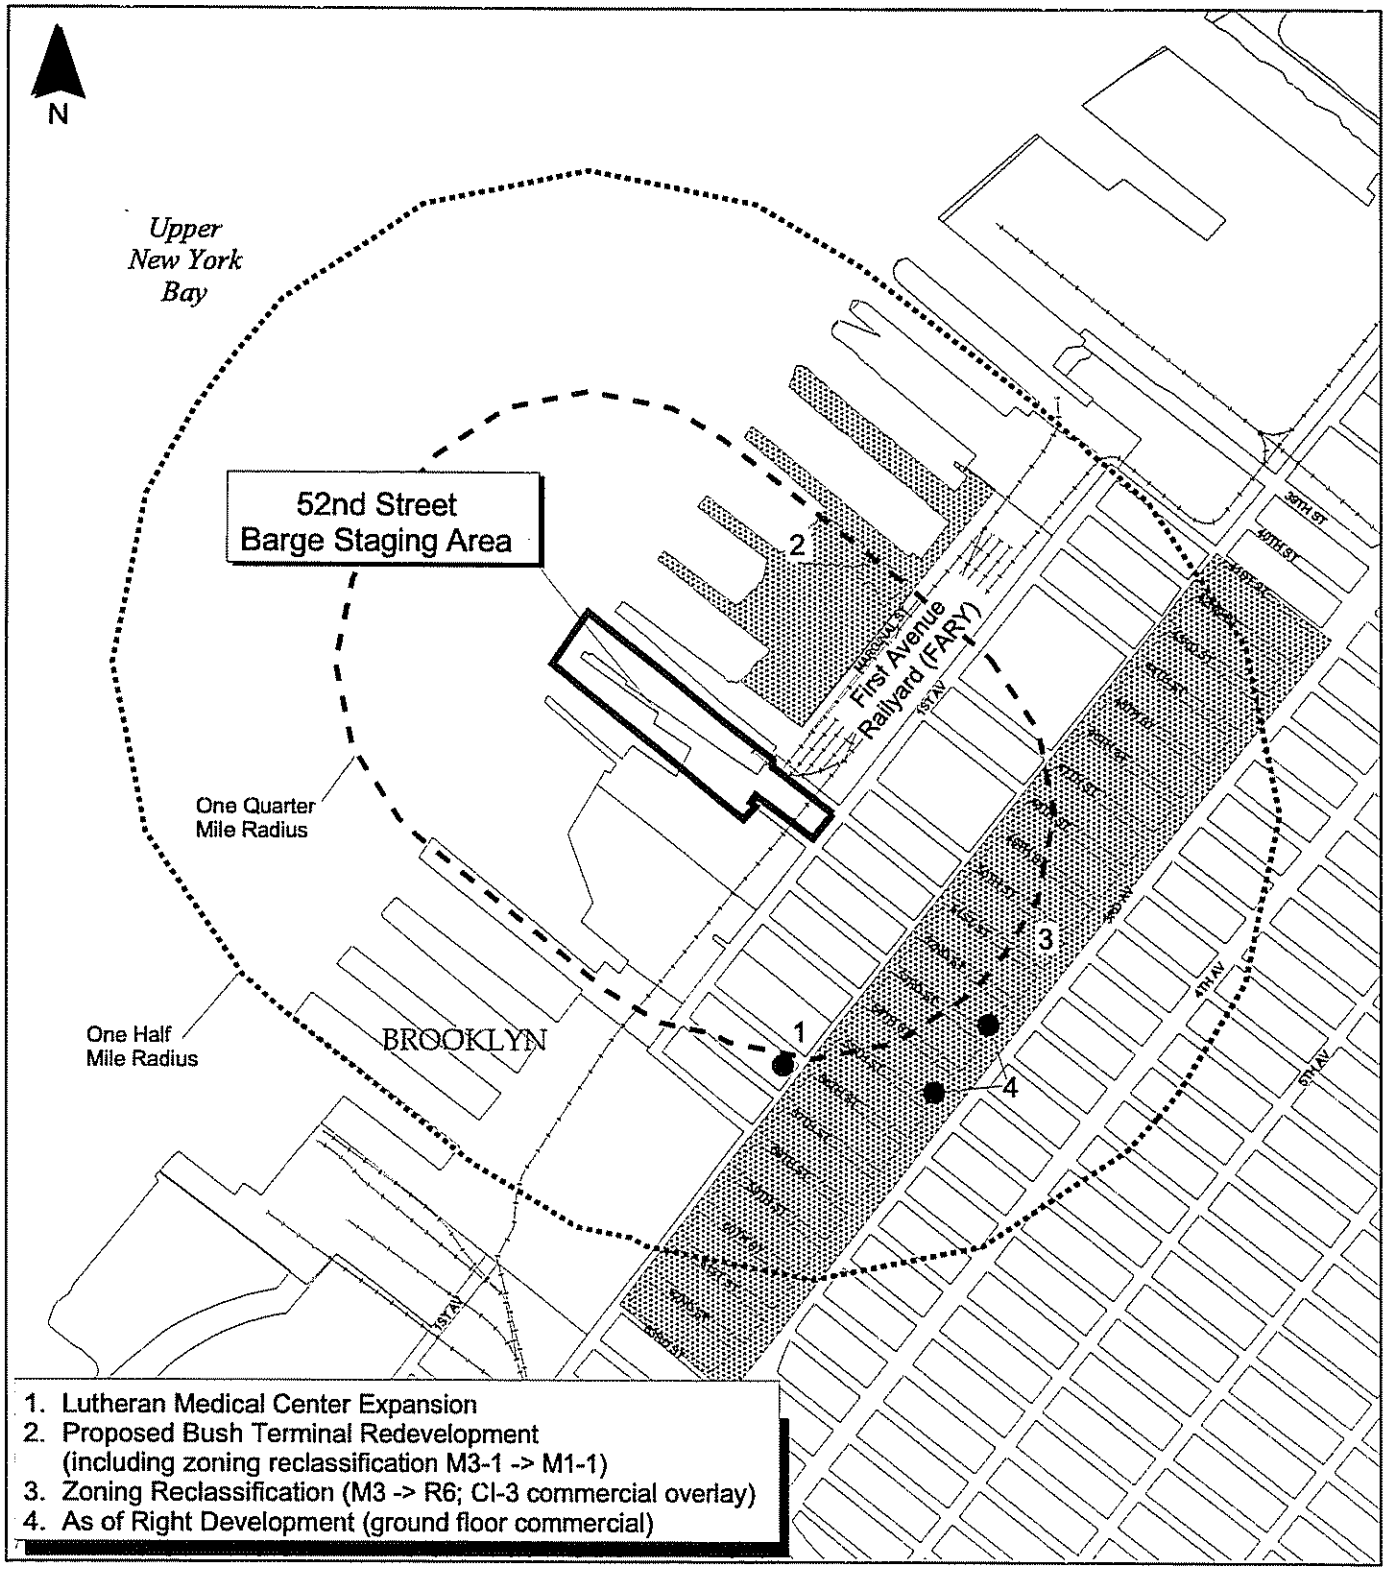
Most of the secondary study area lies within manufacturing districts M3-1, M2-1, M1-2 and M1-2D. The southwestern half of the secondary study area is zoned M2-1 from the shoreline to Second Avenue and M1-2 to the south. Directly east of the primary study area is zoned M1-2D between Second and Third Avenues, and further northeast is a portion of an M1-2 district – north of 45th Street. Southwest of Third Avenue is a large R6 zoning district with a C1-3 commercial overlay that covers most of the Sunset Park neighborhood. Two medium-density residential districts – R6A and R6B – cover the blocks between 54th and 59th Streets, from Second to Third Avenues.

8.2.1.4 Plans and Policies

The project site lies within the City Coastal Zone, and as such is subject to the WRP. For areas near the site, the plan for the Brooklyn Waterfront recommends in Reach 14: Brooklyn Upper Bay, the provision of public access on Piers 4 to 7 in Sunset Park in conjunction with plans for their future use; the construction of access ramps to the Gowanus Expressway in the vicinity of 39th Street; and the implementation of proposed rail improvements in Sunset Park to maximize intermodal connection to carfloat operations.

Efforts aimed at preparing a 197-A Plan for Sunset Park have temporarily been put on hold, and no resumption date is known at the time of this analysis, but Brooklyn CD 7 continues to indicate its planning needs within the FY 2004 CDNS. In that report, Brooklyn CD 7 promoted the Hamilton Avenue MTS, particularly if a new garage for BK-7 on the former incinerator site would be part of its capital program.

The CD supports improvements at South Brooklyn Marine Terminal, which will allow for an integration of economic activities and waterfront access, and development of the Bush Terminal Piers Open Space proposed by the NYCEDC (see Section 8.2.2).



In the 1980s, the state established the Sunset Park In-Place Industrial Park. This complex covers 650 acres in southwest Brooklyn, offers a variety of sizes and types of industrial space, and is part of a New York State EDZ, making firms eligible for special financial incentives and low-cost financing.

The Strategic Plan for the Redevelopment of the Port of New York (1999) outlines a series of targeted investments to develop marine cargo terminals, public access to the waterfront, improved highway and rail access, improved navigation channels and environmental mitigation in the City over the period 1999 to 2020. Within the plan, NYCEDC considered Sunset Park a viable site for three separate, but complementary, development programs: (1) an auto terminal (near-term) at the South Brooklyn Maritime Terminal; (2) a landfill expansion of South Brooklyn Marine Terminal; and (3) a container terminal complex (long-term) over a larger are of Sunset Park, served by major cross-harbor freight improvements. The NYCEDC has since progressed their plan for the redevelopment of Bush Terminal.

8.2.2 Future No-Build Conditions

It is reasonable to anticipate that the Future No-Build Conditions in the primary and secondary study areas will resemble the Existing Conditions generally, except for the following three notable changes. (See Figure 8.2-4)

- **Bush Terminal Piers Open Space.** The NYCEDC proposes to create a 23-acre public open space and recreation facility for active and passive uses on the Bush Terminal Piers, on the Sunset Park waterfront, to serve the unmet demand of the community. The site encompasses five piers (and landfilled area) between 43rd and 51st Street, just north of the DSNY site. The first phase of the project, which would entail necessary site remediation, as well as some infrastructure and open space improvements, would be complete by 2006. The remaining development would then be complete by 2009. The open space would feature a variety of indoor and outdoor facilities (including walkways, natural areas, athletic fields, indoor ice rink, boat-building area, fishing pier, seasonal restaurant booths, environmental education center, community building, historic vessels and banquet hall).

Site delineations and study area boundaries are approximate.

500 0 500 Feet

HDR URBITRAN EEA Hydroqual PB Cambridge Environmental Inc

Figure 8.2-4 Planned Development Sites

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

- **Lutheran Medical Center Expansion and Associated Rezoning.** Lutheran Medical Center proposes to expand and relocate some services to a site on 56th Street between First and Second Avenue, currently a parking lot. The proposed development would consist of a ground floor pharmacy and two floors of medical facility space. Associated with this action would be a rezoning from M3-1 to R6 (with a C1-3 commercial overlay), which would apply to a larger portion of the study area, extending from 41st Street to 63rd Street on First Avenue. The ULURP process for this project has not been initiated at the time of this analysis, but construction is expected to be underway by the Future No-Build year.

- **First Avenue Rail Line.** The third project is the acquisition of an easement between 39th and 56th Streets for the First Avenue rail line, which will be improved and realigned in the area between 37th to 65th Streets. The project was filed through ULURP and approved, and construction on the rail line is expected to be completed in 2005.

8.2.3 Potential Impacts with the 52nd Street Barge Staging Area

8.2.3.1 Land Use and Zoning

The utilization of Pier 52 for a barge staging unit, much like the unit that historically has been operated by DSNY at the same location, would be generally compatible with the existing and proposed water-dependent uses of the Sunset Park waterfront. The barge staging area would not alter established land use patterns, nor would it affect uses inland. It would be in keeping with the industrial presence of the area in general, though its operation would resume near the proposed Bush Terminal Open Space, which will be under development by 2006, just north of the site. Most of the active uses are planned for the upland areas near Marginal Street. A fishing area is proposed at the northern tip of Pier 1 at the end of 51st Street, facing away from the proposed barge staging area (see Section 8.5.3 for discussion of potential impacts to open space.) It would not require or lead to changes in zoning, and it would remain within and surrounded by manufacturing zoning. Therefore, no impacts to land use and zoning would result from the 52nd Street Barge Staging Area.

8.2.3.1 Consistency with Public Plans and Policies

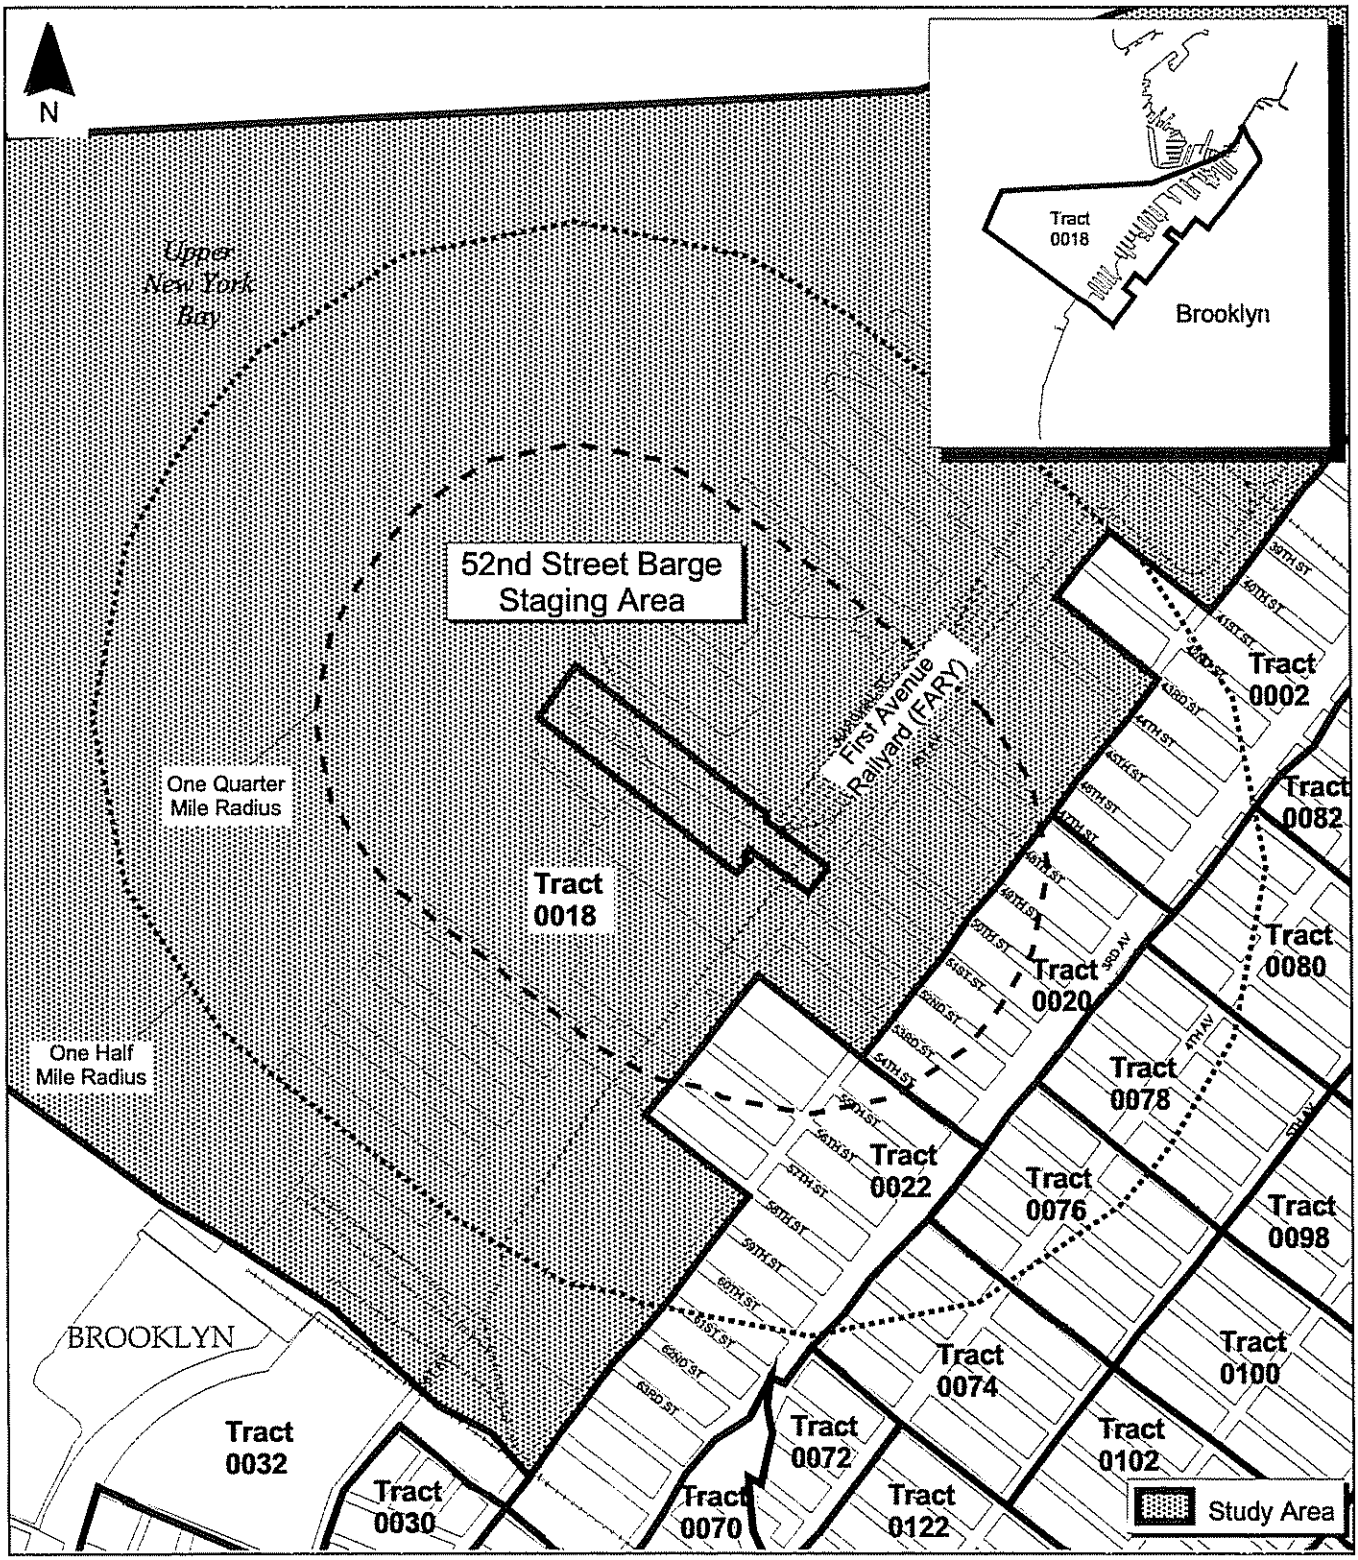
The 52nd Street Barge Staging Area would not be inconsistent with the waterfront plans or CDNS recommendations for the area or with the NYCEDC's plan to develop Bush Terminal Piers as an open space. Its development, however, would be inconsistent with NYCEDC's standing 1999 plans to develop the Sunset Park Container Terminal, which could extend out from the shore to the pierhead, from about 65th Street on the southern end (alongside the BAT) to approximately 50th Street.

Should the site be advanced as part of the Proposed Action, potential inconsistencies with public plans would be resolved by DSNY and appropriate agencies at that time.

8.3 Socioeconomic Conditions

8.3.1 Existing Conditions

8.3.1.1 Definition of the Study Areas



Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site, and (2) a study area related to economic activity that generally covers a larger area ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area is comprised of Brooklyn Census Tract 18 (see Figure 8.3-1). Census Tract 18 covers industrial waterfront areas between Gowanus Creek and approximately 65th Street, generally to the west of Second Avenue. For comparison purposes, census data were also gathered at the borough and City levels.

Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

8.3.1.2 Demographic Characteristics

8.3.1.2.1 Population

In 2000, the study area population was 1,442 persons, which was an approximate 25% increase over 1990 (see Table 8.3-1). There were a greater number of males (1,287) than females (155) within the study area. Therefore, the age-sex distribution of the study area population was dissimilar to the distribution of population in the borough and the City, where there were slightly more females than males in each area.

Site delineations and study area boundaries are approximate

800 0 800 Feet

Figure 8.3-1 Census Tracts
52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Table 8.3-1
1990-2000 Population

Year	Study Area	Brooklyn	City
2000	1,442	2,465,326	8,008,278
1990	4	2,300,664	7,322,564
Percent Change	NA	+7.2%	+9.4%

Source: U.S. Census 1990, 2000

The study area had a smaller percentage of children and teens than either the borough or the City in 2000. About 1.2% of the study area population was under the age of 20, as compared to Brooklyn (30%) and the City (27%).

8.3.1.2.2 Racial and Ethnic Characteristics

The 2000 study area population had a greater proportion of people (49%) of Hispanic origin (all races) than did Brooklyn (20%) and the City (27%). Of the 51% of non-Hispanic origin, 55% were Black and 80% were White. In Brooklyn and the City, Blacks represented approximately 43% and 33% of the non-Hispanic populations, respectively, while Whites represented 43% and 48% respectively. About 8.4% of the non-Hispanic population was Asian or Pacific Islander compared to 9.3% and 13.4% in the borough and City, respectively.

8.3.1.2.3 Families and Households

There were four families in the study area in 2000. The percentage of these families who had children under the age of 18 years (50%) was similar to families in Brooklyn (51%) or the City (49%). The study area had a lower percentage of married-couple families (50%) than Brooklyn (59%) or the City (62%).

There were more households in the study area in 2000, with an average of 3.00 persons per household, more than Brooklyn and the City, each of which averaged about 2.6 persons per household.

Regional projections indicate that employment in Brooklyn CD 7 will remain about 6% of the borough total.[3]

8.3.3 Potential Impacts with the 52nd Street Barge Staging Area

The 52nd Street Barge Staging Area is generally compatible with its industrial surroundings and is not expected to have a significant adverse impact on socioeconomic conditions within the study area.

8.3.3.1 Residential Impacts

No direct residential displacement would occur as a result of the 52nd Street Barge Staging Area. The site and its surrounding industrial uses are relatively isolated from most of the Sunset Park residential areas east of the Gowanus Expressway. Those residences nearer the site along Third Avenue are buffered from the site by other established industrial uses, typically housed in massive industrial lofts. The 52nd Street Barge Staging Area entails only over-water activity associated with barge movement, and no indirect impacts or significant impacts to neighborhood character are anticipated.

8.3.3.2 Direct Business and Institutional Impacts

The 52nd Street Barge Staging Area would utilize a vacant pier and adjacent area already under DSNY jurisdiction and previously used for a similar purpose; therefore, no direct displacement of businesses or institutional uses would result.

8.3.3.3 Indirect Business and Institutional Impacts

The 52nd Street Barge Staging Area is expected to be compatible with its surrounding industrial uses, as well as the Bush Terminal Piers Open Space that will be underway. Because the 52nd Street Barge Staging Area may be inconsistent with NYCEDC plans for Sunset Park Container Terminal Development, however, it may result in indirect business impacts, limiting future transload or intermodal opportunities at the site.

---

[3] Ibid.

Should the site be advanced as part of the Proposed Action, potential inconsistencies with public plans would be resolved at that time.

8.3.3.4 Employment Impacts

The 52nd Street Barge Staging Area is expected to generate approximately 23 jobs associated with the operation and maintenance of the new facility (equipment operators, mechanics, supervisors and laborers), and marine operators (barge personnel). In addition to the direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending. The 52nd Street Barge Staging Area would be operated around the clock with the last shift entailing maintenance and housekeeping activities. Around-the-clock activity would enhance security in this industrial area.

8.4 Community Facilities

8.4.1 Existing Conditions

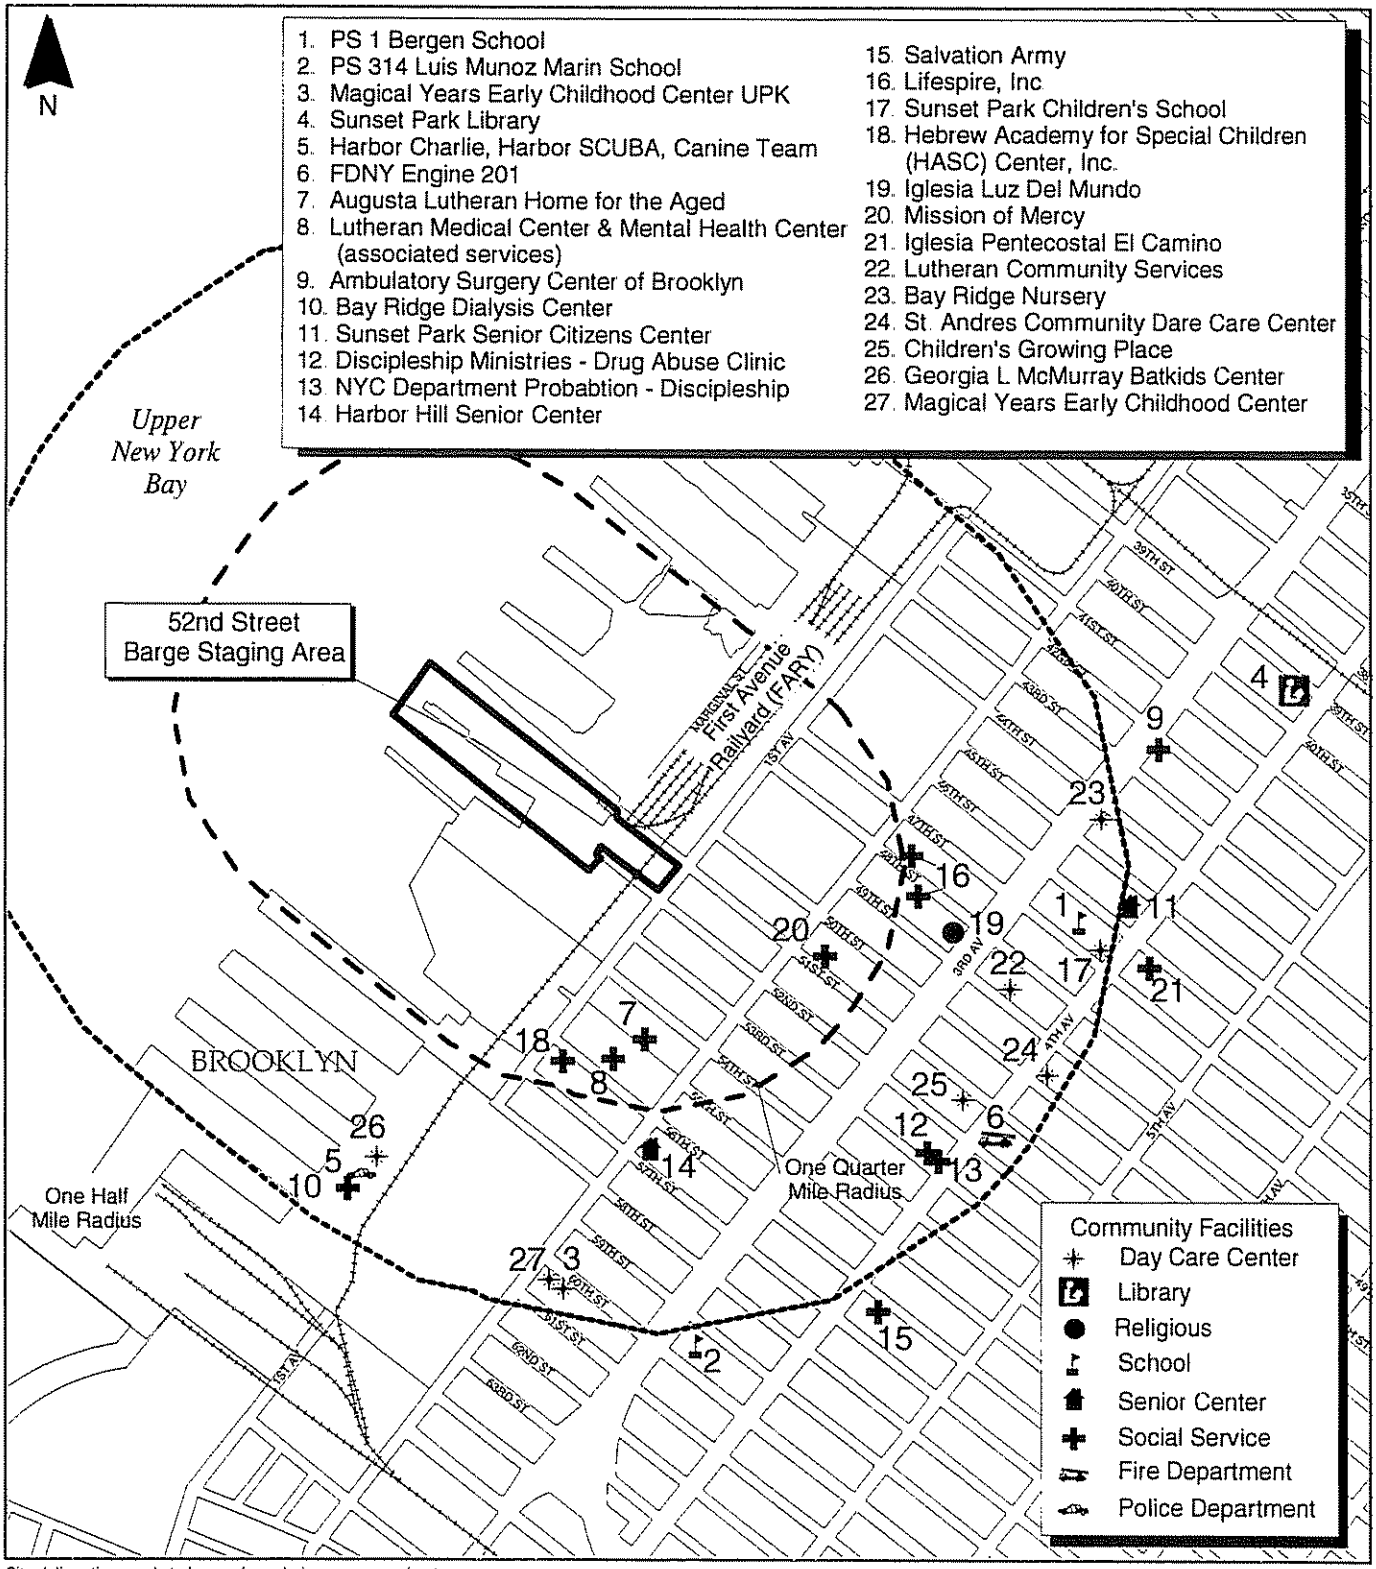
8.4.1.1 Definition of the Study Areas

The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼-mile and ½-mile of the site.

8.4.1.2 Summary of Community Facilities and Services

There are four community facilities within the primary study area, all medical facilities or social services program centers. Fifteen others are located within the secondary study area, and five just beyond. The community facilities are listed below in Table 8.4-1 and shown on Figure 8.4-1.

8.4.2 Future No-Build Conditions



There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

8.4.3 Potential Impacts with the 52nd Street Barge Staging Area

The 52nd Street Barge Staging Area would create no significant new demand on services or community facilities and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the new facility (see Appendix A).

Table 8.4-1

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

8.5 Open Space

8.5.1 Existing Conditions

8.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

8.5.1.2 Summary of Open Space in the Study Area

There are two playgrounds and a community garden within the study area, and one playground just beyond. They are listed in Table 8.5-1 and shown on Figure 8.5-1.

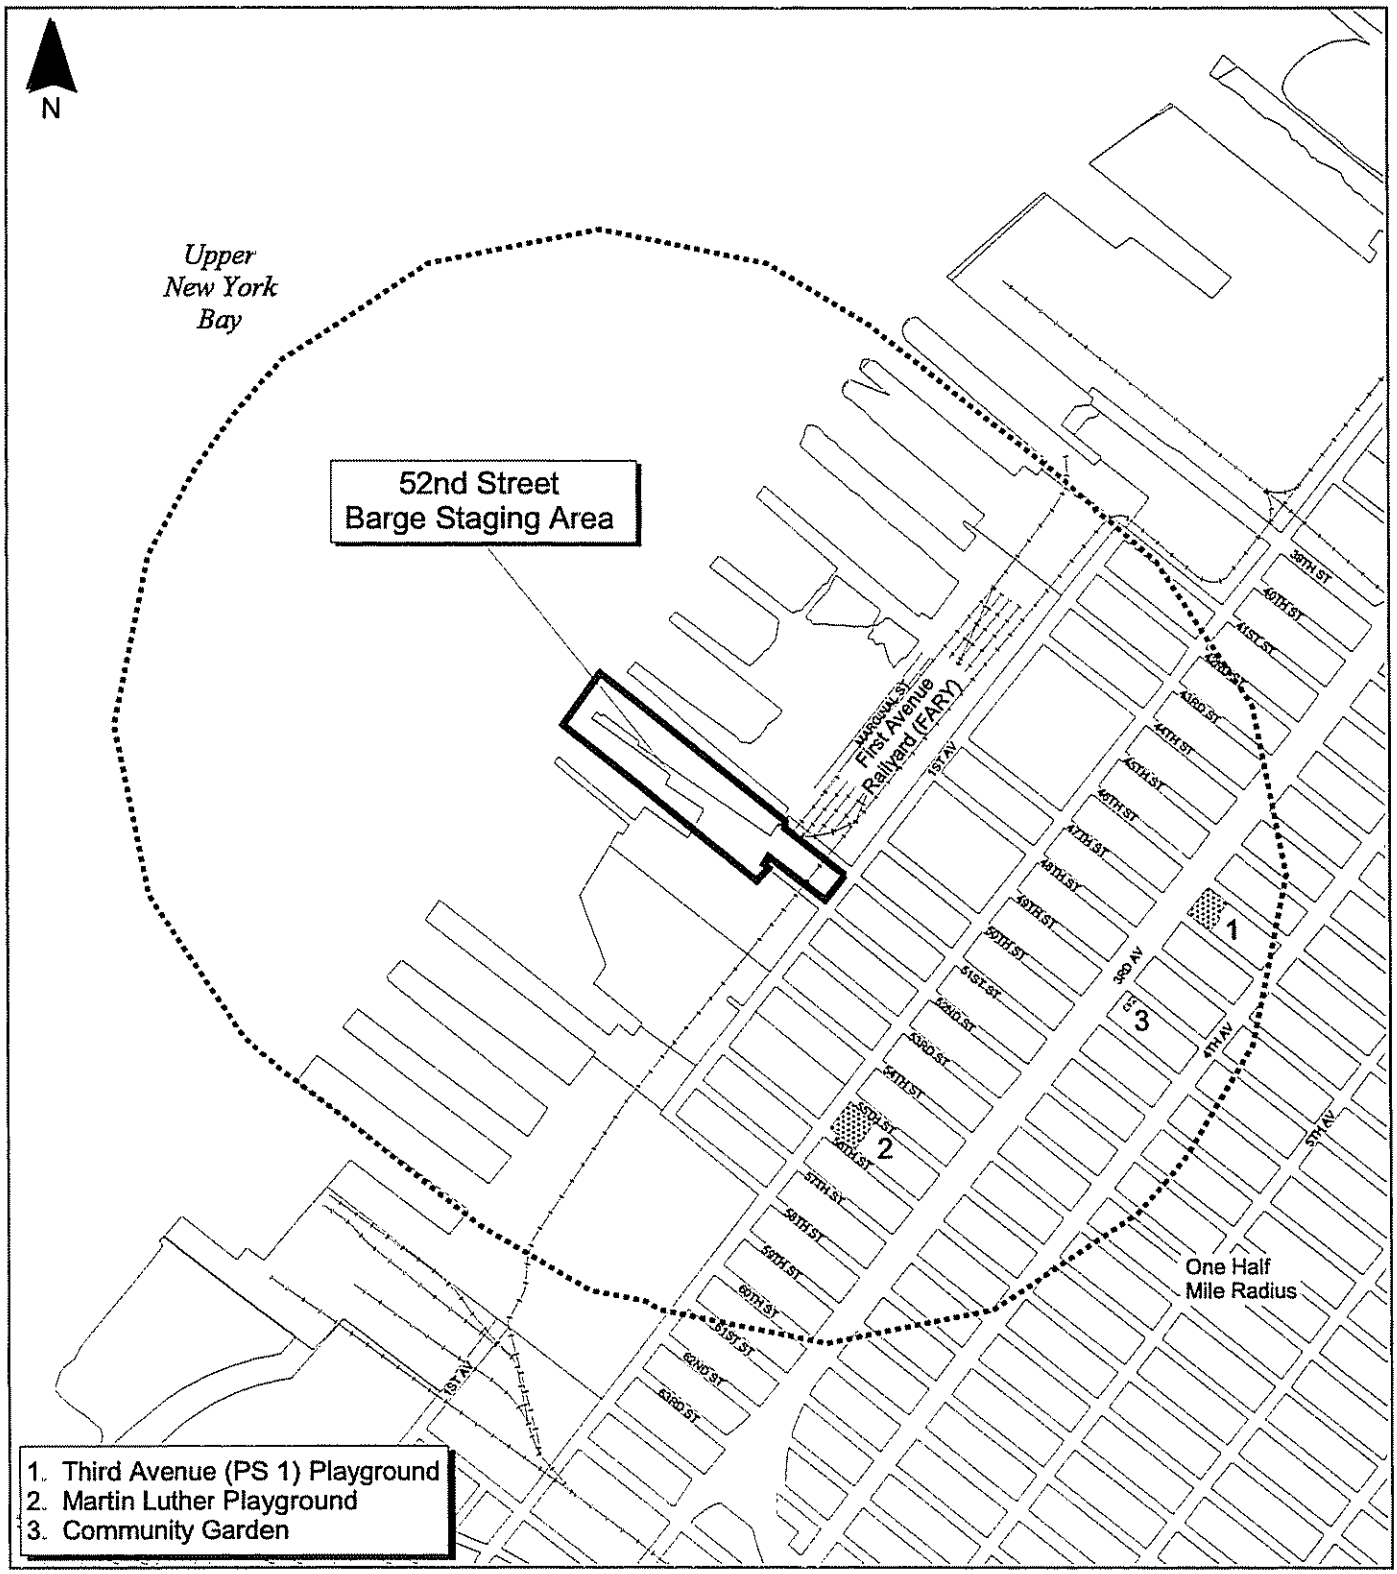

Table 8.5-1
Public Parks and Open Spaces

Name	Address	Acreage
Third Avenue (P.S. 1) Playground	46th Street to 47th Street, east of Third Avenue	1.52
Martin Luther Playground	55th Street to 56th Street, east of Second Avenue	0.913
Community Garden	49th Street, east of Third Avenue	0.1

The study area's open space facilities consist primarily of playgrounds. The nearest, Martin Luther Playground, is also near the Lutheran Medical Center. The residential areas outside the study area, east of the Gowanus Expressway, are generally served by the large Sunset Park located at 47th Street and Seventh Avenue and comprising the equivalent of six City blocks.

8.5.2 Future No-Build Conditions

The Future No-Build Conditions throughout the neighborhood study area are generally anticipated to resemble Existing Conditions, except for the prominent Bush Terminal Piers Open Space project, between 43rd Street and 51st Street west of Marginal Street. Upon its completion in 2009, the proposed park will provide outdoor athletic fields (soccer and softball), a 24-hour indoor ice rink, play areas, game pavilions, mini golf-course, environmental education center,

Site delineations and study area boundaries are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

preserved/enhanced wetland areas, tree conservation/bird watching area, fishing piers, boat building, historic vessels and a waterfront promenade. By the Future No-Build year, development will be underway, and it is expected that some open space will be available for public access, though its ensemble of facilities will not yet be fully constructed by the Future No-Build year. Some sidewalk improvements would be made and bicycle routes designated along 43rd and 51st Streets and the segment of Marginal Street between them. The most notable contribution to open space resources within the study area will be the new opportunity for passive recreation afforded the local population of surrounding residential areas (primarily located east of the study area, beyond the Gowanus Expressway) to visit and observe the working maritime waterfront and its predominantly industrial surroundings.

8.5.3 Potential Impacts with the 52nd Street Barge Staging Area

The facility would not directly displace or significantly change demands on nearby parks. The activities planned for the southern portion of Bush Terminal Piers (closest to the 52nd Street Barge Staging Area), such as the indoor rink and soccer field, would be sited near Marginal Street and not facing the DSNY site. Similarly, the fishing area is proposed on the northern side of Pier 1, also away from the DSNY site, and facing north towards the future waterfront park. Primary access to the park would be via 43rd Street, where streetscape improvements are planned, and secondarily, along 51st Street. Therefore, no impacts to the public open spaces would result from the 52nd Street Barge Staging Area.

8.6 Cultural Resources

8.6.1 Existing Conditions

8.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site.

8.6.1.2 Development History of the Area

The Sunset Park neighborhood originally developed as a Scandinavian enclave in the 1830s and expanded in the 1840s with a great influx of Irish immigrants. Green-Wood Cemetery, located on a hill in the northern portion of the neighborhood (between 20th and 37th Streets east of Fifth Avenue), was laid out in 1839. It is distinguished as one of the earliest rural cemeteries in the nation and notable for its lushly landscaped site, overlooking the harbor and spectacular Gothic Revival gate at Fifth Avenue (designed by Richard Upjohn & Son, 1861-65), which is a designated City landmark. With the construction of the railroads, particularly the South Brooklyn (freight) Railway, and other transit improvements, waterfront industrial activity intensified and inland residential development flourished. After 1870, densely laid-out brick and brownstone row houses replaced the older wood houses of the neighborhood.[4]

The Sunset Park neighborhood, though, began to decline by the 1930s and 1940s, with the cessation of the Third Avenue elevated line and the construction in 1941 (and later widening) of the Gowanus Expressway. The expressway separated the industrial waterfront from the residential portions of the neighborhood.

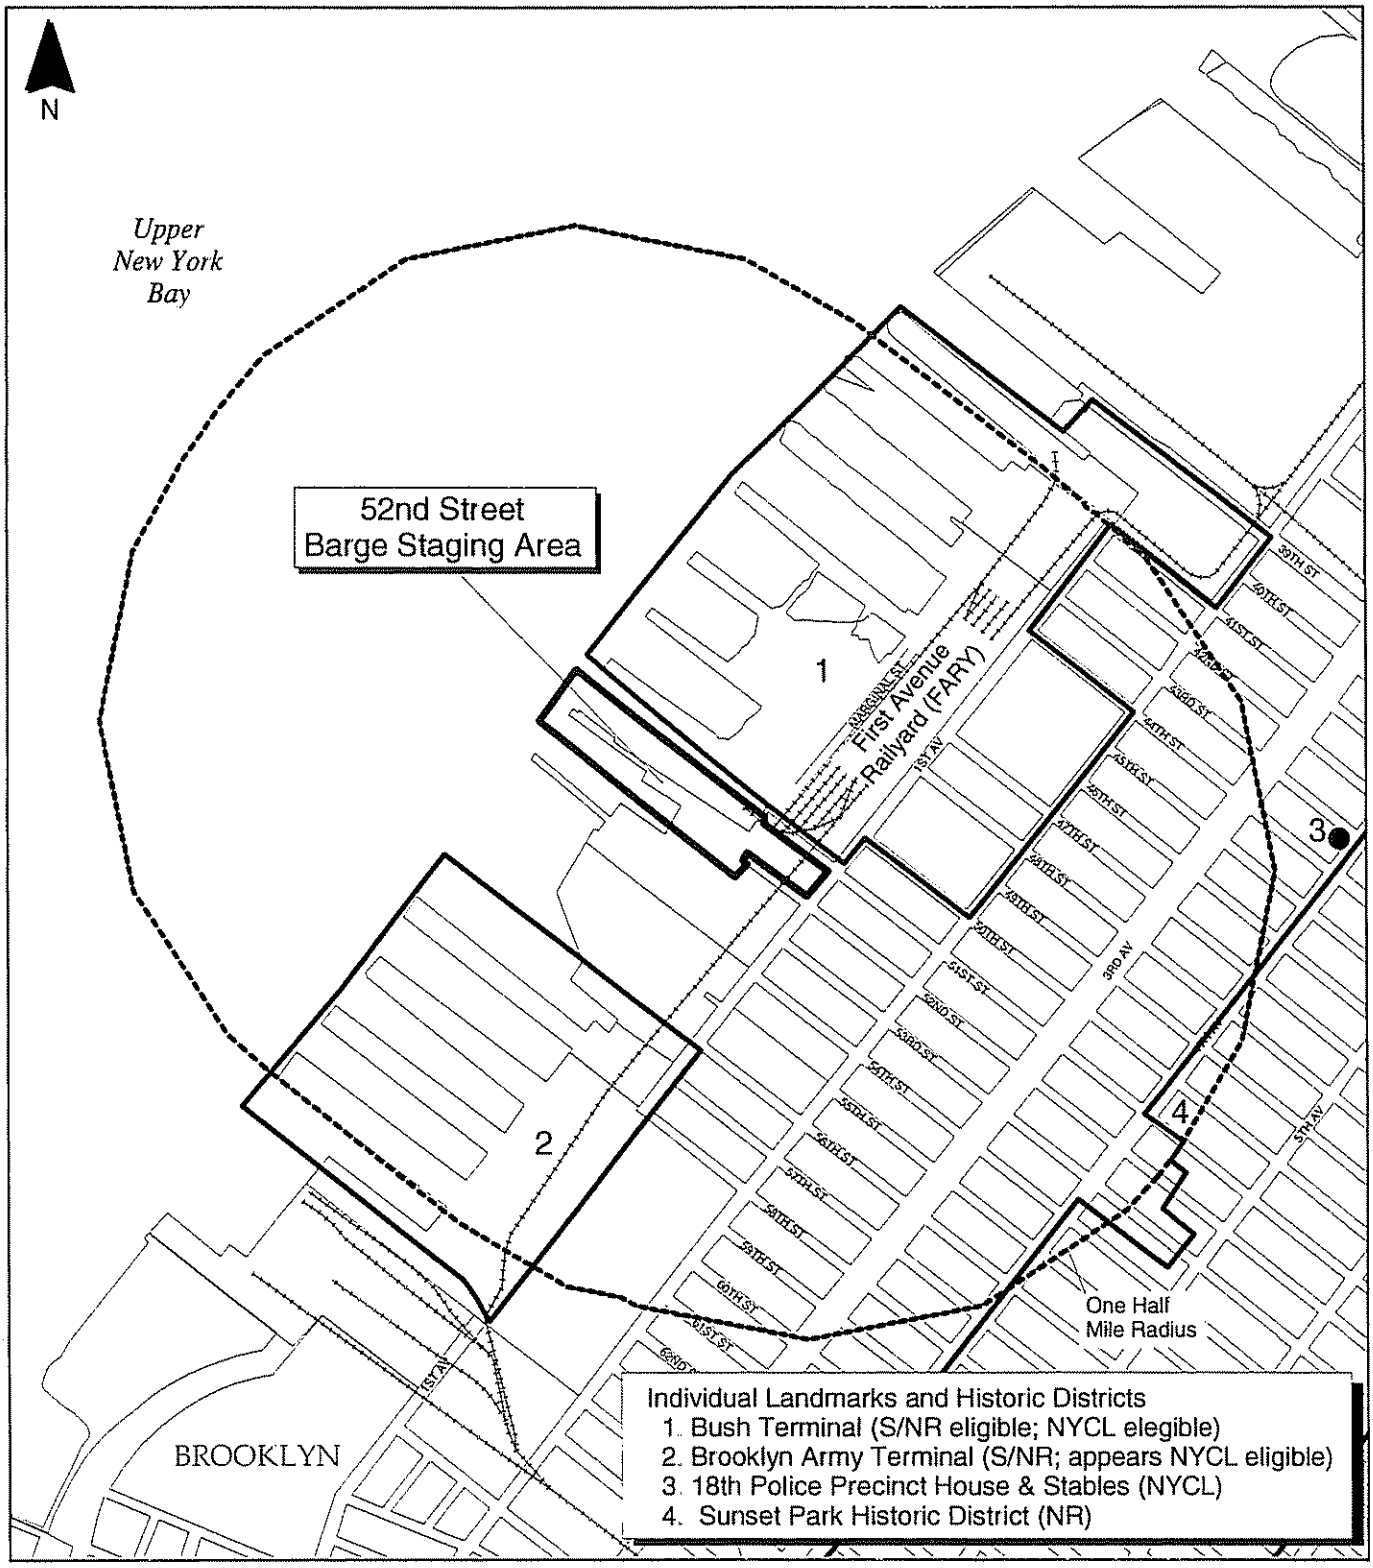
The BAT, a military ocean supply facility, located about ¼-mile south of the project site, was completed in 1919. The terminal is situated on the waterfront between 58th to 64th Streets, covering approximately 97 acres. It originally consisted of 19 structures, including the remaining two eight-story warehouses of reinforced concrete, one of which was the largest warehouse in the world. During the Second World War, many of the three million troops and 63 million tons of supplies sent overseas by the New York Port of Embarkation passed through it.

---

[4] (E. Snyder-Grenier, ENYC 1143.)

The neighborhood continued to suffer the detrimental effects of housing abandonment, migration of the maritime industry to New Jersey and the deactivation of the BAT in the 1970s. Conditions began to improve in the 1970s to the present, however, as the neighborhood experienced a new wave of immigrant and commercial revitalization, including the redevelopment of BAT by the NYCEDC (then, the New York Public Development Corporation)[5] which bought the facility in 1984 and converted it to manufacturing space for many small businesses.[6]

8.6.1.3 Cultural Resources on the Site



There are no significant elements of architectural or historical significance within the site. The only structures on the site is a DSNY salt dome and a DSNY vehicle maintenance facility.

8.6.1.4 Historic Resources Within the Study Area

There are several historic resources in the study area. (See Figure 8.6-1.) Bush Terminal to the north consists of a collection of red brick buildings that are clustered on either side of 43rd Street, between Marginal Street and First Avenue. Piers 1 to 5 (between 43rd and 51st Streets) were built in the early 1900s to serve the bustling intermodal industrial complex, which was developed by Irving Bush at the turn of the century. This terminal was a major component of one of the busiest waterfronts in the nation for decades.

The SHPO determined that Bush Terminal (not the deteriorated piers) is eligible for listing on the S/NR (documented in the Section 106 consultation for the Brooklyn Waterfront Rail Improvements Project EAS, May 2003). The LPC also agreed that the complex is eligible for City landmark designation, based on this same consultation. Similar buildings in the area, such as the rows of red-brick buildings on 52nd Street, east of First Avenue may also potentially be eligible for listing on the S/NR.

Figure 8.6-1 Cultural Resources

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The BAT south of the site is listed on the S/NR and appears to be eligible for LPC designation. The property was listed in the NR because it is "associated with events that have made a significant contribution to the broad patterns of our history" and because it "embodies the distinctive characteristics of a type, period or method of construction; or represents the work of a master; or possesses high artistic values; or represents a significant and distinguishable entity whose components may lack individual distinction."[7] The terminal is architecturally and historically significant as a monumental example of modern industrial design and advanced engineering technology incorporating the work of a nationally prominent architect and for the role the complex played in the military and transportation history of the United States. The original complex of eight structures (two remain) was designed by Cass Gilbert, architect of the Woolworth Building and other City landmarks.

At the eastern edge of the study area is the expansive Sunset Park Historic District, which is listed on the NR for its uniform 19th-century residential development. It is a large district, roughly bounded by Fourth Avenue, 38th Street, Seventh Avenue and 64th Street.

Just beyond the study area is the former 18th Police Precinct House and Stable (4302 Fourth Avenue), now the Sunset Park School of Music. It is a designated City landmark, as one of several station houses in Brooklyn designed by the NYPD architect, George Ingram, in the late 19th century to resemble a medieval fortress.

Table 8.6-1 lists the Cultural Resources in the study area.

8.6.2 Future No-Build Conditions

There are no additional properties in the study area of potential architectural or archaeological significance known to be slated for review. Except for development of a public open space on the site of the former Bush Terminal Piers, north of the site, anticipated Future No-Build Conditions for the project year are assumed to be the same as Existing Conditions. The proposed 23-acre park is being planned on the piers, and no new construction is planned upland near the historic complex.

[7] Resource Evaluation, prepared by Kathleen A. Howe, SHPO, April 2, 1999 (project reference number 99PRO789).

Table 8.6-1
Cultural Resources in the Study Area

Name	Location	Designation
Bush Terminal Complex	Third Avenue to the waterfront (approximately 32nd Street to 51st Street)	NYCL-eligible and S/NR-eligible
Brooklyn Army Terminal	First Avenue to the waterfront, between 58th and 64th Streets	NYCL-eligible and S/NR
18th Police Precinct House and Stable	4208 Fourth Avenue	NYCL
Sunset Park Historic District	Approximately from Fourth to Seventh Avenues, between 38th and 64th Streets	NR

8.6.3 Potential Impacts with the 52nd Street Barge Staging Area

The SHPO and LPC have determined that there are no resources of historical or archaeological value on the site and rehabilitation of the pier to continue to accommodate barge staging would not likely cause adverse effects to any of the study area's historic structures.

8.7 Urban Design, Visual Resources, and Shadows

8.7.1 Existing Conditions

8.7.1.1 Definition of the Study Area

The study area is the same as employed for neighborhood character study area (see Figure 8.8-1), extending inland from the waterfront to the Gowanus Expressway, bound by 39th Street to the north and Shore Parkway (and 66th Street) to the south.

8.7.1.2 Description of the Site

The site, a pier currently used for parking by DSNY, is surrounded by chain-link fencing and, in some places, concrete barrier blocks or sheets of corrugated metal, which are attached to the fence. The pier area outside the fencing is overgrown with vegetation and strewn with litter. (See Figure 8.7-1.)

8.7.1.3 Urban Design and Visual Resources of the Study Area

The site affords views of the Bush Terminal Piers to the north, which consists of five deteriorated piers and filled interpier areas, notable for forested areas and ground vegetation. To the southeast, the monumental BAT buildings area also visible. The site offers expansive harbor views, but it is not part of an important view corridor that would connect important public places and/or historic resources. The industrial massive loft buildings inland are visible from the site to the east, as are the century-old red-brick loft buildings of Bush Terminal. The Gowanus Expressway, which marks the eastern limit of the study area, is visible from the waterfront site. On-street parking contributes to the industrial aesthetic of the area, as does the common appearance of chain-link property fencing, the lack of street trees or other vegetation and the lack of pedestrian amenities (such as benches and, in some cases, useable sidewalks). First Avenue north of 51st Street is in severe disrepair, with potholes and uneven pavement. Overhead wires also run above several side streets, crossing from one side to the other.

The waterfront south of the site, in the vicinity of the BAT, which has been redeveloped to attract varied light industrial and office uses, and as such, sidewalks and streetscapes, are generally tidier. Also, because the BAT is served by City buses, there are benches and similar amenities. The BAT and surrounding buildings, though clearly industrial in design and imposing in scale, are well maintained and visually attractive. (See Figure 8.7-2.)

Just inland from the site is the DSNY Garage 7/10, located on First Avenue at 51st Street, designed like similar garages elsewhere in the City – one story, with multiple garage bays. The sidewalks and streets surrounding it are neat and clean. The Lutheran Medical Center, including its medical facilities, offices and parking structure, located between First and Second Avenues (55th to 57th Streets), is institutional in appearance, with broad expanses of blank wall and bands of glazing. It is visually congruent with its industrial surroundings, though it does feature some landscaping near entrances along with well-traveled sidewalks.

Martin Luther Playground, located between 55th and 56th Streets, just east of Second Avenue and the Lutheran Medical Center, introduces a large (approximately ½-block) open space, with shade trees, landscaping and benches.

The remainder of the study area is a mix of industrial, residential and commercial uses in the blocks along Third Avenue. Many of the residences are well-maintained two- or three-story single-family homes built nearly adjacent to one another with front yards, driveways, mature trees and landscaping, though most are similarly designed three-story row houses with minimally landscaped, shallow front yards or none at all. Generally they are in good repair and feature attractive facades.

Urban Design and Visual Quality
52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

8.7.2 Future No-Build Conditions

The Future No-Build Conditions throughout the neighborhood study area are generally anticipated to resemble Existing Conditions. The Bush Terminals Piers Open Space project will be underway in 2006, and it is expected that some open space will be available for public access. While this will not noticeably change the general, vegetated appearance of much of the Bush Terminal site, it would allow for new vantage points of the 52nd Street Barge Staging Area site and the rest of the working maritime waterfront and its predominantly industrial surroundings. No new or important view corridors will be created, however. The remainder of the study area, through continued development of similar uses (e.g., the expansion of the Lutheran Medical Center) is anticipated to maintain an appearance and provide the same quality of streetscape and pedestrian environs as in Existing Conditions.

8.7.3 Potential Impacts with the 52nd Street Barge Staging Area

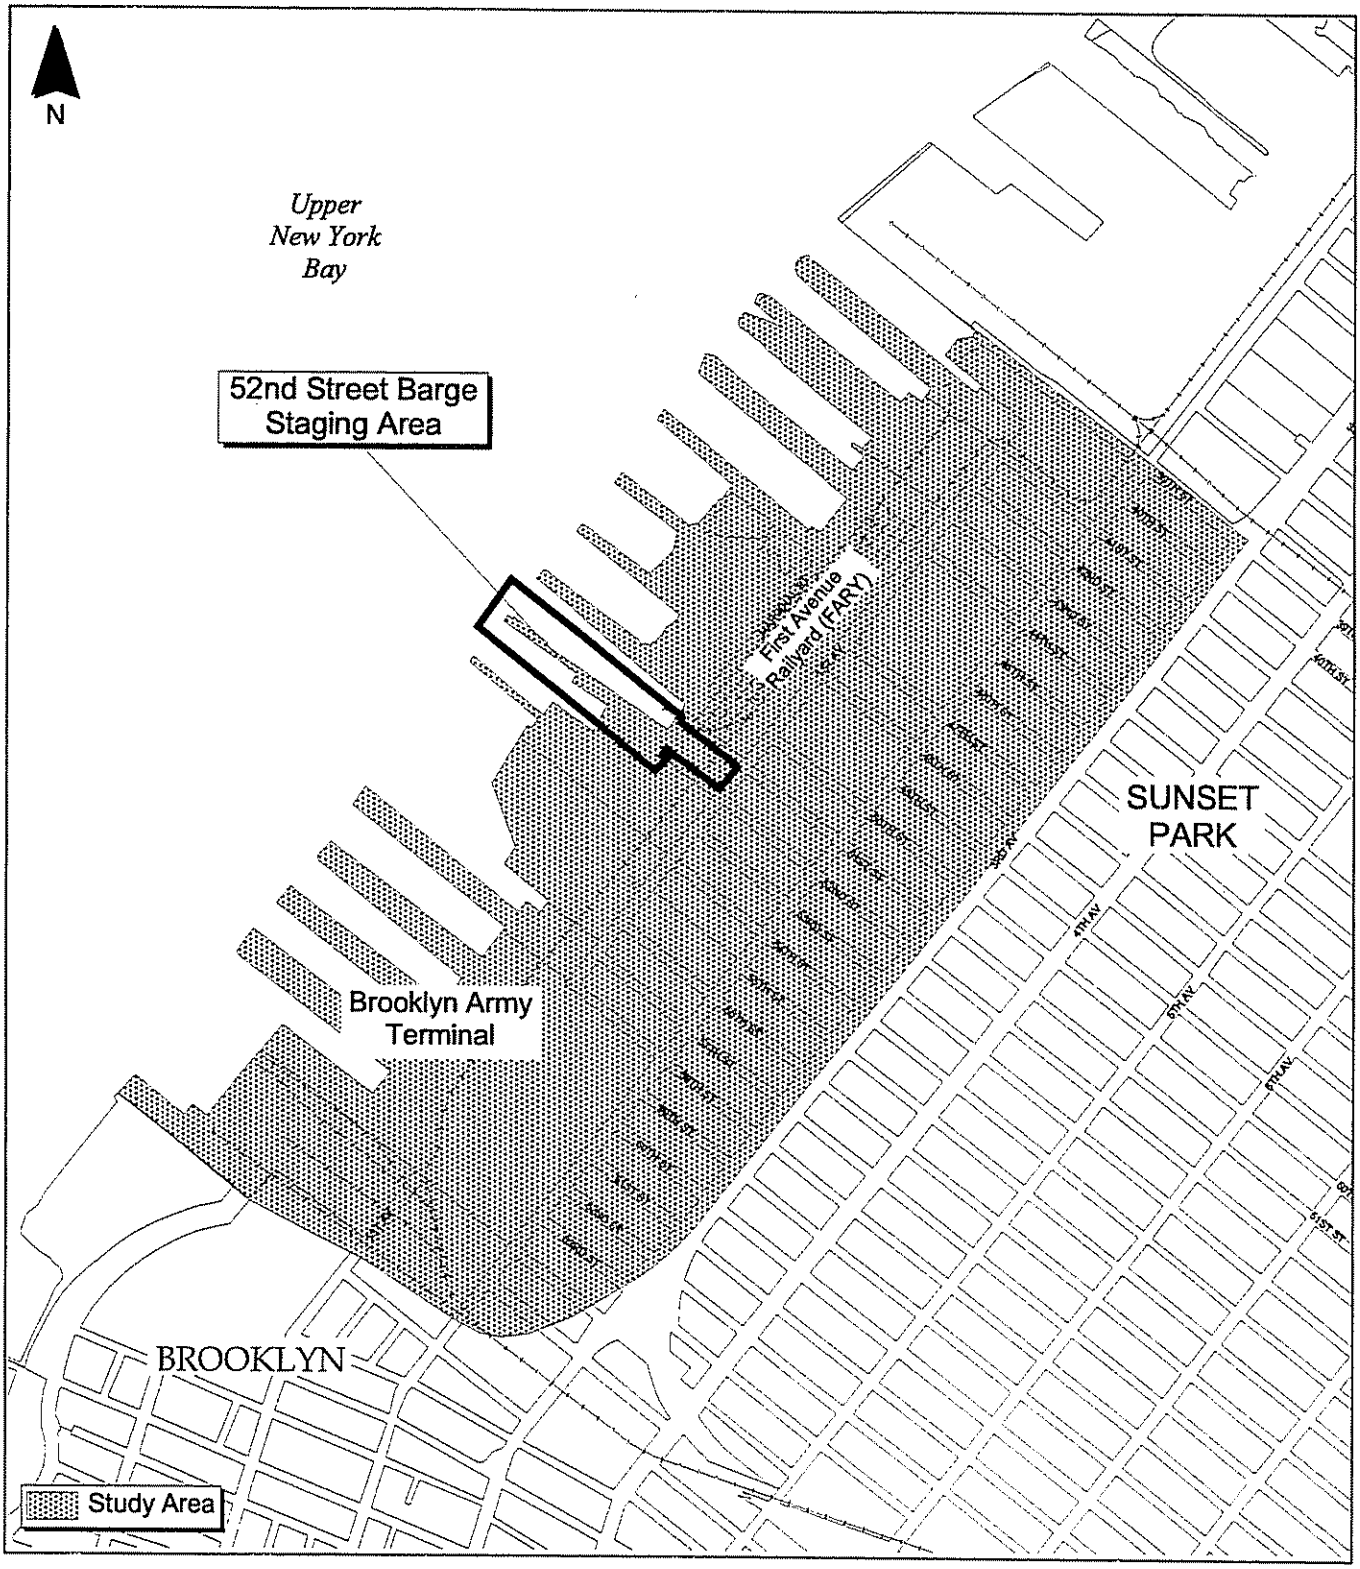
Development of the 52nd Street Barge Staging Area would establish a new visual element on the waterfront, in keeping with the general waterfront industrial aesthetic. Barges would be stored and maneuvered in the water surrounding the pier, including near the Bush Terminal Piers Open Space site, but they would not noticeably contribute to or detract from the visual landscape and waterfront views enjoyed from the proposed open space over the industrial maritime context.

The 52nd Street Barge Staging Area would not alter the development pattern of the waterfront area, as it would not alter street patterns or significantly affect the visual density of the built environment overall. Likewise, it would not it affect the context of the BAT, the nearest cultural resource to the site, in any significant or adverse way, since the BAT is designed to accommodate industrial waterfront activity. Therefore, no significant adverse impacts to urban design or visual resources would result from the 52nd Street Barge Staging Area.

8.8 Neighborhood Character

8.8.1 Existing Conditions

8.8.1.1 Definition of the Study Area



The study area is defined by physical landscape elements that distinctly mark the edge of a specific neighborhood character, visually insulate the site and study area, or physically obstruct pedestrian and vehicular access to it from outlying areas. The neighborhood character study area for the 52nd Street Barge Staging Area is defined by the predominantly industrial land use pattern and associated visual quality.

The site lies on the western shore of Brooklyn, on the Sunset Park waterfront. The study area for neighborhood character extends inland from the waterfront to the Gowanus Expressway and is bound by 39th Street to the north and Shore Parkway (and 66th Street) to the south. (See Figure 8.8-1.)

8.8.1.2 Description of Neighborhood Character

Like many industrial waterfront sites, this site is separated from nearby residential or other sensitive uses by major infrastructure elements, such as the elevated Gowanus Expressway and the First Avenue Rail Yard.

South of the site is the BAT and just beyond that is the narrow 65th Street Rail Yard, which provides barge-to-rail container facilities, alongside the Shore Parkway. The BAT is a large industrial complex that defines the southernmost part of the study area.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

Figure 8.8-1 Neighborhood Location

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The larger Sunset Park neighborhood (beyond the study areas) is a working class neighborhood with an ethnically and economically diverse population of approximately 120,000. A prominent local feature is the elevated Gowanus Expressway, above Third Avenue, that divides the community into its predominantly residential (to the east) and industrial (to the west) sectors. East of Third Avenue, the residential streets extend on an upward slope toward the high point of the community – which is also the highest point in Brooklyn – at about Sixth Avenue. The area's development and streetscapes are sufficiently historic and cohesive such that part of the neighborhood (east of the study area) is included on the NR.

The character of the study area, west of Third Avenue, differs considerably from the areas of Sunset Park to the east. Between Third and Second Avenues, just west of the elevated Gowanus Expressway, land uses are a mixture of residential and industrial. Third Avenue is lined with local retail businesses and walk-up tenement apartments. Second Avenue is primarily industrial, but some residential uses and vacant lots abut industrial uses on the side streets. The area west to First Avenue, within the bounds of the Bush Terminal complex, is solidly industrial, mainly consisting of low-rise warehouses and garages whose activities often spill out into the streets.

8.8.2 Future No-Build Conditions

The Future No-Build Conditions throughout the neighborhood study area are generally anticipated to resemble Existing Conditions. The most prominent development, the Bush Terminals Piers Open Space project, will be underway, and it is expected that some open space will be available for public access. Its ensemble of facilities will not be constructed by the Future No-Build year, however. The most notable change to neighborhood character within the study area will be the new opportunity afforded the local population of surrounding residential areas (east of the study area) to visit the waterfront and observe the predominantly industrial surroundings.

8.8.3 Potential Impacts with the 52nd Street Barge Staging Area

As an active port use on a historically maritime-industrial site, the 52nd Street Barge Staging Area would be consistent with the character of the study area. Although it would introduce a new visual element to the waterfront near the Bush Terminal Open Space, it would not preclude the use or enjoyment of the unique park, as it will not directly affect the park land itself, or indirectly affect access to the park or the quality of the park environs. (See Traffic, Air Quality, Odor and Noise analyses, Sections 8.14, 8.15, 8.16 and 8.17.)

8.9 Natural Resources

8.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise if the 52nd Street Barge Staging Area were developed.

8.9.1.1 Definition of Study Area

The study area includes the site and the waterfront section that is bulkheaded and bounded by Bay Ridge Channel, south of Gowanus Bay. The existing site houses a garage, parking lot, household dump and salt dome just off 52nd Street, and some open land behind the garage. There is a 900-foot-long pier that extends northwest of the property into Bay Ridge Channel. The pier is 40 feet wide at its west end and 56 feet wide at its east end. The concrete pier surface has severely cracked and buckled over time. The study area and the surrounding neighborhood areas are completely developed and, therefore, have very limited terrestrial natural resources. Such resources that do exist are discussed in following sections. Because the pier will be used as a barge staging facility, a description of aquatic communities is also included.

8.9.1.2 Geology

Based on information derived from a review of the Bedrock and Geologic Maps of New York County by Charles A. Baskerville, 1994, the bedrock lies 75 to 100 feet below surface sediment.[8] Surface sediment collected from the Hamilton Avenue MTS, located north of this site at the mouth of the Gowanus Canal, was mainly composed of fine-grained sediment.[9] Sediment at the 52nd Street Barge Staging Area is expected to be similar to that collected from the Hamilton Avenue MTS.

---

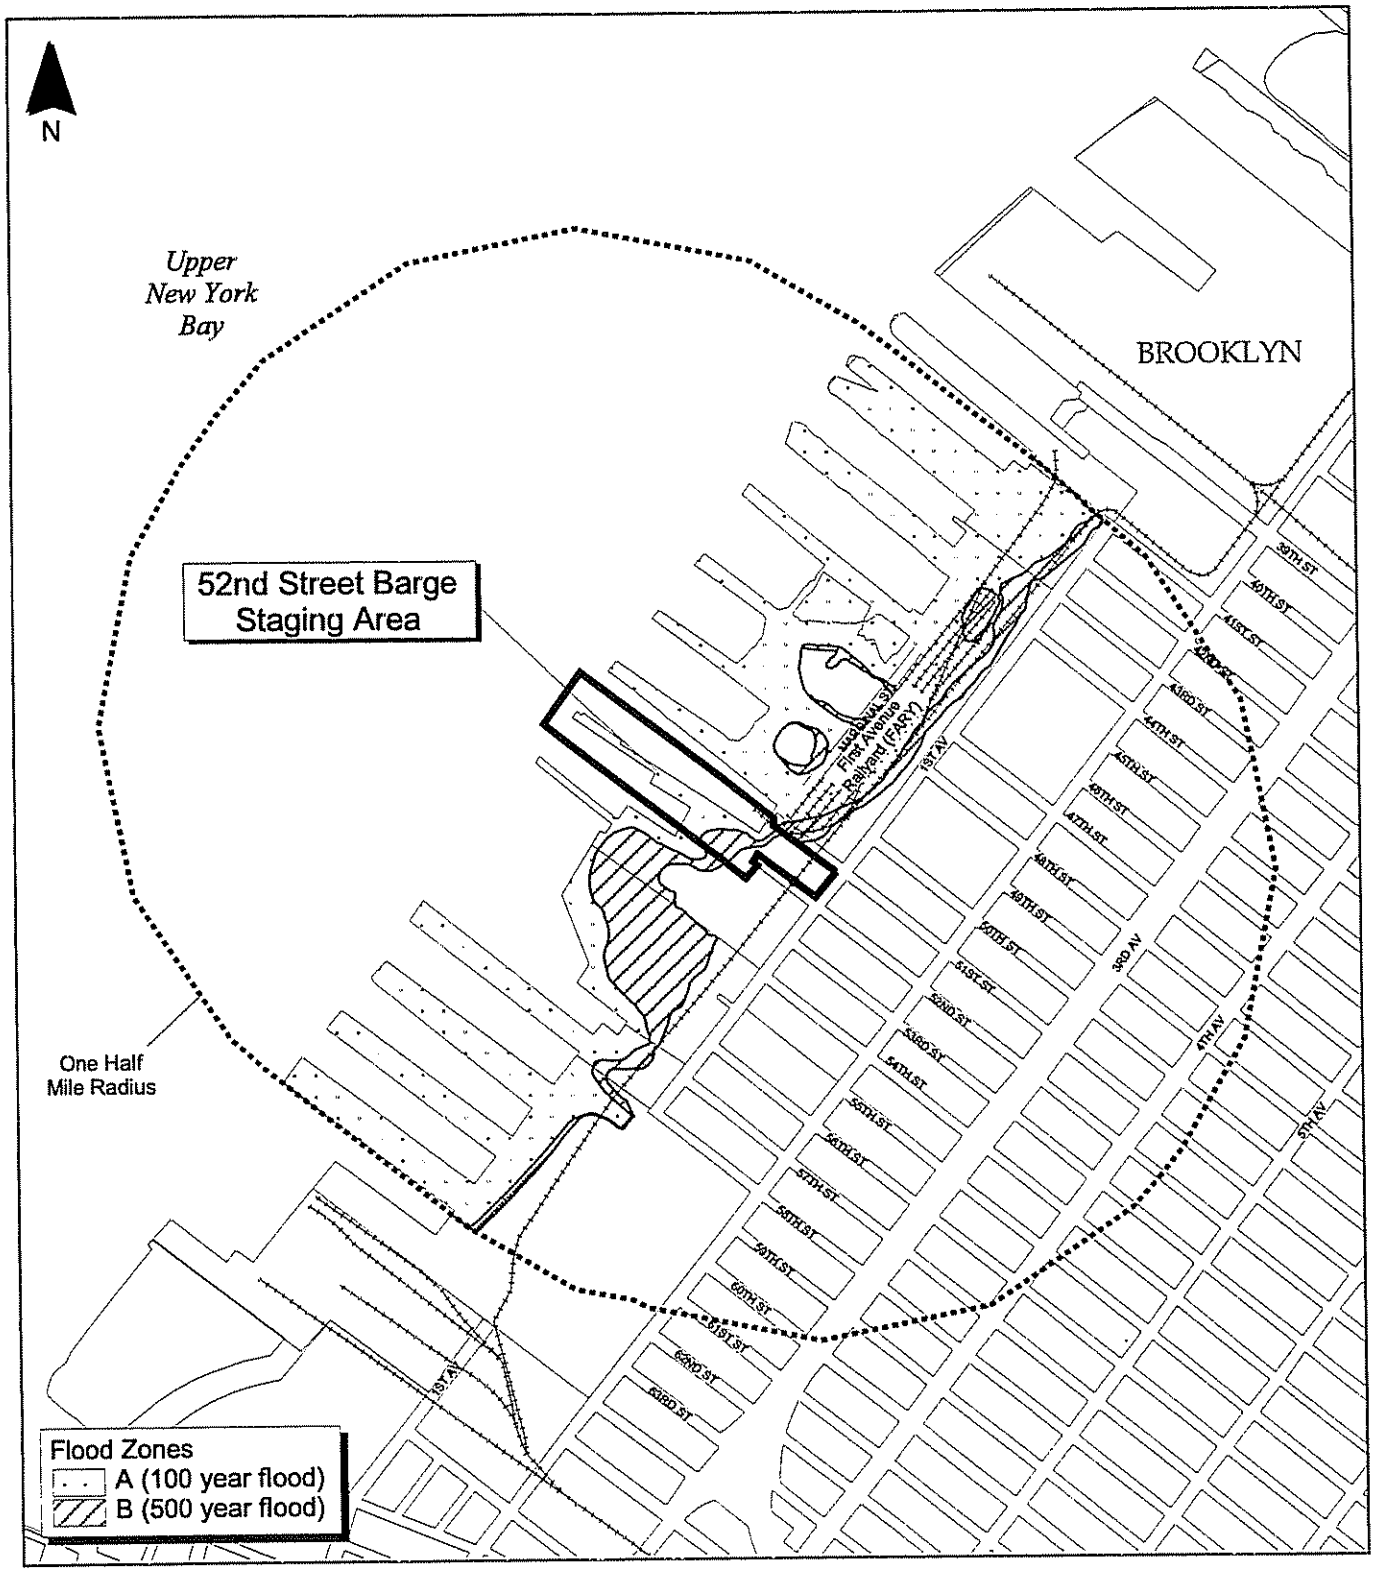
[9] New York City Department of Sanitation, March 2004. Marine Biological Studies of the Marine Transfer Stations Operated by the New York City Department of Sanitation. Prepared by EEA, Inc.

8.9.1.3 Floodplains



The site is within the 100-year coastal floodplain (see Figure 8.9-1). No intertidal wetlands exist on the study area. Bay Ridge Channel, however, is a NYSDEC-designated littoral zone (see Figure 8.9-2). The site is located within the City's WRP boundaries and is a designated SMIA.

8.9.1.4 Ecosystems

The site is essentially fully developed with the existing pier and buildings. Parking areas and paved roadways comprise the remainder of the site, leaving little terrestrial natural resources to be impacted. A few opportunistic, non-native weed species were identified along the edges and within the cracked portion of the pier. Those species identified include spotted spurge (*Chamaesyce maculate*), English plantain (*Plantago lanceolata*), lamb's quarters (*Chenopodium album*), black nightshade (*Solanum nigrum*), wild carrot (*Daucus carota*), lady's thumb (*Polygonum persicaria*), black medic (*Medicago lupulina*), horseweed (Conyza canadensis) and tree-of-heaven (*Ailanthus altissima*). As property limits were not clearly defined at the time of the survey, the investigation was focused along the pier; however, there were predominantly giant reed (*Phragmites australis*) and tree-of-heaven observed on the landward side of the property.

The aquatic natural resources found at the Hamilton Avenue Converted MTS, which were studied for an entire year in 2003[10], can be used to generally categorize the marine communities that would be found at the 52nd Street Barge Staging Area due to its proximity to the pier (the Hamilton Avenue Converted MTS is located at the mouth of the Gowanus Canal, just north of the 52nd Street Barge Staging Area). The dominant finfish larvae collected at the Hamilton Avenue MTS were winter flounder(*Pleuronectes americanus*), anchovy spp. (*Anchoa* spp.), Atlantic menhaden (*Brevoortia tyrannus*) and goby spp. (*Gobiosoma* spp.). The dominant finfish eggs collected were cunner (*Tautogolabrus adspersus*), bay anchovy (*Anchoa mitchilli*),

Figure 8.9-2 Wetlands

52nd Street Barge Staging Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

tautog (*Tautoga onitis*) and Atlantic menhaden. The species that have EFH listing (and the life stage collected) include windowpane (*Scophthalmus aquosus*) (eggs and larvae), winter flounder (larvae) and Atlantic herring (*Clupea harengus*) (larvae). The benthic invertebrates that were found at the Hamilton Avenue Converted MTS are similar to those found throughout New York Harbor. The most abundant species collected were worms – *Capitella capitata*, *Streblospio benedicti* and Oligochaetes – all of which are tolerant of polluted areas. The dominant epibenthic colonizers found at the Hamilton Avenue Converted MTS were *Polydora* sp. (worms), *Molgula manhattensis* (sea grapes), *Balanus* sp. (barnacles), and hydrozoa, mud and algal film.

According to the USF&WS, except for occasional transients, there are no federally-listed or proposed endangered or threatened species, or any "critical habitats" present on the site. According to the NYSDEC, there are no records of rare or state-listed animals or plants, significant natural communities or other significant habitats, on or in the immediate vicinity of the site.

8.9.2 Future No-Build Conditions

If the 52nd Street Barge Staging Area were not developed, the study area would remain as is. The limited aquatic and terrestrial natural resources will remain and the study area will continue to be a stressed urban area with limited ecological productivity.

8.9.3 Potential Impacts with the 52nd Street Barge Staging Area

8.9.3.1 Geology

The geology of the study area would not be impacted as a result of the 52nd Street Barge Staging Area other than by potential dredging activity, which would remove layers of sediments deposited over time.

8.9.3.2 *Floodplains*

Potential development of the 52nd Street Barge Staging Area would have no effect on the elevation of the site. The potential development does not include any provisions for raising any portions of the site over this level. The facility would be constructed within the 100-year floodplain and within the SMIA. The 52nd Street Barge Staging Area does not "substantially hinder" the area, however, and therefore complies with New York State's CMP as expressed in the City's local WRP.

8.9.3.3 *Ecosystems*

Construction of the 52nd Street Barge Staging Area would involve complete removal of the existing pier and construction of a new pier with the same dimensions. Assuming normal operations, this procedure should not involve any permanent impacts to the aquatic or terrestrial natural resources. During the removal of the existing pier, the upper organic silts lying beneath the structure would be disturbed to some degree, resulting in re-suspension of the sediments. However, the amount of re-suspended sediments is expected to be low, and the impacts, if any, highly localized. Turbidity and short-term lowered dissolved oxygen are possible, but not measurable, against the normal background fluctuations. Any dredging activities in the area to accommodate barges would result in an immediate, short-term destruction of the benthic invertebrates in the area; however, recolonization of the area by benthic invertebrates could be expected within 6 to 12 months after cessation of dredging activities.[11]

Given the relatively small size of the project and the existing impacts to the natural resources of the study area, minimal impact is expected from the disturbance of the environment associated with the 52nd Street Barge Staging Area.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from

[11] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft – Phase I-II. During Construction and 1st Year Post-Construction Studies.

construction; flatfish (flounders) are least sensitive. Finfish eggs and larvae are more sensitive to suspended sediment and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. In addition, larvae will be able to swim away from the impacted environments.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water, which results in shading that will block sunlight and hinder primary production. Because the proposed pier will match the footprint of the existing pier, the impacts will be no different than existing conditions. Barges, which were staged in higher numbers in the past than they will be in Future Build Conditions, will constantly be moving and therefore will not create any permanent shading. Additionally, with fewer barges staged on site than were in previous years, there will be a gain of unshaded water at this site, allowing more sunlight to penetrate the water for primary production.

Any upland construction would not have significant impact on the few areas of vegetation present on the site. Existing on-site buildings and paved parking areas have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Vegetation observed on the site was opportunistic weeds and plants, none of which were rare, endangered or particularly important from an ecological perspective. No significant terrestrial impacts would result from the 52nd Street Barge Staging Area because the site is already fully developed.

8.10 Hazardous Materials

8.10.1 Existing Conditions

Existing Conditions associated with the presence or suspected presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527-00). The assessment was performed in July and August of 2004. It included a historic land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps. A Freedom of Information Law request was sent to the NYCDEP for records pertaining to hazardous or toxic materials for the study area. A pedestrian reconnaissance of accessible areas within the study area was conducted in July 2004.

8.10.1.1 Definition of Study Area

The study area includes the existing 52nd Street pier structure located at the most western end of 52nd Street and neighboring properties within an approximate 1,000-foot radius. The pier is approximately 900 feet long; its widths at the western and eastern sections are approximately 40 feet and 56 feet, respectively. Located on the pier were electric winches, cleats, water pumps and several (non-permanent) locked trailers and containers. Reportedly these trailers were once utilized as lockers and offices for previous on-site DSNY barge and tug operations. The containers were reportedly utilized for equipment storage (e.g., welding supplies, boat lines, etc.).

8.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater, surface water and building components/equipment within the study area where the presence or likely presence of hazardous materials exists and the implementation of the 52nd Street Barge Staging Area could lead to an increased exposure of people or the environment to those materials.

No significant areas of concern were identified for this project site during the assessment. However, the western end of the pier appears to be collapsing and, therefore, care should be taken to prevent materials from entering the waters to become drift or pollution hazards.

8.10.2 Future No-Build Conditions

The 52nd Street Barge Staging Area would remain the same and there would be no significant recognized areas of concern with regard to hazardous materials; however, natural dilapidation of the pier would continue.

8.10.3 Potential Impacts with the 52nd Street Barge Staging Area

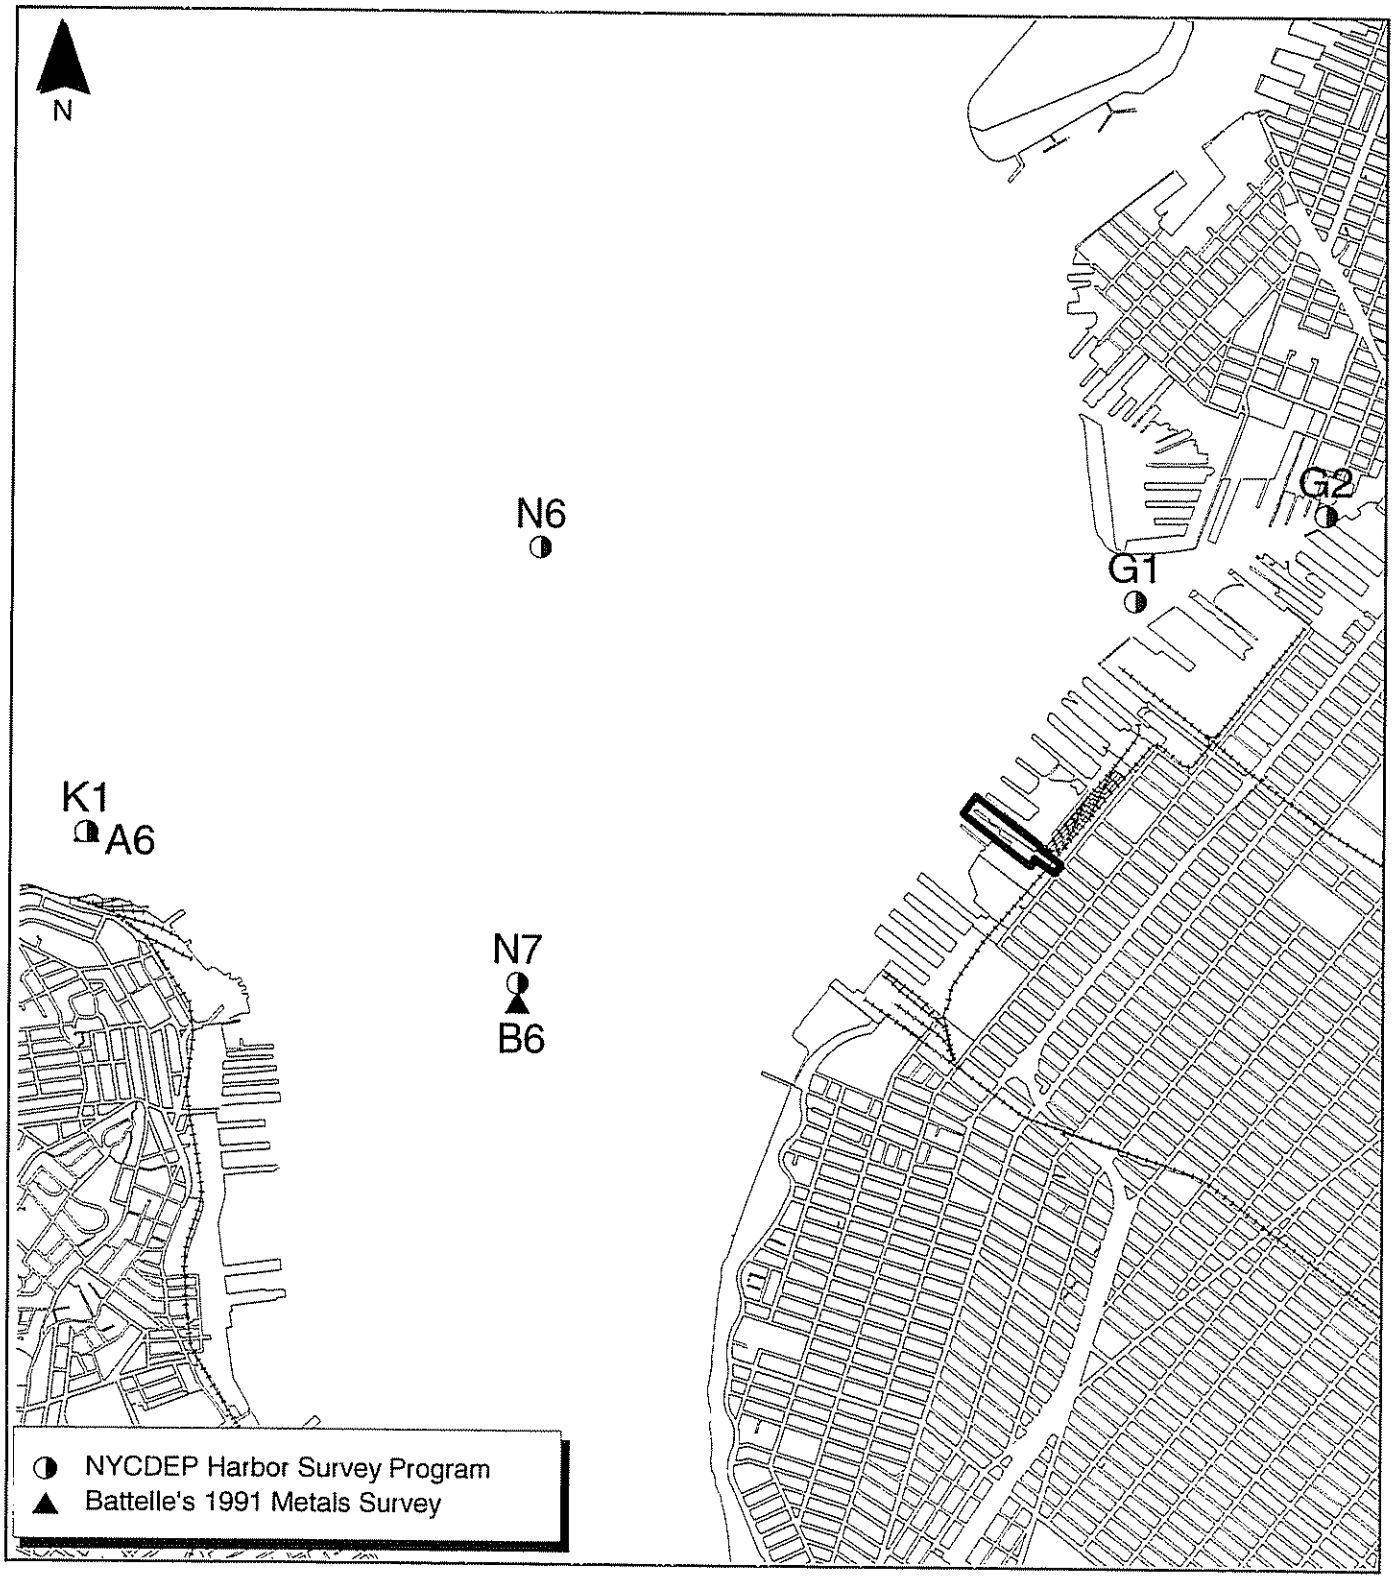
The 52nd Street Barge Staging Area would not result in adverse impacts to the site. Some benefits may be realized because a new pier would replace the existing pier. No testing would be required prior to the demolition of the existing pier. If any areas of concern were identified during the demolition or construction phase, an analysis would be made to determine what, if any, mitigation measures should be applied.

8.11 Water Quality

8.11.1 Existing Conditions

8.11.1.1 Definition of the Study Area

The water quality study area encompasses Upper New York Bay and includes discharges from point sources and CSOs located within ½-mile of the site.



8.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 8.11-1, are generally representative of conditions in the study area:

- NYCDEP Harbor Survey Program – Stations N-6 and N-7 in Upper New York Bay; and
- Battelle's 1991 Metals Survey – B-6 in Upper New York Bay.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 8.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class SD," which indicates fish survival only.

As shown in Table 8.11-1, on average, NYSDEC standards and guidance values are met. The mercury concentration for Battelle Station B-6 did not conform to the water quality standard for mercury.

Site delineations are approximate

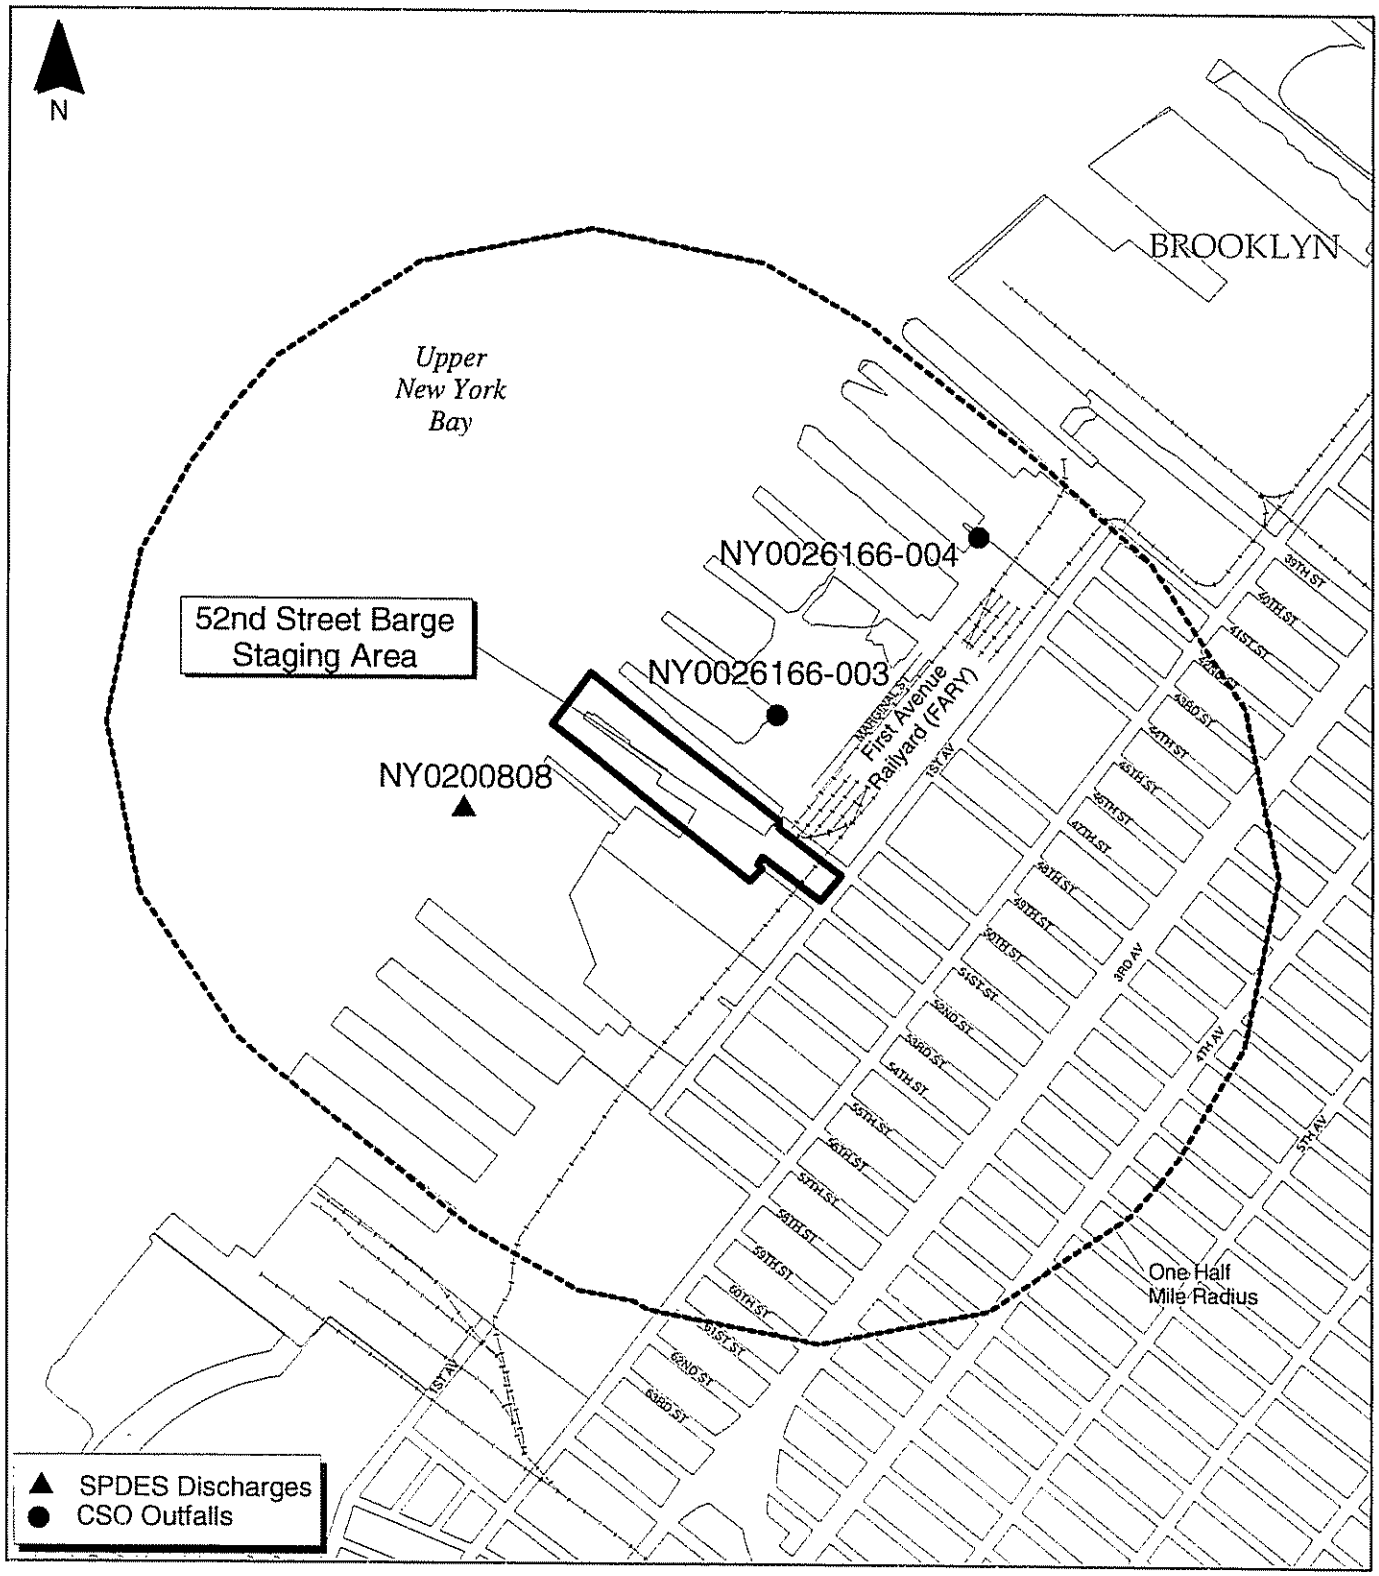
8.11.1.3 Permitted Discharges



A review of the most recently available NYSDEC and USEPA databases indicated that there are several permitted discharges in the vicinity of the site. Those within a ½-mile radius of the 52nd Street Barge Staging Area are shown in Figure 8.11-2 and listed in Table 8.11-2 The discharges consist of two CSOs and one industrial site, all of which are permitted by the NYSDEC.

8.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, estimates of stormwater pollutant loadings were calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and/or infiltration. A runoff flow of 0.059 cfs was calculated using the impervious site area (0.98 acres), an average rainfall intensity per storm of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 8.11-3, represent the existing loads at the site.

Site delineations and study area boundaries are approximate

Estimated Existing Pollutant Loads and Runoff Flows
52nd Street Barge Staging Area

Pollutant	Concentration	Pollutant Loading (lbs/day)
Fecal Coliform MPN/100ml	34,000	10,808[1]
BOD mg/L	11	3.5
Heavy Metals		
Copper µg/L	35	0.011
Lead µg/L	28	0.009
Zinc µg/L	154	0.049
Total Impervious Area (acre) = 0.98 Average Rainfall Intensity per Storm (inch/hour) = 0.06[2]		Runoff Coefficient (C) = 1.00 Runoff Flow (cfs) = 0.059

Notes:
[1] Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
[2] Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

8.11.2 Future No-Build Conditions

Water quality would be expected to be the same as Existing Conditions.

8.11.3 Potential Impacts with the 52nd Street Barge Staging Area

The potential impact of the stormwater pollutant loadings on surface water quality was evaluated using the 208 Model. This model was developed under Section 208 of the Clean Water Act to help state and local water quality management agencies integrate water quality activities and goals. The 208 Model was used to predict the incremental changes in BOD, fecal coliform, copper, zinc and lead that resulted from the stormwater loadings.

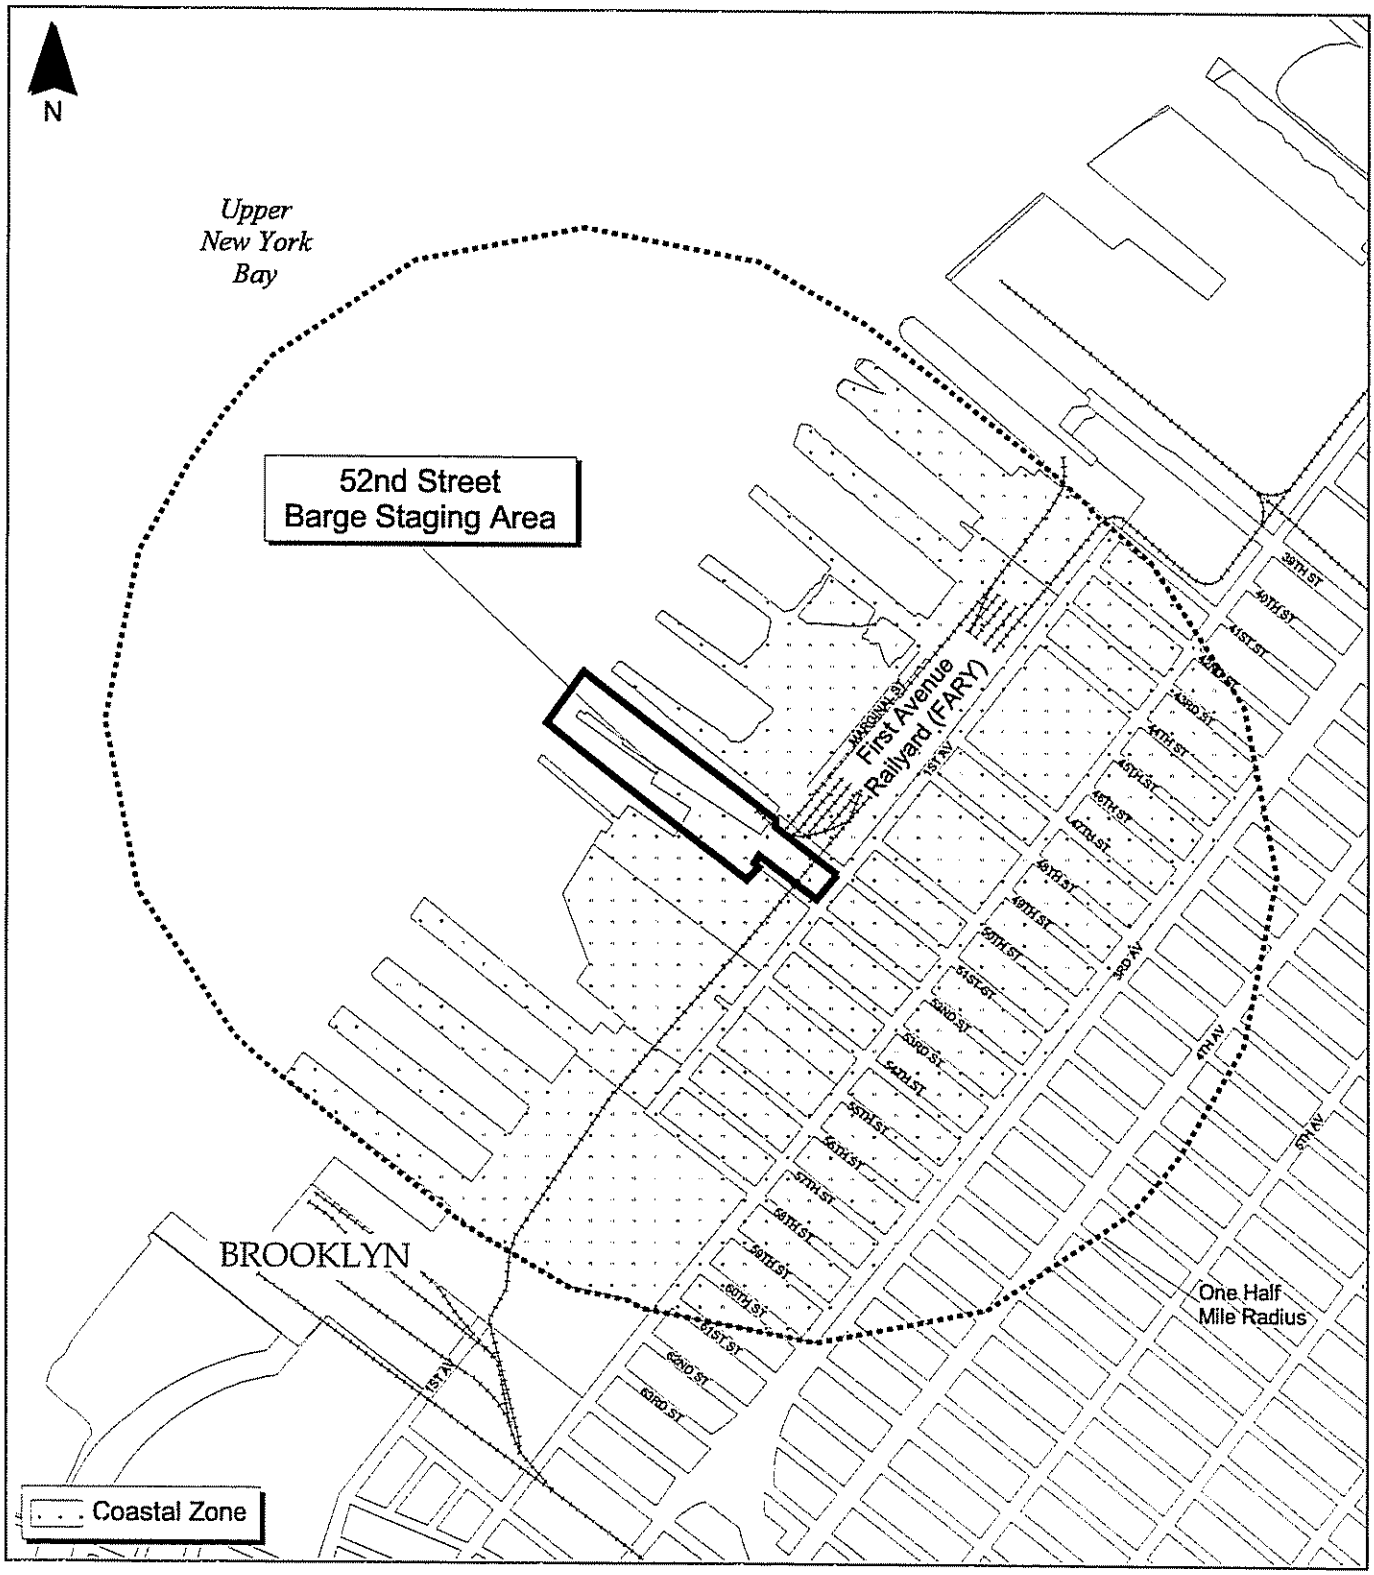
The 208 Model predicted no significant impact on existing surface water quality due to fecal coliform, BOD, copper, zinc and lead loadings from the 52nd Street Barge Staging Area. (See Table 8.11-4.) Stormwater runoff from the 0.98 acres of the barge staging area would not result in any further violation of water quality standards or guidance values beyond any existing violations.

Therefore the rebuilding of the 52nd Street Barge Staging Area would not affect water quality.

Table 8.11-4
Impervious Area and Estimated Pollutant Loads
52nd Street Barge Staging Area

			Estimated Pollutant Loadings/Incremental Change[1]				
Condition	Total Impervious Area (acres)	Change in Impervious Area (acres)	Fecal Coliform[2]	BOD (lbs/day)	Copper (lbs/day)	Lead (lbs/day)	Zinc (lbs/day)
Existing Conditions	0.98	NA	10,808/NA	3.5/NA	0.011/NA	0.009/NA	0.049/NA
Future Build Conditions	0.98	0	10,808/0	3.5/0	0.011/0	0.009/0	0.049/0

Notes:
[1] Incremental change refers to the difference in pollutant loading between the Existing Conditions and the Future Build Conditions.
[2] Coliform loads are not shown in pounds/day. Loading comparable to MPN/100 ml.
NA = Not Applicable



Unimpeded operation of the 52nd Street Barge Staging Area will also require dredging activities to construct the waterfront structures and to improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired before any such activities commenced. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not be expected to result in any significant adverse long-term impacts.

8.12 Waterfront Revitalization Program

8.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of the Upper New York Bay, the 52nd Street Barge Staging Area would be within the City's coastal zone boundary (see Figure 8.12-1). According to "The New Waterfront Revitalization Program," the 52nd Street Barge Staging Area would be classified as a water-dependent, industrial use. The site is located within a designated SMIA and Reach 14/East River and Upper New York Bay as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Brooklyn Waterfront." The 52nd Street Barge Staging Area is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The 52nd Street Barge Staging Area was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3 and 8.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14-1. In instances where a component of the 52nd Street Barge Staging Area required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below.

Site delineations and study area boundaries are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

8.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

The 52nd Street Barge Staging Area would not result in a significant increase in the need for public facilities or changes in infrastructure as the action would involve the replacement-in-kind of a previously existing pier. The 52nd Street Barge Staging Area would serve as a barge maintenance unit (BMU) to service barges and tugboats staged at the pier. No permanent structures would be constructed on the pier. A maximum of eight DSNY personnel would work at the site at one time. The Proposed Action would not have an adverse effect on the capacity of public facilities and infrastructure. The 52nd Street Barge Staging Area would, therefore, be consistent with this subpolicy.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The 52nd Street Barge Staging Area would be located within the limits of the NYCDCP-designated Sunset Park SMIA. The replacement of the 52nd Street Barge Staging Area would be an integral component of the City's Long Term Export Program. Under this program, the DSNY is proposing to convert the existing DSNY MTSs into TCB facilities that would allow for the containerization and transfer of DSNY-managed Waste by flat deck barges to intermodal facilities where the containers would be transloaded to either rail or ocean-going vessels for ultimate transport to out-of-City disposal facilities.

The proposed 52nd Street Barge Staging Area would provide a staging area with a maintenance unit for barges transporting containerized DSNY-managed Waste to and from the MTSs or intermodal facilities. In its current condition, the existing pier is unusable due to its deteriorated state. The proposed barge staging area would involve the removal and replacement of the existing pier structure. The proposed demolition and replacement of the existing pier would largely represent the continuation of an existing industrial and water-dependent use. The proposed replacement of the existing structure would be consistent with existing land uses in the immediate vicinity of the site and would not prevent the siting of any additional water-dependent uses. The Proposed Action would serve to maintain this use, while restoring and revitalizing industrial waterfront property. The Proposed Action would be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The Proposed Action would involve the replacement and revitalization of a previously existing use. Once rehabilitation efforts are complete, the 52nd Street Barge Staging Area would provide a staging area and maintenance unit for barges transporting containerized DSNY-managed Waste to and from the MTSs or intermodal facilities.

The proposed 52nd Street Barge Staging Area would involve the removal of the existing pier and a replacement with a comparable structure. Waterfront development would involve the complete removal of the existing structure. The new structure would be located at the same site as the existing pier and would be of comparable size. The structure would consist of a concrete deck supported by timber piles and substructure elements. The timber fender system would be constructed of 12-inch-by-12-inch timber fender wales mounted to timber piles, with timber chocks and panels and rubber fender units.

Dredging would be required to improve existing water depths at and in the immediate vicinity of the site and in order to allow for the unimpeded operation of barges and tugboats. All dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be acquired prior to any proposed dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 *Minimize conflicts between recreational, commercial, and ocean-going freight vessels.*

Development of the 52nd Street Barge Staging Area would involve the replacement-in-kind of a previously existing waterfront use and would not interfere with any maritime industrial, commercial or recreational vessel activities in the area. The proposed structure would have the capacity to accommodate up to 27 barges; however, it is assumed that normal transportation operations would only require approximately 16 barges to be staged at the 52nd Street Barge Staging Area at any one time. There would be no anticipated impact on other uses within the water body as "barge-swapping" activities would be in close proximity to the proposed structure. In addition, barge movements associated with the 52nd Street Barge Staging Area would be comparable to previous activities. Therefore, the 52nd Street Barge Staging Area would be consistent with this subpolicy.

3.3 *Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.*

The Proposed Action would involve the replacement and reactivation of an existing pier structure. Once development of the 52nd Street Barge Staging Area is complete, the pier would serve as a staging area for barges transporting containerized DSNY-managed Waste to and from the Converted MTSs or intermodal facilities. Barges staged at the proposed 52nd Street Barge Staging Area would be loaded with sealed, air- and watertight containers containing

DSNY-managed Waste processed at the Converted MTSs. No handling of solid waste would occur at the site.

For the BMU, it is expected that no permanent structures would be constructed on the pier. Two trailers for DSNY personnel use would be provided. Equipment (e.g., portable pumps, winch lines, boat lines) would be housed in storage containers. If applicable, on-site storage of petroleum products and hazardous materials related to the operation of the 52nd Street Barge Staging Area and BMU would be done in accordance with applicable federal, state and local regulations. The Proposed Action would be consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs, as described in "The New Waterfront Revitalization Program," as well as Recognized Ecological Complexes, the 52nd Street Barge Staging Area would not be located within a designated area. SCFWH information maintained by the New York State Department of State indicates that the 52nd Street Barge Staging Area would not be located within an SCFWH.

Development of the 52nd Street Barge Staging Area would involve the demolition of the existing facility and replacement-in-kind with a similarly sized and constructed structure. The proposed replacement of the pier would require dredging within Upper New York Bay to improve existing water depths at and in the immediate vicinity of the site in order to allow for unimpeded barge and tugboat operations. The 52nd Street Barge Staging Area would represent a revitalization of an existing previous industrial use and would not be anticipated to significantly impact natural resources in the vicinity of the site. The 52nd Street Barge Staging Area would, therefore, be consistent with this subpolicy.

4.2 *Protect and restore tidal and freshwater wetlands.*

A review of NYSDEC tidal and freshwater wetland maps was conducted in order to determine the presence of wetlands within the project site. As noted in Section 8.9, the 52nd Street Barge Staging Area would be located within portions of Upper New York Bay, designated by NYSDEC as a littoral zone, and no freshwater wetlands exist on the site. Development of the 52nd Street Barge Staging Area would involve the demolition of the existing structure and replacement-in-kind with a similarly sized facility. Dredging would be required to improve existing water depths at and in the immediate vicinity of the site to allow for the unimpeded operation of barges and tugboats. Dredging activities associated with the replacement of the existing pier would result in limited, short-term impact to these tidal wetlands.

The proposed 52nd Street Barge Staging Area is not anticipated to have significant impacts on wetland areas in the vicinity due to the previous and ongoing activities at and in the vicinity of the site and previous dredging activities that have historically occurred at the existing pier. Mitigation of potential impacts, if required, would be proposed during the permitting of the 52nd Street Barge Staging Area. This mitigation, if required, would address potential impacts that may occur due to the Proposed Action and would effectively restore these wetlands and their associated value. The 52nd Street Barge Staging Area, therefore, would be consistent with this subpolicy.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

A review of the NYSDEC NHP database indicates that there are no protected vulnerable plant, fish and wildlife species or rare ecological communities on or in the immediate vicinity of the proposed site.

As part of the 52nd Street Barge Staging Area, the existing pier and its foundation pilings would be removed. Dredging would be necessary to allow for the unimpeded operation of barges and tugboats. As stated in Section 8.9, modifications to the site would pose little, if any, adverse ecological impacts or loss of habitat for rare or endangered species due to previous and ongoing industrial and dredging activities at and in the vicinity of the site. Stormwater runoff from the 52nd Street Barge Staging Area and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The 52nd Street Barge Staging Area would also not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The Proposed Action would involve the removal and reactivation of an existing barge staging area. Once development of the 52nd Street Barge Staging Area is complete, the pier would serve as a staging area and maintenance unit for barges traveling to and from the converted MTSs or intermodal facilities. Barges staged at the 52nd Street Barge Staging Area would either be empty or would be loaded with sealed, air- and watertight containers carrying DSNY-managed Waste processed at the MTSs. No waste handling activities would be associated with the operation and use of the proposed barge staging area. All construction activities associated with the removal and subsequent replacement of the pier would be done in accordance with applicable regulations.

In addition, no permanent structures would be constructed on the pier. Two trailers for DSNY workers' use would be provided. Equipment (e.g., portable pumps, winch lines, boat lines) would be housed in three storage containers. If required, on-site storage of petroleum products and hazardous materials related to the operation of the 52nd Street Barge Staging Area would be done in accordance with applicable federal, state and local regulations. The Proposed Action would be consistent with this subpolicy.

5.2 *Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.*

The Proposed Action would involve the removal of the existing pier structure and subsequent replacement with a new, comparable structure. During the proposed replacement of the existing pier, BMPs would be used to the extent possible during all phases of construction and operation of the 52nd Street Barge Staging Area in order to minimize any nonpoint discharges. During construction, non-structural and, if necessary, structural, measures would be employed to minimize impacts to the surrounding environment. The 52nd Street Barge Staging Area would comply with federal, state and local requirements concerning the management of stormwater runoff and erosion. The Proposed Action would, therefore, be consistent with this subpolicy.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

Development of the 52nd Street Barge Staging Area would involve a replacement-in-kind of the existing pier structure with a comparable structure. Dredging would be necessary to provide sufficient water depths for unimpeded operations once the proposed barge staging area is operational. Any dredging done as part of construction may result in temporary impacts and would be conducted in a manner to minimize short-term impacts to water quality. In addition, non-structural and, if necessary, structural, measures would be used to minimize potential adverse impacts to tidal wetlands in the vicinity of the site. All dredged materials would be disposed of at a permitted facility in accordance with applicable federal, state and local regulations. Therefore, the 52nd Street Barge Staging Area would be consistent with this subpolicy.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The proposed development of the 52nd Street Barge Staging Area would have no impact on the quality or quantity of surface or ground waters. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer

or water supply. The 52nd Street Barge Staging Area would be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to a review of the FEMA National Flood Insurance Program maps, the 52nd Street Barge Staging Area would be located within the 100-year and 500-year floodplains (Zones A and B, respectively). The 52nd Street Barge Staging Area would involve the reconstruction of an existing facility at the same location as the existing pier structure. Replacement of the 52nd Street Barge Staging Area would not affect the potential for flooding or erosion. During construction, appropriate erosion and sediment controls would be employed to prevent significant erosion. In addition, no permanent structures would be constructed on the pier. To the extent practicable, non-structural measures would be used to minimize damage from flooding and erosion during the demolition of the existing pier and subsequent construction of the 52nd Street Barge Staging Area.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

No hazardous waste or other pollutants would be introduced to the environment due to the removal or replacement of the pier structure. The 52nd Street Barge Staging Area would serve as a staging area for barges transporting containerized DSNY-managed Waste to and from the Converted MTSs or intermodal facilities. Waste would be transported on barges in sealed, airtight containers. Barges staged at the 52nd Street Barge Staging Area could be empty or loaded with these sealed containers. No loss of this material would be anticipated.

In addition, no permanent structures would be constructed on the pier. Two trailers for DSNY worker's use would be provided. Equipment (e.g., portable pumps, winch lines, boat lines) would be housed in three storage containers. If applicable, on-site storage of petroleum products and hazardous materials related to the operation of the 52nd Street Barge Staging Area would be done in accordance with applicable federal, state and local regulations. The 52nd Street Barge Staging Area and BMU would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8. Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

The Proposed Action would involve the rehabilitation of an existing industrial use. Due to the industrial uses at and in the immediate vicinity of the 52nd Street Barge Staging Area, public access would not be compatible with the principal use of the site. Therefore, this subpolicy is not applicable.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The existing pier would involve the replacement-in-kind of a previously existing use with a comparable structure. The Proposed Action would represent a revitalization of a previously existing waterfront use. According to NYCDCP's "Plan for the Brooklyn Waterfront," development of a public access corridor is recommended for 52nd Street, located immediately adjacent to the proposed 52nd Street Barge Staging Area. The Proposed Action, however, would involve the rehabilitation of an existing industrial use and, due to the industrial activities being proposed at the site, public access would not be compatible. However, development of the 52nd Street Barge Staging Area would not preclude any future development of public access at other locations in the area that have been identified as potential public access sites.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

The 52nd Street Barge Staging Area would be considered a revitalization of an existing waterfront-industrial use and would not further impair visual access to coastal lands, waters or open space. See also response to Subpolicy 9.1.

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

The 52nd Street Barge Staging Area would represent a removal and replacement of an existing industrial use. The 52nd Street Barge Staging Area would, therefore, not result in any new impact on open space resources within the study area. Furthermore, the development of the 52nd Street Barge Staging Area would not preclude development of waterfront parks north or south of the site. Therefore, the Proposed Action would be consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The 52nd Street Barge Staging Area would be a replacement and revitalization of an existing waterfront use and would be compatible with the existing urban design context and visual conditions of this portion of the Upper New York Bay, as noted in Section 8.7. Based on the information presented in that section, the 52nd Street Barge Staging Area would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The 52nd Street Barge Staging Area would involve the revitalization of a previously existing use. The replacement-in-kind of the existing structure would pose no additional impact to scenic values associated with natural resources. Therefore, this subpolicy is not applicable.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

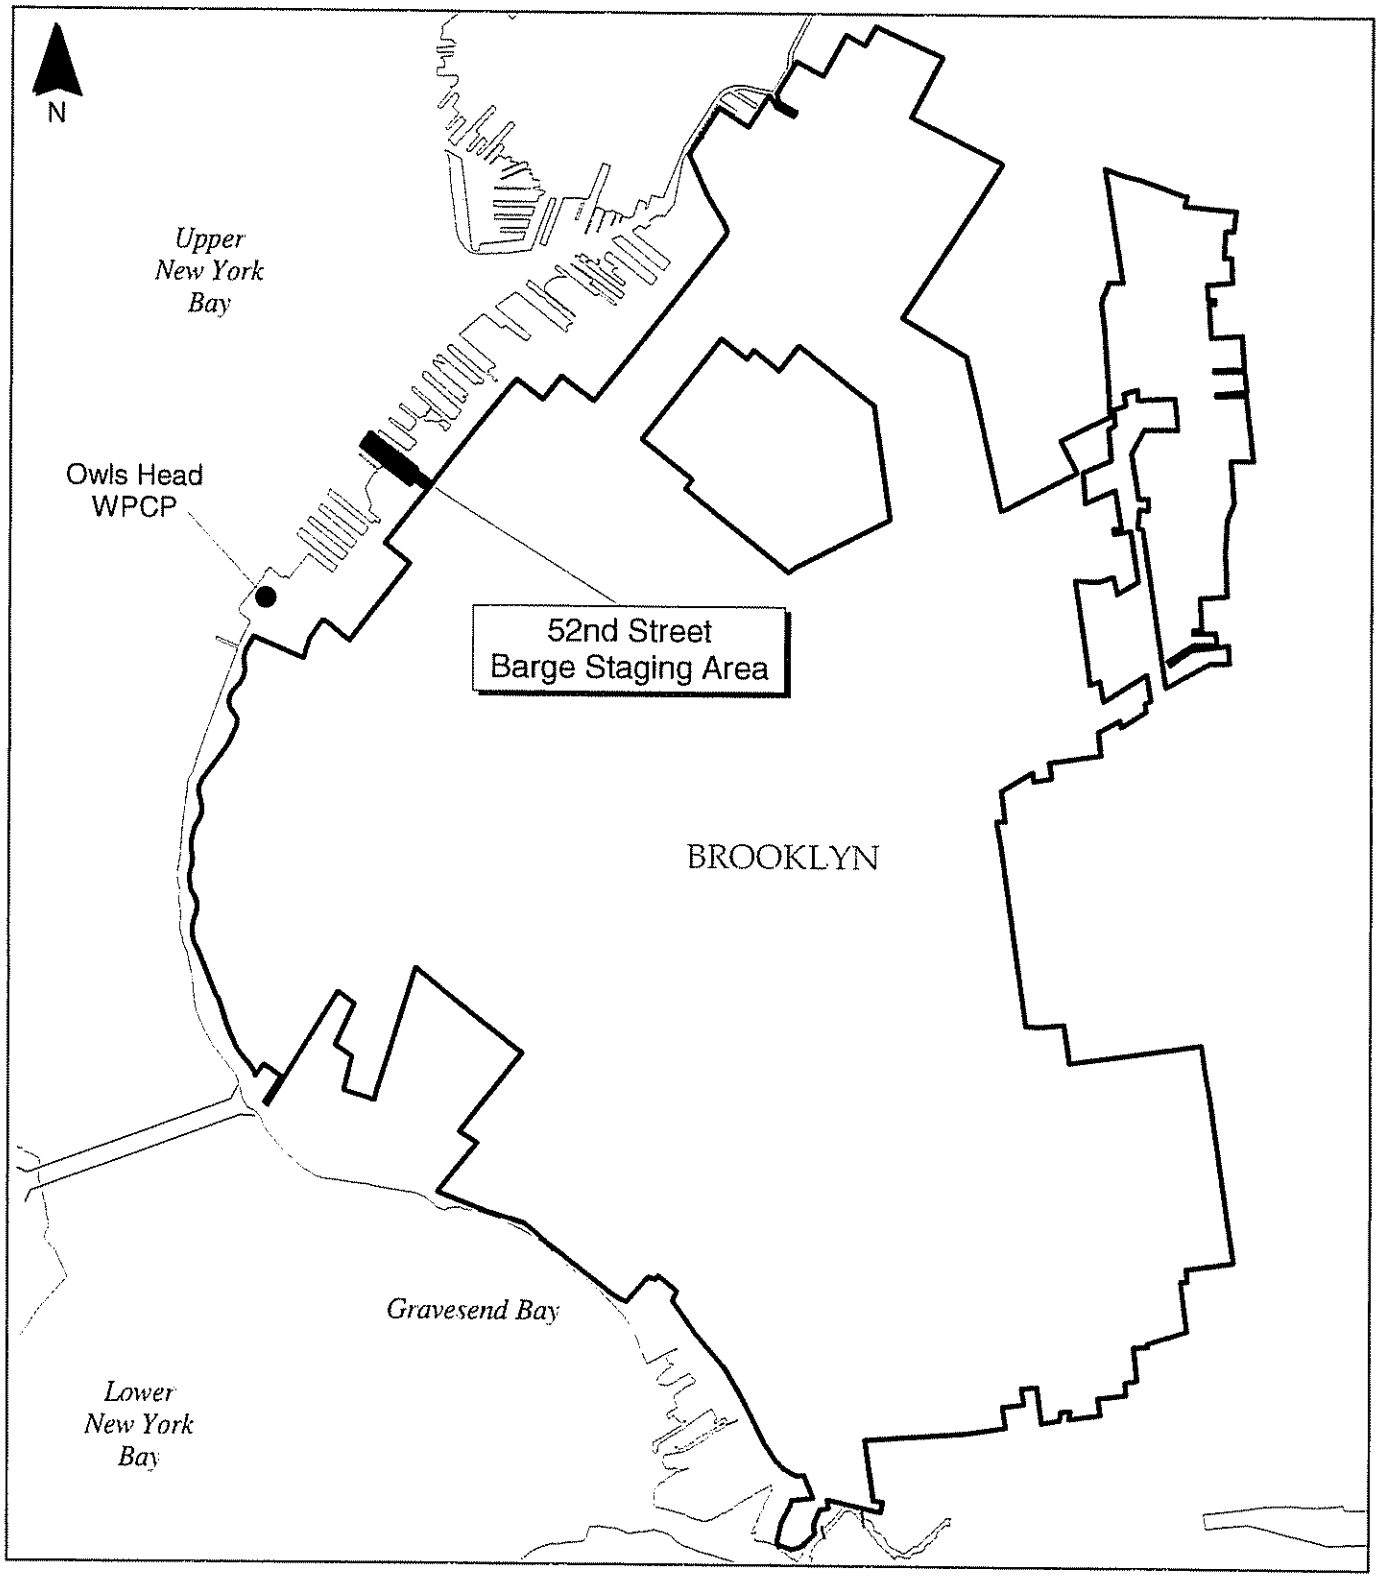
10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

The 52nd Street Barge Staging Area would have no effect on any cultural resources on or near the site, as noted in Section 8.6. Based on the information presented in that section, the 52nd Street Barge Staging Area would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site or in the study area. This subpolicy, therefore, is not applicable.

8.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



8.13.1 Existing Conditions

8.13.1.1 Water Supply

Potable water is supplied to the vicinity of the existing 52nd Street Barge Staging Area from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. A 12-inch-diameter water main exists along 52nd Street and the marginal street at the base of the pier along the waterfront, based on a review of NYCDEP water distribution maps. The 12-inch-diameter main is connected to a 20-inch-diameter water supply line that runs along 1st Avenue. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

8.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Owls Head WPCP, which serves the southwestern portion of Brooklyn. The WPCP drainage area is illustrated in Figure 8.13-1. From July 2002 through June 2003, the WPCP treated an average of 95 mgd of wastewater under dry weather flow conditions and an average flow of 104 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 8.13-1). The maximum dry weather flow during this period was 99 mgd in October 2002 and the maximum average flow was 114 mgd during June 2003. Effluent from the plant is discharged to Upper New York Bay and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the Owls Head WPCP is 120 mgd. As the 52nd Street Barge Staging Area is currently not staffed and no operations take place at the site, no water is used by personnel or process operations.

Site delineations are approximate

3000 0 3000 Feet

Figure 8.13-1 Existing WPCP Drainage Area

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Table 8.13-1
Average Monthly Dry Weather and Average Flows
Owls Head Water Pollution Control Plant
Fiscal Year 2003

Month	Dry Weather Flow (mgd)	Average Monthly Flow-(1) (mgd)
July 2002	90	93
August	94	99
September	97	107
October	99	113
November	96	111
December	96	104
January 2003	93	99
February	91	101
March	94	103
April	95	105
May	94	102
June	98	114
Average Effluent	**95**	**104**

Note:
~~(1)~~(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

Based on a review of the I&I maps and information provided by the NYCDEP, Brooklyn Water and Sewer Permits, the area in proximity to the 52nd Street Barge Staging Area is served by a 30-inch-diameter combined sewer line that flows in a northeast direction along 1st Avenue. The 30-inch line is connected to a regulator at the intersection of 1st Avenue and 49th Street. Combined sewage flows southwest from the regulator to the Owls Head WPCP through a 72-inch-diameter interceptor along 1st Avenue and Colonial Avenue. Overflow from the regulator is conveyed west along 49th Street to a CSO outfall in Upper New York Bay. In addition to the sewer lines along 1st Avenue, a 15-inch-diameter combined sewer line also flows from the east along 52nd Street to 1st Avenue and the 30-inch line. A 4-inch force main exists along 51st Street running from the DSNY-owned facilities east of the site to the 30-inch sewer on 1st Avenue.

8.13.1.3 Solid Waste

Commercial and industrial solid wastes generated in the City are collected by private companies. Residential solid waste and solid waste generated by certain City agencies is collected and managed by the DSNY. Based on information provided by the DSNY, the 52nd Street Barge Staging Area is not currently staffed, no operations take place, and no solid waste is generated at the site.

8.13.1.4 Energy

Consolidated Edison of New York supplies electricity to the existing facility. A review of utility maps from Consolidated Edison shows electric lines along 1st Avenue, 52nd Street and the marginal street at the foot of the barge staging area pier. Electricity is supplied to the pier through a connection located on the eastern edge of the marginal street.

Based on a review of relevant Keyspan Energy utility plates, several petroleum lines exist within the vicinity of the 52nd Street Barge Staging Area. Two 5-and-9/16-inch oil lines run in parallel and are located along 1st Avenue south of 52nd Street and along 52nd Street. These oil lines terminate roughly mid-block on 52nd Street west of 1st Avenue. An active 6-inch gas line runs west along 52nd Street from a 12-inch line located on 1st Avenue. At roughly mid-block, the 6-inch line is retired. Two additional retired 6-inch lines are also located along 1st Avenue: (1) on the east side of 1st Avenue to the north of 52nd Street; and (2) on the west side of 1st Avenue to the south of 52nd Street.

The 52nd Street Barge Staging Area currently utilizes a negligible amount of gas and electricity due to the absence of staff and a lack of operations.

8.13.2 Future No-Build Conditions

The 52nd Street Barge Staging Area would continue to be unstaffed and used for barge staging. Potable water use, process and wastewater generation, solid waste generation and energy use would remain at or near levels of zero as with Existing Conditions. Wastewater flows to the Owls Head WPCP would continue to increase and would be projected to be 104.6 mgd by 2006.

8.13.3 Potential Impacts with the 52nd Street Barge Staging Area

8.13.3.1 Water Supply

The 52nd Street Barge Staging Area would have up to 16 employees working three shifts per day. They would require approximately 400 gallons of potable water per day. The combined total usage of 400 gpd of potable water would represent an increase of 400 gpd above current consumption levels.

The 52nd Street Barge Staging Area would have no impact on the existing system's ability to supply water reliably. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

8.13.3.2 Sanitary Sewage

Based on the estimated water usage of 400 gpd for the Southwest Brooklyn Converted MTS, the small quantities of wastewater sent to the Owl's Head WPCP would not significantly impact the sewage flow rate or the ability of the Owl's Head WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 104.6 mgd in 2006, which would be well below the permitted capacity of 120 mgd. In addition, the new wastewater flow due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

8.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 16 facility employees per day, 125 pounds of solid waste would be generated per week (21 lbs/day) and would represent an incremental increase of approximately 125 pounds per week (21 lbs/day) above current waste generation levels. This volume would be managed at the Hamilton Avenue Converted MTS and would not significantly impact the system.

8.13.3.4 Energy

The 52nd Street Barge Staging Area has the necessary existing utility connections for electric supply in order to operate at its past levels of demand. Future electrical consumption demands are expected to revert to levels previously used by the 52nd Street Barge Staging Area when Fresh Kills Landfill on Staten Island was still operational. These levels of demand could be met by Consolidated Edison, as they were previously at this site, with no adverse affects on either the electrical utilities.

8.14 Traffic, Parking, Transit, and Pedestrians

8.14.1 Introduction

The 52nd Street Barge Staging Area would be a replacement-in-kind of the existing pier that would be used for staging of container barge movements between the Converted MTSs and intermodal transload facilities (barge-to-barge operations). Since this is a barge-to-barge operation, there is no truck traffic associated with this operation, and site-generated traffic resulting from employee trips and other miscellaneous trips would be minimal. Therefore, no off-site impacts are anticipated and no traffic analysis of this site was required.

8.15 Air Quality

8.15.1 Existing Conditions

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the 52nd Street Barge Staging Area.

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 8.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 8.15-1
Representative Ambient Air Quality Data
52nd Street Barge Staging Area

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	MTA, Flatbush Avenue, Between Tillary Street and Johnson Avenue	8-Hour	3,435 µg/m³	10,000 µg/m³
		1-Hour	4,695 µg/m³	40,000 µg/m³
NO_2	College Point Post Office	Annual	56 µg/m³	100 µg/m³
PM_{10}[(2)]	P.S. 314	Annual	25 µg/m³	50 µg/m³
		24-Hour	55 µg/m³	150 µg/m³
SO_2	P.S. 321	3-Hour	152 µg/m³	1,300 µg/m³
		24-Hour	94 µg/m³	365 µg/m³
		Annual	24 µg/m³	80 µg/m³

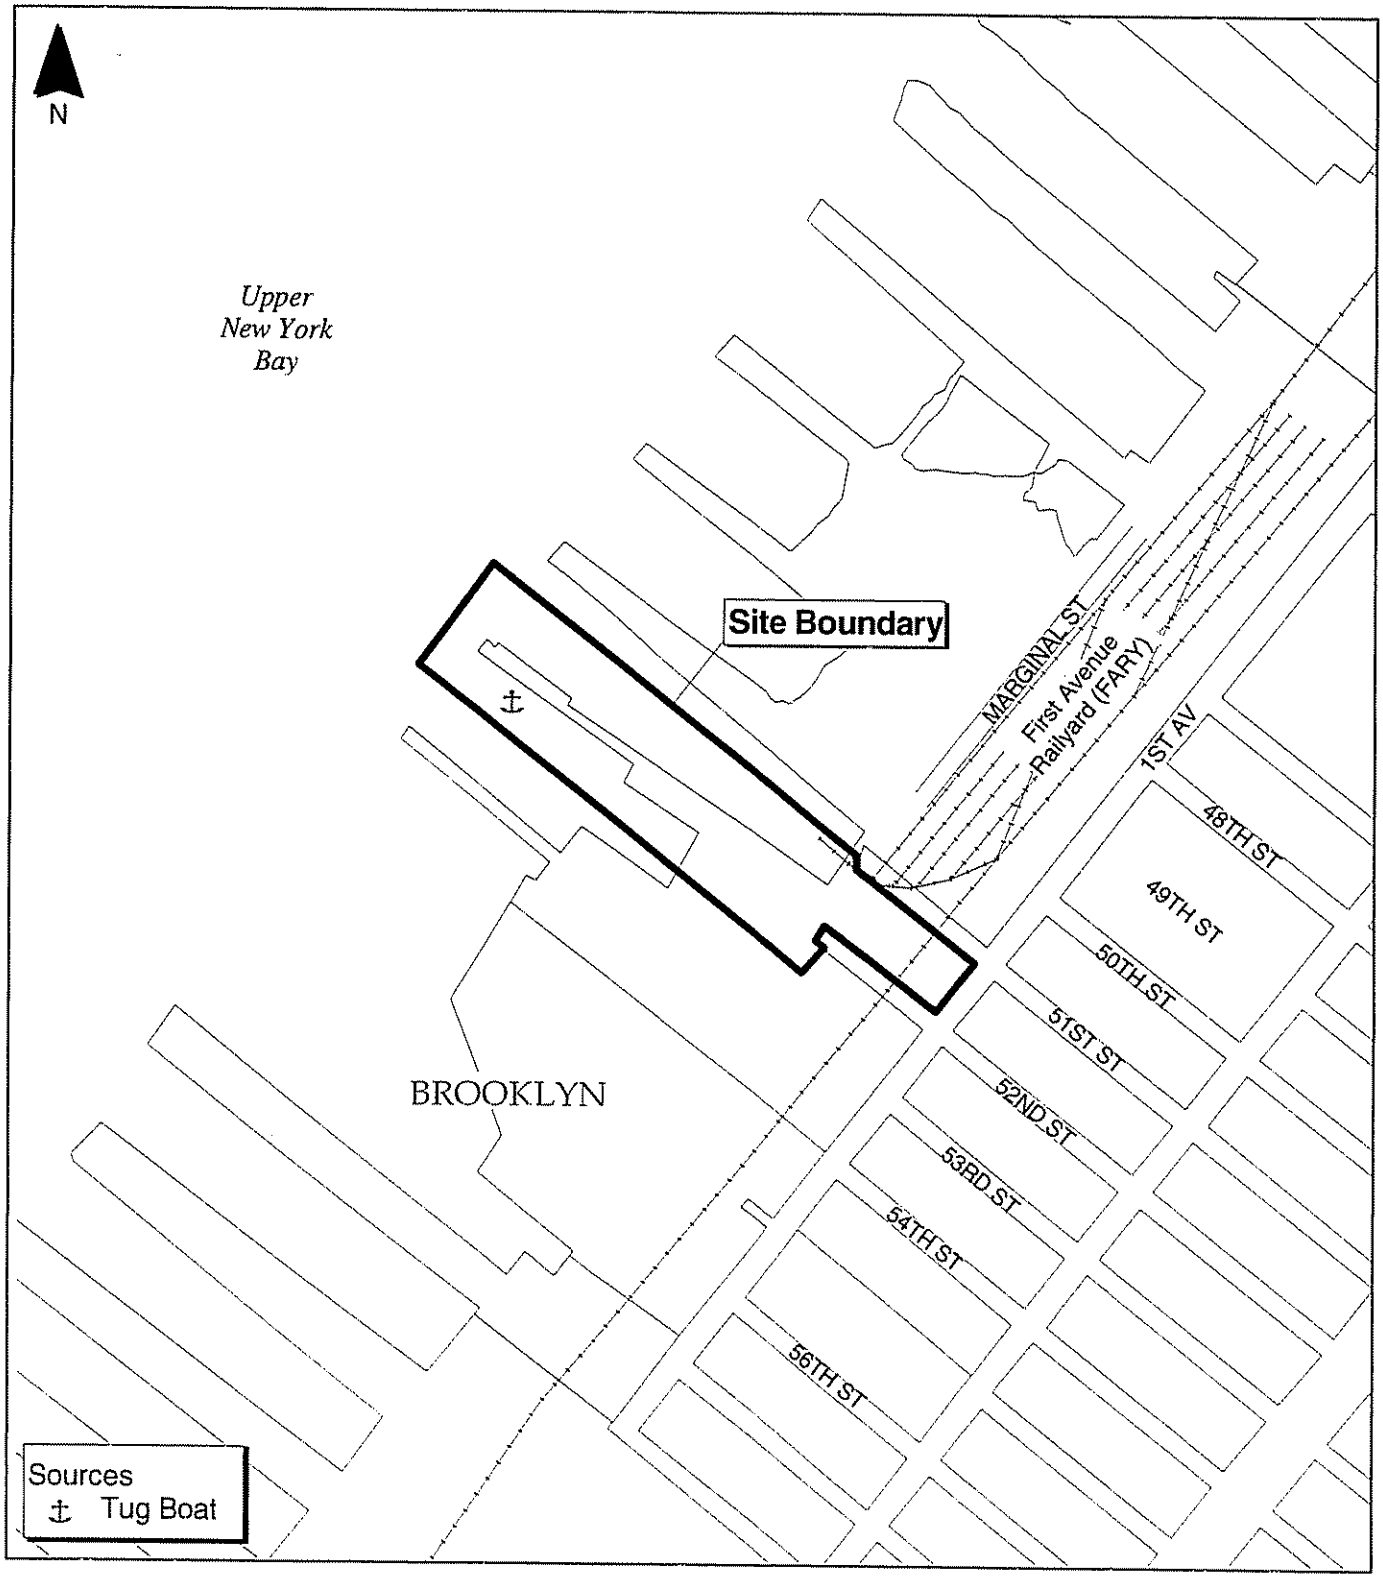
Note:
Source: NYCDEP, April 2003 & USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.
(2) Values are the highest pollutant levels recorded during the 1998 calendar year.

8.15.2 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the No-Build analysis year (2006). As such, no significant changes to air quality levels are anticipated, and Future No Build Conditions are expected to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be reduced by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

8.15.3 Potential Impacts with the 52nd Street Barge Staging Area

8.15.3.1 On-Site Analysis



8.15.3.1.1 Sources Considered in the Analysis

The source of emissions and the number of each type of source that is anticipated to be in operation during the peak hour and under the daily average conditions are provided in Table 8.15-2. Figure 8.15-1 shows the locations of these sources within the site.

Table 8.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
52nd Street Barge Staging Area

Type of Emission Source[1]	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated Over 24-hour and Annual Average Periods
Oceangoing Tugboats	1	1

Notes:
(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.
(2) This is based on operational capacity of the barge staging area.

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

8.15.3.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 8.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual PM_{25} concentrations from 52nd Street Barge Staging Area – generated equipment at any receptor locations considered, which are also presented in Table 8.15-3, are below the STVs. The 52nd Street Barge Staging Area would not, therefore, significantly impact air quality in the area.

8.15.3.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 8.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by USEPA as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the 52nd Street Barge Staging Area are not considered to be significant.

8.15.4.2 Off-Site Analysis

8.15.4.2.1 Pollutants Considered and Analyses Conducted

The 52nd Street Barge Staging Area is a barge-to-barge operation so it would not generate any truck traffic; therefore, no off-site impacts were analyzed.

Table 8.15-3
Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions
52nd Street Barge Staging Area

Pollutant	Averaging Time Period	Maximum Impacts from On-Site Emission Sources (1)	Background Pollutant Concentrations (2)	Highest Estimated On-Site Pollutant Concentrations	NAAQS(3)	STV(4)
Carbon Monoxide (CO), $\mu g/m^3$	1-hour(~~7~~6)	731	~~2,635~~ 3,781	~~3,366~~ 4,512	40,000	NA
	8-hour(~~7~~6)	80	~~3,322~~ 2,635	~~3,402~~ 2,715	10,000	NA
Nitrogen Dioxide (NO_2), $\mu g/m^3$	Annual	6	56	62	100	NA
Particulate Matter (PM_{10}), $\mu g/m^3$	24-hour(7)	1	~~57~~ 90	~~58~~ 91	150	NA
	Annual	0.2	~~23~~ 20	~~23~~ 20	50	NA
Particulate Matter ($PM_{2.5}$), $\mu g/m^3$	24-hour	1	NA	NA	NA	5
	Annual Neighborhood Average(~~6~~5)	0.03	NA	NA	NA	0.1
Sulfur Dioxide (SO_2), $\mu g/m^3$	3-hour(7)	185	~~189~~ 186	~~374~~ 371	1,300	NA
	24-hour(7)	4	~~87~~ 107	~~91~~ 111	365	NA
	Annual	1	~~21~~ 18	~~22~~ 19	80	NA

Notes:

~~(2)~~(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

~~(3)~~(2) Background concentrations were obtained from the NYCDEP in ~~April 2003.~~memorandum dated February 18, 2005.

~~(4)~~(3) NAAQS = National Ambient Air Quality Standard.

~~(5)~~(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

~~(6)~~(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

~~(7)~~(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

~~(8)~~(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

Notes to Table 8.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC.

(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.

(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

NA = Not Applicable

8.16 Odor

The 52nd Street Barge Staging Area would be used for the temporary mooring of barges and storage of marine supplies. The 2001 FEIS odor study included odor samplings from the following types of sources:

- Full barges (containing uncovered, loose, solid waste) moored outdoors;
- Empty barges (with solid waste debris) moored outdoors;
- Process building vents/stacks; and
- Shipping container (containing compacted waste) vent openings.

Samplings of the shipping container vents found no significant odor emissions. Therefore, an odor analysis for this site is not required.

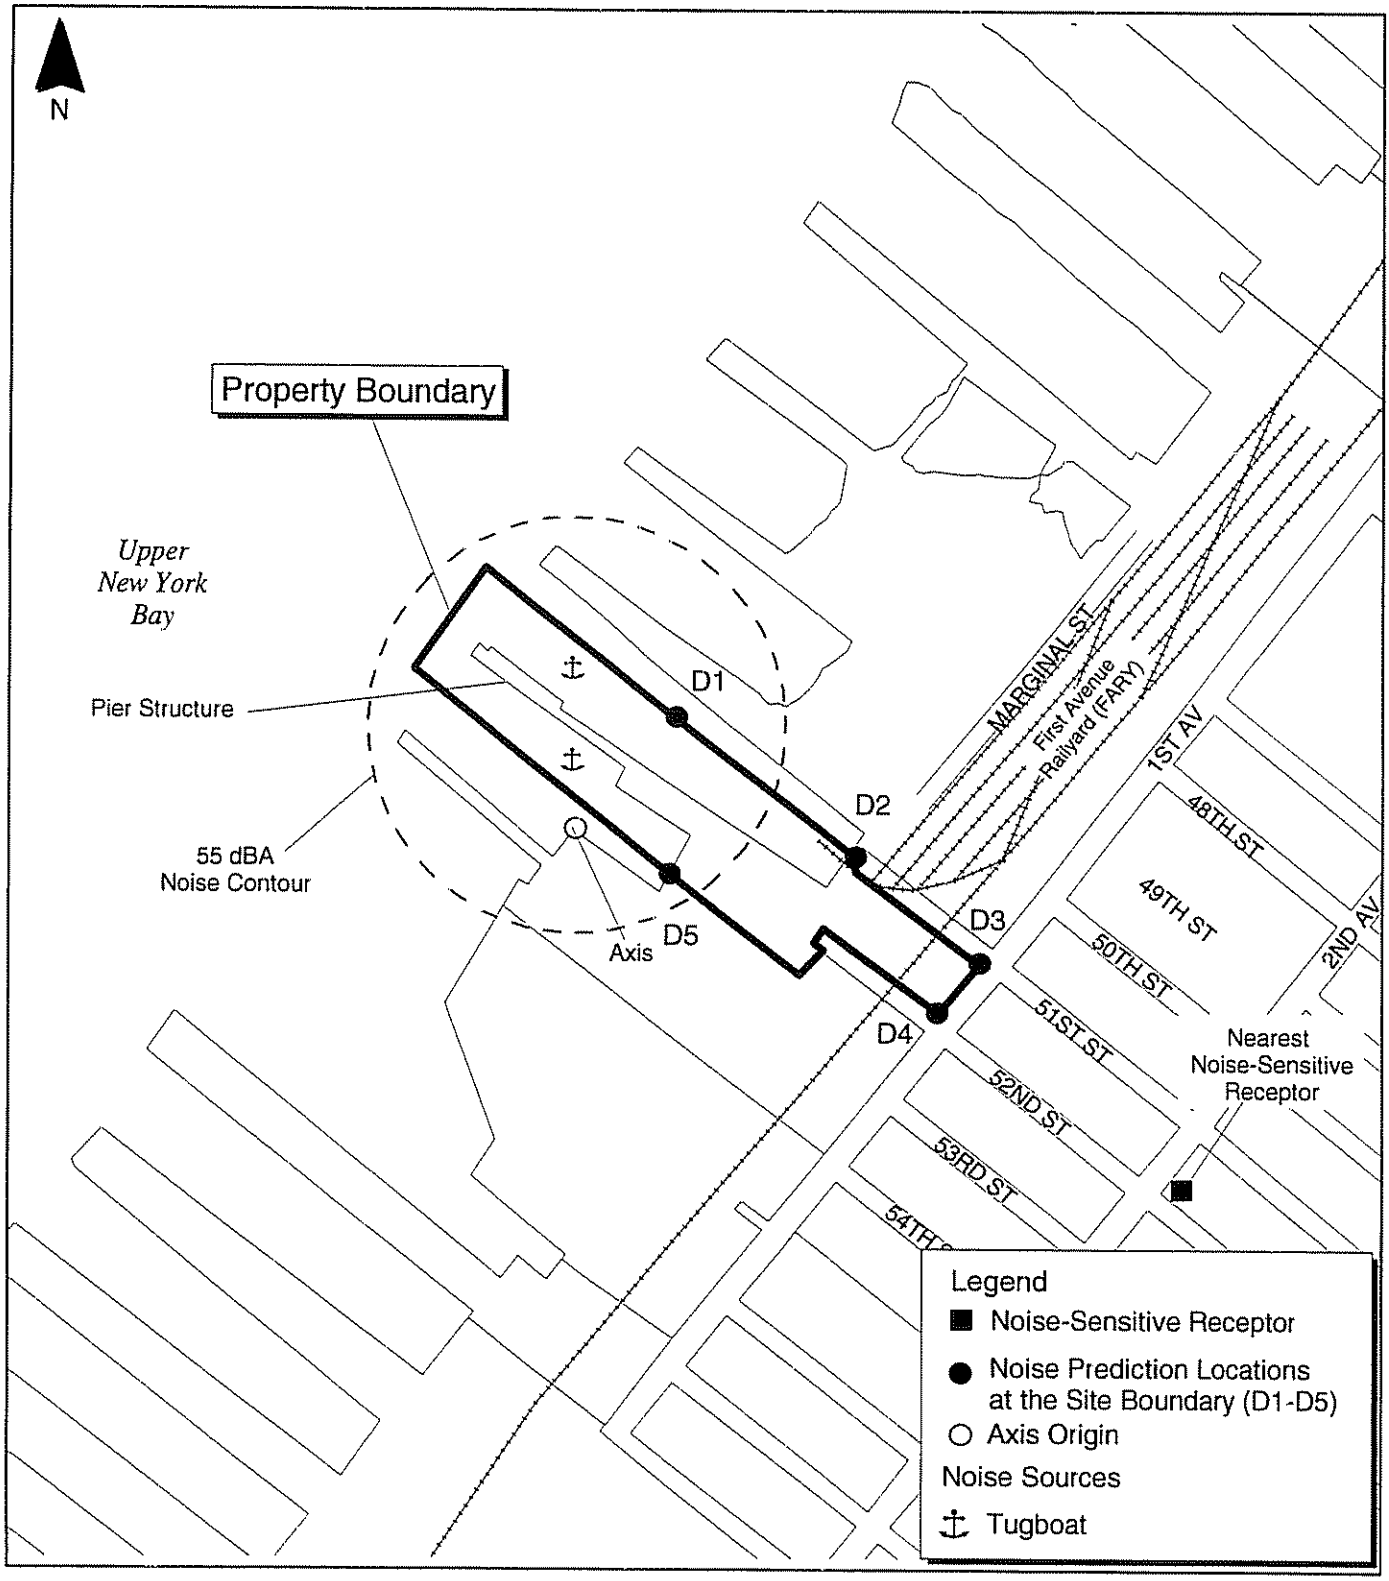
8.17 Noise

The noise analysis addresses on-site sources of noise emissions from the 52nd Street Barge Staging Area-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual and the Current New York City Noise Code. A New York City Zoning Code analysis was not performed for the 52nd Street Barge Staging Area since the only equipment proposed are tugboats, which are seen as transportation facilities and, therefore, were not included in a New York City Zoning Code analysis. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis. The 52nd Street Barge Staging Area would not generate any truck traffic; therefore, no off-site impacts were analyzed.

8.17.1 Existing Conditions

8.17.1.1 Introduction

Figure 8.17-1 shows the location of the 52nd Street Barge Staging Area, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is an apartment building located on the corner of 2nd Avenue and 52nd Street, approximately 263 meters (862 feet) from the site boundary.



8.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the apartment building. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[12] and the statistical metrics of L_5, L_{50} and L_{90}.[13] Table 8.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 1:00 a.m. and 2:00 a.m. and had an $L_{eq(1)}$ of 46.6 dBA on June 4, 2004. Activities and events that contribute to the on-site noise levels are as follows:

- Traffic from the BQE; and
- Other noise sources associated with activities in the surrounding industrial areas.

---

[12] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[13] Terms L_5, L_{50} and L_{90} are defined in Section 3.19.2.

Note:
[1] The 24-hour background noise levels were measured at the site boundary nearest to the closest sensitive receptor to identify the quietest background hour.

8.17.2 Future No-Build Conditions

8.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

8.17.3 Potential Impacts with the 52nd Street Barge Staging Area

8.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the 52nd Street Barge Staging Area and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 8.17-2. Shown earlier, Figure 8.17-1 indicates the 52nd Street Barge Staging Area layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 8.17-2
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
52nd Street Barge Staging Area

Equipment Name (quantity)(1)	Reference Sound Pressure Noise Level at 50 feet (dBA)(2)
Outdoor	
Oceangoing Tugboat (2)	73

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of individual pieces of equipment.

8.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the 52nd Street Barge Staging Area. Noise levels from all sources were combined to determine the location of the 55 dBA contour line. Since the on-site equipment for the 52nd Street Barge Staging Area consists of only two tugboats, the 55 dBA contour lies within the property boundary. The distance from the 55 dBA contour line to the property boundary is 359 meters (1,178 feet) in the direction of the nearest noise-sensitive receptor, which is 263 meters (862 feet) from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA, (i.e., the point off site where noises generated on-site attenuate to 55 dBA), is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (See Figure 8.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was not required.

8.17.3.1 Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the 52nd Street Barge Staging Area boundary to determine the total L_{eq} from outdoor sources for comparison to the current Noise Code. This is shown in Table 8.17-3. Based on this analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.

8.17.3.2 Combined On-Site and Off-Site Noise Levels

As a result of the on-site screening analysis performed for the 52nd Street Barge Staging Area, an on-site noise analysis was required. An off-site noise analysis was not required, therefore, a combined noise analysis was not performed.

CHAPTER 9 ENVIRONMENTAL REVIEW – HARLEM RIVER YARD BARGE TO RAIL INTERMODAL YARD.

9.1 Introduction

The HRY Barge to Rail Intermodal Yard, located within the HRY complex and on property contiguous to the HRY Truck to Rail TS, would receive barge deliveries of containers from one or more Converted MTSs. The HRY Barge to Rail Intermodal Yard site was previously analyzed as a site for an EBUF in the 2000 SWMP FEIS, which found there were no unmitigatible adverse environmental impacts associated with the EBUF operations. At that time, however, no $PM_{2.5}$ analysis was required and the HRY Truck to Rail TS was not yet operating. Therefore, this FDEIS presents the on-site air quality analysis of $PM_{2.5}$ and an on-site noise analysis that includes operations of the HRY Truck to Rail TS at its currently permitted 4,000 tpd capacity in conjunction with the operation of the HRY Barge to Rail Intermodal Yard. The information presented in Sections 9.2 through 9.12 of this (New SWMP) DFEIS ~~will be~~has been updated from the 2000 SWMP FEIS ~~in the subsequent New SWMP FEIS~~. Because the HRY Barge to Rail Intermodal Yard would not receive any collection vehicle deliveries of waste, off-site traffic, air quality and noise analyses are not required.

The results of the environmental analyses of the HRY Barge to Rail Intermodal Yard are presented in the following sections:

9.2 Land Use, Zoning, and Public Policy
9.3 Socioeconomic Conditions
9.4 Community Facilities and Services
9.5 Open Space
9.6 Cultural Resources
9.7 Urban Design, Visual Resources, and Shadows
9.8 Neighborhood Character
9.9 Natural Resources
9.10 Hazardous Materials
9.11 Water Quality

9.12 Waterfront Revitalization Program

9.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

9.14 Traffic, Parking, Transit, and Pedestrians

9.15 Air Quality

9.16 Odor

9.17 Noise

Section 2.2.6 provides a summary description of the site and important characteristics of the design and operation of the facility. The following sections provide additional information on the site or the study area, as appropriate to each analysis.

A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3.

9.2 Land Use, Zoning, and Public Policy

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.3 Socioeconomic Conditions

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.4 Community Facilities and Services

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.5 Open Space

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.6 Cultural Resources

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.7 Urban Design, Visual Resources, and Shadows

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.8 Neighborhood Character

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.9 Natural Resources

9.9.1 Existing Conditions

Existing conditions include stressed aquatic and terrestrial communities that are typical of this area of the Bronx. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from implementation of the HRY Barge to Rail Intermodal Yard.

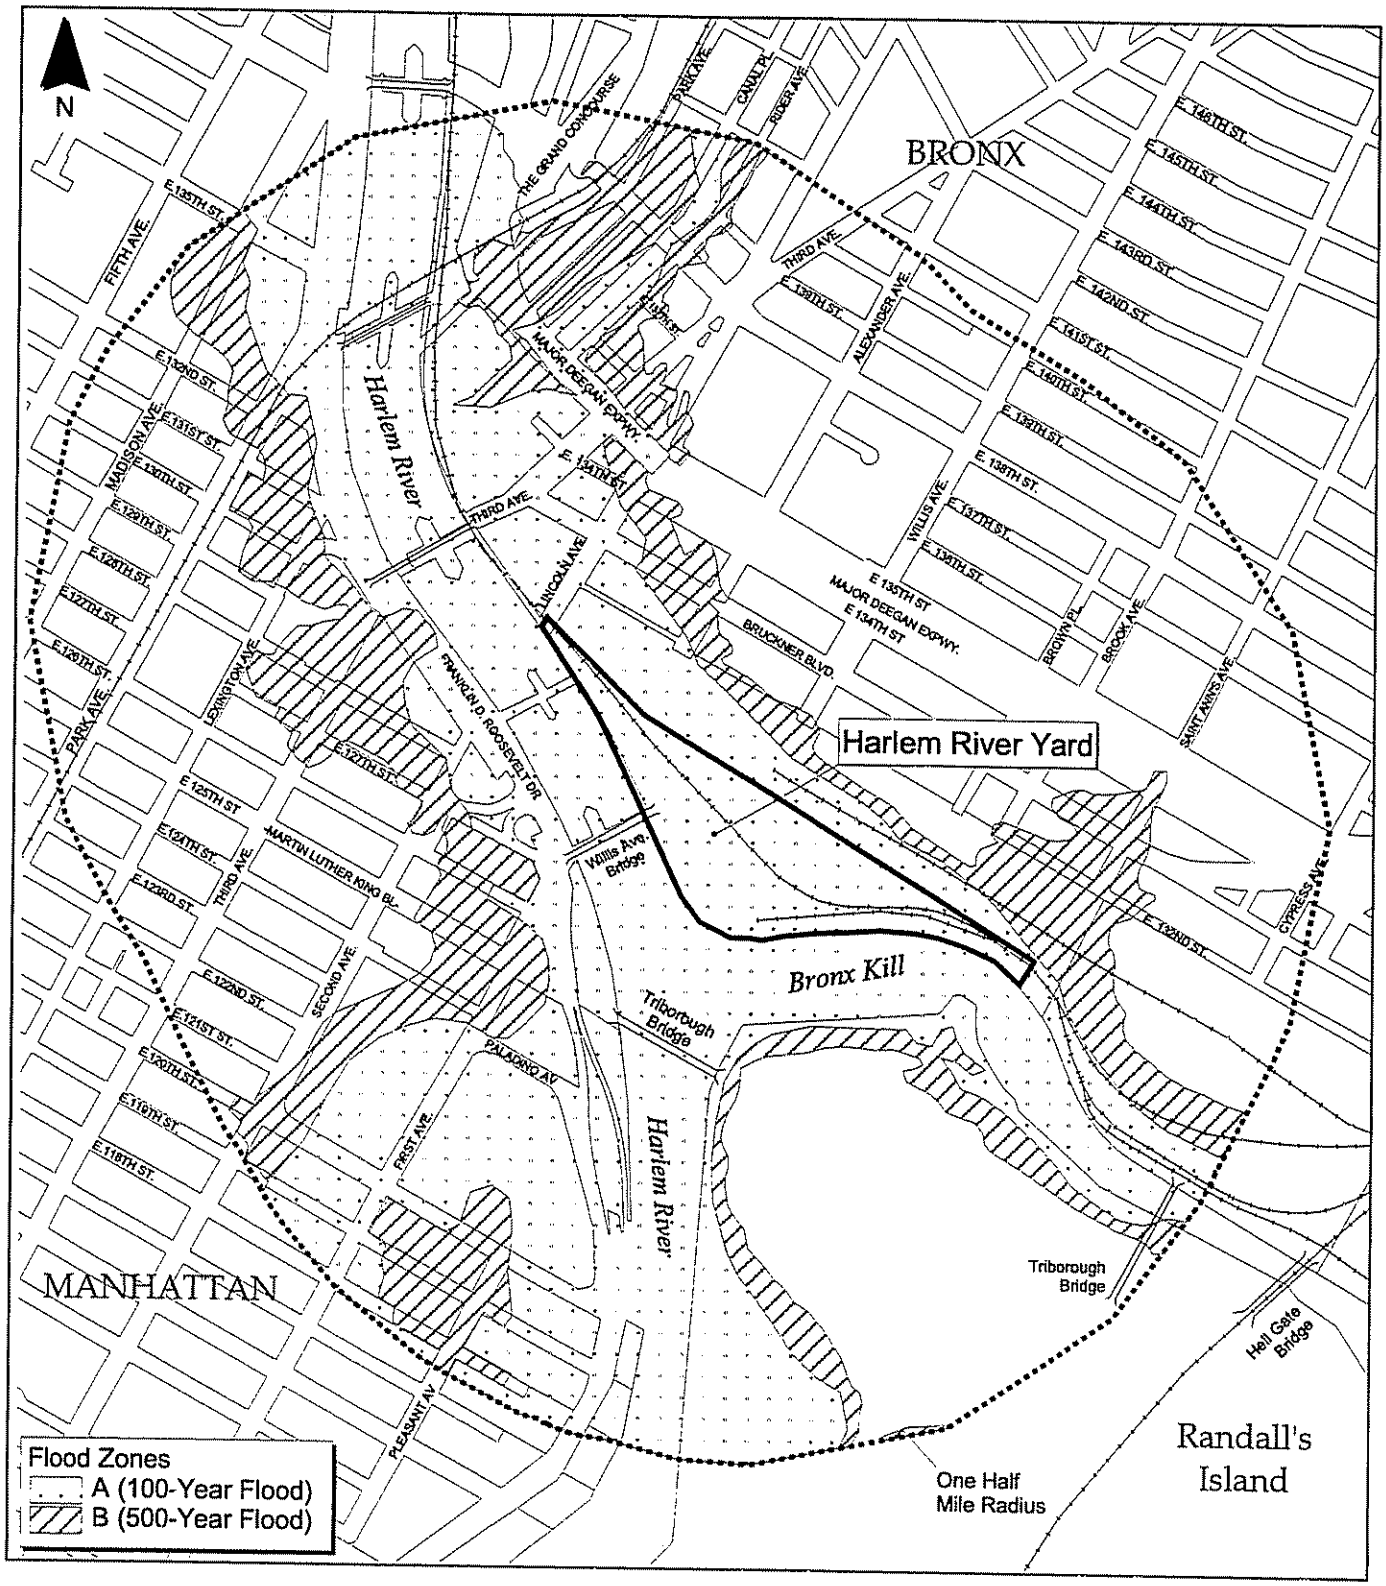
9.9.1.1 Definition of Study Area

The study area includes the site and the waterfront sections that are bulkheaded and bounded by the Harlem River to the southwest and Bronx Kill to the southeast (see Figure 2.3-1). The entire upland parcel and surrounding neighborhood is fully developed and, therefore, has very limited natural resources. Such resources that do exist are discussed in the following sections.

9.9.1.2 Geology

The study area is underlain by consolidated pre-Cambrian rocks. Formations of Fordham Gneiss and narrow bands of infolded Inwood Marble are typical of the southern portion of Bronx County, where the study area is located. A large deposit of stratified drift composed mostly of sand and gravel underlies the study area. This deposit is roughly ¼-mile wide and extends south-southwestward across the western part of the county.

Historically, the banks of the Harlem River were comprised of extensive intertidal marshes and the waterbody was much wider than it is presently. Over the past 100 years, extensive filling and hardening of the banks has taken place and the geology has little, if any, resemblance to its former state.



9.9.1.3 Floodplains

The study area is located within the 100-year coastal floodplain (see Figure ~~5.14~~ 9.9-1). The Harlem River and Bronx Kills, which are NYSDEC designated littoral zones, border the study area (see Figure ~~5.14~~ 9.9-2). No NYSDEC designated wetlands exist on the study area.

9.9.1.4 Ecosystems

The terrestrial ecology of the study area has been altered by intense residential and commercial development. Indigenous wildlife, insofar as it occurs, is comprised of animals associated with urbanized areas, such as feral cats and dogs and ubiquitous species such as rats, mice, and squirrels. The only naturally occurring wildlife is the resident or transient avifauna (birds), and rabbits.

The study area is nearly completely covered by hard surfaces, predominantly railroad tracks and paved parking areas, with the exception of a small patch under the Willis Avenue Bridge. A few buildings and office trailers are also present on the study area. Vegetation on the study area is

consistent with that of an urban vacant lot as classified by Reschke.[1] The sparse vegetation is dominated by mugwort (*Artemisia vulgaris*), with scattered specimens of evening primrose (*Oenothera biennis*), and goldenrod (*Solidago species*). A few woody saplings are present on the study area, including tree-of-heaven (*Ailanthus altissima*) and common cottonwood (*Populus deltoides*). A wood vine, Asiatic bittersweet (*Celastrus orbiculatus*), was observed growing on the fence.

9.10 Hazardous Materials

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.11 Water Quality

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.12 Waterfront Revitalization Program

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

The HRY Site was analyzed previously, as discussed in Section 9.1.

9.14 Traffic, Parking, Transit, and Pedestrians

As stated in Section 9.1, the HRY Barge to Rail Intermodal Yard would not receive any collection vehicle deliveries of waste, so traffic analysis is not required.

9.15 Air Quality

9.15.1 Definition of Study Areas

The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of HRY Barge to Rail Intermodal Yard.

9.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 9.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 9.15-1
Representative Ambient Air Quality Data
HRY Barge to Rail Intermodal Yard

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	200th Street and Southern Boulevard	8-Hour	2.9 ppm	9 ppm
		1-Hour	4.3 ppm	35 ppm
NO_2[(2)]	East 156th Street, between Dawson and Kelly Streets	Annual	0.03 ppm	0.05 ppm
PM_{10}[(2)]	East 156th Street, between Dawson and Kelly Streets	Annual	22 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	60 $\mu g/m^3$	150 $\mu g/m^3$
SO_2[(2)]	East 156th Street, between Dawson and Kelly Streets	3-Hour	0.089 ppm	0.5 ppm
		24-Hour	0.052 ppm	0.14 ppm
		Annual	0.011 ppm	0.03 ppm

Note:
Source: NYCDEP, April 2003 and USEPA Air data – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2002 calendar year.
(2) Values are the highest pollutant levels recorded during the 2003 calendar year.

9.15.4.2 Off-Site Emissions

As stated in Section 9.1, the HRY Barge to Rail Intermodal Yard would not receive any collection vehicle deliveries of waste, so off-site air quality analysis is not required.

9.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build Conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

9.15.4 Potential Impacts with the Harlem River Yard Barge to Rail Intermodal Yard

9.15.4.1 On-Site Emissions

Based on the 2000 SWMP FEIS, the potential impacts from the operation of the Harlem River Yard EBUF were estimated for criteria pollutants and found to be within applicable standards and guidelines. Since the Harlem River Yard Barge to Rail Intermodal Yard would have less on-site emission generating equipment than those of the EBUF, impacts under the HRY Barge to Rail Intermodal Yard would also be within standards and guidelines, so an analysis of this facility would likewise not result in a finding of significant impacts.

9.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be operating during the peak hour and in an average hour are provided in Table 9.15-2.

9.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any one of the receptor sites considered are provided in 2000 SWMP FEIS. These values are compared with the applicable standards for the appropriate averaging time periods. $PM_{2.5}$ results are presented in Table 9.15-3. Based on the results presented in Table 9.15-3 and 2000 SWMP FEIS, the HRY Barge to Rail Intermodal Yard would not adversely impact air quality in the area. The total predicted concentrations (including appropriate background concentrations) are below the national and state ambient air quality standards.

Table 9.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
HRY Barge to Rail Intermodal Yard

Type of Emission Source	Maximum Number of Sources Operated During a Single Peak Hour	Number of Sources Operated During Annual Average Hour
Outside Processing Building		
Yard Tractor	4	4
Reachstacker Taylor GPPH885	2	2
Line-Haul Locomotive 1989 GE	1	1
Switch Locomotive 2003/04 Shuttlewagon	1	1
Tugboat	2	2

Notes:
(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.

Table 9.15-3
Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions
HRY Barge to Rail Intermodal Yard

Pollutant	Averaging Time Period	Maximum Impacts from On-Site Emission Sources	STV[2]
$PM_{2.5}$, $\mu g/m^3$[3]	24-hour[1]	2.70	5
	Annual Neighborhood Average	0.04	0.1

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

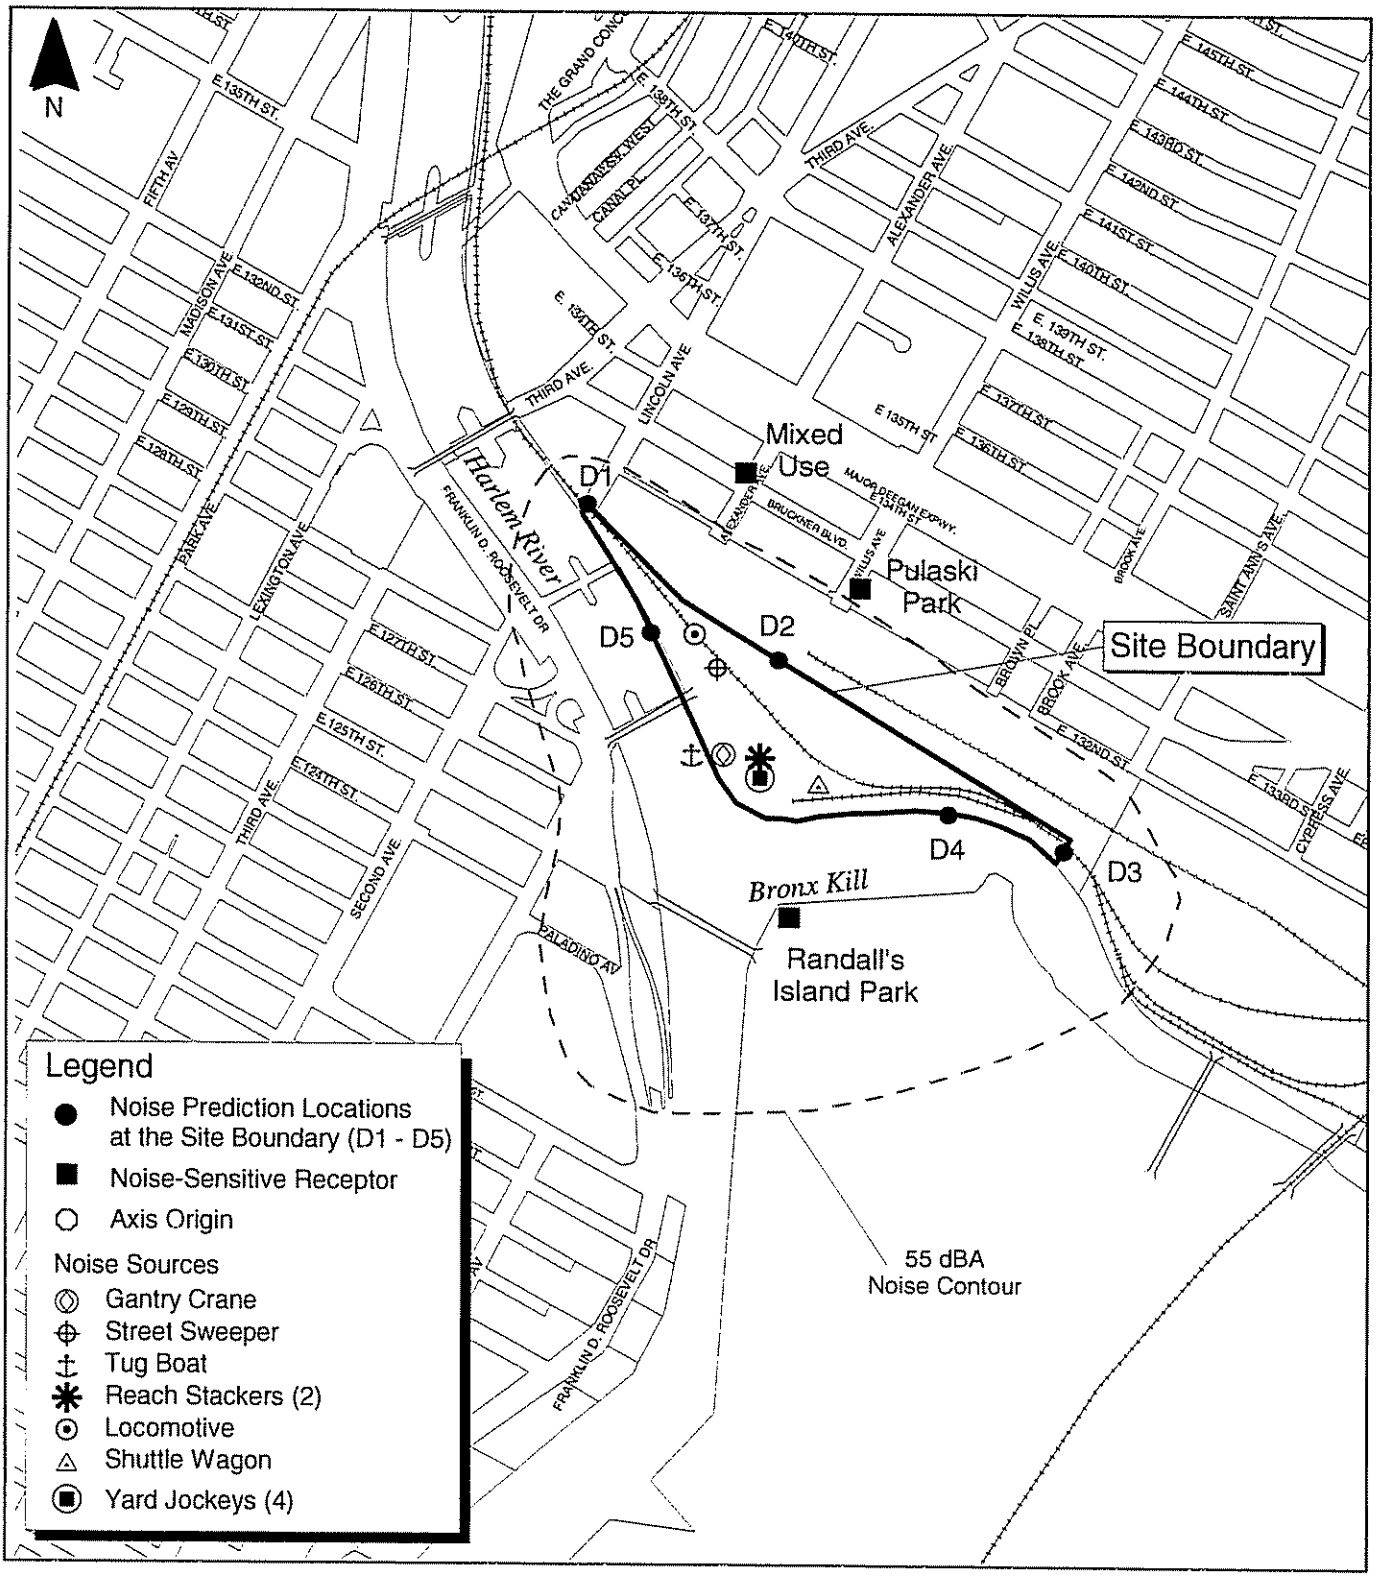
(2) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(3) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

9.16 Odor

There would be no waste processing operations at the HRY Barge to Rail Intermodal Yard. Since the HRY Intermodal Yard is a barge to rail operation, based on calculations the emission rates from the containers are estimated to be negligible. Therefore, no odor impacts were analyzed for the HRY Barge to Rail Intermodal Yard.

9.17 Noise



The noise analysis addresses on-site sources of noise emissions from HRY Barge to Rail Intermodal Yard -related activities. It is based on Section R of the 2001 CEQR Technical Manual for on-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodology used in this analysis.

9.17.1 Existing Conditions

The HRY Truck to Rail TS is adjacent to the HRY Barge to Rail Intermodal Yard and is currently permitted to operate at 4,000 tpd. The HRY Barge to Rail Intermodal Yard portion of the HRY site is currently undeveloped, so there are no noise sources associated with a barge to rail intermodal transfer operation at this site under Existing Conditions.

9.17.1.1 Introduction

Figure 9.17-1 shows the location of the HRY Barge to Rail Intermodal Yard, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The HRY Barge to Rail Intermodal Yard is set within a larger industrial area as described in Sections 2.2.6 and 2.2.8. The nearest potential noise-sensitive receptors are the Bruckner Avenue Antique Shop (mixed use) at a distance of approximately 220 meters (720 feet) from the property line, Pulaski Park, approximately 157 meters (515 feet) north of the property boundary, and ball fields located on Randall's Island, approximately 129 meters (425 feet) south of the property line.

Site delineations are approximate

Figure 9.17-1 Noise Sources and Receptors
Harlem River Yard Site
Barge to Rail Option

CITY OF NEW YORK
DEPARTMENT OF SANITATION

9.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the former Willis Avenue Railroad Station. Noise monitoring data collected included $L_{eq(1)}$, L_{min} and L_{max},[2] and the statistical metrics of L_{10}, L_{50} and L_{90}.[3] Table 9.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 3:00 a.m. to 4:00 a.m. and 4:00 a.m. to 5:00 a.m., and had an $L_{eq(1)}$ of 57 dBA on March 18th, 1999. Activities and events that contribute to the on-site noise levels include:

- Other noise sources associated with activities in the surrounding industrial areas.

9.17.2 Future No-Build Conditions

9.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by the Future No-Build 2006 analysis year; therefore, Future No Build Conditions are expected to be the same as Existing Conditions.

9.17.3 Potential Impacts with the HRY Barge to Rail Intermodal Yard

9.17.3.1 On-Site Noise Levels

Equipment assumed to be operating on site at the HRY Barge to Rail Intermodal Yard and its reference noise levels used in the CEQR analysis are shown in Table 9.17-2. The number and types of equipment assumed for this analysis were based on the HRY Barge to Rail Intermodal Yard's ~~peak~~ average design capacity.

Tugboat (1)	73
Gantry Crane (1)	77.2

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Indoor sources are not proposed for the HRY Barge to Rail Intermodal Yard.
(3) Noise levels are representative of each piece of equipment.

9.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the HRY Barge to Rail Intermodal Yard. Noise levels from outdoor sources were combined to determine the location of the 55 dBA contour line. For the Bruckner Antique Shop, the 55 dBA contour line is approximately 134 meters (440 feet) from the property line in the direction of the Bruckner Antique Shop. For the Pulaski Park, the 55 dBA contour line is approximately 122 meters (400 feet) from the property line in the direction of the Pulaski Park. For Randall's Island, the 55 dBA contour line is approximately 457 meters (1,500 feet) from the property line in the direction of Randall's Island. The distance from the property boundary to these noise-sensitive receptors is provided in section 9.17.1.1. The 55 dBA contour line was selected as a limit or the study area because 55 dBA, (i.e., the point off site where noises generated on-site attenuate to 55 dBA), is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that a noise-sensitive receptor, specifically Randall's Island, is located within the 55 dBA contour line (see Figure 9.17-1); therefore, an on-site noise analysis, including noise monitoring at Randall's Island, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 9.17-1 above. Table 9.17-3 below identifies the existing background noise level during the quietest hour. The table shows the distance from the HRY Barge to Rail Intermodal Yard to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, HRY Barge to Rail Intermodal Yard-related noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptor. The difference represents the predicted incremental change in noise level from the HRY Barge to Rail Intermodal Yard. Because this incremental change is less than the CEQR threshold of 3 dBA, since the daytime background noise level is greater than 62 dBA at the noise-sensitive receptor, there is no predicted impact that would be caused by the HRY Barge to Rail Intermodal Yard on-site operations.

9.17.3.3 Off-Site Noise Levels

As stated in Section 9.1, the HRY Barge to Rail Intermodal Yard would not receive any collection vehicle deliveries of waste, so off-site noise analysis is not required.

9.17.3.4 Combined On-Site and Off-Site Noise Levels

An on-site noise analysis was performed for the HRY Barge to Rail Intermodal Yard. An off-site noise analysis was not required; therefore, a combined noise analysis was not performed.

Table 9.17-3
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
HRY Barge to Rail Intermodal Yard

Receptor ID	Distance from Facility (meters/feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
Randall's Island Park	107 / 350	62.5	~~61.8~~62.3	~~65.2~~65.4	~~2.7~~2.9	No

Notes:

(1) Twenty-minute noise level readings measured at the closest sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

(2) Existing noise levels were measured on August 17, 2004 at 11:00 a.m.

(3) Predicted noise level calculations at sensitive receptor include on-site and off-site shielding from structures.

(4) According to CEQR, an increase of 3 dBA is considered an impact when the daytime noise level is greater than 62 dBA. The impact analysis compares the loudest noise emissions from daily operations at the facility with the quietest background noise levels that occur during facility operation.

CHAPTER 10 ENVIRONMENTAL REVIEW: 65TH STREET INTERMODAL YARD

10.1 Introduction

The 65th Street Intermodal Yard would be subject to DSNY's new rules, as a non-discretionary action, and thus is not subject to environmental review. The 65th Street Intermodal Yard would receive DSNY-managed Waste by barge and export it by rail. There is no truck traffic associated with this operation and site-generated traffic resulting from employee trips and other miscellaneous trips would be minimal. Therefore, no off-site analyses are required.

The results of the environmental analyses of the 65th Street Intermodal Yard are presented in the following sections:

10.2 Land Use, Zoning, and Public Policy
10.3 Socioeconomic Conditions
10.4 Community Facilities and Services
10.5 Open Space
10.6 Cultural Resources
10.7 Urban Design, Visual Resources, and Shadows
10.8 Neighborhood Character
10.9 Natural Resources
10.10 Hazardous Materials
10.11 Water Quality
10.12 Waterfront Revitalization Program
10.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
10.14 Traffic, Parking, Transit, and Pedestrians
10.15 Air Quality
10.16 Odor
10.17 Noise

Section 2.2.7 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

10.2 Land Use, Zoning, and Public Policy

See Section 10.1 for a description of the review required.

10.3 Socioeconomic Conditions

See Section 10.1 for a description of the review required.

10.4 Community Facilities and Services

See Section 10.1 for a description of the review required.

10.5 Open Space

See Section 10.1 for a description of the review required.

10.6 Cultural Resources

See Section 10.1 for a description of the review required.

10.7 Urban Design, Visual Resources, and Shadows

See Section 10.1 for a description of the review required.

10.8 Neighborhood Character

See Section 10.1 for a description of the review required.

10.9 Natural Resources

See Section 10.1 for a description of the review required.

10.10 Hazardous Materials

See Section 10.1 for a description of the review required.

10.11 Water Quality

10.14 Traffic, Parking, Transit, and Pedestrians

See Section 10.1 for a description of the review required.

10.15 Air Quality

See Section 10.1 for a description of the review required.

10.16 Odor

See Section 10.1 for a description of the review required.

10.17 Noise

See Section 10.1 for a description of the review required.

CHAPTER 11 ENVIRONMENTAL REVIEW – HARLEM RIVER YARD TRUCK TO RAIL TS

11.1 Introduction

The HRY Truck to Rail TS is currently permitted at 4,000 tpd based upon a 1993 FEIS for 3,000 tpd of capacity, and negative declaration finding on an EAS completed in 2003 for an additional 1,000 tpd of capacity. The HRY Truck to Rail TS was further evaluated for accepting and processing DSNY-managed Waste from all wastesheds in the Bronx under DSNY's Interim Export Program with a negative declaration finding on that EAS, which was completed in 2001.

Copies of the environmental review documents for the HRY Truck to Rail TS are available upon request on compact disk. Because the HRY Truck to Rail TS is an existing facility permitted to process up to 4,000 tpd of waste, which is greater than the DSNY-managed Waste Bronx wasteshed, no further environmental review is required.

The results of the environmental analyses of the HRY Truck to Rail TS are presented in the following sections:

11.2 Land Use, Zoning, and Public Policy
11.3 Socioeconomic Conditions
11.4 Community Facilities and Services
11.5 Open Space
11.6 Cultural Resources
11.7 Urban Design, Visual Resources, and Shadows
11.8 Neighborhood Character
11.9 Natural Resources
11.10 Hazardous Materials
11.11 Water Quality
11.12 Waterfront Revitalization Program
11.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
11.14 Traffic, Parking, Transit, and Pedestrians

11.15 Air Quality

11.16 Odor

11.17 Noise

Section 2.2.8 provides a summary description of the site and important characteristics of the design and operation of the facility. The following sections provide additional information on the site or the study area, as appropriate to each analysis.

A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3.

11.2 Land Use, Zoning, and Public Policy

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.3 Socioeconomic Conditions

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.4 Community Facilities and Services

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.5 Open Space

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.6 Cultural Resources

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.7 Urban Design, Visual Resources, and Shadows

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.8 Neighborhood Character

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.9 Natural Resources

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.10 Hazardous Materials

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.11 Water Quality

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.12 Waterfront Revitalization Program

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.14 Traffic, Parking, Transit, and Pedestrians

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.15 Air Quality

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.16 Odor

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

11.17 Noise

The HRY Truck to Rail TS was analyzed previously, as discussed in Section 11.1.

CHAPTER 12 ENVIRONMENTAL REVIEW – EAST 132ND STREET SITE

12.1 Introduction

The East 132nd Street Site is currently permitted to handle 2,999 tpd of putrescible waste, with a negative declaration finding on an EAS for that capacity completed in 1994. It is currently contracted to accept up to 1,500 tpd of Bronx DSNY-managed Waste under Interim Export for long haul in transfer trailers to out-of-City disposal locations. It is proposed to accept all of the Bronx DSNY-managed Waste long term (approximately 2,337 tons on an average peak day) with no increase in capacity. This site was also the subject of an EAS in 1997 for Interim Export that evaluated the receipt of all Bronx DSNY-managed Waste. At that time, no off-site PM_{10} or $PM_{2.5}$ analyses were performed. The 2000 SWMP FEIS evaluated on-site, but not off-site, impacts related to delivery of all Bronx waste to this site under a variety of different export scenarios. The EAS for Interim Export, updated in 2001, evaluated sending only a portion of the Bronx waste (24 collection vehicles during the peak hour between 11:00 a.m. to 12:00 p.m.) to East 132nd Street. Traffic analyses were completed at multiple locations and PM_{10} analyses were completed at two intersections. $PM_{2.5}$ was not analyzed and CO and mobile noise analyses screened out. The average peak quantity of DSNY-managed Waste delivered to this facility for Interim Export averages approximately 1,033 tpd. Copies of the environmental review documents for the East 132nd Street Site are available upon request on compact disk.

Under Long Term Export, DSNY-managed Waste would be containerized and then drayed to Oak Point Rail Yard, where the containers would be loaded onto rail cars. The trucking of containers of DSNY-managed ~~waste~~ Waste to Oak Point Rail Yard is considered part of the environmental review, since, at present, all waste from the East 132nd Street Site goes out by transfer trailer. However, the review would be limited to off-site impacts of draying of containerized waste to Oak Point. Oak Point has been permitted as an intermodal yard and any changes in this permit would be subject to DSNY's new rules, as a non-discretionary action, and thus not subject to environmental review. The RFP procurement issued by the City requires that proposers commit to exporting all waste (both DSNY and commercial) processed at their facility by rail or barge. Although historically some waste processed at the East 132nd Street Site was

containerized and drayed to Oak Point Rail Yard for export by rail, currently all waste moves out via transfer trailer. Thus the draying of full containers of waste and return of empties between East 132nd Street and Oak Point Rail Yard equivalent to the fully permitted capacity of the facility (2999 tpd) would be a change in the Existing Condition.

The results of the environmental analyses of the facility options at the East 132nd Street Site are presented in the following sections:

12.2 Land Use, Zoning, and Public Policy
12.3 Socioeconomic Conditions
12.4 Community Facilities and Services
12.5 Open Space
12.6 Cultural Resources
12.7 Urban Design, Visual Resources, and Shadows
12.8 Neighborhood Character
12.9 Natural Resources
12.10 Hazardous Materials
12.11 Water Quality
12.12 Waterfront Revitalization Program
12.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
12.14 Traffic, Parking, Transit, and Pedestrians
12.15 Air Quality
12.16 Odor
12.17 Noise

The facility elements evaluated for this site are:

- East 132nd Street Truck to Rail TS; and
- Oak Point Rail Yard.

Section 2.2.9 provides a summary description of the site and important characteristics of the design and operation of each element. The following sections provide additional information on the site or the study area, as appropriate to each analysis.

A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3.

12.2 Land Use, Zoning, and Public Policy

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Land Use, Zoning, and Public Policy environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.3 Socioeconomic Conditions

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Socioeconomic Conditions environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.4 Community Facilities and Services

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Community Facilities and Services environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.5 Open Space

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Open Space environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.6 Cultural Resources

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Cultural Resources environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.7 Urban Design, Visual Resources, and Shadows

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Urban Design, Visual Resources, and Shadows environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.8 Neighborhood Character

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Neighborhood Character environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.9 Natural Resources

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Natural Resources environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.10 Hazardous Materials

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Hazardous Materials environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.11 Water Quality

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Water Quality environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.12 Waterfront Revitalization Program

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Waterfront Revitalization Program environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

The East 132nd Street Site was previously analyzed as discussed in Section 12.1. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed Infrastructure, Solid Waste and Sanitation Services, and Energy environmental review.

Refer to Section 12.1 for an explanation of the analysis required for the Oak Point Rail Yard.

12.14 Traffic, Parking, Transit, and Pedestrians

The East 132nd Street Site is currently permitted to process 2,999 tons of waste per day and is currently contracted to accept up to 1,500 tpd of Bronx DSNY-managed Waste under Interim Export. Under this Alternative, it is assumed that the East 132nd Street Site would process all of the Bronx DSNY-managed Waste long term (approximately 2,337 tons on an average peak day) with no increase in capacity. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in DSNY collection vehicles in the study area (which is defined below) and on other site-generated traffic resulting from the acceptance of additional DSNY-managed Waste. (See Section 3.16 for a discussion of CEQR analysis thresholds.) Conservatively, it was assumed that DSNY collection vehicle trips would not eliminate non-DSNY collection vehicle trips associated with existing commercial waste operations at the East 132nd Street Site that would be displaced by this action.

DSNY-managed Waste would be containerized and then drayed to Oak Point Rail Yard, where the containers would be loaded onto rail cars. The draying of containers carrying DSNY-managed Waste to Oak Point Rail Yard is considered part of this environmental review, since, at present, all waste from the East 132nd Street Site is transported out by transfer trailer. (Although historically some waste processed at the East 132nd Street Site was containerized and drayed to Oak Point Rail Yard for export by rail, currently all waste moves out via transfer trailer.) However, it is assumed that both DSNY and other waste processed at this site will be transported to Oak Point Rail Yard. Thus, the analysis was performed for draying of full containers of waste and return of empties between the East 132nd Street Site and Oak Point Rail Yard equivalent to the fully permitted capacity of the facility of 2,999 tpd.

12.14.1 Existing Conditions

This site is located in the Port Morris area of the Bronx bounded on the north by the Port Morris Rail Yard, on the south by the Bronx Kill, on the east by the East River and on the west by the combination of the elevated Bruckner Expressway, Triborough Bridge approach span and the at-grade Bruckner Boulevard. Access to and from the area is generally limited to East 138th Street through its major intersection with Bruckner Boulevard and along East 132nd Street. Thus, geography, the limited street network and the adjacent Bruckner Boulevard provide a well-defined boundary for the study area where concentrations of trips to and from the site would be expected to occur. The study area is characterized by a mixture of light industrial/manufacturing land uses.

Bruckner Boulevard is a major corridor that extends from the Third Avenue Bridge to the interchange of the Bruckner and Sheridan Expressways. East 138th Street and Locust Avenue are the primary routes leading to and from the East 132nd Street Site.

12.14.1.1 Definition of Study Area

The traffic analysis study area was defined as the Port Morris area surrounding the site as described above. Figure 12.14-1 shows the locations of the intersections selected for analysis (locations A through C). Intersections analyzed were selected using the procedures defined in Section 3.16.

12.14.1.2 Surface Network

Trucks are required by NYCDOT Title 34 to travel on truck routes directly to the site or the intersection nearest the site if streets adjacent to the site are not designated truck routes. A map showing all major truck routes and local truck routes in the Bronx is provided in Section 3.16 (see Figure 3.16-2).

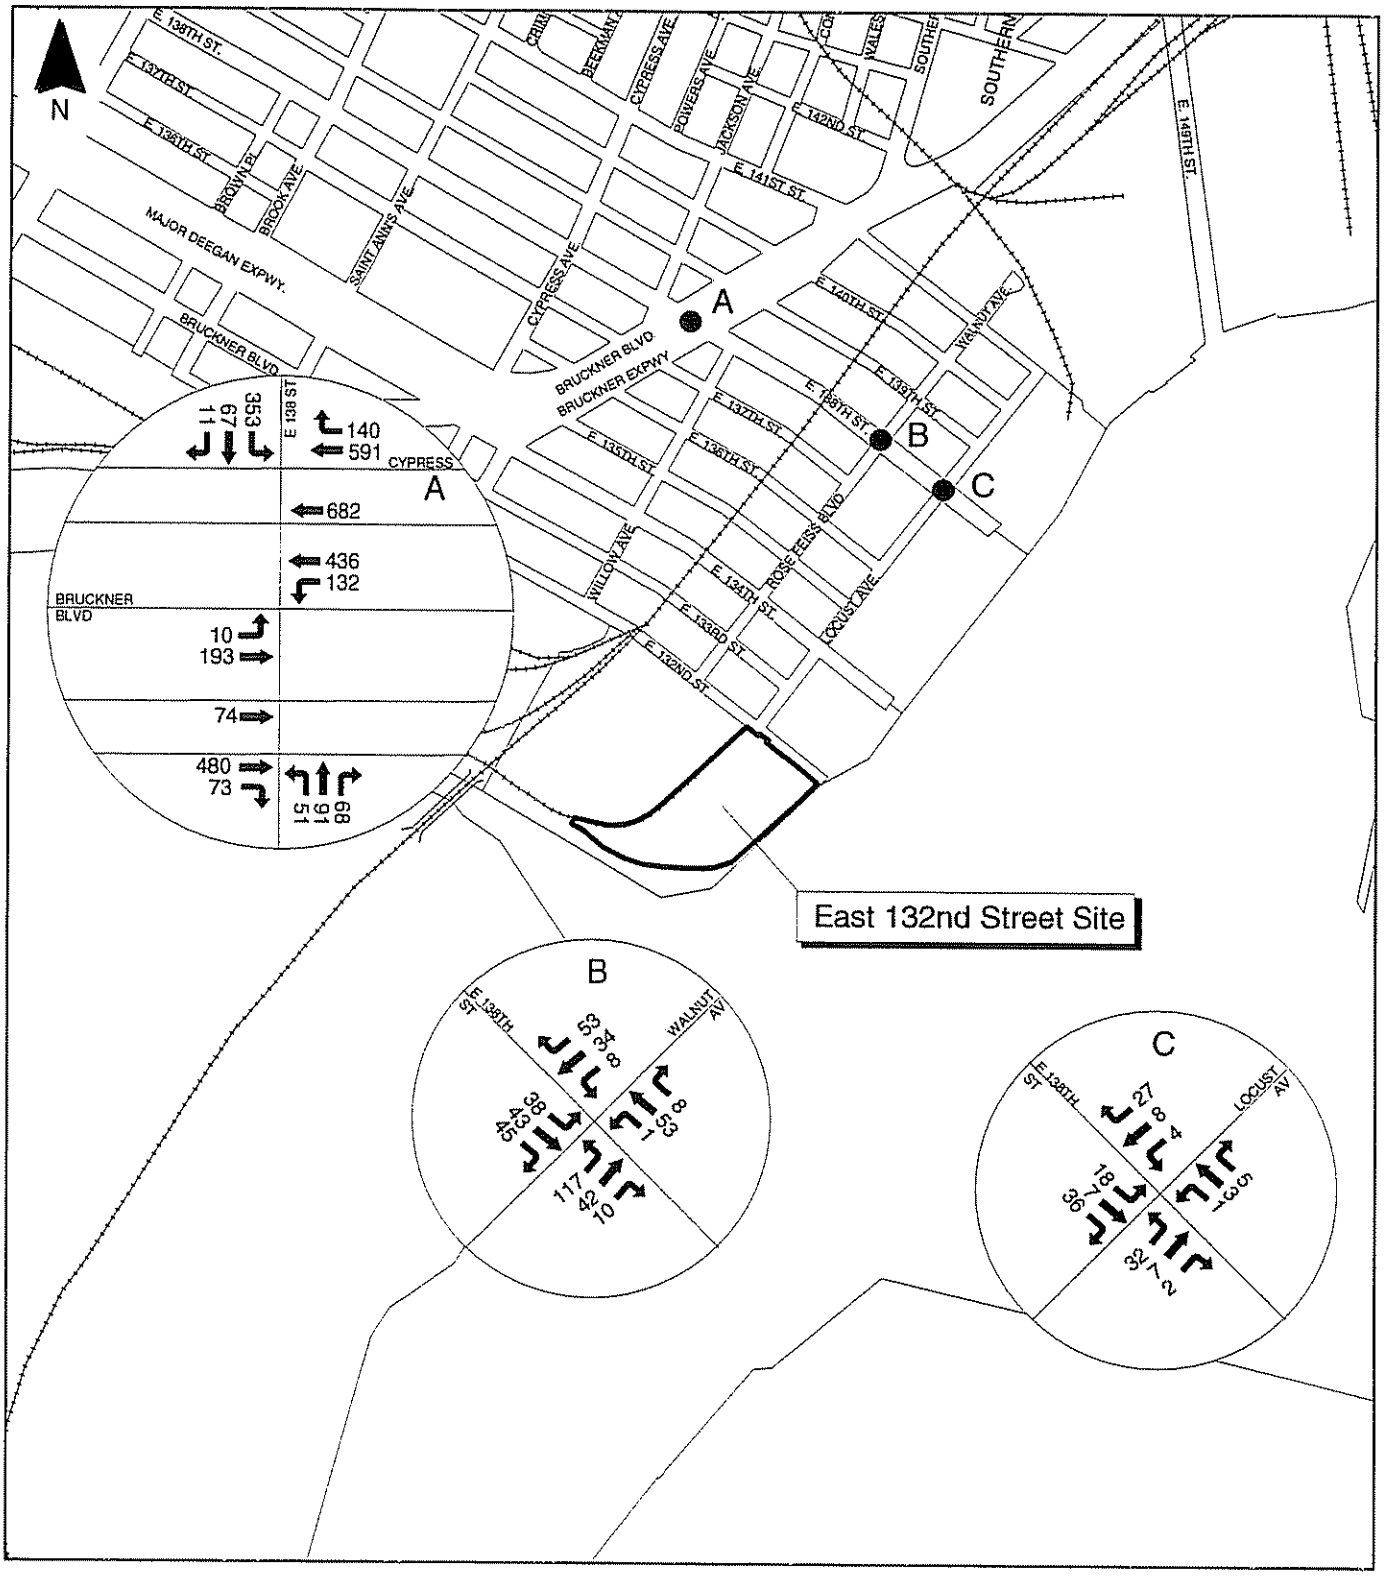
CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION



The primary truck access route to the Port Morris area is Bruckner Boulevard, a major arterial and designated truck route located at grade and below the Bruckner Expressway (I-278) for much of its length, with both express (mainline) and service road separated roadways. Through-truck routes connect the South Bronx with Queens via the Triborough, Bronx-Whitestone or Throgs Neck Bridges, and with Manhattan via the Willis Avenue, Third Avenue or Madison Avenue Bridges. East 138th Street is also designated as a local truck route from the East River to the Madison Avenue Bridge.

12.14.1.3 Existing Traffic Operations

The three intersections listed below were identified for analysis because they are most likely to be affected from additional truck trips generated by the East 132nd Street Site. (Diagrams of these intersections were included in technical backup submitted to NYCDOT and are shown on Figure 12.14-1.)

- Bruckner Boulevard and East 138th Street – Signalized Intersection (Location A)
- East 138th Street and Walnut Avenue – Unsignalized Intersection (Location B)
- East 138th Street and Locust Avenue – Unsignalized Intersection (Location C)

Manual turning movement counts, including vehicle classification, were conducted; and ATR counts were undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted in June 2003 and June 2004, while ATR counts were conducted in June and July 2004. Figures 12.14-2, 12.14-3 and 12.14-4 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 12.14-1 presents the v/c ratio, delay and LOS for the four intersections during the AM, Facility, and PM peaks. The AM peak generally occurred between 8:00 a.m. and 9:00 a.m., the Facility peak between 11:00 a.m. and 12:00 p.m., and the PM peak between 5:00 p.m. and 6:00 p.m.

EB = eastbound
NB = northbound
SB = southbound
WB = westbound
NA = Not Applicable

For simplicity in this analysis, Bruckner Boulevard is described as north-south and East 138th Street as east-west. On Bruckner Boulevard at East 138th Street, existing traffic volumes peak between 7:00 a.m. and 9:00 a.m., then decrease, but remain at a fairly high relative level throughout the Facility peak period. Traffic volumes peak again between 4:00 p.m. and 6:00 p.m. On East 138th Street and Locust Avenue, traffic generally peaks from 8:00 a.m. to 10:00 a.m., and then decreases very gradually throughout the day.

The composition of vehicles in the traffic stream varies by location and time of day, but is typically comprised of a high proportion of trucks. Along Bruckner Boulevard, trucks and buses comprise between 10% and 30% of the total traffic during the AM peak and midday, depending upon the direction of travel and whether on the service road or main road, and generally less than 10% during the PM peak. On East 138th Street east of Bruckner Boulevard and on Locust Avenue, trucks usually comprise more than 50% of the total traffic volume throughout most of the day, with some reduction in the late afternoon.

The intersection of Bruckner Boulevard with East 138th Street has been identified as a high accident location. In the three-year period between 1999 and 2001, a total of 361 accidents occurred at this intersection, of which about half (181) were reportable with no fatalities and 106 accidents involved injuries. Most accidents involved other motor vehicles and eight accidents were pedestrian-related. Of the 168 accidents where collision type was reported, 25% were right angle, 20%t overtaking, 19% left turn and 14% rear-end collisions. Approximately 80% of the vehicles involved in accidents were autos/vans/pickups and 11% were trucks. The predominant travel direction of vehicles was northbound (39%) followed by southbound (27%).

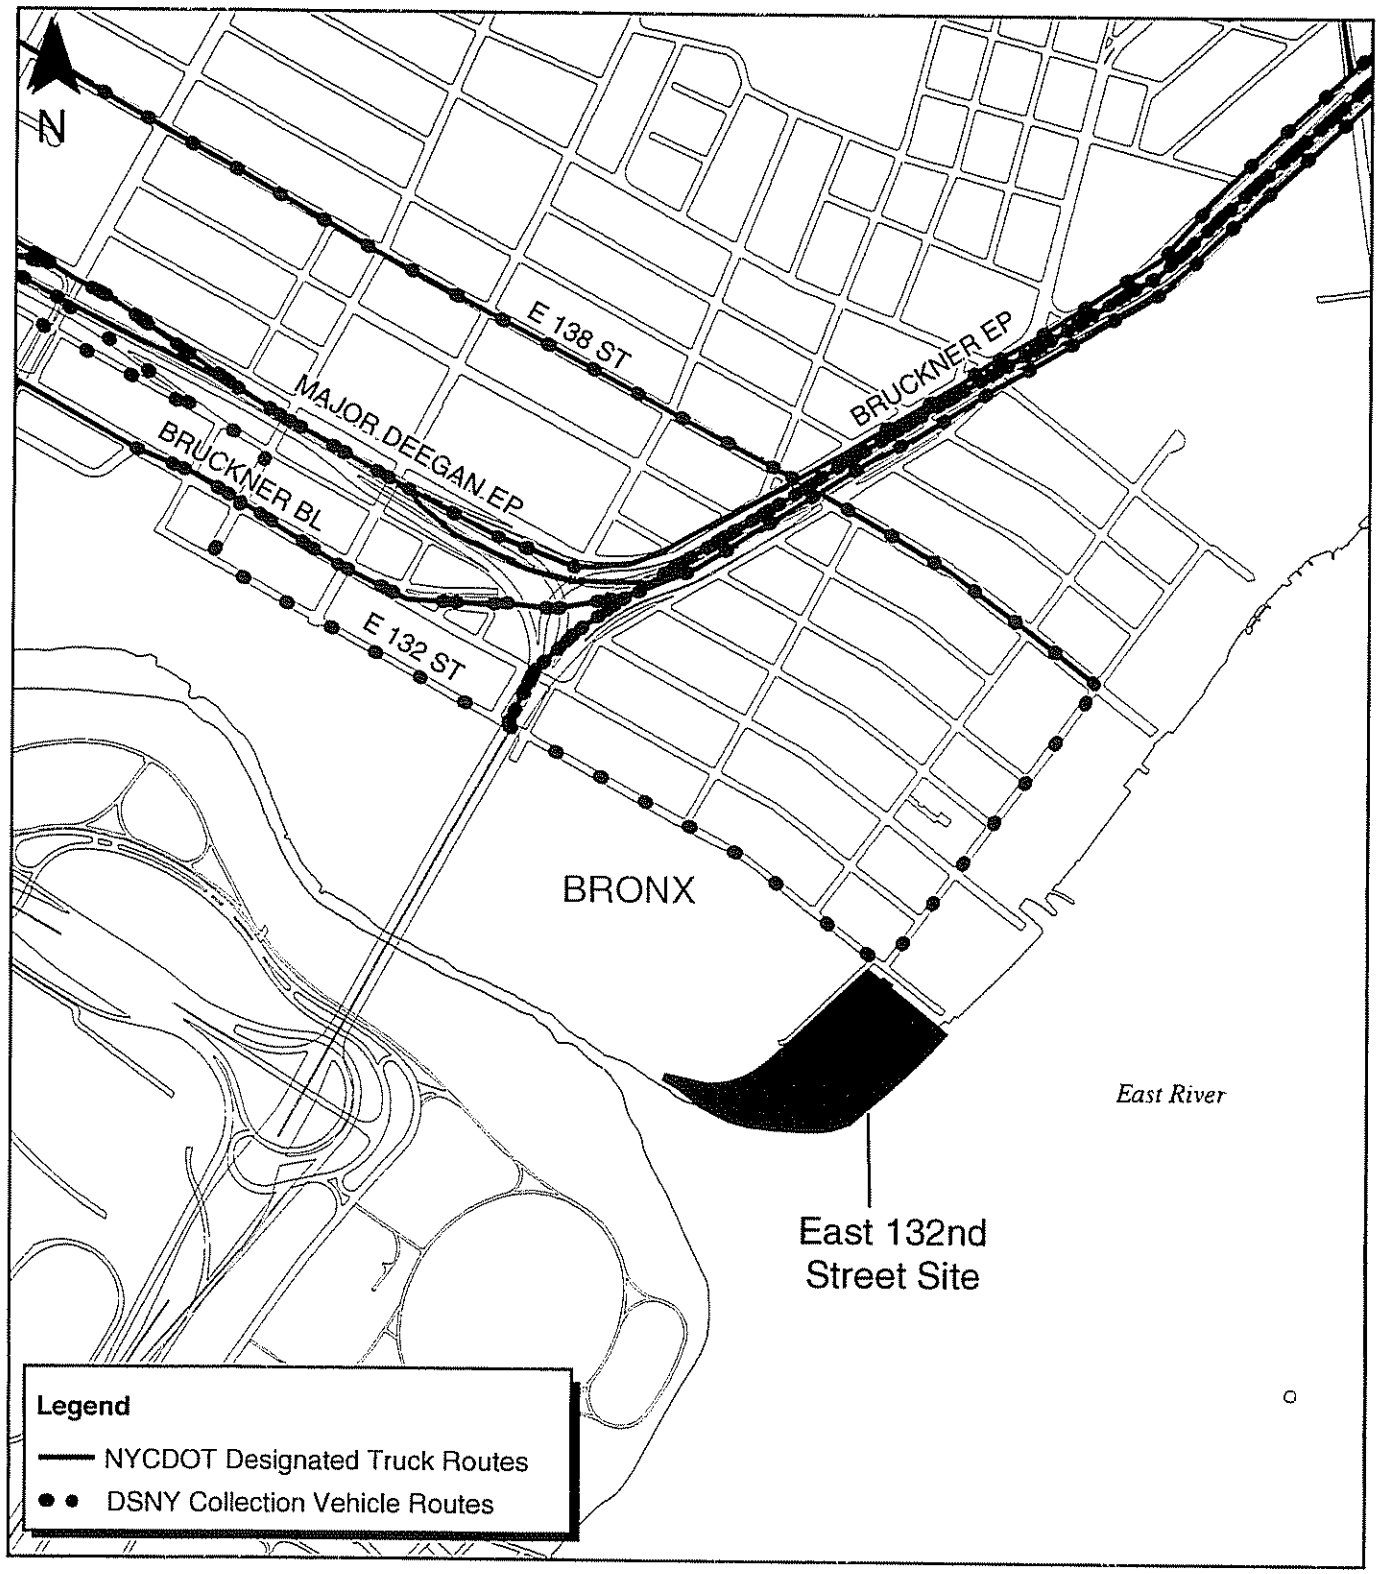
12.14.1.3.1 LOS at Signalized Intersections

Bruckner Boulevard at East 138th Street consists of two mainline roadways (differentiated into an inner and outer roadway, with the northbound outer mainline roadway feeding directly onto the Bruckner Expressway on-ramp) and a service road. Therefore, there are three distinct northbound and southbound approaches and, for analysis purposes, the intersection was divided into three intersections, as presented in Table 12.14-1. All movements operate at LOS D or better, except those on the East 138th Street eastbound approach, which operate at LOS E/F due to the high left-turning traffic volume from East 138th Street.

12.14.2.3.2 LOS at Unsignalized Intersections

The unsignalized intersections of East 138th Street with Walnut Avenue and Locust Avenue operate at LOS B or better during all time periods.

12.14.1.4 Existing DSNY-Related Traffic



Currently, approximately 1,033 tpd of DSNY-managed ~~waste~~ Waste generated in CDs 9 and 10 in the Bronx is transported to the East 132nd Street Site on an average peak day, which, for this proposed Alternative would accept all Bronx DSNY-managed ~~waste~~Waste. (DSNY-managed Waste generated by Bronx CDs 1 through 8, 11 and 12 is currently transported under the Bronx Interim Export Program to the Harlem River Yard facility located at 98 Lincoln Avenue in the Port Morris section of the Bronx). E-Z Pack loads from CD 1 and 6 are delivered to either the East 132nd Street facility or to Triboro Fibers, located at 770 Barry Street in the Bronx, as are all borough-wide collection activities. Existing DSNY collection vehicles proceeding to and from these vendors are routed primarily along Bruckner Boulevard. The existing access route defined for the East 132nd Street Site extends from Bruckner Boulevard along East 138th Street and Locust Avenue. NYCDOT-designated truck routes are provided in Figure 12.14-5.

12.14.1.5 Public Transportation

Two bus routes provide service in the Port Morris area of the Bronx and directly serve the East 132nd Street Site. The Bx17 route provides local service between Port Morris and Fordham Plaza. Service frequency is between 8 and 12 minutes during weekdays. The Bx33 connects Port Morris with Harlem in Manhattan. It provides service approximately every 15 minutes weekdays.

12.14.1.6 Pedestrian Activity

Pedestrian activity is generally low within the study area. During several field visits, pedestrian activity was observed to be minimal and is not expected to significantly affect operations or be affected by them.

12.14.2 Future No-Build Conditions

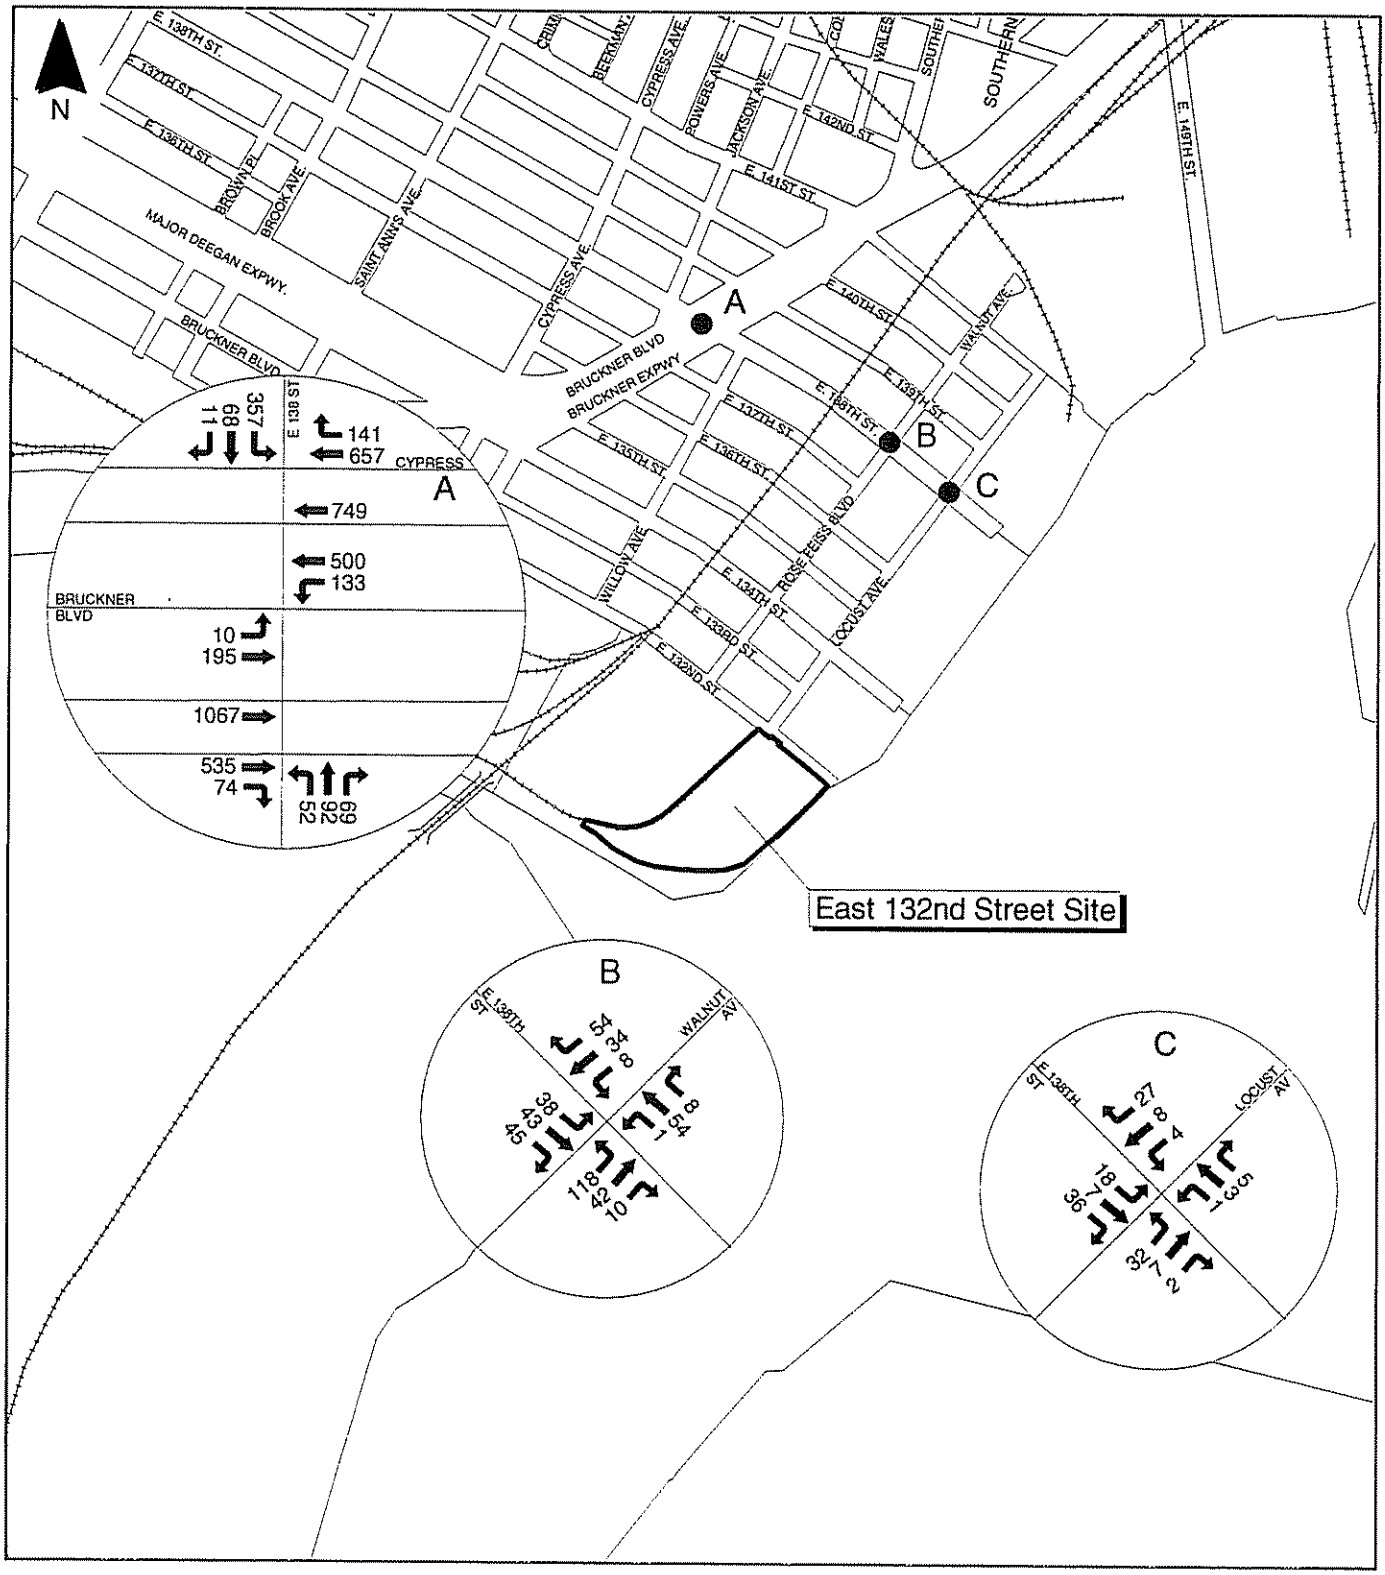
12.14.2.1 Traffic Conditions

The following assumptions and traffic assignments were applied in the development of Future No-Build traffic volumes:

- Continued operation of the Bronx Interim Export Program with MSW delivered to the vendors noted above; and
- Background traffic growth of 0.5% per year in accordance with the 2001 CEQR Technical Manual.

There are no new developments planned in the study area that would affect Future No-Build traffic volumes in the study area.

Figures 12.14-6, 12.14-7 and 12.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peak hours at the intersections analyzed. Table 12.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the study intersections.

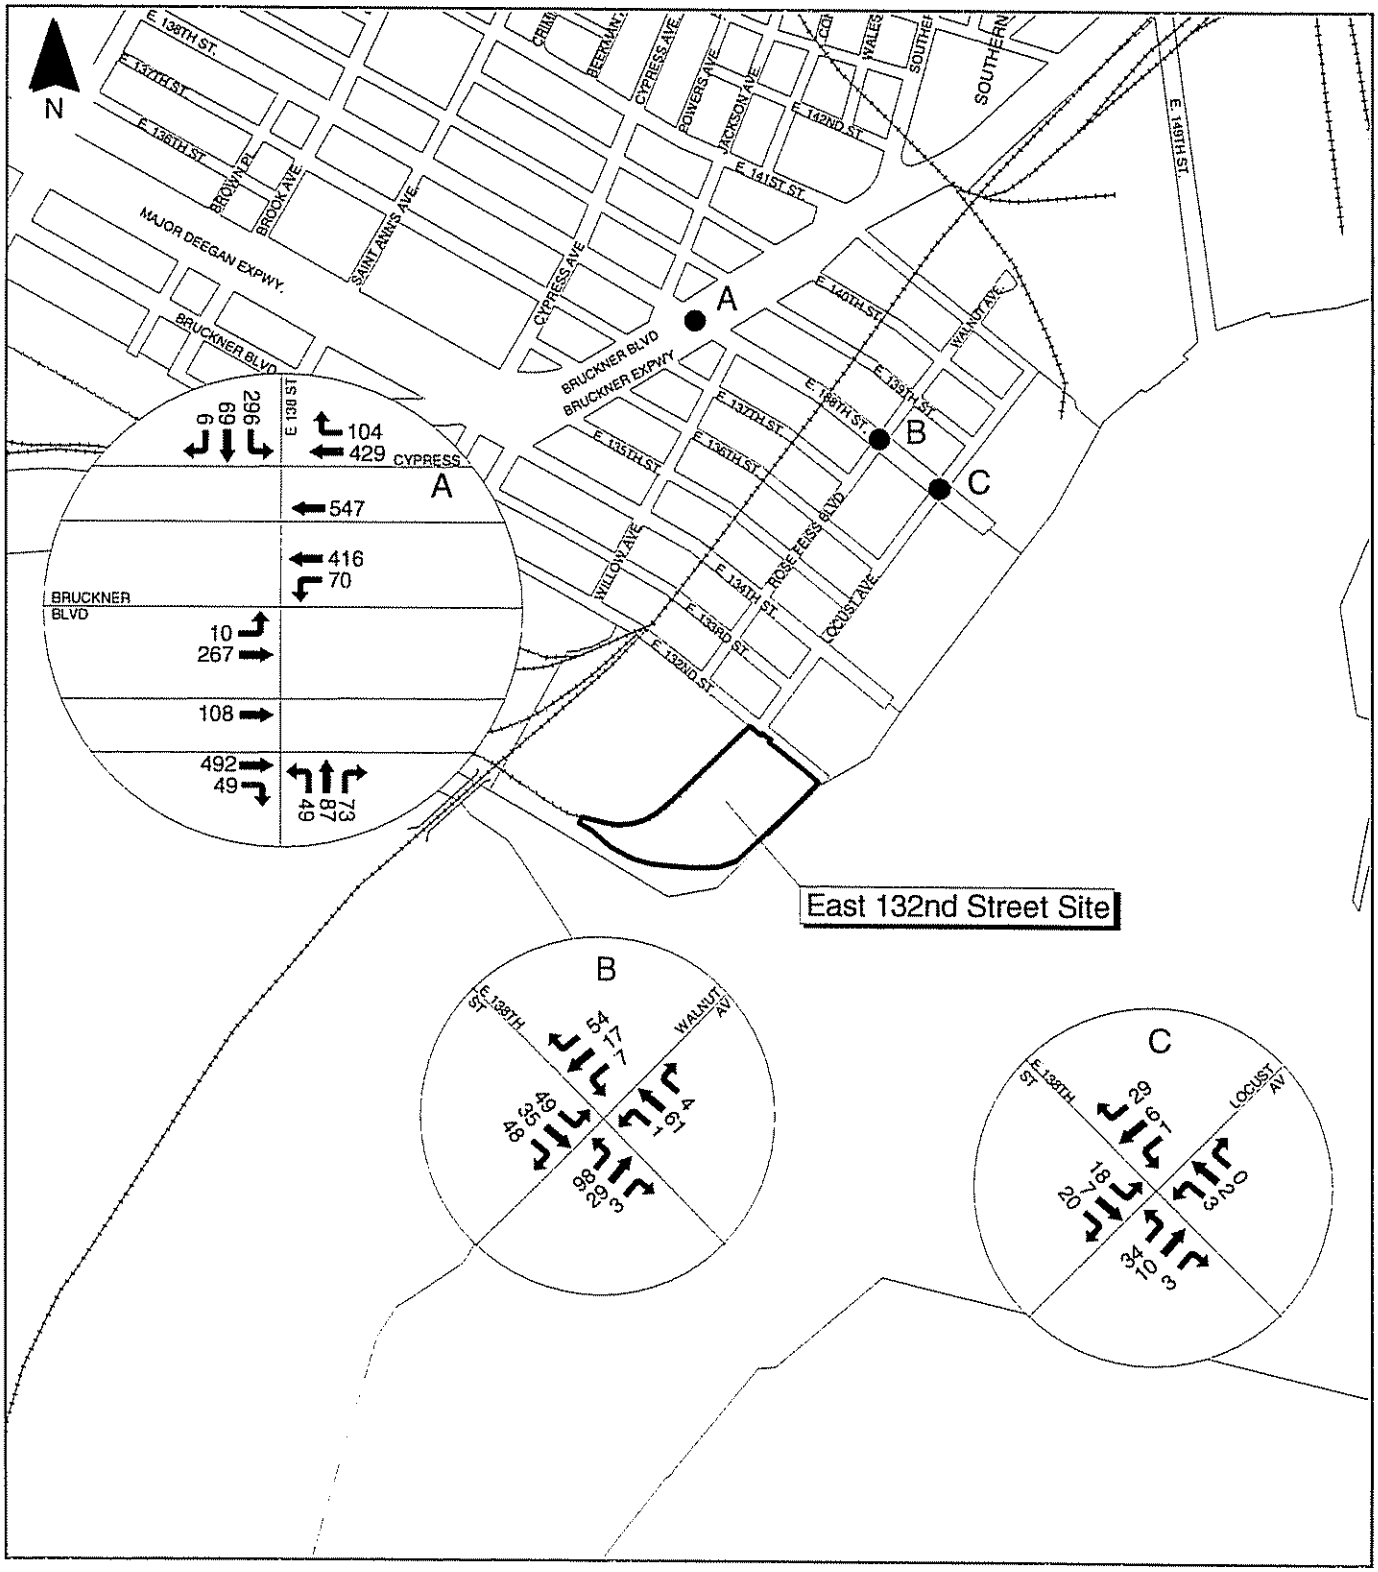


As shown, very little change in traffic operations is anticipated from Existing Conditions. The unsignalized study intersections demonstrate a negligible increase in delay. For the signalized study intersection of Bruckner Boulevard with East 138th Street, the highest increase in delay was indicated on the eastbound East 138th Street approach.

12.14.2.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

12.14.2.3 Pedestrian Activity



Future No-Build Conditions are expected to remain the same as Existing Conditions.

12.14.3 Potential Impacts with the East 132nd Street Truck to Rail TS

12.14.3.1 2006 Future Build Traffic Conditions

Under Build Conditions, the East 132nd Street Truck to Rail TS would receive DSNY-managed Waste from all twelve CDs in the Bronx, approximately 2,337 tpd on an average peak day. All DSNY-managed Waste and any commercial waste processed at the East 132nd Street Truck to Rail TS would be drayed to the Oak Point Rail Yard with the dray vehicles exiting the facility and proceeding north on Locust Avenue, west on East 138th Street, north on Bruckner Boulevard, east on Leggett Avenue and south on Barry Street to Oak Point, returning by the same route. On Locust Avenue and East 138th Street, the dray trucks would replace a portion of existing transfer trailer activity and a credit was taken to adjust for these existing trips. However, on the remainder of the route, all truck activity associated with draying containerized waste to Oak Point represents new truck trips.

Potential traffic impacts may result from the increase in DSNY collection vehicle trips and transfer trailer trips to and from the site during all peak hours. Additionally, employee trips to and from the site may contribute to these traffic impacts during the AM peak hour.

The proposed collection vehicle and dray routes for the East 132nd Street Truck to Rail TS are shown in Figure 12.14-9.

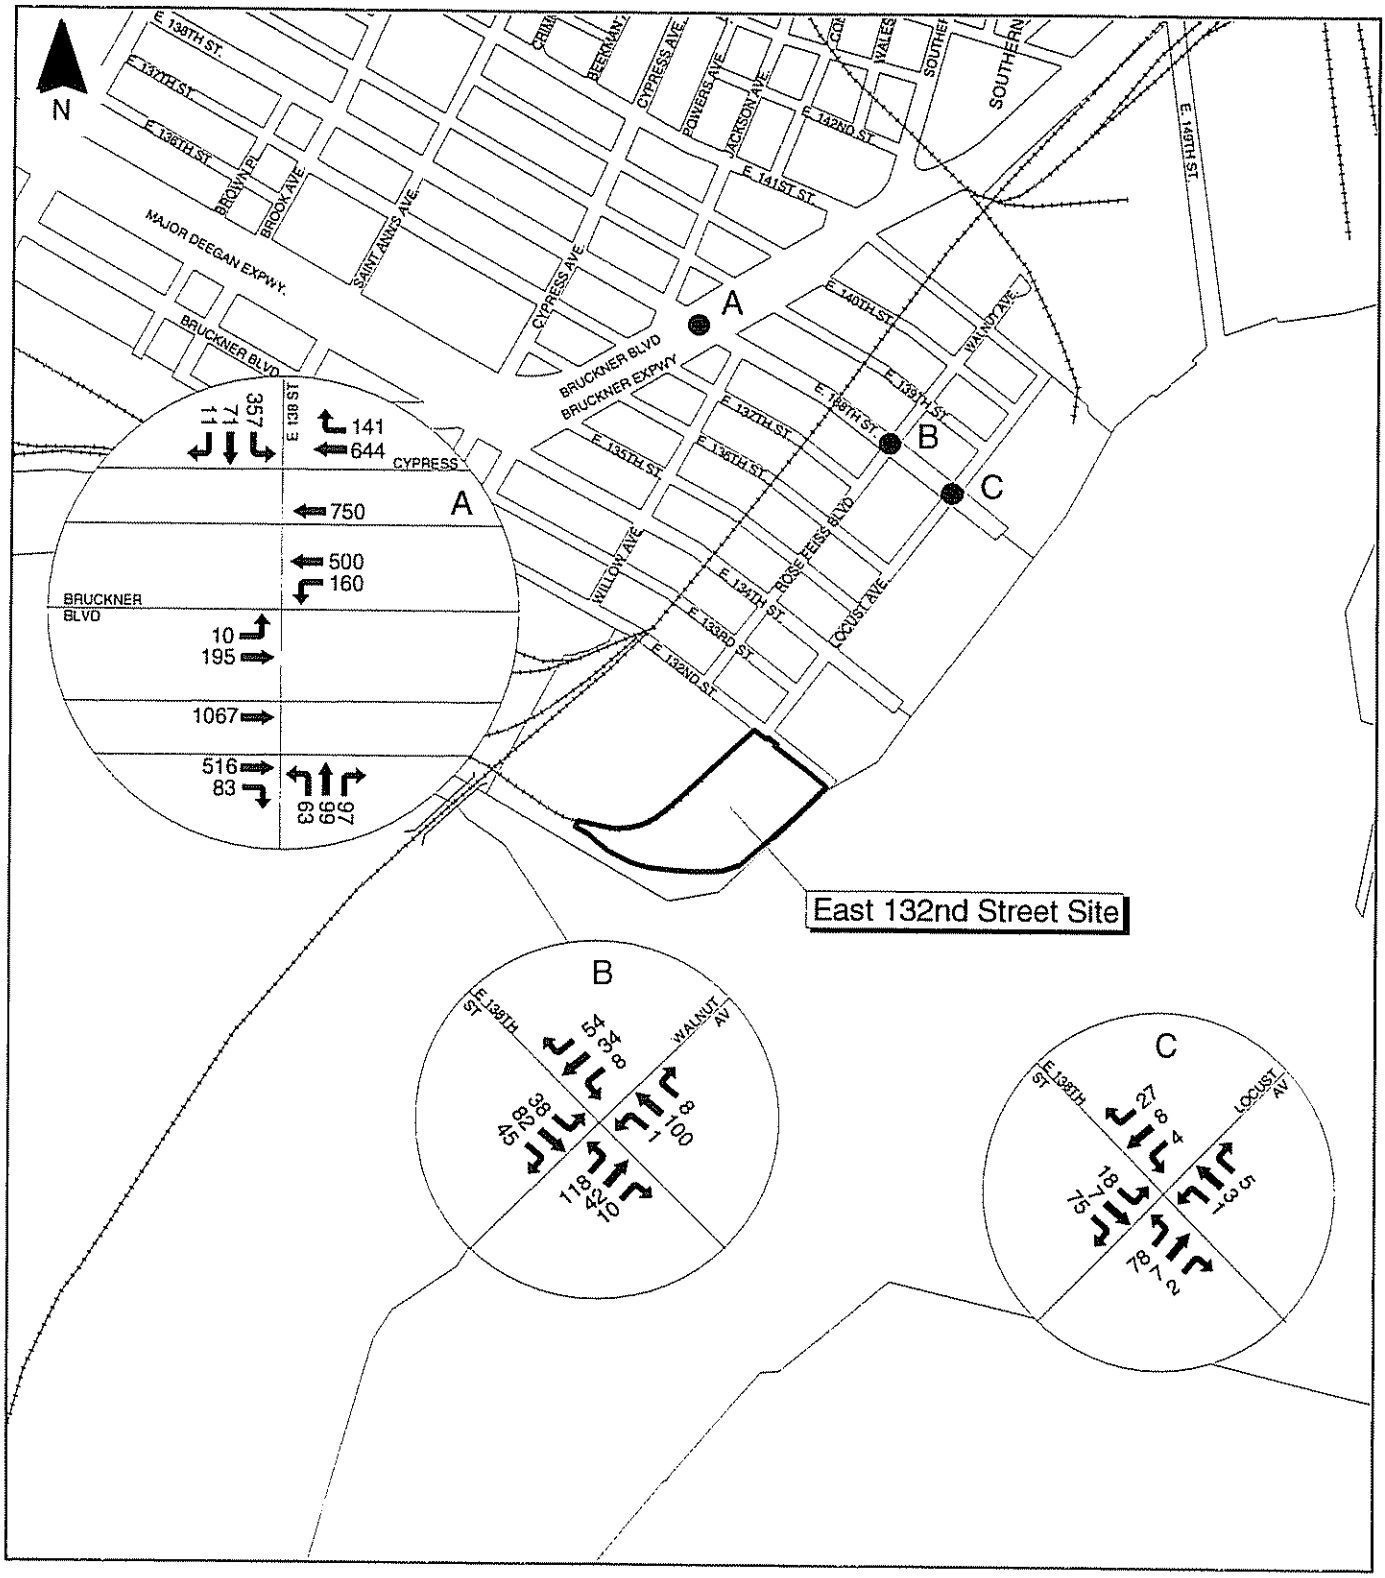

Figure 12.14-10 presents the average peak day temporal distribution of additional collection vehicle trips that would be generated by the East 132nd Street Truck to Rail TS acceptance of all Bronx DSNY-managed Waste. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of additional collection vehicle trips generated by the East 132nd Street Truck to Rail TS is expected to vary between zero and approximately 14 truck trips per hour in the late evening/early morning, 18 truck trips to approximately 75 truck trips per hour in the mid-morning/early afternoon, and approximately 5 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (76, or 38 inbound plus 38 outbound) is expected to occur from 11:00 a.m. to 12:00 p.m. The volume of dray trips to Oak Point is expected to average 8 trips in and 8 trips out per hour over the 24-hour period.

Additional employee trips are expected to be generated as a result of the acceptance of all DSNY-managed Waste by the East 132nd Street Truck to Rail TS. Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Most related trips would occur around shift changes when employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m. Because only the AM peak (8:00 a.m. to 9:00 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the East 132nd Street Truck to Rail TS during the shift change were considered part of the net increase in site-generated traffic. A net increase of 10 vehicle trips at the East 132nd Street Truck to Rail TS and one vehicle trip at Oak Point was estimated for the East 132nd Street Truck to Rail TS.

Figures 12.14-11, 12.14-12 and 12.14-13 provide the 2006 Future Build Condition traffic volumes at the study intersections, which are a combination of Future No-Build traffic volumes and incremental traffic volumes associated with the acceptance of all Bronx DSNY-managed Waste at the East 132nd Street Site. These traffic volumes were derived using a two-stage process. First, the truck trips generated by the existing Interim Export Program were subtracted from the truck trips expected to be generated by the acceptance of all Bronx DSNY-managed Waste at the East 132nd Street Site and increased by 20% to allow for contingency due to potential fluctuations in Waste deliveries. These net trips were added to the Future No-Build traffic volumes along the paths specified in Figure 12.14.-5 and 12.14-9.

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Figures 12.14-14, 12.14-15 and 12.14-16 illustrate the resulting net change in traffic volumes at each study intersection. A negative value indicates that the volume of existing DSNY-related collection vehicle trips to the interim export facilities removed from a movement would be greater than the volume of truck traffic added to the movement by trips generated through the acceptance of all Bronx DSNY-managed Waste at the East 132nd Street Site. The highest increases in traffic would occur on the northbound right and southbound left turns on Bruckner Boulevard at East 138th Street, the westbound right and left turns from East 138th Street at Bruckner Boulevard, the eastbound and westbound through movements on East 138th Street at Walnut Avenue, the eastbound right turn from East 138th Street to Locust Avenue southbound and the northbound left turn from Locust Avenue to East 138th Street westbound.

As noted in Section 12.14.2.2, the intersection of Bruckner Boulevard with East 138th Street is identified as a high accident location. The Build Condition would increase the traffic levels through this intersection as discussed above, with trucks comprising most of the incremental vehicles. Existing accident records indicate that trucks were involved in approximately 11% of the accidents at this intersection. Therefore, trucks are no more frequently involved in accidents at this intersection than their occurrence in the total traffic stream. It also appears that no collision type or travel direction is prevalent in the accident history, possibly indicating that the high accident history at this intersection is due primarily to its overall complexity. However, the proportion of accidents involving eastbound/westbound vehicles (34%) appears to be higher than the proportion of total traffic entering this intersection from the eastbound/westbound approaches. This possibly indicates the need for additional clearance time for the eastbound/westbound approaches.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 75% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 63% of weekday traffic volumes. Table 12.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency incremental collection vehicle traffic expected to be generated on the weekend due to the study Alternative. No analysis was performed for Sunday because the East 132nd Street Truck to Rail TS would not accept DSNY-managed Waste on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 12.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the East 132nd Street Truck to Rail TS. Overall 2006 Future Build intersection traffic operations, expressed in terms of delay, would deteriorate slightly for the unsignalized intersections of East 138th Street and Walnut Avenue and East 138th Street and Locust Avenue, but lane group and overall intersection LOS would be maintained at LOS B or better. However, significant traffic impacts, as defined by the 2001 CEQR Technical Manual and listed in Section 3.16, were identified for specific lane groups at the signalized intersection of Bruckner Boulevard with East 138th Street. These impacts and suggested mitigation are discussed below.

12.14.3.2 Impacts and Mitigation

Table 12.14-5 provides a comparison of v/c ratio, delay and LOS for the Future No-Build, Future Build before mitigation, and Future Build after mitigation scenarios at each intersection where impacts were identified. The following describes proposed mitigation and projected results with mitigation.

Impacts were identified at the intersection of Bruckner Boulevard at East 138th Street, mostly during the Facility peak hour. On the eastbound approach during the Facility peak hour, the eastbound left-turn lane group and eastbound left-turn and through lane group delay increased from 102.0 seconds to 112.4 seconds and from 88.2 seconds to 100.2 seconds, respectively. In addition, during the Facility peak hour, the delay for the southbound defacto left-turn lane group increased from 44.8 seconds at LOS D to 68.5 seconds at LOS E, and the delay for the westbound through and right-turn lane group increased from 42.0 seconds to 49.1 seconds. The existing signal operates as a three-phase signal. The mitigation proposed is as follows:

- Add two seconds of green time to the eastbound/westbound phase.
- Add four seconds of green time to the northbound/southbound protected left turn phase.
- Decrease the northbound/southbound green phase by six seconds.

This change would mitigate the eastbound impact by decreasing the average delay per vehicle of the eastbound left-turn lane group from 112.4 seconds to 89.5 seconds and decreasing the delay on the eastbound left-turn and through lane group from 100.2 seconds to 80.9 seconds. This change would also reduce the southbound defacto left-turn lane group delay from 68.5 seconds to 54.0 seconds and improve the level of service from LOS E to LOS D, as well as reduce the westbound through and right-turn lane group delay from 49.1 seconds to 45.1 seconds, but not fully mitigate the impacts on these lane groups. To reduce the delay on the southbound defacto left-turn and westbound through and right-turn lane groups to mid-LOS D (mitigated) would require that 17 fewer trucks deliver to the facility from the north (inbound). This would also result in a reduction of 17 vehicles departing (outbound) the facility. Therefore, the net additional

Notes for Table 12.14-5:

(1) HCM output is included in technical backup submitted to the NYCDOT.

DFL = defacto left
LT = left through movement
L = left movement
TR = through right movement
T = through movement
ML = mainline
SR = service road
EB = eastbound
NB = northbound
SB = southbound
WB = westbound

DSNY collection vehicles through this intersection would be limited to 21 inbound plus 21 outbound trips (42 trip ends). This in addition to the existing 26 inbound and 26 outbound trips assumed to travel through this intersection under interim export during the Facility peak hour. Therefore, the total DSNY collection vehicle trips through this intersection during the Facility peak hour must be limited to 47 inbound plus 47 outbound, a total of 94 trip ends. There would be no impacts induced for the northbound/southbound lane groups due to this shift in cycle time.

During the AM peak hour, impacts were identified on the southbound defacto left-turn lane group (delay increase from 46.6 seconds to 61.1 seconds), the westbound defacto left-turn lane group (delay increase from 54.8 seconds to 75.2 seconds) and the westbound through and right-turn lane group (delay increase from 40.6 seconds to 46.8 seconds). The mitigation measures proposed for use during the Facility peak hour are also proposed for use during the AM peak hour. The impact on the westbound through and right-turn lane group would be mitigated by the proposed measure (delay reduced from 46.8 seconds to 43.4 seconds); however, the delay on the westbound defacto left-turn lane group and southbound defacto left-turn lane group would be reduced, but the impacts not fully mitigated. On the westbound defacto left-turn lane group, the delay would be reduced from 75.2 seconds to 62.0 seconds with the LOS remaining at LOS E, and the delay on the southbound defacto left-turn lane group would be reduced from 61.1 seconds to 49.6 seconds and the LOS improving from LOS E to LOS D. To reduce the delay on the westbound defacto left-turn and southbound defacto left-turn lane groups to Future No-Build levels (mitigated) would require that nine fewer trucks deliver to the facility from the north (inbound) during the AM peak hour. This would also result in a reduction of nine vehicles departing (outbound) the facility. Therefore, the net additional DSNY collection vehicles through this intersection would be limited to 25 inbound plus 21 outbound trips (46 trip ends). This in addition to the existing 19 inbound and 17 outbound trips assumed to travel through this intersection under interim export during the AM peak hour. Therefore, the total DSNY collection vehicle trips through this intersection during the AM peak hour must be limited to 44 inbound plus 38 outbound, a total of 82 trip ends. There would be no impacts induced for the northbound/southbound lane groups due to this shift in cycle time.

12.14.3.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

12.14.3.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

12.14.4 Potential Impacts with the Oak Point Rail Yard

As discussed above in Section 12.14.3.1, all waste from the East 132nd Street Truck to Rail TS would be drayed to the Oak Point Rail Yard. These dray vehicles were included in the Build traffic volumes for the intersections analyzed with an adjustment to account for the displacement of transfer trailers under existing operations. On Bruckner Boulevard north of 138th Street, Leggett Avenue and Barry Street, all the dray trips are considered incremental traffic associated with the Build Condition. However, considering the threshold assumed for warranting traffic impact analysis (see Section 3.16 for a discussion of CEQR analysis thresholds), the draying activity of 16 trip ends per hour (or 32 PCEs) does not warrant a traffic analysis on the dray route solely due to dray vehicles.

12.15 Air Quality

The East 132nd Street Site is currently permitted at 2,999 tpd, based upon a negative declaration finding on an EAS for that capacity completed in 1994, and was further evaluated for accepting and processing all Bronx DSNY-managed Waste, with a negative declaration finding on that EAS in 1997. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed air quality environmental review. Copies of the environmental review documents for the East 132nd Street Site are available upon request on compact disk.

The Oak Point Rail Yard is an intermodal facility that would receive containers drayed from the East 132nd Street Site. DSNY issues a non-discretionary permit to intermodal facilities handling containerized waste, which is not subject to environmental review for potential on-site impacts. An off-site air quality analysis for the acceptance and processing of 2,999 tpd of waste at the Oak Point Rail Yard was completed.

12.15.1 Existing Conditions

The study area for the off-site air quality analysis consists of the two intersections listed in Section 12.15.3.2 between the East 132nd Street Truck to Rail TS and the Oak Point Rail Yard.

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 12.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 12.15-1
Representative Ambient Air Quality Data
East 132nd Truck to Rail Street TS and Oak Point Rail Yard

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO(1)	200th Street and Southern Boulevard	8-Hour	2.2 ppm	9 ppm
		1-Hour	4.1 ppm	35 ppm
NO_2(1)	East 156th Street, between Dawson and Kelly	Annual	0.030 ppm	0.05 ppm
PM_{10}(1)	East 156th Street, between Dawson and Kelly	Annual	22 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	60 $\mu g/m^3$	150 $\mu g/m^3$
SO_2(1)	East 156th Street	3-Hour	0.089 ppm	0.5 ppm
		24-Hour	0.052 ppm	0.14 ppm
		Annual	0.011 ppm	0.03 ppm

Notes:
Source: USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.

12.15.2 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the project's future analysis year (2006). As such, no changes to air quality levels are anticipated, and Future No-Build air quality conditions are assumed to be the same as Existing Conditions for all pollutants, except CO. CO concentrations are expected to be affected by increasingly stringent, federally-mandated vehicular emission controls, offset by increases in regional traffic volumes.

Using 2001 CEQR Technical Manual guidelines, two intersections were identified as potentially having significant impacts from proposed DSNY and other agency collection vehicles. Detailed mobile source analyses were then conducted at these two locations during the applicable (i.e., worst-case) time periods:

- The intersection of Bruckner Boulevard and East 138th Street; and
- The intersection of Locust Avenue and East 138th Street.

Analyses were conducted to determine whether the site-generated traffic has the potential to cause exceedances of the PM_{10}, NAAQS, or NYCDEP's and NYSDEC's 24-hour and annual

$PM_{2.5}$ STVs. No CO analysis was conducted because the number of proposed vehicles trips to and from the facility is below CEQR CO screening thresholds.

12.15.3 Results of the Off-Site Analysis

Maximum pollutant concentrations estimated near each selected intersection are shown in Table 12.15-2. Using a Tier I analysis, these results show that all estimated concentrations are within (less than) the applicable state and federal ambient air quality standards and/or STVs (for $PM_{2.5}$), except for the intersection of Locust Avenue and East 138th Street. Therefore, a Tier II analysis was conducted at this intersection. Using the Tier II analysis, it was determined that the operations of the East 132nd Street Truck to Rail TS and Oak Point Rail Yard would result in no significant off-site air quality impacts.

Table 12.15-2
Estimated Pollutant Concentrations Near Selected Roadway Intersections
East 132nd Street Transfer Station/Oak Point Rail Yard

Air Quality Receptor Site	PM_{10}		$PM_{2.5}$ [2]	
	24-hr PM_{10} Concentrations[1] $\mu g/m^3$ (NAAQS: 150 $\mu g/m^3$)	Annual PM_{10} Concentrations[1] $\mu g/m^3$ (NAAQS: 50 $\mu g/m^3$)	Impacts from Off-Site Emission Sources[3][4] $\mu g/m^3$ (24-Hour STV: 5 $\mu g/m^3$)	Impacts from Off-Site Emission Sources[3] $\mu g/m^3$ (Annual Neighborhood Average STV: 0.1 $\mu g/m^3$)
Bruckner Boulevard & East 138th Street				
Existing Conditions	~~109.6~~133	~~40.1~~37		
Future No-Build Conditions	~~111.0~~134	~~40.6~~38		
Future Build Conditions	~~111.7~~135	~~41.2~~38		
Future Build Incremental			0.932	0.09030
Locust Avenue & East 138th Street				
Existing Conditions	~~78.2~~96	~~26.9~~23		
Future No-Build Conditions	~~78.1~~96	~~26.9~~23		
Future Build Conditions	~~82.4~~101	~~28.4~~24		
Future Build Incremental			~~1.~~30.3	0.03040

Notes:

(1) PM_{10} concentrations are the maximum concentrations estimated using the AM, Facility, and PM peak traffic information plus background values; 24-hr PM_{10} = ~~73~~91 $\mu g/m^3$; Annual PM_{10} = ~~25~~21 $\mu g/m^3$).

(2) ~~The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project induced [or Future Build] traffic only) estimated by taking the~~ The maximum difference between ~~the maximum~~ $PM_{2.5}$ concentrations ~~for~~ under ~~the~~ Future No-Build and Future Build ~~scenarios~~ conditions at ~~any~~ sidewalk receptors. ~~three meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.~~

(3) ~~The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project induced [or Future Build] traffic only) estimated by taking the~~ The average difference between ~~the maximum~~ $PM_{2.5}$ concentrations ~~for~~ under the Future No-Build and Future Build ~~scenarios~~ conditions at ~~any~~ average receptors 15 meters from the edge of the roadways. ~~using AM, Facility, or PM peak traffic conditions.~~

(4) Results determined ~~based on~~using a Tier II analysis.

ppm = parts per million

$\mu g/m^3$ = microgram per cubic meter
