The East 132nd Street Site is currently permitted at 2,999 tpd, based upon a negative declaration finding on an EAS for that capacity completed in 1994, and was further evaluated for accepting and processing all Bronx DSNY-managed Waste, with a negative declaration finding on that EAS in 1997. The minor modification of adding the lidding operation on site would not result in any changes to the previously completed odor environmental review. Copies of the environmental review documents for the East 132nd Street Site are available upon request on compact disk.

The Oak Point Rail Yard is an intermodal facility that would receive containers drayed from the East 132nd Street Site. DSNY issues a non-discretionary permit to intermodal facilities handling containerized waste, which is not subject to environmental review for potential on-site impacts. An off-site traffic, air quality and noise analysis for the acceptance and processing of 2,999 tpd of waste at the Oak Point Rail Yard was completed. Results are reported in those sections of this FDEIS.

12.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from the East 132nd Street Site-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual ~~and the Current New York City Noise Code~~ for both on-site and off-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

12.17.1 Existing Conditions

12.17.1.1 Introduction

The East 132nd Street Site is currently permitted at 2,999 tpd, based upon a negative declaration finding on an EAS for that capacity completed in 1994, and was further evaluated for accepting and processing all Bronx DSNY-managed Waste, with a negative declaration finding on that EAS in 1997. An off-site noise analysis for the acceptance and processing of 2,999 tpd of waste at the Oak Point Rail Yard was completed. The Oak Point Rail Yard is an intermodal facility that would receive containers drayed from the East 132nd Street Site. DSNY issues a non-discretionary permit to intermodal facilities handling containerized waste, which is not subject to environmental review for potential on-site impacts.

12.17.1.2 On-Site Noise Levels

Only a minor modification of adding the lidding operation on-site for the East 132nd Street Site is proposed. The nearest noise sensitive receptor is a park located on Randall's Island, located over 600 feet away. Background daytime noise levels monitored at this location for the 2000 FEIS were 58 dBA. Daytime noise levels (7:00 a.m. to 10:00 p.m.) can increase up to 5 dBA without causing a noise impact when background noise levels are 60 dBA or lower.

12.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the East 132nd Street Site-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was not required and, therefore, off-site noise monitoring was not conducted.

12.17.2 Future No-Build Conditions

12.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

12.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 12.17-1 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and the background noise levels is greatest) during the daytime (if any) and nighttime based on the first-level screening.

Table 12.17-1
Off-Site Noise Traffic Volume
East 132nd Street Site

Location	Hour	Existing Traffic Volume(1) (Vehicle/Hour)	Future No-Build Traffic Volume(2) (Vehicle/Hour)
Bruckner Boulevard between East 149th Street and Leggett Avenue	3:00 a.m.	408	415
East 138th Street, between Bruckner Boulevard and Walnut Street	~~12~~1:00 a.m.	~~56~~59	~~56~~60

Notes:
(1) -Existing traffic volumes are based on ATR data.
(2) -Future No-Build Traffic volumes are based on CEQR annual traffic growth rates.

12.17.3 Potential Impacts with the East 132nd Street TS

12.17.3.1 On-Site Noise Levels

L_{eq} noise levels associated with this type of lidding operation were measured at 79.1 dBA at 50 feet from the source, which would attenuate to an L_{eq} of 57.4 dBA at the Randall's Island park. The combined noise level at the Randall's Island park from the lidding operations and the background noise level at the park would result in an estimated L_{eq} of 60.7 dBA. The estimated increase in L_{eq} at the park from this operation is 2.7 dBA; therefore, no impact is predicted. Copies of the environmental review documents for the East 132nd Street TS are available upon request on compact disk.

12.17.3.2 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the East 132nd Street TS, including the routes to be used for the draying of the containers to the Oak Point Rail Yard. The

assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required. Results of the screening for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) based on first-level screening are provided in Table 12.17-2 below.

Because the screening results provided below showed that PCEs would not double on a roadway due to DSNY and other agency collection vehicles coming to or going from the East 132nd Street TS, a detailed off-site noise analysis was not required.

Table 12.17-2
Off-Site Noise Screening Results
East 132nd Street TS

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Dray Trucks	Dray Truck PCEs	Future Build PCEs[1][2]	Possible Impact[3]
East 138th Street between Bruckner Boulevard and Walnut Street	1:00 a.m.	1172	12	0	564	12	564	2300	No

Notes:
(1) Total PCEs are rounded to the nearest whole numbers.
(2) Future Build PCEs include East 132nd Street TS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted using a factor of 1.
(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

12.17.3.3 Combined On-Site and Off-Site Noise Levels

An on-site noise analysis was performed for the East 132nd Street TS. As a result of the off-site screening analysis, which is described above in 12.17.3.2, no off-site noise analysis was required. Since an off-site analysis was not required, a combined noise analysis was not performed.

This page intentionally left blank.

CHAPTER 13 ENVIRONMENTAL REVIEW – SCOTT AVENUE TRUCK TO BARGE TS

13.1 Introduction

The Scott Avenue Transfer Station is currently permitted for receipt and processing of waste into outbound transfer trailers at 1,500 tpd with a negative declaration and EAS for that capacity dated January 2003. The current proposal does not propose any increase in capacity. A permit modification is required for container lidding and barge loading in response to the DSNY's RFP. Part 360 Permit application documents for the modification were submitted to the NYSDEC in April 2003. Scott Avenue is currently contracted to accept up to 1,400 tpd of DSNY-managed Waste under Interim Export and receives, on an average peak day, approximately 1,114 tons.

The facility was also the subject of an EAS in 1998/1999 for Interim Export. At that time, no off-site $PM_{2.5}$ analysis was performed. The EAS for Interim Export, updated in 2002, assumed continuation of the 1998/1999 EAS action, so no traffic, $PM_{2.5}$, CO or mobile noise analyses were completed as there was no net change. PM_{10} was analyzed at four locations. The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation. Copies of the environmental review documents for the Scott Avenue Truck to Barge TS are available upon request on compact disk.

The results of the environmental analyses of the facility options at the Scott Avenue Site are presented in the following sections:

13.2 Land Use, Zoning, and Public Policy
13.3 Socioeconomic Conditions
13.4 Community Facilities and Services
13.5 Open Space
13.6 Cultural Resources
13.7 Urban Design, Visual Resources, and Shadows
13.8 Neighborhood Character
13.9 Natural Resources

13.10 Hazardous Materials

13.11 Water Quality

13.12 Waterfront Revitalization Program

13.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

13.14 Traffic, Parking, Transit, and Pedestrians

13.15 Air Quality

13.16 Odor

13.17 Noise

Section 2.2.10 provides a summary description of the site and important characteristics of the design and operation of each option. The following sections provide additional information on the site or the study area, as appropriate to each analysis.

A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3.

13.2 Land Use, Zoning, and Public Policy

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the land use, zoning, and public policy impacts.

13.3 Socioeconomic Conditions

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the socioeconomic impacts.

13.4 Community Facilities and Services

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the community facilities and services impacts.

13.5 Open Space

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the open space impacts.

13.6 Cultural Resources

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the cultural resources impacts. As indicated in the 2000 SWMP FEIS, consultation with SHPO regarding possible archaeological resources on site are required once a detailed design is developed.

13.7 Urban Design, Visual Resources, and Shadows

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the urban design, visual resources, and shadows impacts.

13.8 Neighborhood Character

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the neighborhood character impacts.

13.9 Natural Resources

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the natural resources impacts.

13.10 Hazardous Materials

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the hazardous materials impacts. As indicated in the 2000 SWMP FEIS, a Phase II subsurface site investigation to sample and test any soils that would be disturbed during construction would be required.

13.11 Water Quality

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of water quality impacts.

13.12 Waterfront Revitalization Program

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the waterfront revitalization impacts.

13.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the infrastructure, solid waste and sanitation services, and energy impacts.

13.14 Traffic, Parking, Transit, and Pedestrians

Currently, the Scott Avenue Truck to Barge TS is contracted to accept 1,400 tpd of DSNY-managed Waste under the Interim Export Program. Data indicates that the facility receives approximately 1,114 tpd of DSNY-managed Waste. Under Future Build Conditions, this facility would accept no more than the current amount of DSNY-managed Waste. The Future Build Conditions represent no net change in amount of waste delivered to this facility (or resulting DSNY collection vehicles) under Existing Conditions. Additionally, waste is taken off site via transfer trailers under Existing Conditions. Under Future Build Conditions, waste would be exported from the site via barge, thus resulting in a reduction of outbound transfer trailer traffic generated by the Scott Avenue Truck to Barge TS. Due the reduction of site-generated traffic under Future Build Conditions, no traffic analysis was performed for this facility.

13.15 Air Quality

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of air quality impacts. Since the Future Build Conditions represent no net change in the amount of waste delivered to this facility (or resulting DSNY collection vehicles) under Existing Conditions and a decrease in outbound transfer trailers, no off-site air quality analysis was performed for this facility.

13.16 Odor

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the odor impacts.

13.17 Noise

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the noise impacts. Since the Future Build Conditions represent no net change in amount of waste delivered to this facility (or resulting DSNY collection vehicles) under Existing Conditions and a decrease in outbound transfer trailers, no off-site noise analysis was performed for this facility.

This page intentionally left blank.

CHAPTER 14 ENVIRONMENTAL REVIEW - SCOTT AVENUE/SCHOLES STREET TRUCK TO RAIL TS

14.1 Introduction

The Scott Avenue/Scholes Street TS is currently permitted to handle 220 tpd of putrescible waste. It is currently contracted to accept up to 220 tpd of DSNY-managed Waste under Interim Export and receives approximately 143 tons on an average peak day. This facility was the subject of an EAS in 1998/1999 for Interim Export at its permitted 220 tpd capacity. At that time, no off-site $PM_{2.5}$ analysis was performed. The EAS for Interim Export, updated in 2002, assumed continuation of the 1998/1999 EAS action, so no traffic, $PM_{2.5}$, CO or mobile noise analyses were completed since there was no net change. PM_{10} was analyzed at four locations.

The Scott Avenue/Scholes Street TS is proposed to increase putrescible waste capacity in two phases: (1) a Phase I expansion to 1,368 tpd (using tonnage offsets of putrescible, C&D and glass/tire/yard waste from other facilities in Brooklyn CD 1, several of which are located on the site); and (2) a Phase II expansion from 1,368 tpd to 3,000 tpd (offsets for this increment in capacity are not clearly defined).

The facility is proposed to accept 891 tpd of DSNY ~~Managed~~ managed Waste Long Term. A Part 360 Solid Waste Facility Permit Modification application has been submitted to the NYSDEC with an accompanying EAS for the 1,368 tpd expansion in September 2003, and supplemental traffic analyses submitted in March 2004 to support the phased expansion. A Negative Declaration has not been issued by DSNY on the EAS. Among the offsets proposed for the Phase I expansion are 588 tpd of non-putrescible and recycling processing capacity at the Scott Avenue/Scholes Street Truck to Rail TS.

The Phase II expansion is not required for Long Term Export of DSNY-managed ~~waste~~ Waste and, therefore, is not evaluated in this F~~D~~EIS.

The Scott Avenue/Scholes Street Transfer Station is evaluated at its 1,368 tpd design capacity for on-site impacts and for an incremental shift in tonnage of 637 tpd (1,368 tpd proposed permitted capacity minus 143 tpd existing average peak day deliveries, 388 tpd of offsets for C&D material from 594 Scholes Street, and 200 tpd of glass/tire/yard waste material from 598 Scholes Street).

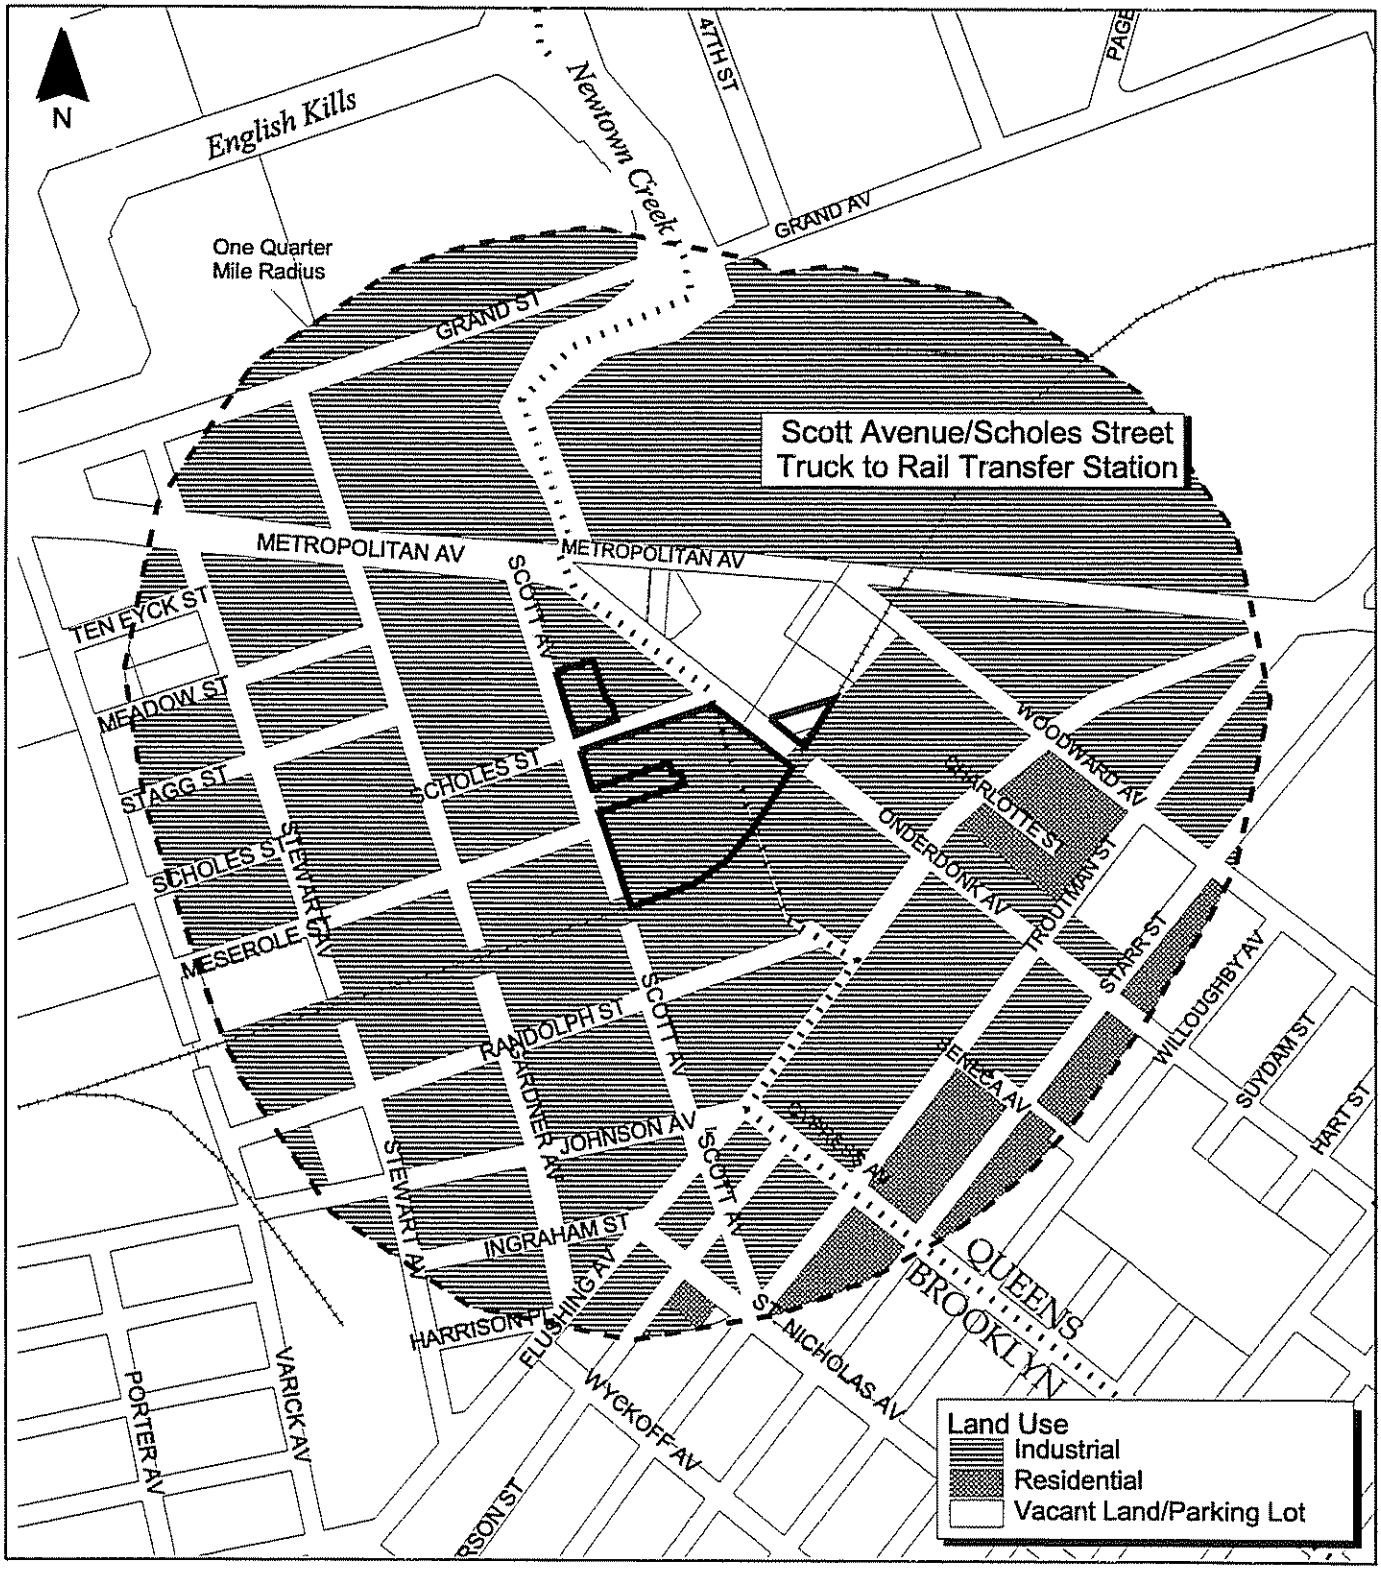
The results of the environmental analyses of the Scott Avenue/Scholes Street Truck to Rail TS are presented in the following sections:

14.2 Land Use, Zoning, and Public Policy
14.3 Socioeconomic Conditions
14.4 Community Facilities and Services
14.5 Open Space
14.6 Cultural Resources
14.7 Urban Design, Visual Resources, and Shadows
14.8 Neighborhood Character
14.9 Natural Resources
14.10 Hazardous Materials
14.11 Water Quality
14.12 Waterfront Revitalization Program
14.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
14.14 Traffic, Parking, Transit, and Pedestrians
14.15 Air Quality
14.16 Odor
14.17 Noise

Section 2.2.11 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

14.2 Land Use, Zoning, and Public Policy

14.2.1 Existing Conditions



14.2.1.1 Definition of the Study Areas

For the land use, zoning, and public policy analyses, the primary study area is defined as the area within ¼-mile of the site (see Figure 14.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 14.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.2.11 provides information on existing land uses and operations on the site.

14.2.1.2 Land Use Patterns

14.2.1.2.1 General Context

The Scott Avenue/Scholes Street Truck to Rail TS site is located in Community District 1 near the Brooklyn/Queens border, in the predominantly industrial section of East Williamsburg, Brooklyn. It is largely surrounded by canals and railroad tracks: English Kills on the west, Newtown Creek on the east and LIRR tracks to the east and south, thus making it directly accessible on land only from the north.

Site delineations and study area boundaries are approximate.
Base Map Source: New York City Department of City Planning
This figure illustrates predominant land uses by lot in the primary study area.

Figure 14.2-2 Land Use in the Secondary Study Area
Scott Avenue/Scholes Street
Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

14.2.1.2.2 Land Uses in the Primary Study Area

The Scott Avenue/Scholes Street Truck to Rail TS site is situated just west of the Brooklyn/Queens border which separates East Williamsburg, Brooklyn to the west and Maspeth, Queens to the east. The primary study area is characterized by several private waste transfer stations (including BFI Waste Systems facilities on Scholes Street and Gardner Avenue, and Waste Management of New York facilities on Stewart Avenue and Varick Avenue) as well as a DSNY parking lot on Meserole Street, a new CD 1 and 4 garage under construction on Varick Avenue and an existing garage on Johnson Avenue.

The English Kills canal runs along the eastern border of the primary study area, is approximately 200 feet wide and connects with Newtown Creek at the Brooklyn/Queens boundary. The LIRR tracks bisect the ½-mile study area east to west and pass immediately south of the site between Meserole and Randolph Streets. The NY&A operates freight trains on these tracks, with a terminal nearby, in Bushwick (to the west).

North and south of the existing site are scrap metal yards and plastic manufacturing facilities, window and door manufacturing facilities, lumber yards and hydraulic equipment leasing companies. Development surrounding the site is primarily low density with open parking lots and low-scale masonry buildings ranging from two to four stories in height.

The area surrounding the Scott Avenue/Scholes Street Truck to Rail TS site includes some vacant land to the north on Gardner and Stewart Avenues, as well as lots undergoing construction. Some sites have been rehabilitated to accommodate new industrial loft space and community facilities such as a Peter Jay Sharp Center for Opportunity on Porter Street (89-111). The other community facilities include a fire station on Morgan Avenue and a daycare center on Knickerbocker Street. The area is also characterized by abundant parking lots and garage facilities, some of which are leased by DSNY for trucks and other equipment storage.

14.2.1.2.3 Land Uses in the Secondary Study Area

Within ½-mile of the site there is a mix of residential, industrial and some commercial uses. Industrial uses in the secondary study area tend to be lighter than those found in the primary study area. These uses include printers, auto salvage and repair shops and food product manufacture and distribution companies. The residential area closest to the site is Bushwick, which is characterized by three- and four-story apartment buildings along Willoughby and Starr Streets to the southeast, as well as single-family homes and townhouses ½-mile south of the site, and in Ridgewood (Queens), ½-mile east of the site.

The secondary study area contains a major City park: Maria Hernandez Park, located ½-mile south of the site. Another open space, the five-acre Grover Cleveland High School Athletic Field about 1/3-mile to the southeast, provides recreational opportunities to neighborhood residents, as well as students of the school.

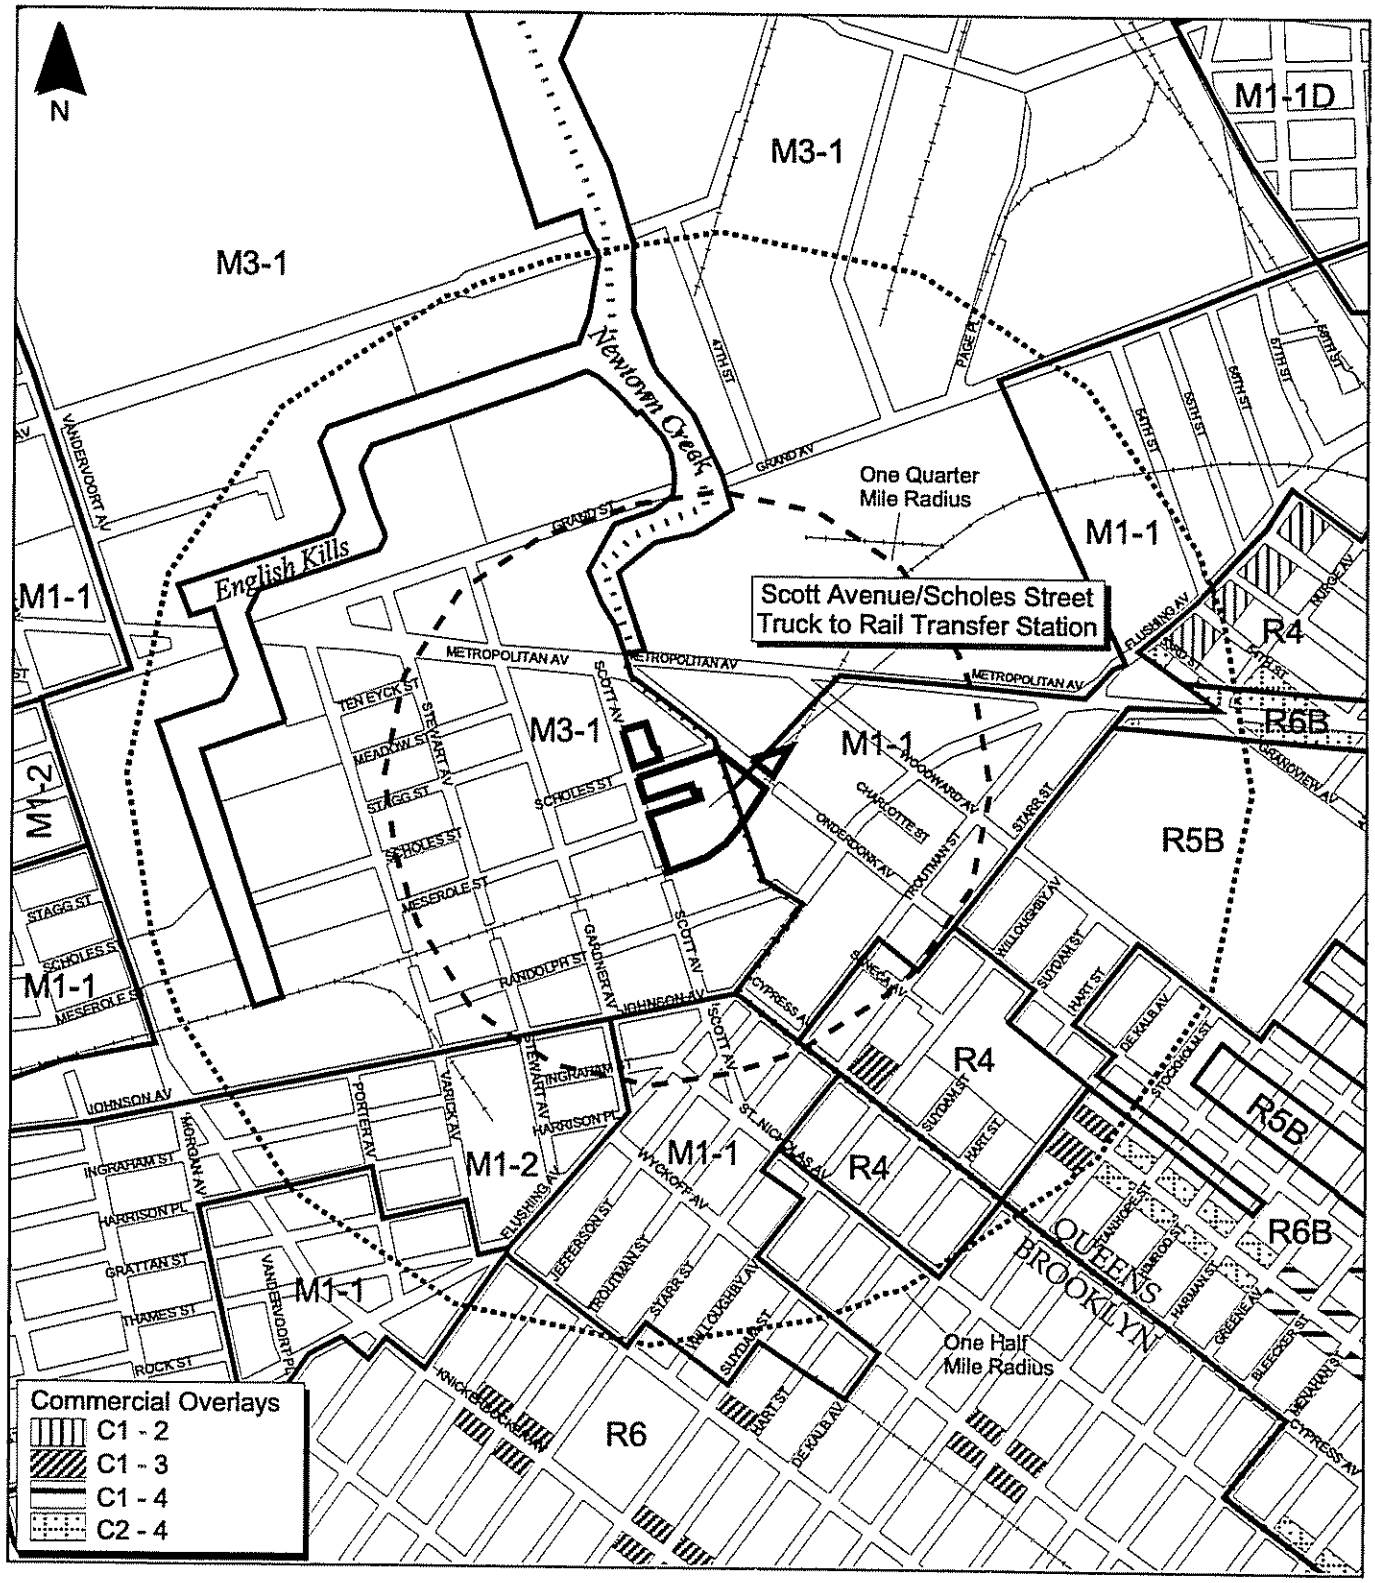
Local commercial and retail activities are primarily concentrated along the western border of the secondary study area along Knickerbocker and Morgan Avenues. These corridors are characterized by ground floor retail uses and upper floor residences. Flushing and Jefferson Avenues serve as local retail streets as well as hubs of wholesale activity. Bakery and restaurant suppliers, plumbing and electrical equipment manufacturers, and window and door products manufacturers, are all found on these mixed-use streets.

14.2.1.3 Zoning On and Near the Site

14.2.1.3.1 Zoning Within the Primary Study Area

The project site is located within an M3-1 zoning district. This M3-1 zone extends from beyond the northern boundary of the primary study area to Johnson Avenue in the south. M1-2 and M1-1 zoning districts comprise most of the remainder of the primary study area to the south in Brooklyn and east into Queens, though a block of R4 zoning is also located southeast of the site in the primary study area, just east of Troutman Street and North of Cypress Avenue. The M1

zones act as a buffer between the residential and the heavier manufacturing districts and feature both residential and light manufacturing (e.g., distribution) activities. (See Figure 14.2-3 and Table 3.4-1: Zoning District Characteristics.)



14.2.1.3.2 Zoning Within the Secondary Study Area

Zoning in the secondary area is largely comprised of M3-1 districts in the north and M1-1 and M1-2 districts in the south and east. In addition, there are R4 zoning districts covering Ridgewood (Queens and Brooklyn) and a small portion of a large R6 zoning district in Bushwick, which both permit residential development such as single-family homes and apartment buildings. Knickerbocker Avenue is mapped R6 with a commercial overlay of C1-3 which permits ground floor retail uses.

14.2.1.4 Plans and Policies

The project site lies within the City Coastal Zone, the East Williamsburg In-Place Industrial Park and the North Brooklyn Empire Zone. Since it is situated within the Coastal Zone, it is subject to the WRP. The Plan for the Brooklyn Waterfront recommends a restriction of public access within the Newtown Creek environs for Reach 13, since it is an important industrial area that should be retained.

The site is located within the East Williamsburg In-Place Industrial Park, which is now a 650-acre manufacturing district covering 150 City blocks in northern Brooklyn. The East Williamsburg Valley Industrial Development Corporation (EWVIDC), a local development corporation, provides comprehensive business services and helps local firms access public incentive programs. The EWVIDC administers the North Brooklyn Empire Zone (a New York State designation), which offers tax and financial incentives to attract and retain businesses in the area.

Site delineations and study area boundaries are approximate

Figure 14.2-3 Zoning
Scott Avenue/Scholes Street
Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

In its FY 2004 CDNS, Brooklyn CD 1 encourages the construction and rehabilitation of a roughly equal number of subsidized and market rate housing units under the Williamsburg Urban Renewal Area. The plan also encourages street resurfacing and sidewalk improvements to Flushing Avenue, which is heavily traveled by local/truck traffic. Infrastructure improvements are recommended throughout the industrial area, for example from Metropolitan Avenue to Vandervoort Avenue. In addition, the upgrading and replacement of the sewers in CD 1 remains an on-going necessity. CD 1 continues to support manufacturing jobs and hopes to increase the percentage of residents employed by local industries.

14.2.2 Future No-Build Conditions

No major development changes are expected to result in the immediate project area by the Future No-Build year. The large DSNY Varick Avenue Garage (serving CDs 1 and 4) at 137-165 Varick Street is currently under construction a few blocks northwest of the site and due to be completed at the end of 2004.

The larger Greenpoint-Williamsburg neighborhood, north and west of the site (beyond the secondary study area), is expecting more mixed development as a result of the MX-1 rezoning (NYCDCP). This rezoning would introduce changes such as the conversion of manufacturing lofts to residential use. Long-term projects for the area include the Bushwick Creek Inlet Development, the Greenpoint Terminal Market and the Sludge Tank Adaptive Reuse Project, though the Build years for these projects are 2012 and 2013.

14.2.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

14.2.3.1 Land Use and Zoning

The potential land use impacts of the proposed Scott Avenue/Scholes Street Truck to Rail TS would be equivalent to the existing waste transfer operations that occur at the site. While improvements would be made to the site, and the capacity of the facility increased, existing and proposed land uses in the area would not be significantly affected since land use would not

change. Existing buildings on the site will be demolished to accommodate new site construction. However, no significant adverse land use or zoning impacts are anticipated.

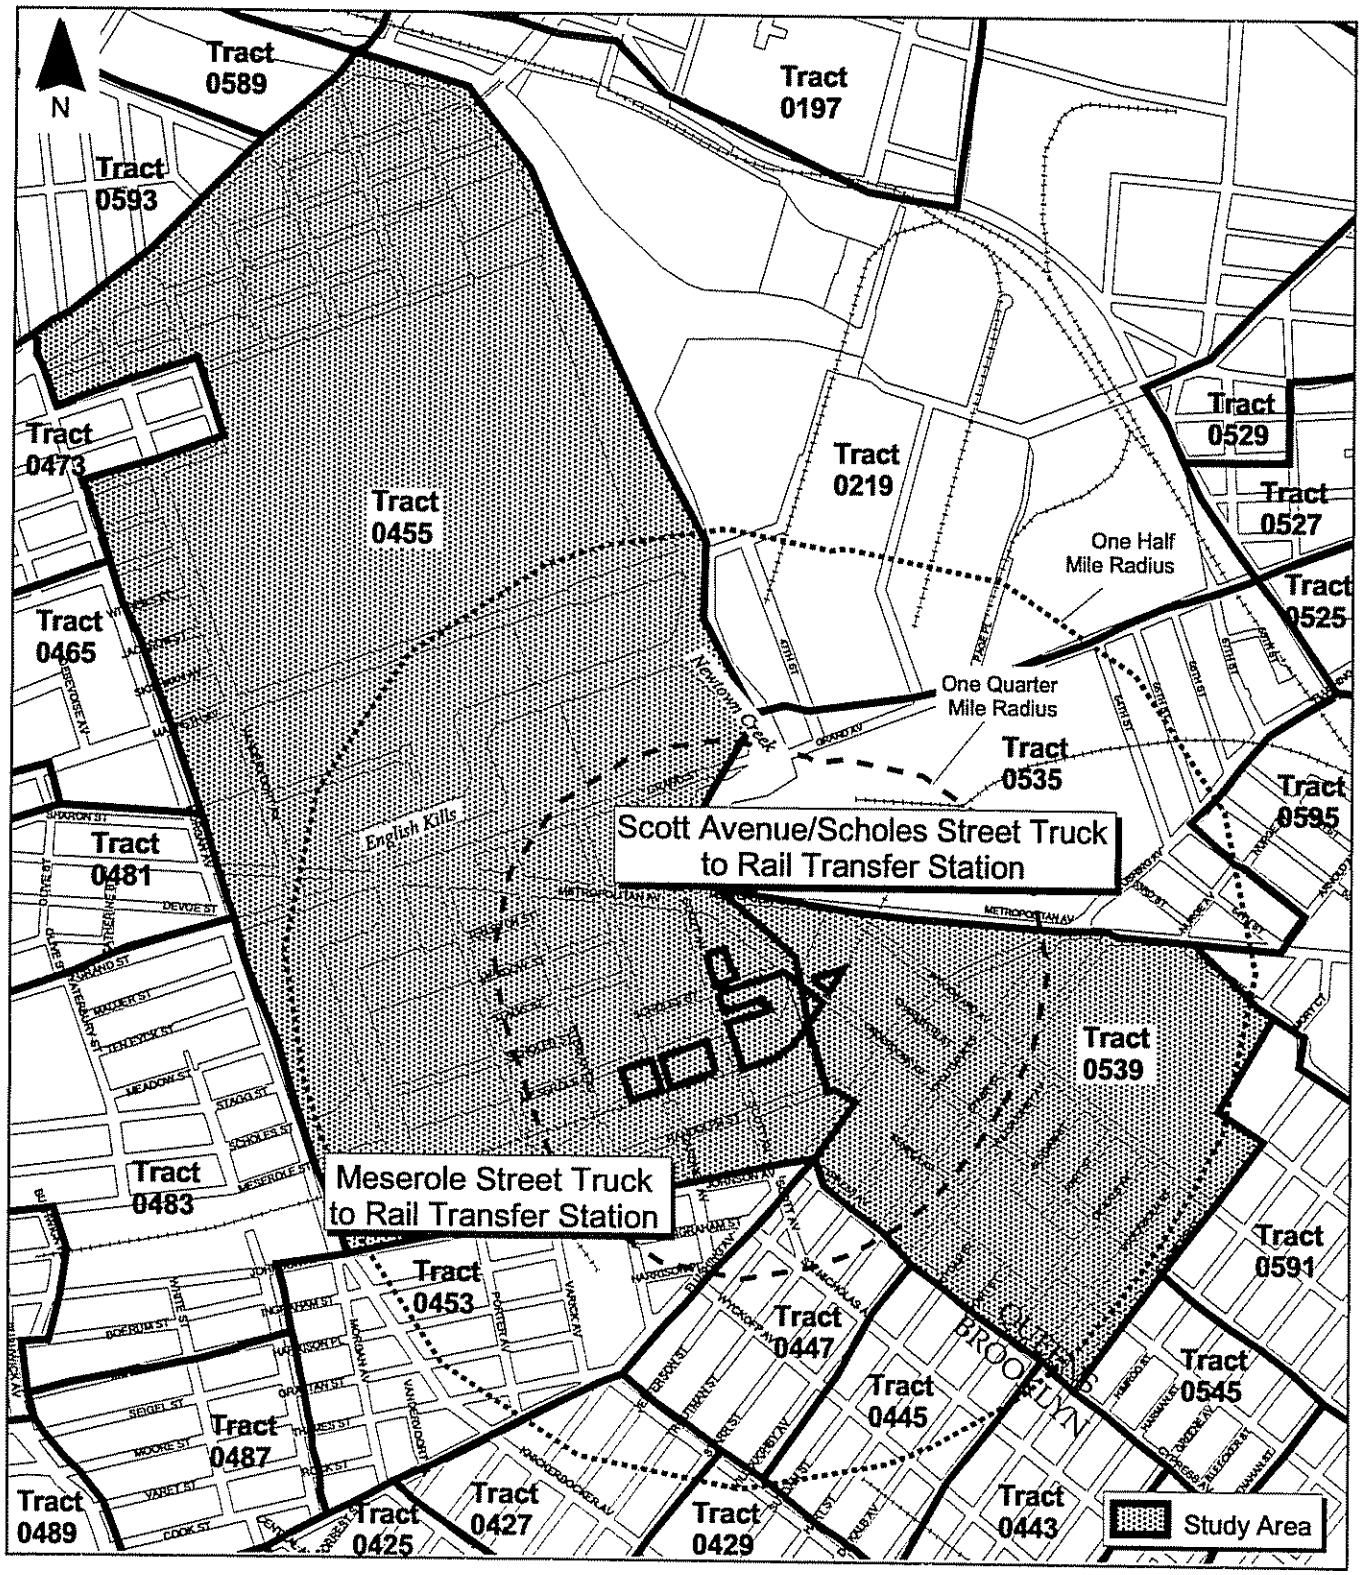
14.2.3.1 Consistency with Public Plans and Policies

The Scott Avenue/Scholes Street Truck to Rail TS would be consistent with the stated objectives of the pertinent plans and policies affecting the site and environs.

14.3 Socioeconomic Conditions

14.3.1 Existing Conditions

14.3.1.1 Definition of the Study Areas



Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) This large tract surrounds the English Kills and the area west of Newtown Creek. It encompasses predominantly industrial areas on or around the site along the northern border of Brooklyn. For comparison purposes, census data were also gathered at the borough and City levels. (See Figure 14.3-1.)

Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

14.3.1.2 Demographic Characteristics

14.3.1.2.1 Population

In 2000, the study area population was 4,095 persons, which was an approximate 17% decrease from 1990 (Table 14.3-1). The age-sex distribution of the study area population was similar to the distribution of population in the borough and the City, with slightly more females than males in each area.

Site delineations and study area boundaries are approximate

Table 14.3-1
1990-2000 Population

Year	Study Area	Brooklyn	City
2000	4,095	2,465,326	8,008,278
1990	4,960	2,300,664	7,322,564
Percent Change	-17.4%	+7.2%	+9.4%

Source: U.S. Census 1990, 2000

The study area had a greater percentage of children and teens than either the borough or the City in 2000. About 54% of the study area population was under the age of 20, as compared to Brooklyn (30%) and the City (27%).

14.3.1.2.2 Racial and Ethnic Characteristics

The 2000 study area population had a smaller proportion of people (12%) of Hispanic origin (all races) than did Brooklyn (20%) or the City (27%). Of the 88% of non-Hispanic origin, 4% were Black and 70% were White. In Brooklyn and the City, Blacks represented approximately 43% and 33% of the non-Hispanic populations, respectively, while Whites represented 43% and 48%, respectively. Within the study area, Asian or Pacific Islanders represented 0% of the non-Hispanic population, while representing 9% and 13% in the borough and City, respectively.

14.3.1.2.3 Families and Households

There were 807 families in the study area in 2000. A somewhat larger percentage of these families had children under the age of 18 (58%) than families in Brooklyn or the City. The study area had a higher percentage of married-couple families (76%) than Brooklyn or the City and a smaller percentage of families with only a female householder (20%).

There were 1,891 households in the study area in 2000, with an average of 2.14 persons per household, less than Brooklyn and the City, each of which averaged about 2.6 persons per household.

14.3.1.2.4 Employment

The study area had a slightly lower percentage of persons aged 16 and older in the labor force (37% of the population) compared to Brooklyn and the City (an average of about 57% of the population). Private wage and salary workers, followed by government workers, were the largest classes of worker in all three areas.

14.3.1.2.5 Housing

As of 2000, there were 957 housing units with a 0% vacancy rate. Approximately 87% of housing units were renter-occupied, a higher percentage than Brooklyn or the City. Both the median rent in the study area ($530) and the median value of housing units ($30,000) were greater than in the larger areas.

14.3.1.2.6 Education

The percentage of residents enrolled in school in the study area in 2000 (4%) was lower than for the borough and the City. The study area also had similar levels of educational attainment as the borough and the City. In the study area, about 25% of people aged 25 and older had only a high school diploma and about 4% had a college degree.

14.3.1.2.7 Income and Poverty

In 2000, both median household income ($16,917) and median family income ($20,847) in the study area exceeded the levels of the borough and the City. About 25% of households and 31% of families had incomes greater than $34,999, a smaller proportion than in either the larger areas. Moreover, more households and families made less than $10,000 annually than in the borough and the City.

No families with related children under 18 years old were living below the poverty level in the study area in 2000. However, families with children under 18 years old living below the poverty level within Brooklyn and the City were about 22% and 18%, respectively.

Within the study area, 990 persons were under the age of 18 and 146 were 65 years and older.

14.3.1.3 Economic Conditions

Current forecasts indicate that about 68,787 employees worked in Brooklyn CD 1 in 2005, which was about 9.4% of the borough's total employment.[1]

14.3.2 Future No-Build Conditions

14.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Brooklyn CD 1 will remain about the same as current conditions.[2]

14.3.2.2 Economic Conditions

Regional projections indicate that employment in Brooklyn CD 1 will remain about 9.4% of the borough total.[3]

14.3.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

The Scott Avenue/Scholes Street Truck to Rail TS represents the continuation of waste transfer operations on the site. It would be compatible with its industrial surroundings and not be expected to have a significant adverse impact on socioeconomic conditions within the study area.

---

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.
[2] Ibid.
[3] Ibid.

14.3.3.1 Residential Impacts

Because the site would be far removed from the nearest residential concentrations (approximately ½-mile to the east and south of the site), it is not expected to significantly affect residential populations in the general area. Analyses of traffic, air quality and noise indicate that there would be no significant project-related impacts at these locations (see Sections 14.14, 14.15 and 14.17). Therefore, the Scott Avenue/Scholes Street Truck to Rail TS is not expected to result in indirect displacement of residents.

14.3.3.2 Direct Business and Institutional Impacts

No direct displacement of businesses or institutions would occur as a result of the Scott Avenue/Scholes Street Truck to Rail TS.

14.3.3.3 Indirect Business and Institutional Impacts

The site would continue to operate as a waste transfer facility under Future No-Build Conditions, and so the Scott Avenue/Scholes Street Truck to Rail TS would be compatible with its industrial surroundings. The adjacent industrial uses are not expected to experience significant adverse effects related to air quality or odor as a result of the operations of the transfer facility. While noise levels will increase on the site, they are not expected to affect the surrounding industrial operations of businesses in the study area.

Increased truck volumes on designated truck routes in the area resulting from the Scott Avenue/Scholes Street Truck to Rail TS would not be expected to result in indirect displacement of existing businesses or institutional uses, as these routes are already heavily used by trucks (some serving the existing operations) and have an industrial character.

14.3.3.4 Employment Impacts

The Scott Avenue/Scholes Street Truck to Rail TS would be expected to generate approximately 40 new jobs associated with its new operation and maintenance (crane operators, mechanics, supervisors) and transportation operations (drivers, dispatchers). In addition to direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

14.4 Community Facilities and Services

14.4.1 Existing Conditions

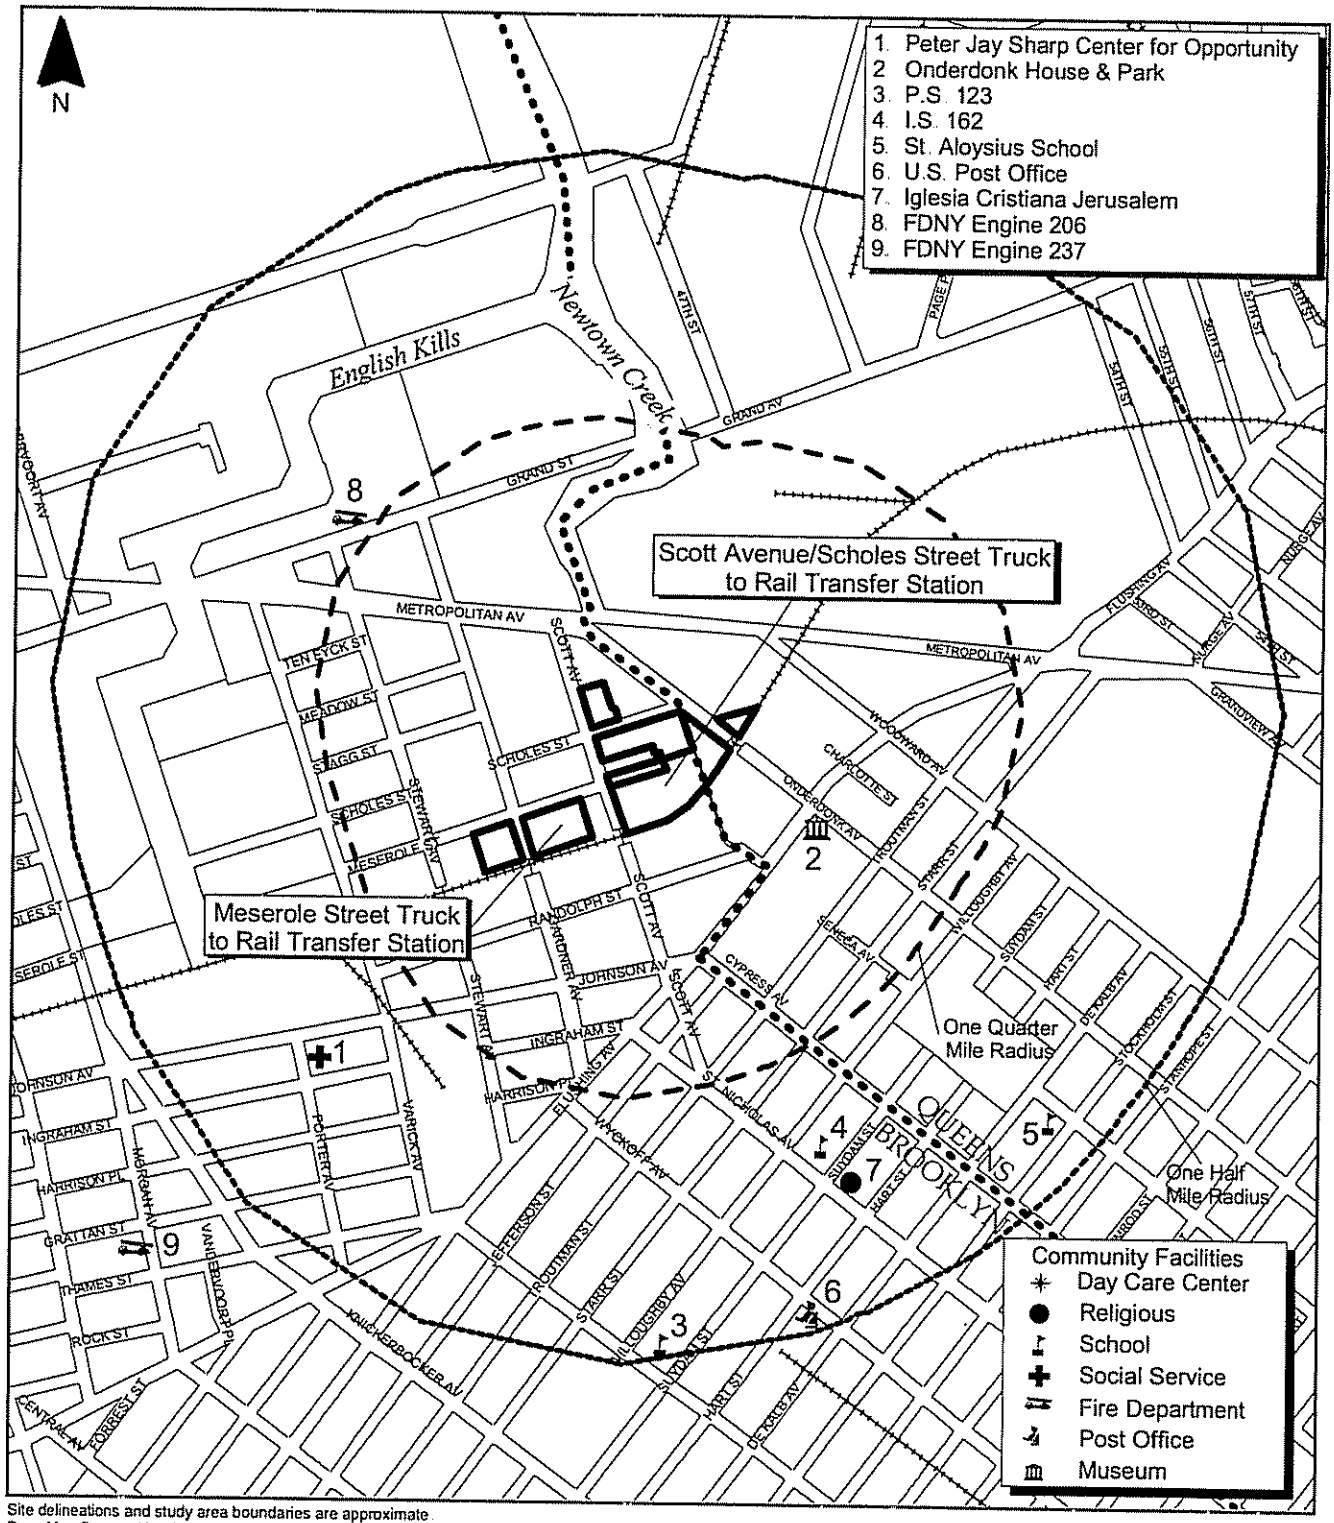
14.4.1.1 Definition of the Study Area

The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼-mile and ½-mile of the site.

14.4.1.2 Summary of Community Facilities and Services

There is one community facility within the primary study area: the Onderdonk House and Park (a local historical museum). Nine others are located within the secondary study area. The community facilities are listed below in Table 14.4-1 and shown on Figure 14.4-1.

14.4.2 Future No-Build Conditions



There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

14.4.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

The Scott Avenue/Scholes Street Truck to Rail TS would create no significant new demand on services or community facilities, and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the new facility (see Appendix A).

14.5 Open Space

14.5.1 Existing Conditions

14.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

14.5.1.2 Summary of Open Space in the Study Area

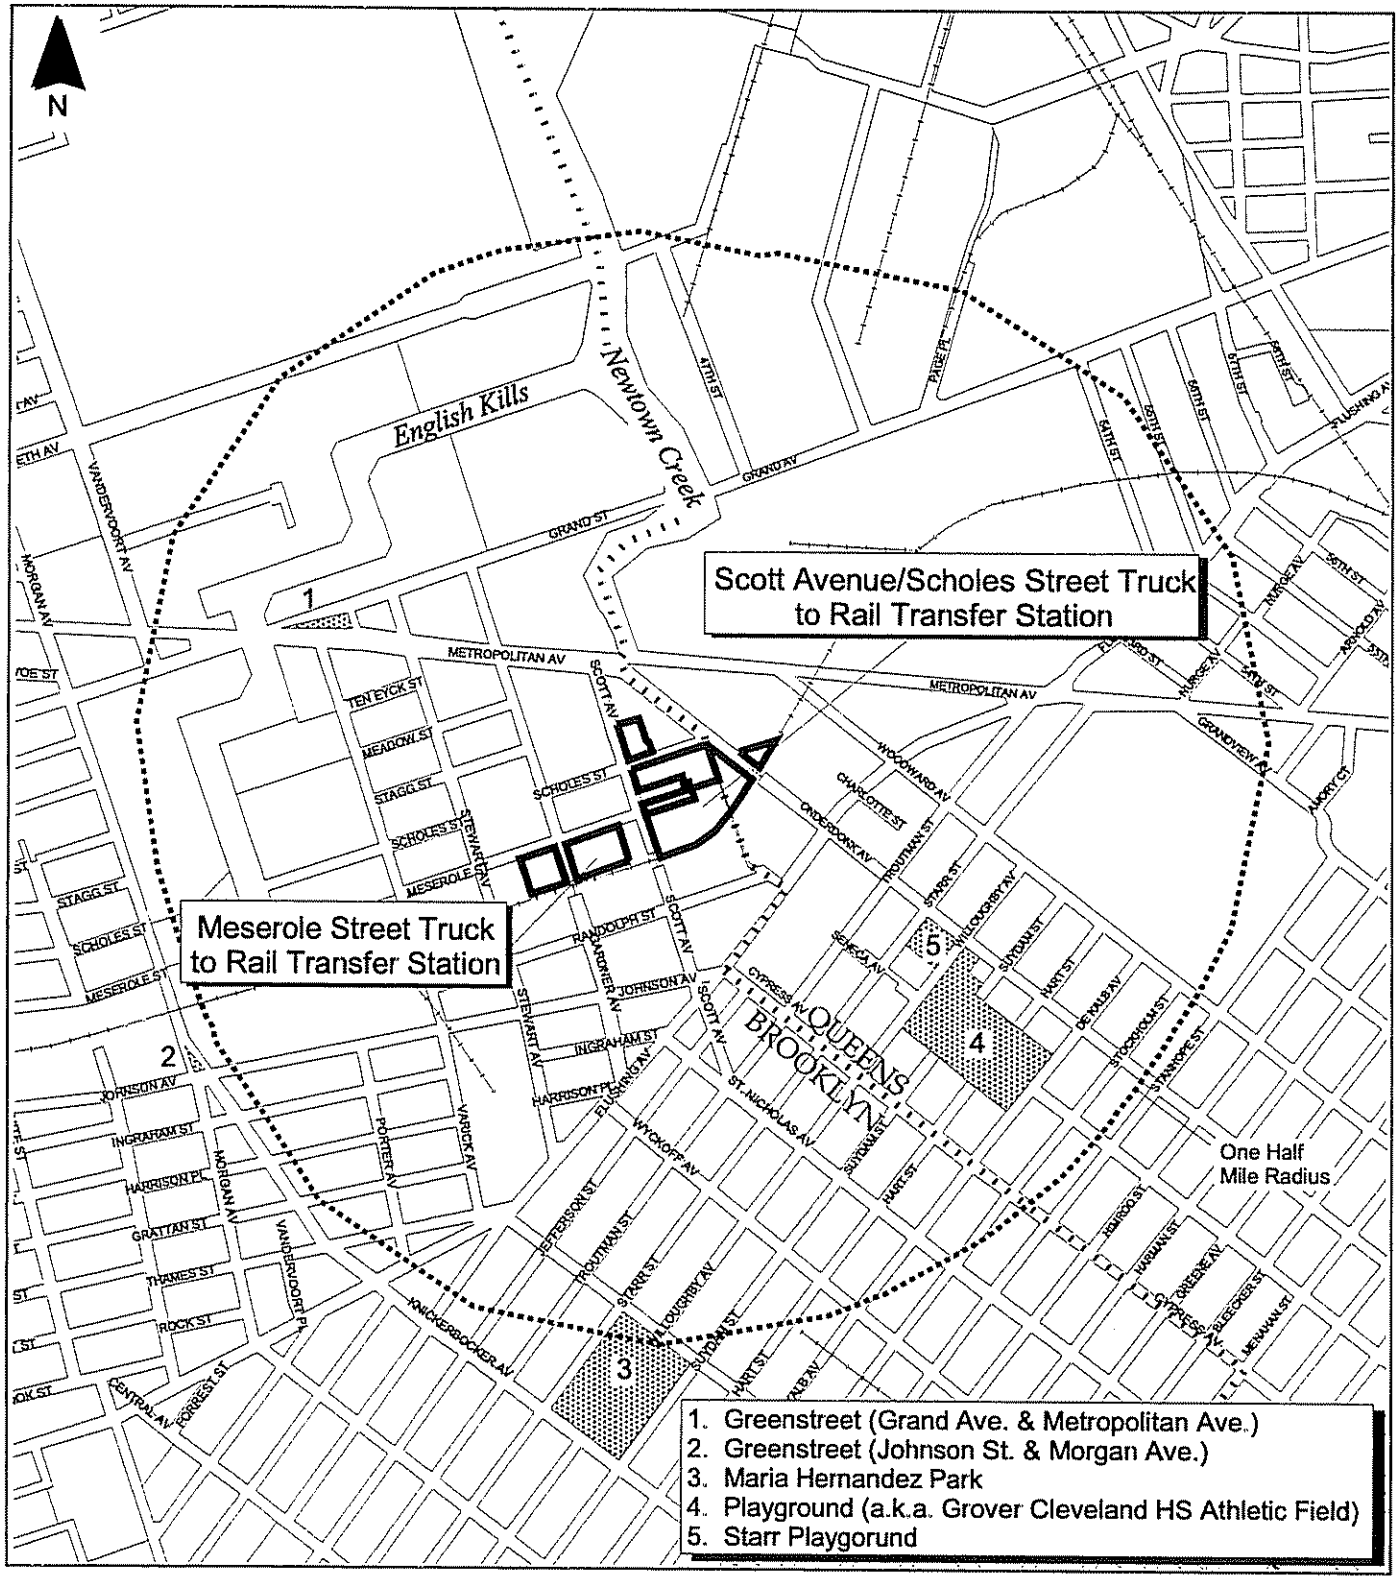
There are five public parks and open spaces within or just beyond the study area. They are listed in Table 14.5-1 and shown on Figure 14.5-1.

The study area's major recreational facility, Maria Hernandez Park, is located in Bushwick.

Maria Hernandez Park (formerly Bushwick Park) is a large City park – nearly seven acres – located ¼-mile south of the site. This community park recently underwent significant reconstruction to provide additional courts, game tables, paths, benches and other infrastructural improvements, as well as public performance space, ornamental gates, etc.

Though not NYCDPR property or jurisdiction, the five-acre Grover Cleveland High School Athletic Field was also recently reconstructed to provide passive and active recreational space for the neighborhood, including new play equipment for young children.

Table 14.5-1
Public Parks and Open Spaces



Name	Address	Acreage
Greenstreet	Grand Avenue and Metropolitan Avenue	--
Greenstreet	Johnson Street and Morgan Street	--
Maria Hernandez Park (formerly Bushwick Park)	Bounded by Knickerbocker Avenue, Starr Street, Irving Avenue and Suydam Street	6.87
Playground (a.k.a. Grover Cleveland High School Athletic Field)	210 Onderdonk Avenue	5.1
Starr Playground	Bounded by Starr Street, Onderdonk Avenue, Willoughby Avenue and Seneca Street	0.9

14.5.2 Future Baseline Conditions

NYCDPR has no new development plans or notable development projects associated with open spaces in the study area. Therefore, Future No-Build conditions are anticipated to resemble Existing conditions.

14.5.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

The facility would not directly displace or significantly change demands on nearby parks. Therefore, no impacts to the public open spaces would result from the Scott Avenue/Scholes Street Truck to Rail TS.

Site delineations and study area boundaries are approximate.

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

14.6 Cultural Resources

14.6.1 Existing Conditions

14.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site, and includes portions of four historic neighborhoods, all clustered along Newton Creek: East Williamsburg and Bushwick in Brooklyn, and Maspeth and Ridgewood in Queens.

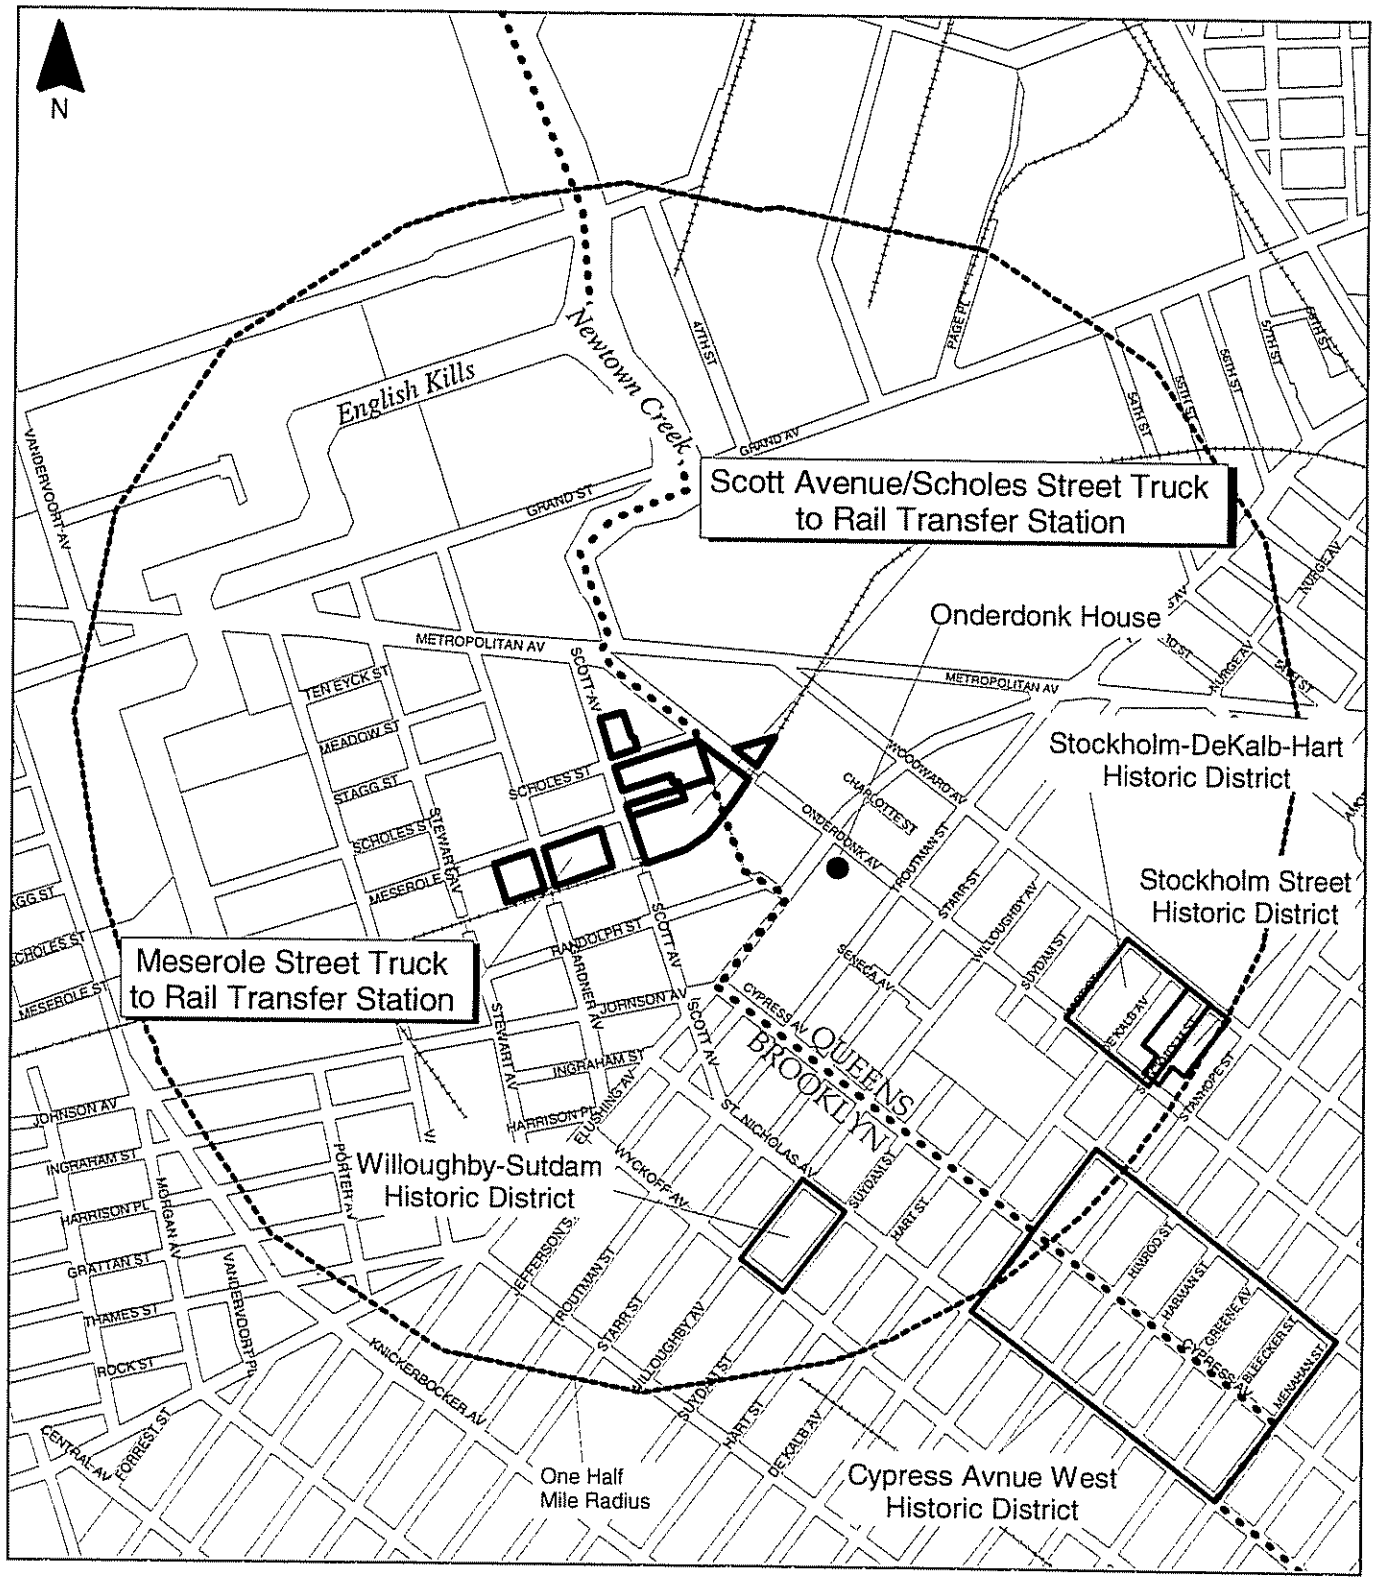
14.6.1.2 Development History of the Area

East Williamsburg in Brooklyn was established as an independent village in 1664 and remained a small farming community until the opening of the Erie Canal in 1825. Williamsburg became an independent city in 1827 and joined the city of Brooklyn in 1854. During the Civil War, The Monitor, the world's first ironclad warship, was built at the Brooklyn Navy Yard in Williamsburg. It remains an industrial neighborhood along the waterfront with an expanding residential population further inland.

Bushwick in the southern portion of the study area was one of six original towns in Brooklyn during Dutch rule in the 17th century. It was an established farming community well into the 19th century. With a large influx of German immigrants in the mid 1800s, many breweries were established; between 1850 and 1880 there were at least 11 breweries located in the neighborhood. Bushwick became part of Brooklyn, along with Williamsburg, in 1854. Housing development and associated residential population surged after the opening of the elevated railroad to Manhattan in 1888. The area's demographics changed over the decades with the improved access and available housing supply. As with many other neighborhoods in the outer boroughs, Bushwick declined in the 1960s and 1970s, and has recently experienced some revitalization of its housing stock.

The Ridgewood neighborhood of Queens was originally developed as part of Newtown, the first of Queens' three original towns, established in 1642. Following the protracted economic depression of the mid-1870s, Ridgewood boomed as a residential community after the Brooklyn City Railroad built its car barns there in 1881. The coming of the Myrtle Avenue Elevated in 1888 furthered this process, attracting great numbers of people from other parts of the City.

Maspeth is a large neighborhood in west central Queens, named for the Mespat Indians who lived there, near the headwaters of Newtown Creek. Though it was initially settled by Europeans in 1642, it remained sparsely developed until the mid-19th century. Heavy industrial uses lined Newtown Creek (in the study area) and that section of Maspeth remains industrial, though there are many vacant sites where fertilizer plants, lumber yards and linoleum plants once stood.



14.6.1.3 Cultural Resources on the Site

According to SHPO and LPC, there are no historic structures or areas of archaeological importance on the site.[22]

14.6.1.4 Historic Resources within the Study Area

Within or just beyond the study area, there are three early-20th-century historic districts and one individual property that are listed on the S/NR. The property and a large portion of one of the districts are also designated by the LPC. (See Figure 14.6-1.)

The Vander Ende-Onderdonk House (a.k.a., The Adrian and Anne Wyckoff Onderdonk House), located nearly ¼-mile east of the site, is a City landmark and is listed on the S/NR. It is the oldest Dutch-American fieldstone house in the City and houses the Greater Ridgewood Historical Society. The stone part of the house was built around 1709 and parts of the older frame date as far back as 1655. It served as a locus of 17th- and 18th-century Dutch and Huguenot settlement, and played a role in the boundary settlement between Kings and Queens Counties.

Site delineations and study area boundaries are approximate

Figure 14.6-1 Cultural Resources
Scott Avenue/Scholes Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The three historic districts within (or just beyond) the study area are all intact groupings of late-19th-century/early-20th-century working class rowhouse and tenement housing. They are all in the bisected neighborhood of Ridgewood, which spans the Queens and Brooklyn border.

The Willoughby-Suydam Historic District covers 1½ blocks composed of 50 three-story brick tenements built between 1904 and 1906. Located more than ¼-mile southeast of the site, the district reflects the earliest phase of working class tenement housing constructed in Ridgewood, distinct from the rest of the Brooklyn Ridgewood community, which was developed with large industrial buildings at the time of construction. The district is listed on the S/NR.

The Stockholm-DeKalb-Hart Historic District covers 2½ blocks at the edge of the study area, east of the site. The two-story brick structures, designed in Romanesque and Renaissance Revival styles, are "an intact and cohesive neighborhood containing distinctive examples of working-class row houses constructed during Ridgewood's major period of development," between 1905 and 1921.[4] (The central portion of this district is also designated by LPC as the Stockholm Street Historic District.)

Located just beyond the study area boundary, further southeast of the site, the Cypress Avenue West Historic District is a 16-block district that stretches between Queens and Brooklyn. It serves as "an intact example of low-scale, working-class housing built at the turn of the twentieth century by German immigrants."[5] This district also contains two-story Romanesque and Renaissance Revival brick houses and other public buildings that were built between 1888 and 1906.

[4] The New York State/National Register, Number 92NR00293, page 4.
[5] The New York State/National Register, Number 90NR01600, page 4.

14.6.2 Future No-Build Conditions

There are no additional elements of potential architectural or archaeological significance slated for review; therefore, anticipated Future No-Build Ceonditions are assumed to be the same as Existing eConditions.

14.6.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

The SHPO and the LPC have determined that there are no elements of architectural or archaeological significance within the site.

14.7 Urban Design, Visual Resources, and Shadows

14.7.1 Existing Conditions

14.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (see Figure 14.8-1). The site has been developed in a manner consistent with urban design of the adjacent properties and visual quality of the overall study area. It is a non-sensitive industrial area, in terms of urban design and visual quality assessment. There are no sensitive-view corridors, publicly accessible open areas or points of waterfront access – areas that would likely experience visual quality impacts from the proposed transfer facility development.

14.7.1.2 Description of the Site

The existing transfer station comprises most of the on-site development. There is no formal landscaping on or adjacent to the site, but the perimeter walls are well maintained and free of graffiti. The interior of the site is generally not visible from the street, and so the site is recognized primarily by blank walls and screening fences. As such, it makes no notable contribution to the streetscape or urban design and visual quality of the general area.

14.7.1.3 Urban Design and Visual Resources of the Study Area

There are no sensitive-view corridors or important visual resources within the study area. The site is visually compatible with its industrial surroundings, which include several other waste transfer stations, recycling facilities and truck parking lots. Most industrial buildings in the area are two or three stories tall, with truck bays, and many with accompanying off-street parking. There is also on-street parking throughout the study area, but there is little daytime pedestrian activity. Vacant lots are adjacent to many of the buildings, though they tend to be maintained, some planted in grass. Although there is no formal and consistent landscaping for the public area, there are small strips of lawn along many of the area sidewalks, and there are mature trees throughout the study area. The area is generally tidy, and the low-scale buildings, numerous parking lots, and vacant lots give the area an open quality. See Figures 14.7-1 and 14.7-2.

Figure 14.7-1 : Looking north from facility entrance.

This page intentionally left blank.

14.7.2 Future No-Build Conditions

There are no plans for development that would change the general street grid and development pattern throughout the area. Therefore, the urban design and visual resources of the area under Future No-Build Conditions are anticipated to resemble Existing Conditions.

14.7.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

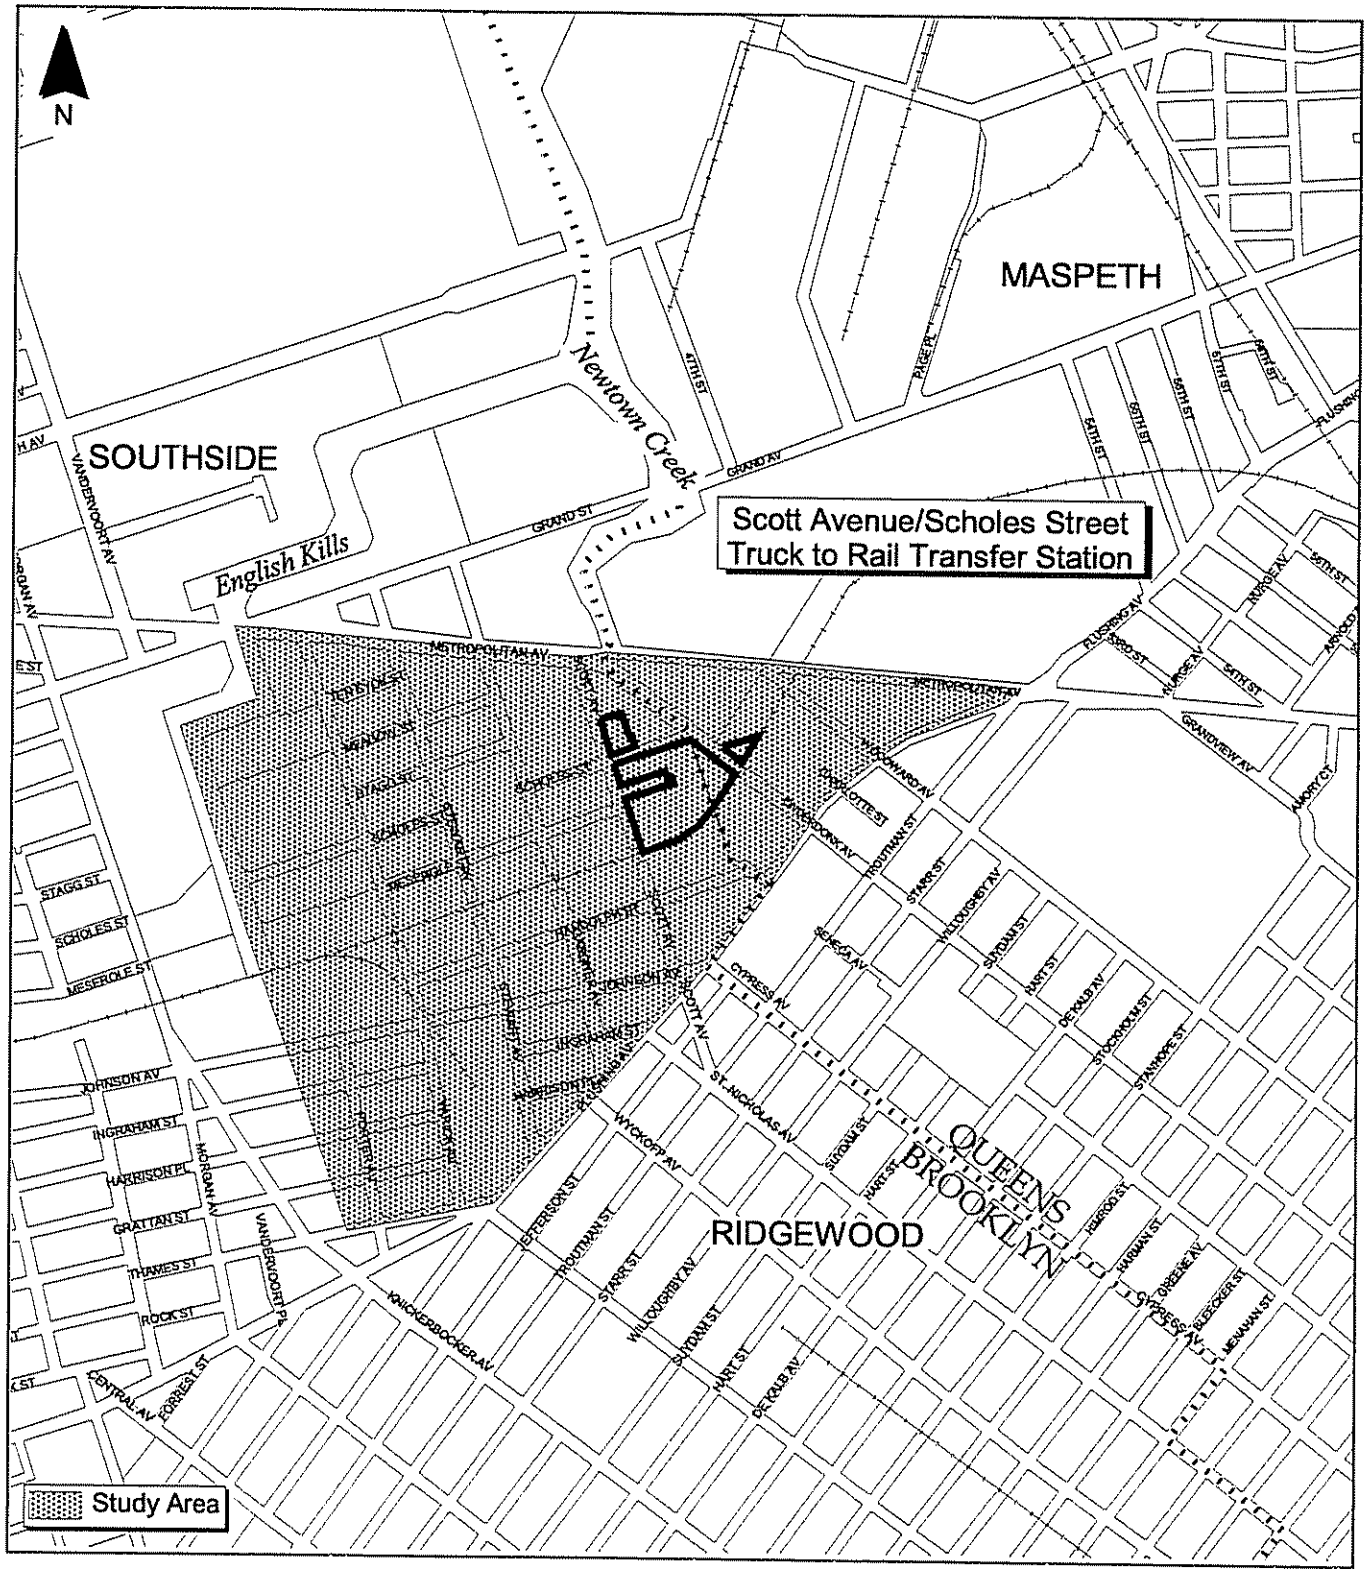
While improvements would be made to the site, the use would generally remain unchanged, and physical changes would be limited to the site. Although existing buildings on site will be demolished to accommodate new site construction, the improvements will likely produce a processing building, outdoor truck parking and container storage similar to the functional structures and open lot operations currently on the site. No significant adverse impacts to the urban design and visual quality of the area are anticipated.

14.8 Neighborhood Character

14.8.1 Existing Conditions

14.8.1.1 Definition of the Study Area

The neighborhood character study area and site is defined by predominantly industrial land use and visual quality. The study area is defined by physical landscape elements that distinctly mark the edge of a specific neighborhood character, visually insulate the site and study area or physically obstruct pedestrian and vehicular access to it from outlying areas.



With these criteria, the study area is bounded by the English Kills to the west, LIRR tracks to the south, Newtown Creek to the east and Metropolitan Avenue to the north (see Figure 14.8-1).

14.8.1.2 Description of Neighborhood Character

The study area is characterized by industrial uses, including several waste transfer and recycling operations. Consistent with a heavily industrial area, there are no sensitive visual resources or unique features, and while there are sidewalks and the area is generally tidy, with a few trees and some grass, there is little pedestrian activity. This is largely the result of there being no commercial or residential uses within the study area, heavy truck traffic through the area and limited pedestrian access into the study area.

14.8.2 Future No-Build Conditions

Future development plans in the vicinity of the site are beyond the study area and would not be expected to alter neighborhood character in their surroundings, particularly as they are industrial developments. The site will continue to operate as a waste transfer station, and Future No-Build Conditions would generally resemble Existing Conditions.

Site delineations are approximate
Base Map Source: New York City Department of City Planning

500 0 500 Feet

Figure 14.8-1 Neighborhood Location
Scott Avenue/Scholes Street
Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

14.8.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

No change to the industrial neighborhood character would be expected because the Scott Avenue/Scholes Street Truck to Rail TS operation would be similar to Future No-Build Conditions. Technical analyses for the new facility predict no unmitigatible impacts associated with traffic, air, odor or noise. Therefore, no impacts to neighborhood character are predicted.

14.9 Natural Resources

14.9.1 Existing Conditions

Existing Conditions include stressed terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise if the Scott Avenue/Scholes Street Truck to Rail TS were developed.

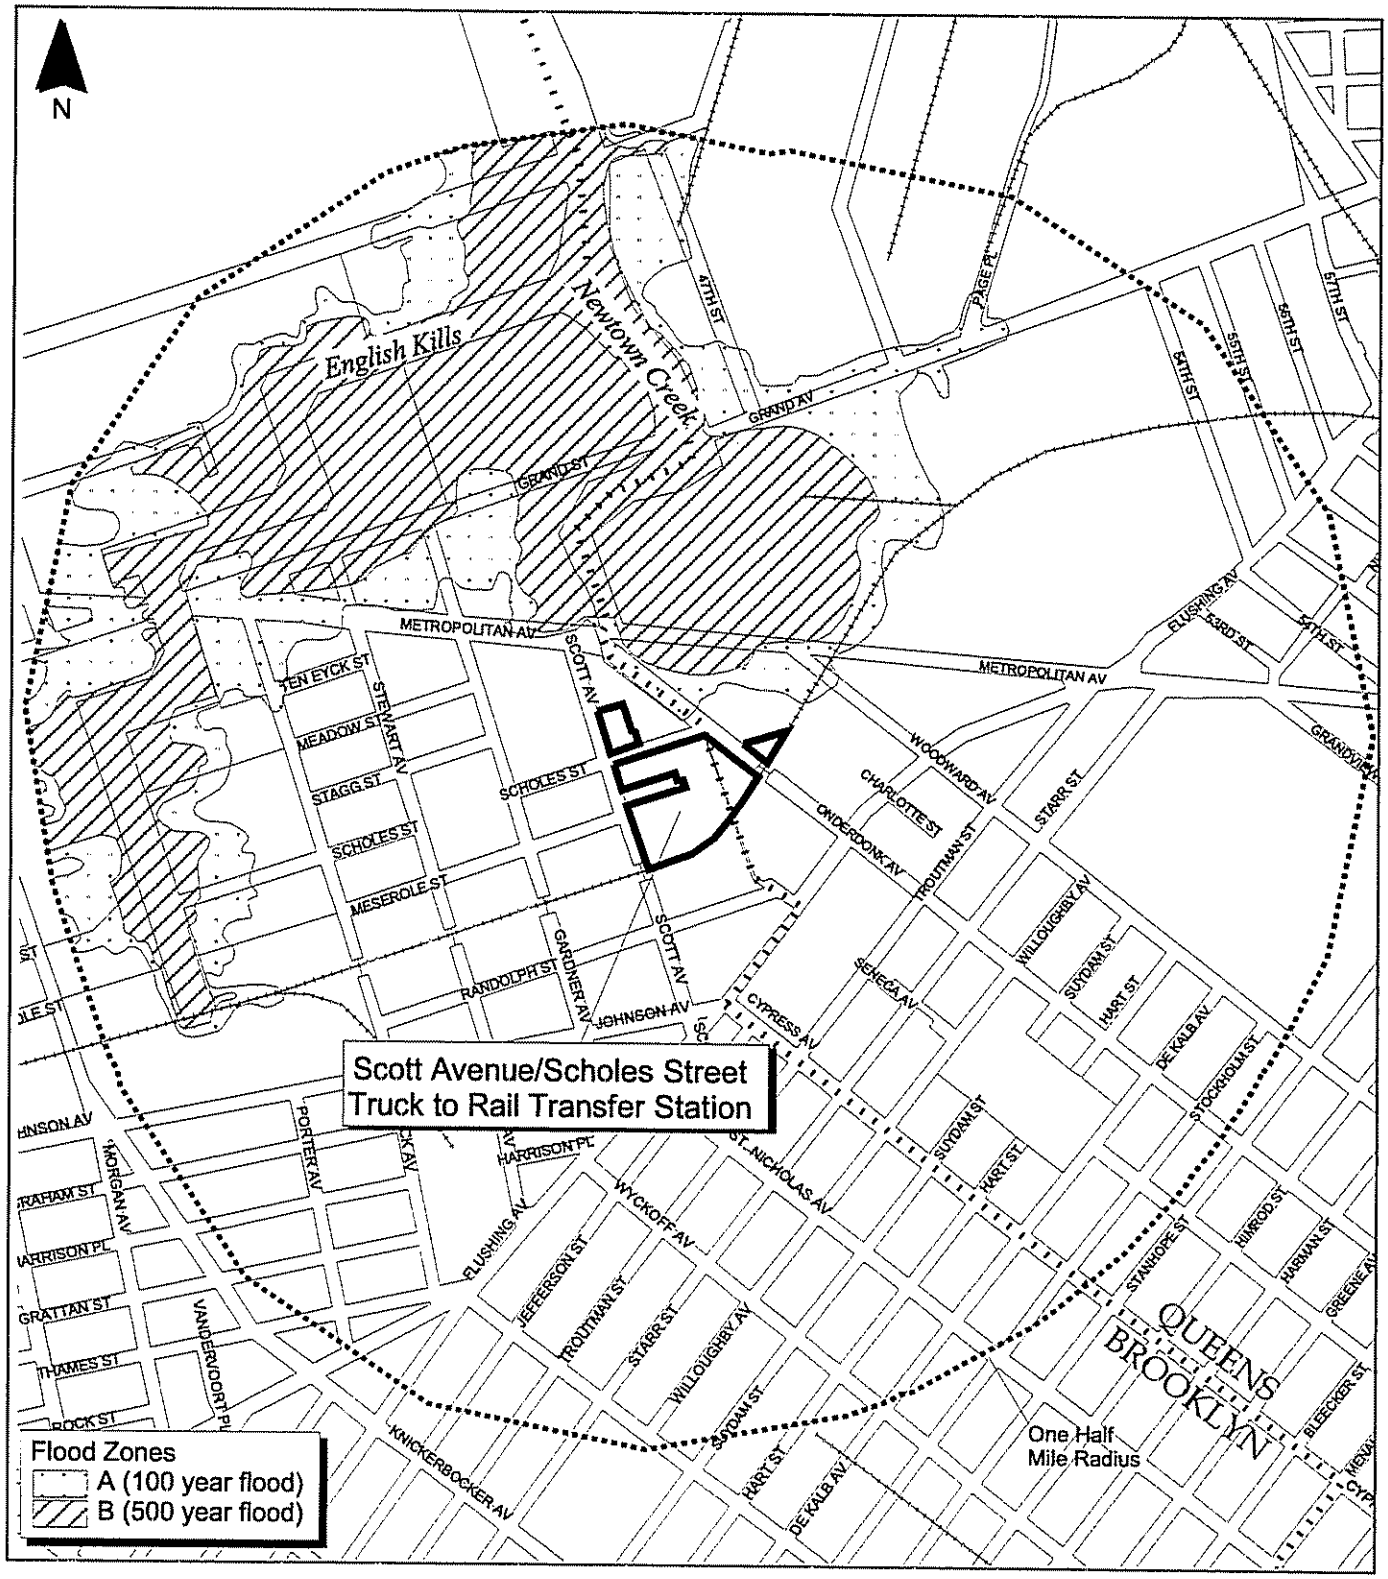
14.9.1.1 Definition of Study Area

The study area includes the site located at 598 Scholes Street in Brooklyn. The 598 Scholes Street site is located on the southeast corner of the intersection of Scholes Street and Scott Avenue, Brooklyn (see Figure 2.2.11-1). BFI Waste Systems of New Jersey, Inc. is presently located on the site and operates as a solid waste and recycling facility. It is proposed that BFI increase its solid waste capacity and add rail export to the facility's waste shipping capabilities at the 598 Scholes Street facility. MSW will be trucked to the site, containerized and exported by rail and truck. The existing LIRR Bushwick Branch, an underutilized freight line located at the south end of the property, will be used for rail transport. Rail transport will locally reduce traffic and emissions.

The existing solid waste operations will continue at the Scholes Street facility; it is also proposed that other operations of facilities held by BFI Waste Systems be transferred to the 598 Scholes Street site. This includes the transfer of the operations of the solid waste facility at 105-115 Thames Street, the C&D debris facility at 594 Scholes Street, and the glass/tire facility at 575 Scholes Street. The Thames Street and 575 Scholes Street facilities will then be closed and the permit for the C&D facility at 594 Scholes Street will be transferred to a third party. The area is zoned M3-1 for heavy manufacturing and M1-1 light industry and is heavily developed. Therefore, the site has very limited terrestrial natural resources. Such resources that do exist are discussed in following sections.

14.9.1.2 Geology

Based on information derived from a review of the Bedrock and Engineering Geologic Maps of New York County by Charles A. Baskerville, 1994, the depth to bedrock is 125 feet below the soil surface.[6] The surface soil on site is paved with concrete and covered with buildings.



14.9.1.3 Floodplains

The proposed Scott Avenue/Scholes Street Truck to Rail TS is located within a zone of minimal flooding (see Figure 14.9-1). No intertidal wetlands exist in the study area. Newtown Creek and English Kills, which are NYSDEC-designated littoral zones, are to the north and west of the study area (see Figure 14.9-2). The end of Newtown Creek lies within a ¼-mile radius of the site and English Kills lies outside of the ¼-mile, but within a ½-mile, radius of the site. The site is located within the City's WRP boundaries and is a designated SMIA.

14.9.1.4 Ecosystems

The site is essentially fully developed with buildings and paved lots, leaving little terrestrial natural resources to be impacted. The transfer station facility was devoid of vegetation; however, there was vegetation documented along the railroad tracks located immediately south of the facility and in cracks of pavement on the property. The species observed were non-native weed species, including: poor man's peppergrass (*Lepidium virginicum*), yellow nutsedge (*Cyperus esculentus*), lady's thumb (*Polygonum persicaria*), common mugwort (*Artemisia vulgaris*), redroot pigweed (*Amaranthus retroflexus*), common sow thistle (*Sonchus oleraceus*), crabgrass (*Digitaria sanguinalis*), green foxtail (*Setaria viridis*), common ragweed (*Ambrosia artemisiifolia*), Japanese knotweed (*Polygonum cuspidatum*), lamb's quarters (*Chenopodium album*), brome (*Bromus* sp.), daisy fleabane (*Erigeron annuus*), tree-of-heaven (*Ailanthus altissima*), black cherry (*Prunus serotina*), black medic (*Medicago lupulina*), horseweed (Conyza canadensis) common evening primrose (*Oenothera biennis*), pokeweed (*Phytolacca*

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

americana), bindweed (*Convolvulus arvensis*), and thistle (*Cirsium* sp.). Any construction along the railroad would impact the above-mentioned vegetation, but none of the species are threatened or endangered and all are invasive weed species.

According to the USF&WS, except for occasional transients, there are no federally-listed or proposed endangered or threatened species, or any "critical habitats" present on the site. According to the NYSDEC, there are no records of rare or state-listed animals or plants, significant natural communities or other significant habitats, on or in the immediate vicinity of the site.

14.9.2 Future No-Build Conditions

If the Scott Avenue/Scholes Street Truck to Rail TS were not developed, the study area would remain as is. The limited terrestrial natural resources will remain and the study area will continue to be an ecologically unproductive and stressed urban area.

14.9.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

14.9.3.1 Geology

The geology of the study area would not be impacted as a result of the building of the Scott Avenue/Scholes Street Truck to Rail TS.

14.9.3.2 Floodplains

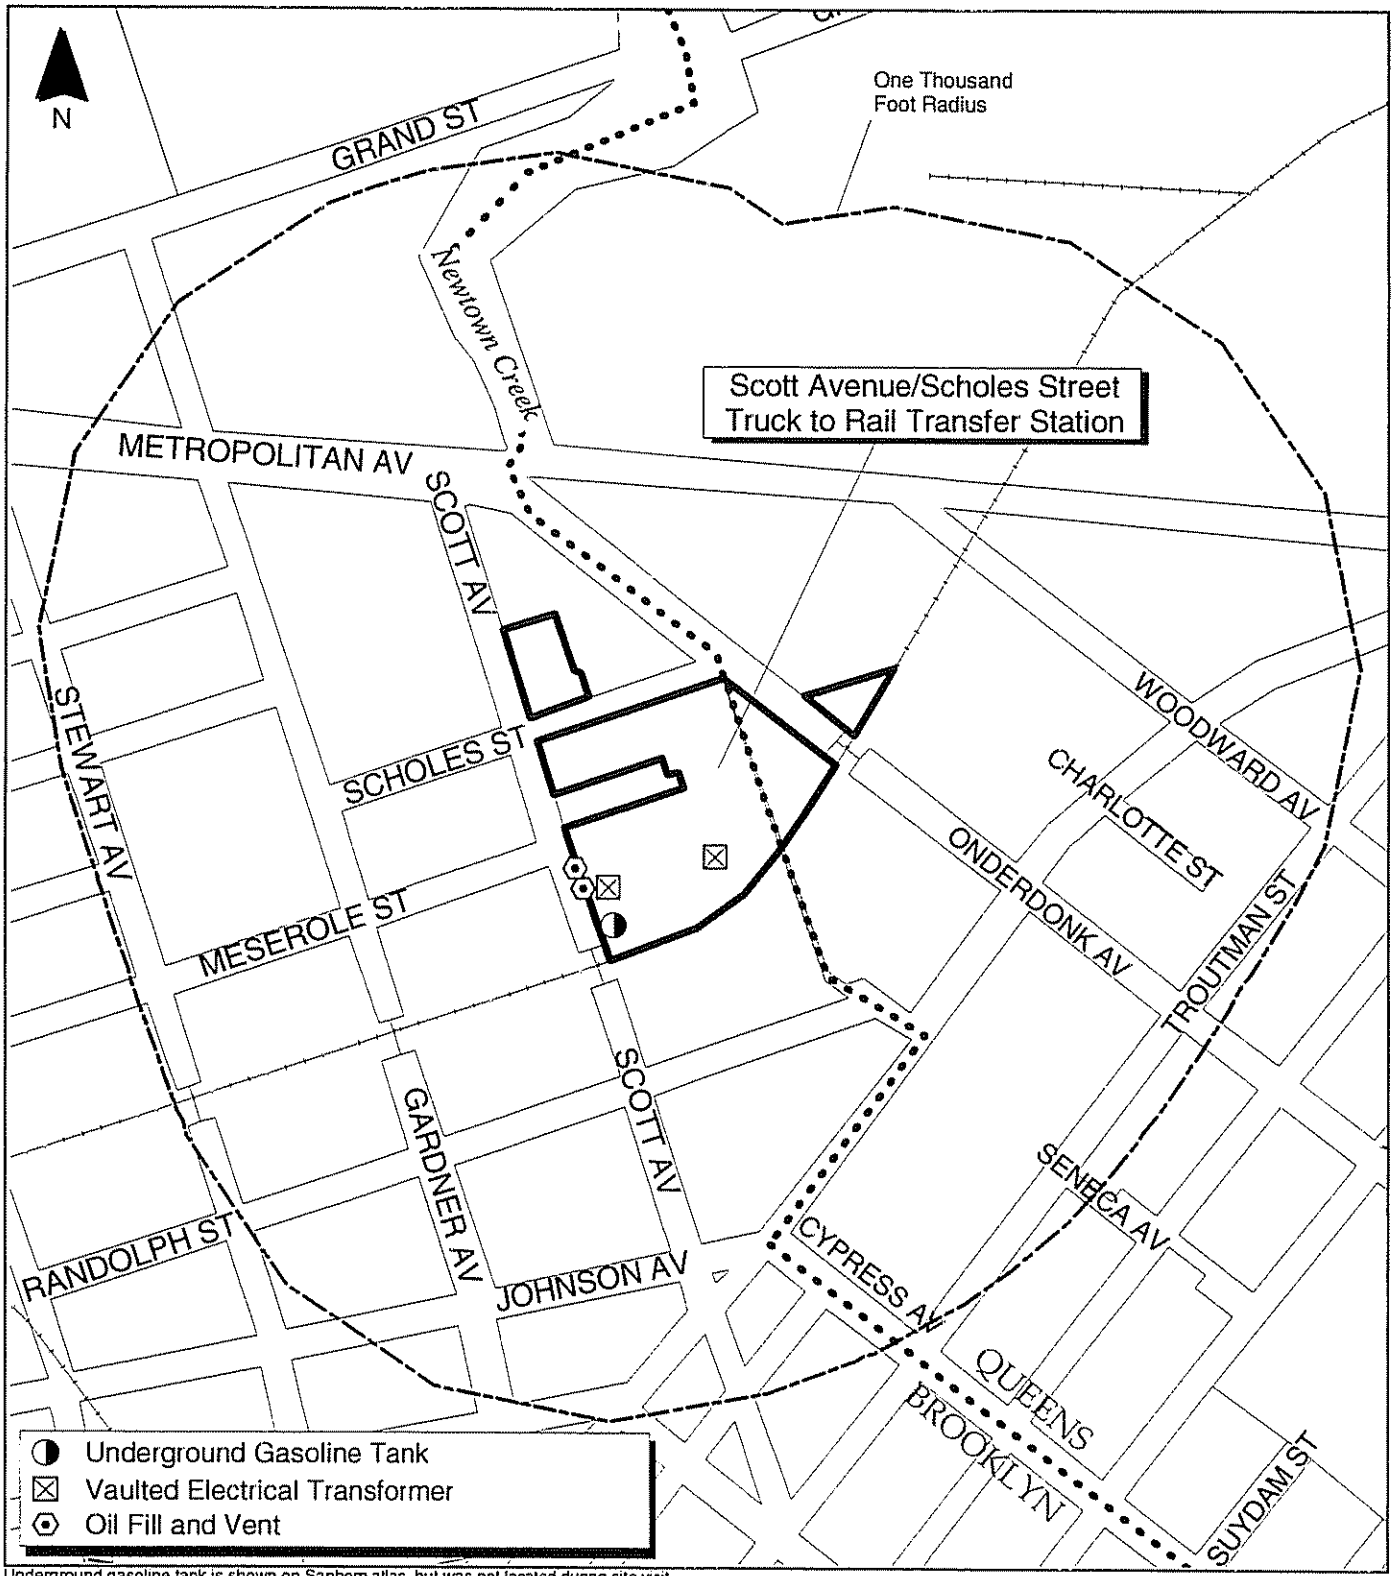
Potential development of the Scott Avenue/Scholes Street Truck to Rail TS would have no effect on the elevation of the site. The potential development does not include any provisions for raising any portions of the site over the present elevation level. The facility would be constructed within the zone of minimal flooding and within the SMIA. The proposed activity, however, complies with New York State's CMP as expressed in the City's approved local WRP.

14.9.3.3 Ecosystems

The Scholes Street facility is covered with buildings and paved lots which have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Vegetation observed on the site was opportunistic weeds and plants, none of which were rare, endangered or particularly important from an ecological perspective. Implementation of the new facility would not have any significant impact on the few areas of vegetation present on the site. The few opportunistic, invasive, weed species on the property are located along the railroad tracks. Any construction or alteration of the property will not impact the vegetative community, as only weeds are present. There may be a loss of the vegetative communities along the railroad tracks with increased usage, but the species present along the tracks are also opportunistic species that do not have a significant community value.

The consolidation of several of BFI Waste Systems of New Jersey, Inc.'s facilities to the 598 Scholes Street facility will positively impact the surrounding community. The use of rail export of waste will decrease truck emissions in the area, improving air quality. This will also help to decrease traffic and noise in the surrounding area.

14.10 Hazardous Materials



14.10.1 Existing Conditions

Existing Conditions associated with the presence or suspected presence of hazardous materials in soil, groundwater, and building components/equipment were assessed within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual, and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527-00). The assessment was performed in July and August of 2004. It included a historic land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps and information contained within City Building Department database records for the study area. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A Freedom of Information Law request was submitted to the NYCDEP to solicit records pertaining to toxic or hazardous materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted in July 2004. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers, and unusual stains and odors.

14.10.1.1 Definition of Study Area

The study area includes the existing site and its neighboring properties within an approximate 1,000-foot radius. (See Figure 14.10-1.) The existing site consists of two separate parcels: (1) a paved fenced-in yard located at 595 Scholes Street/162 Scott Avenue (Block 2966, Lot 1) used for container storage by BFI Waste Systems of New Jersey and a BFI solid waste management/paper recycling facility located at 598-636 Scholes Street and 138 Scott Avenue (Block 2979, Lots 1 and 5); and (2) an administrative office/equipment maintenance and

Underground gasoline tank is shown on Sanborn atlas, but was not located during site visit

shelter/vehicle maintenance building located at 72 Scott Avenue (Block 2990, Lot 1). According to information provided by BFI, the one-story brick building located at 172 Scott Avenue (Block 2966 Lot 4), formerly used by BFI as a garage, had been sold approximately one year ago and is longer owned or used by BFI.

14.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater, and building components/equipment within the study area where the presence or likely presence of hazardous materials exists and implementation of the Scott Avenue/Scholes Street Truck to Rail TS could lead to possible increased exposure of people or the environment to those materials. The areas of concern within the study area identified during the assessment include:

- Past and Present Occupants and Uses – Historical Sanborn atlases and regulatory database records indicated former occupants and uses of the existing site included a steel tube manufacturing facility (i.e., Steel & Tubes Inc. of New York, Brooklyn Steel & Tube Corp./Brooklyn Steel Company, Republic Steel Corporation, and LTV Steel Co., Inc.). Former building occupant, Brooklyn Steel & Tube Corp./Brooklyn Steel Company listed at 72 Scott Avenue, was identified within the following regulatory databases: NYSDEC Chemical Bulk Storage (CBS) Facility, Toxic Release Inventory (TRI) Facility and Air Discharge Facility; and USEPA and NYSDEC RCRA Hazardous Waste Generator. LTV Steel Co. Inc. and Republic Steel were also identified within the NYSDEC TRI Facility and Air Discharge Facility databases, respectively. BFI of New York and JLJ Recycling Contractors Corp., listed at 72 Scott Avenue, were identified within the USEPA and NYSDEC Hazardous Waste Generator database. Any improper releases of chemicals stored or used by these former on-site businesses, especially those occurring on then-unpaved property areas or within paved areas with drains, could have resulted in potential subsurface contamination. It should be noted that exterior portions of the existing site, not covered by on-site buildings and structures, were paved with asphalt and concrete. No visual evidence of stained soil or stressed vegetation was observed on the existing site during the site assessment.

- Underground Storage Tanks (USTs) - Historical Sanborn atlases (i.e., 1933, 1951, 1977, 1981 and 1991) depicted a buried gasoline tank inside the 72 Scott Avenue ground-floor loading dock area fronting Scott Avenue. According to BFI this tank was 550 gallons in size and was used for diesel fuel storage prior to closure circa 1997. City Building Department database records indicated oil burner applications were filed in 1967 for the 138 Scott Avenue building, and in 1968 and 1974 for the 72 Scott Avenue building. It is unknown if the storage tanks associated with the installation of on-site oil-fired heating systems were located above ground and/or

below ground. Review of NYSDEC database records indicated that seven USTs (i.e., 4,000-gallon diesel, 4,000-gallon leaded gasoline, 15,000-gallon No. 6 fuel oil, 15,000-gallon No. 6 fuel oil, 6,000-gallon, 2,000-gallon unleaded gasoline and 550-gallon No. 2 fuel oil) were registered under Facility Registration ID 2-212245 that was issued to BFI at 72 Scott Avenue. This registration expired on September 19, 2001.

According to Facility Registration records on file with the NYSDEC, three of the seven USTs (i.e., 4,000-gallon leaded gasoline and two 15,000-gallon No. 6 fuel oil) were closed sometime prior to April 1991. Two USTs (i.e., 550-gallon No. 2 fuel oil and 2,000-gallon unleaded gasoline) were closed and removed in May 1997. The 6,000-gallon UST was reportedly closed and removed from the ground. However, the date of closure/removal is not listed within NYSDEC database records. The 4,000-gallon diesel tank is listed as "in-service" on this facility registration. No fill ports or vent lines, normally associated with the presence of USTs, were noted within visible and accessible interior and exterior portions of the existing site, with one exception. A fill port and vent line was observed extending through the exterior wall of the 138 Scott Avenue building that is adjacent to Scott Avenue. This fill port and vent line were cut, and not connected to any interior tank that may have been present in the general vicinity. According to BFI, the UST located in this area of the 138 Scott Avenue building was closed circa 1997.

Two spill incidents, associated with the closure/removal of USTs listed at the existing site, were identified within the NYSDEC Spill Log databases (i.e., Spill Nos. 9702085 dated May 18, 1997 and Spill No. 9708693 dated October 24, 1997). Spill No. 9702085 listed at 72 Scott Avenue consisted of the discovery of soil contaminated with gasoline upon removal of an on-site UST. According to NYSDEC database records, the spill was contained within the soil and did not reach groundwater. Contaminated soils were to be excavated and removed. Spill No. 9708693 listed at 72 Scott Avenue consisted of the pressure test failure of a 4,000-gallon UST. Both of these spill incidents are listed as "active" within NYSDEC Spill Log databases, indicating that the spill incidents are either still under remediation or awaiting completion of paperwork for file closure.

- Older Electrical Transformers and Equipment – Possibility of PCBs in older electrical transformers located within secured concrete vaults inside existing on-site buildings (ground-floor equipment maintenance and shelter sections inside 72 Scott Avenue building). It should be noted that there were no obvious indications these transformers and equipment had leaked. However, in case of a fire, potential emissions of PCBs can be released from these transformers.

- Lead-Based Paint – Based on the age of the existing buildings, it is highly likely that interior portions of these buildings contain some lead-based paint, in underlying layers. Painted surfaces were in relatively good condition, with isolated damaged areas noted. Underlying paint in good condition does not represent any risk to current employees or visitors to the existing buildings.

- Asbestos-Containing Materials (ACM) – Based on the age of the existing buildings, it is highly likely that interior and exterior portions of these buildings contain ACM. Suspected ACM noted within, and affixed to these buildings, included thermal pipe insulation, vinyl floor tiles, corrugated cement panels (i.e., transite panels) and roofing materials. Isolated damaged areas of pipe insulation and vinyl floors within the existing buildings were noted during site reconnaissance.

- Past and Present Adjacent and Neighboring Uses – Review of historical Sanborn atlases and regulatory agency databases, as well as the pedestrian reconnaissance of neighboring properties, indicated the study area is located within a neighborhood that has historically been developed for and occupied by a variety of manufacturing and industrial uses. Manufacturing and industrial operations typically involve the storage and use of toxic or hazardous materials, and generation of toxic or hazardous wastes. Based upon this information, it is considered likely that some level of groundwater degradation exists within the study area.

14.10.2 Future No-Build Conditions

Under Future No-Build Conditions, the study area would remain as is. Contamination may exist within the study area from previous historic uses, suspected USTs, and/or from documented and undocumented hazardous material releases at adjacent or neighboring properties. In addition, lead-based paint, suspected ACMs and suspected PCB-containing electrical transformers would remain at the existing buildings in their present conditions.

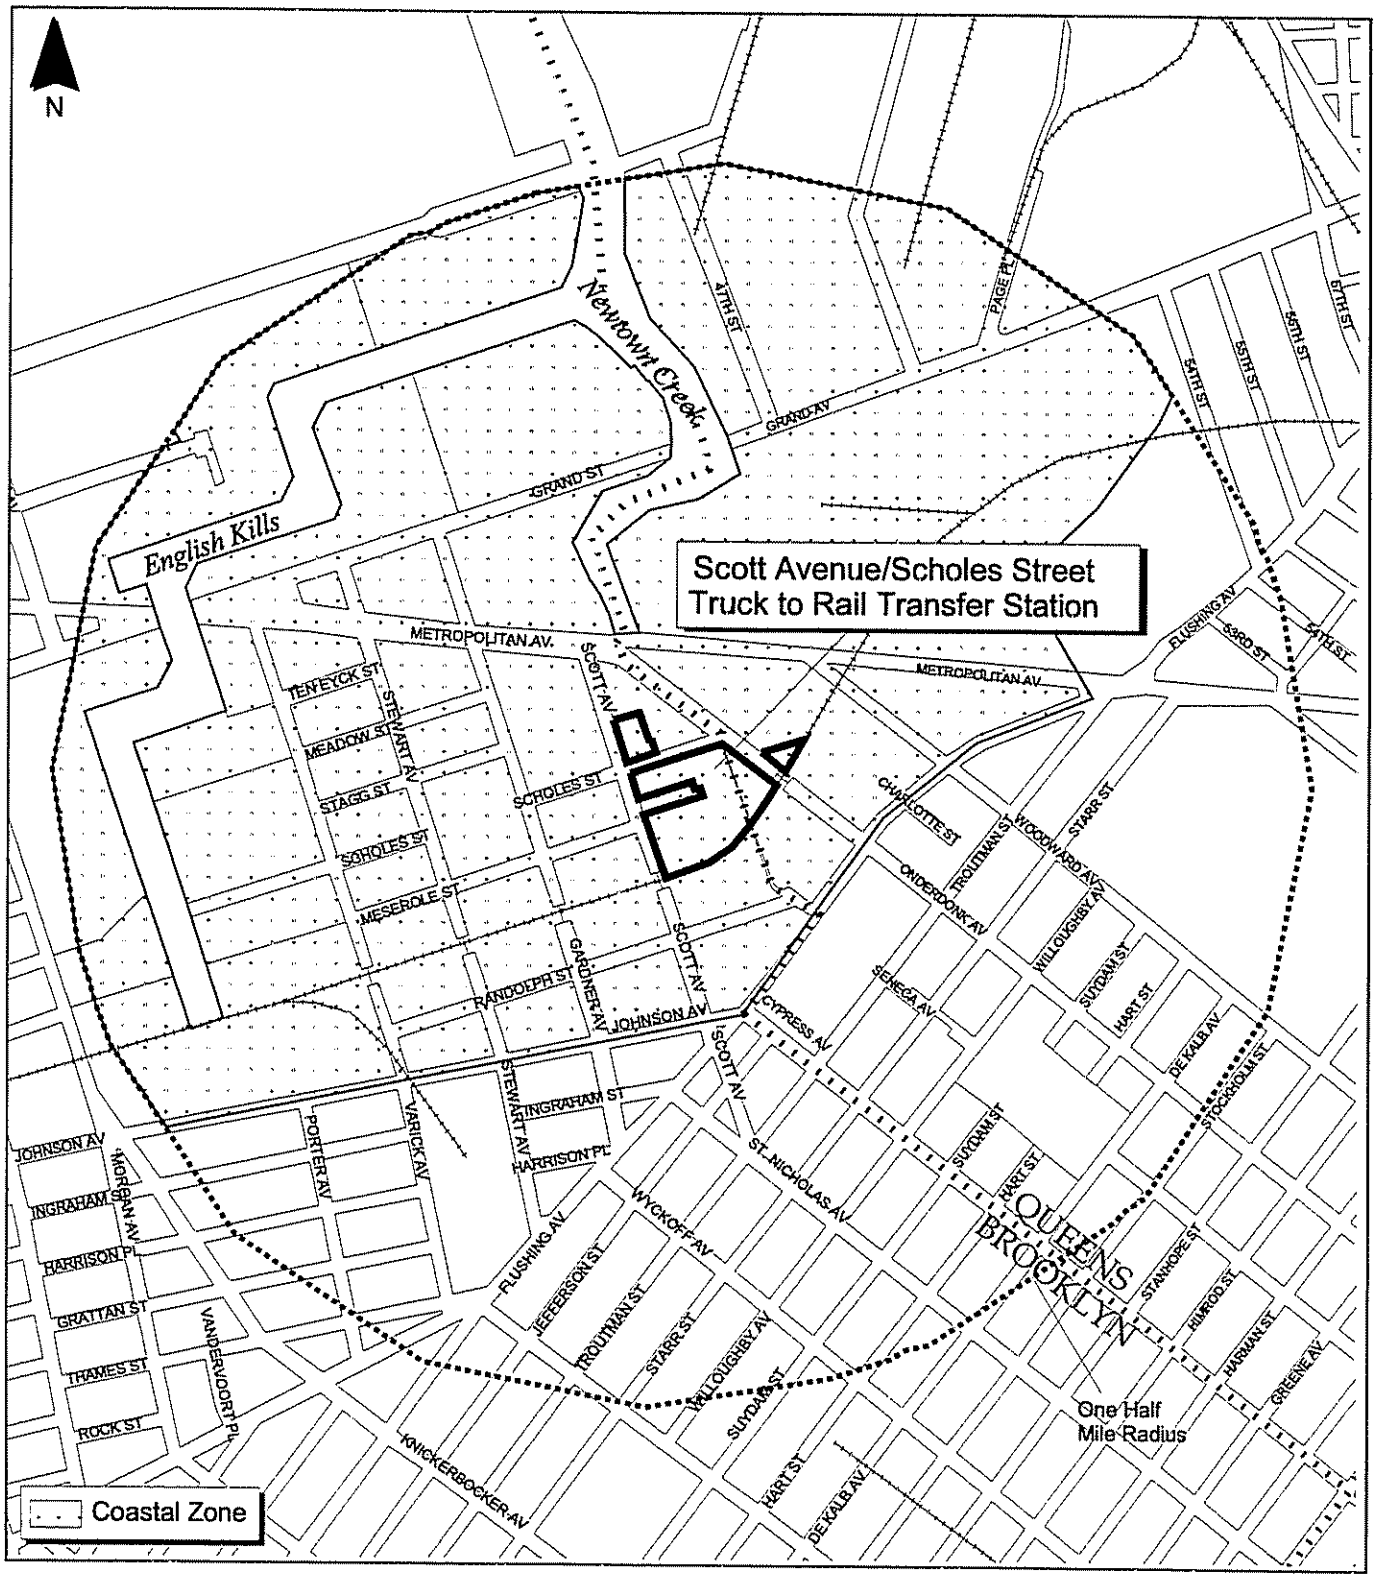
14.10.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

Based on the land use history of the study area and possible presence of on-site USTs, contamination may exist within the study area where the construction of the Scott Avenue/Scholes Street Truck to Rail TS would occur. If the Scott Avenue/Scholes Street Truck to Rail TS project was to be implemented, a soil and groundwater Phase II sampling protocol would be developed for review and approval by NYCDEP (NYSDEC may be involved in the decisions to test and remediate the study area depending on the actual events and levels of

contamination encountered). If elevated levels of contamination are encountered, remediation of said contamination would be performed in a manner that is consistent with the levels of contamination discovered to ensure that no significant impact to on-site and off-site occupants occurs.

Additional areas of concern include lead-based paint, suspected ACMs and possible PCB-containing electrical transformers. Lead-based paint and ACMs that may be present within the existing buildings would be abated prior to any construction activities in accordance with City Building Codes and practices. All electrical transformers containing PCBs should be removed from the existing buildings to avoid future potential liabilities. Since construction and excavation may increase the exposure to contaminants by dermal contact, ingestion or inhalation, the necessary and appropriate health and safety measures would be implemented to mitigate and minimize any exposure risk to workers and the general public.

14.11 Water Quality



The Scott Avenue/Scholes Street TS is not located near or adjacent to surface water and would have no potential to impact water quality. Therefore, no analysis was required.

14.12 Waterfront Revitalization Program

14.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of English Kills and Newtown Creek, the proposed Scott Avenue/Scholes Street Truck to Rail TS would be located within the City's coastal zone boundary (see Figure 14.12-1). The site is located within a designated SMIA and would be within Reach 13/Newtown Creek as indicated in the "New York City Comprehensive Waterfront Plan" and the "Plan for the Brooklyn Waterfront." The proposed Scott Avenue/Scholes Street Truck to Rail TS is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The Scott Avenue/Scholes Street Truck to Rail TS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3 and 8.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14-1. In instances where a component of the proposed Scott Avenue/Scholes Street Truck to Rail TS required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below. A description of waste handling operations that would occur at the proposed site is provided in Section 2.2.11.

Site delineations and study area boundaries are approximate.

14.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the Scott Avenue/Scholes Street Truck to Rail TS. The facility would, therefore, be consistent with this subpolicy.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The Scott Avenue/Scholes Street Truck to Rail TS would not be a water-dependent facility; however, it would be located within the boundaries of the NYCDCP-designated Newtown Creek SMIA. The existing facility, located at 598 Scholes Street, currently operates as an MSW transfer station with a permitted capacity for 220 tpd. As part of the Proposed Action, the facility would be modified in order to accommodate MSW transferred from three other existing facilities in the immediate area. One of these three facilities would be shut down after the proposed modification is complete. The Proposed Action would result in the modification of the existing facility in order to increase its permitted capacity to 3,000 tpd of MSW, and add rail export to the facility's waste shipping capabilities. Modification to the existing facility would involve: (1) installation of two over-the-top loading stations accommodating both intermodal containers and/or tractor trailers; (2) installation of new inbound/outbound truck scales and

drainage structures; (3) refurbishment of existing rail; (4) development of a rail container transfer system and enclosed delidding/lidding area; and (5) the upgrading of dust/odor control systems. The Scott Avenue/Scholes Street Truck to Rail TS would be consistent with existing land uses in the immediate vicinity of the site and would be compatible with surrounding uses. Therefore, the proposed facility would be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The proposed Scott Avenue/Scholes Street facility would not be considered a waterfront use and is not located on the waterfront. The Proposed Action would involve the modification of the existing facility into a truck-to-rail transfer station that would allow the transport of MSW by rail to out-of-City disposal facilities. In addition, the Proposed Action would allow for the permanent closure of a fully-operational and permitted transfer station located in the vicinity of the proposed site. The proposed modification of the Scott Avenue/Scholes Street Truck to Rail TS would not result in a need for significant infrastructure improvements and would, therefore, be consistent with this subpolicy.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 *Minimize conflicts between recreational, commercial, and ocean-going freight vessels.*

The Scott Avenue/Scholes Street Truck to Rail TS would not be a waterfront use and would not be located in an area that would cause conflicts with recreational, commercial or ocean-going vessels. This subpolicy would, therefore, not be applicable.

3.3 *Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.*

The proposed ~~Alternative~~ facility would involve the modification of an existing facility to serve as a truck-to-rail facility where MSW would be delivered, processed and containerized, then transported via rail lines to out-of-City disposal facilities. The proposed site would not be located on the waterfront. No impacts on the aquatic environment and surrounding land and water uses would result from the development of the facility. Therefore, this subpolicy would not be applicable.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 *Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.*

Based upon a review of SNWAs, as described in "The New Waterfront Revitalization Program," as well as Recognized Ecological Complexes, the Scott Avenue/Scholes Street Truck to Rail TS would not be within a designated area. SCFWH information maintained by the New York State Department of State indicates that the Scott Avenue/Scholes Street Truck to Rail TS would also not be located within an SCFWH.

Development of the Scott Avenue/Scholes Street Truck to Rail TS would involve the modification of an existing facility. The modified facility would not be a water-dependent use and would not be anticipated to result in significant impacts to natural resources at or in the vicinity of the site. The Scott Avenue/Scholes Street Truck to Rail TS would, therefore, be consistent with this subpolicy.

4.2 *Protect and restore tidal and freshwater wetlands.*

A review of NYSDEC tidal and freshwater wetland maps was conducted in order to determine the presence of wetlands within the proposed site. No tidal or freshwater wetlands exist on the site. The proposed Scott Avenue/Scholes Street Truck to Rail TS would be a land-based facility. No impacts to wetlands would occur as a result of the Proposed Action. This subpolicy would, therefore, not be applicable.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

A review of the NYSDEC NHP database indicates that there are no vulnerable plant, fish and wildlife species or rare ecological community on or in the immediate vicinity of the proposed site.

The Proposed Action would involve the modification of an existing facility in order to increase its permitted MSW tpd capacity and to allow for the transport of MSW by rail. Modifications to the Scott Avenue/Scholes Street Truck to Rail TS would result in little, if any, adverse impacts upon natural resources due to previous and ongoing industrial activities at the site. Sanitary and process wastewaters would be routed to on-site treatment systems and then discharged to the municipal sewer system. Management of stormwater runoff from the Scott Avenue/Scholes Street Truck to Rail TS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The Scott Avenue/Scholes Street Truck to Rail TS would also not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The Scott Avenue/Scholes Street Truck to Rail TS would be constructed and operate in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, processing areas would be cleaned on a regular basis. All sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site disposal treatment system and then discharged to the municipal sewer system. Stormwater runoff from the Scott Avenue/Scholes Street Truck to Rail TS would be managed in accordance with applicable regulations. The proposed facility would be consistent with this subpolicy.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

During the proposed modification of the Scott Avenue/Scholes Street Truck to Rail TS, BMPs would be used to the extent possible to minimize any nonpoint discharges. The facility would comply with applicable federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be performed inside an enclosed processing building, limiting the risk for the introduction of hazardous wastes or other pollutants into the environment. Control methods would be implemented at the facility to minimize or eliminate the potential for litter to escape into the surrounding environment. The proposed modification of the existing facility would be consistent with this subpolicy.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

The Scott Avenue/Scholes Street facility is not situated near navigable waters or natural areas. The Proposed Action would involve modification of an existing facility in order to increase its MSW tpd capacity and allow rail transport of containerized MSW to out-of-City disposal facilities. There would be no excavation or placement of fill within any surface waters or wetlands associated with the Proposed Action. Therefore, this subpolicy would not be applicable.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The proposed development of the Scott Avenue/Scholes Street Truck to Rail TS would have no impact on the quality or quantity of surface or ground waters. The proposed site is not located adjacent to surface waters. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer or water supply. The Scott Avenue/Scholes Street Truck to Rail TS would be consistent with this policy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 *Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.*

The proposed Scott Avenue/Scholes Street Truck to Rail TS would not be a waterfront facility. In addition, according to a review of the FEMA National Flood Insurance Program maps, the Scott Avenue/Scholes Street Truck to Rail TS would not be located within a designated floodplain. This subpolicy would, therefore, not be applicable.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The proposed Scott Avenue/Scholes Street Truck to Rail TS would involve the modification of an existing permitted solid waste transfer station. Activities at the facility would involve the management and processing of solid waste through a truck-to-rail system. Waste would be transported in sealed containers via rail to out-of-City disposal facilities. All waste handling operations would occur inside an enclosed processing building, which would minimize the escape of litter into the surrounding environment. Solid waste would generally be containerized within 48 hours of arriving at the facility. All solid waste handling operations would be conducted in accordance with the NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to modify and operate the proposed facility.

Contingency plans would be put in place to address the potential receipt of unauthorized waste and/or other situations that could disrupt the operation of the facility. Control methods would be implemented at the facility to minimize or eliminate the potential for litter entering the environment. The proposed Scott Avenue/Scholes Street Truck to Rail TS would not result in adverse impacts and would be operated in a manner to ensure that there would be no impact to surface and ground waters, significant fish and wildlife habitats, recreational areas and scenic resources. The proposed facility would be consistent with this subpolicy.

7.2 Prevent and remediate discharge of petroleum products.

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

The proposed facility would not be located on the waterfront, and, due to the existing heavy industrial uses at and in the immediate vicinity of the proposed Scott Avenue/Scholes Street Truck to Rail TS, public access would generally not be compatible with the principal use of the site. The facility would not affect existing access to the waterfront. Therefore, this subpolicy would not be applicable.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The Scott Avenue/Scholes Street Truck to Rail TS would not be a waterfront facility. Public access would also generally not be compatible with the principal use of the site. Therefore, this subpolicy would not be applicable.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

The Proposed Action would be compatible with existing uses in the vicinity of the site. It would involve the modification of an existing facility. As discussed in Section 14.7, visual access to the coastal lands is minimal due to the highly industrial nature of the surrounding vicinity. Therefore, no impacts to visual access would be anticipated. See also response to Subpolicy 9.1.

8.4 Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

No mapped parklands or open space areas have been identified at or within the immediate vicinity of the proposed site. Therefore, this subpolicy is not applicable.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The proposed Scott Avenue/Scholes Street Truck to Rail TS would involve the modification of an existing use and would not result in a significant impact upon visual quality, as noted in Section 14.7. Based on the information discussed in that section, the proposed facility would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The Proposed Action would involve the modification of an existing operating facility, and would result in no new impacts to scenic values associated with natural resources. It would, therefore, be consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

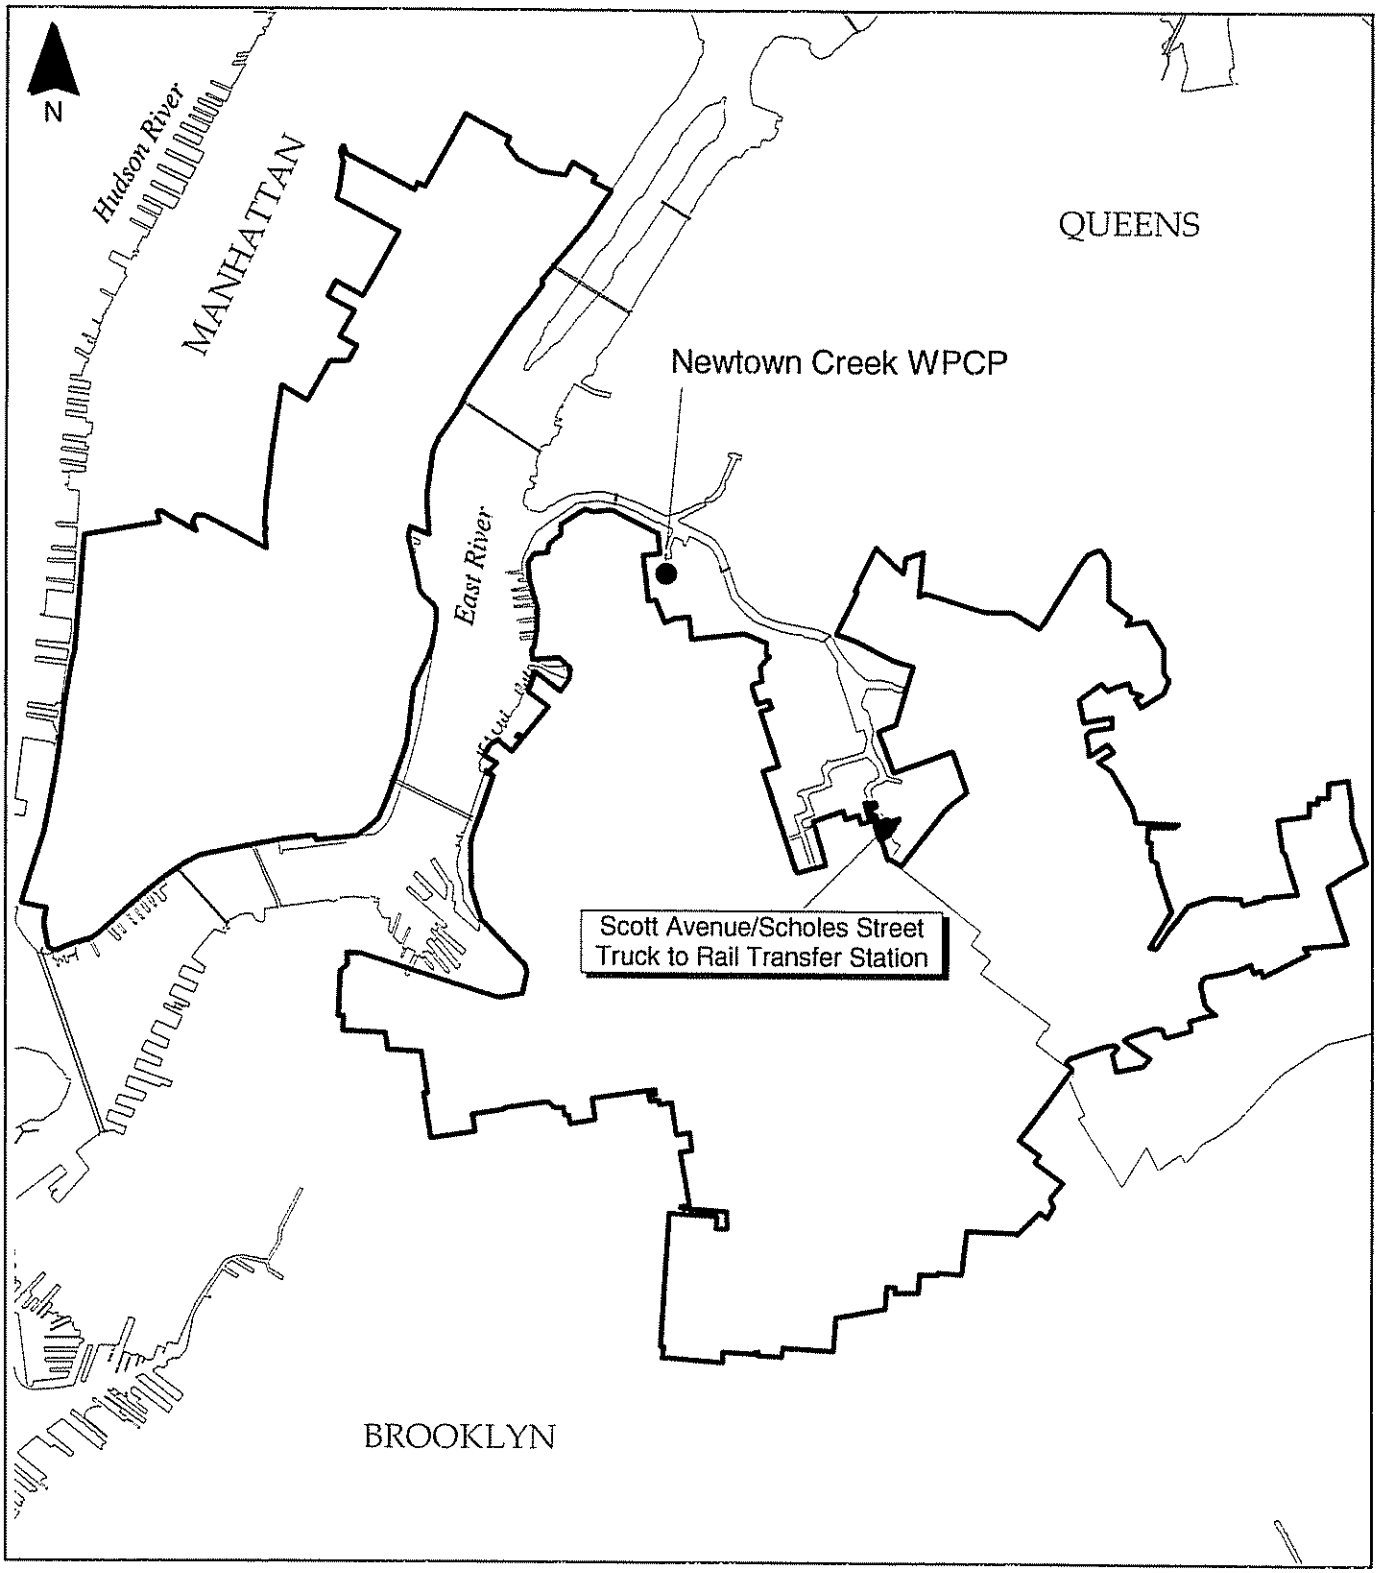
10.1 *Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.*

No adverse effects on cultural resources would result from the development of the Scott Avenue/Scholes Street Truck to Rail TS, as stated in Section 14.6. Based on the information presented in that section, the proposed facility would be consistent with this subpolicy.

10.2 *Protect and preserve archaeological resources and artifacts.*

No archaeologically significant resources are located at the site or in the study area. This subpolicy, therefore, is not applicable.

14.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



14.13.1 Existing Conditions

14.13.1.1 Water Supply

Potable water is supplied to the Scott Avenue/Scholes Street Truck to Rail TS site from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. Based on a review of NYCDEP water distribution maps, several water supply lines exist in the vicinity of the facility, including an 8-inch-diameter line along Scholes Street, a 20-inch line along Scott Avenue, a 12-inch line along Onderdonk Avenue and an 8-inch line along Meserole Street. A review of the information provided in the September 2003 EAS, supplemental information indicates that the existing facility has several connections to the 20-inch City water supply line on Scott Avenue. One 8-inch, two 6-inch and one 2-inch line connect to the City supply for the provision of potable water for process, sanitary and fire suppression purposes throughout the facility. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

14.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Newtown Creek WPCP, which serves portions of Manhattan, Queens and Brooklyn. The WPCP drainage area is illustrated in Figure 14.13-1. From July 2002 through June 2003, the WPCP treated an average of 216 mgd of wastewater under dry weather flow conditions and an average flow of 238 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 14.13-1). The maximum dry weather flow during this period was 239 mgd in August 2002 and the maximum average flow was 259 mgd during June 2003. Effluent from the plant is discharged to the East River and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the Newtown Creek WPCP is 310 mgd. The facility currently uses an estimated 9,000 gallons per day of water for process and sanitary purposes based on

Site delineations are approximate

5000 0 5000 Feet

Figure 14.13-1 Existing WPCP Drainage Area
Scott Avenue/Scholes Street
Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

information provided in the CEQR application and EAS supplemental information provided as part of the solid waste management facility permit modification documentation, indicating that the existing facility produces approximately 9,000 gallons per day of wastewater.

Table 14.13-1
Average Monthly Dry Weather and Average Flows
Newtown Creek Water Pollution Control Plant
Fiscal Year 2003

Month	Dry Weather Flow (mgd)	Average Monthly Flow[(1)] (mgd)
July 2002	223	229
August	239	256
September	229	253
October	224	255
November	208	238
December	213	228
January 2003	212	223
February	204	224
March	218	240
April	207	228
May	201	219
June	218	259
Average Effluent	**216**	**238**

Note:
(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

Based on a review of the I&I maps and information provided by the NYCDEP, Brooklyn Water and Sewer Permits, the area within the vicinity of the Scott Avenue/Scholes Street Truck to Rail TS site is served by several sewer lines. A 10-inch-diameter sanitary sewer flows south along Scott Avenue and connects to a 24-inch interceptor sewer that flows west on Randolph Street. A 24-inch interceptor also runs south on Scott Avenue, connecting with the 24-inch Randolph Street interceptor. The 24-inch interceptor changes to a 36-inch interceptor on Randolph Street near Gardner Avenue and conveys sanitary flow to the west and north along Varick, Johnson, Knickerbocker, Morgan and Lombardy Avenues and Monitor and Russell Streets, to the Newtown Creek WPCP.

Stormwater sewers in the vicinity of the site include a 12-inch-diameter storm sewer that flows west along Scholes Street to a 10-foot-by-11-foot double-barrel storm sewer flowing north on Scott Avenue to Newtown Creek. A 12-inch-diameter storm sewer also exists at the intersection of Scott Avenue and Meserole Street and conveys flow to the west along Meserole Street. This storm sewer increases in diameter to a 42-inch line at the intersection of Meserole Street and Gardner Avenue and connects to a 48-inch storm sewer at the intersection of Meserole Street and Stewart Avenue, which conveys flow to the north along Stewart Avenue. The 48-inch line connects to a 54-inch storm sewer that flows west along Scholes Street and increases to a 60-inch diameter line at the Varick Avenue intersection before reaching the outfall at Scholes Street and English Kills.

Information provided in the technical proposal and related CEQR application and EAS supplemental information for the facility indicates that the facility conveys sanitary sewage to the City-maintained sewer line through three lines connected to the 10-inch sewer main on Scott Avenue. Stormwater is conveyed to the 10-foot-by-11-foot double-barrel storm sewer on Scott Avenue via three roof drains.

26.13.1.3 Solid Waste

Based on operations data from the Scott Avenue/Scholes Street Truck to Rail TS, the facility currently manages up to 220 tpd of putrescible solid waste from commercial and residential sources. Throughput of non-putrescible waste from commercial and residential sources currently includes up to 1,450 tpd of commingled recyclable material.

According to the CEQR application and EAS supplemental information, the Scott Avenue/Scholes Street Truck to Rail TS currently employs a staff of 80 personnel. Based on information from the 2001 CEQR Technical Manual, it was estimated that each employee produces approximately nine pounds of solid waste per week for a facility total of 720 pounds per week (approximately 103 pounds per day or 0.05 tpd). The waste generated by the facility staff is managed by adding it to the incoming waste to be containerized for intermodal transport to licensed solid waste management facilities.

14.13.1.4 Energy

Based on a review of applicable Consolidated Edison utility plates, the area in proximity to the Scott Avenue/Scholes Street Truck to Rail TS is served by electric lines along Scholes and Meserole Streets and Scott and Onderdonk Avenues. The service plates indicate that the existing transfer station electrical system is connected to the Consolidated Edison system at Scott Avenue near the intersection of Meserole Street.

A review of applicable Keyspan service plates shows several gas lines in the vicinity of the site. Six-inch diameter, 15-psi lines run along Scott and Onderdonk Avenues and Scholes Street. South of Scholes Avenue, an 8-inch gas line exists on Onderdonk Avenue. An additional retired 6-inch line also exists on Scott Avenue south of Scholes Street. The service plates also indicate that the facility is connected to the Keyspan 6-inch gas line on Scott Avenue.

14.13.2 Future No-Build Conditions

The Scott Avenue/Scholes Street Truck to Rail TS would continue current waste receiving operations. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near the Existing Conditions levels for the site. Wastewater flows to the Newtown Creek WPCP would continue to increase and would be projected to be 240.4 mgd in 2006.

14.13.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

14.13.3.1 Water Supply

The Scott Avenue/Scholes Street Truck to Rail TS would require an additional 40 employees working three shifts per day. They would require approximately 1,000 gallons of additional potable water per day. The Scott Avenue/Scholes Street Truck to Rail TS would have no impact on the existing system's ability to supply water reliably. According to NYCDEP, the water pressure in the area is about 45 psi. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

14.13.3.2 Sanitary Sewage

Based on the estimated water usage of 10,000 gpd (9,000 gpd from Existing Conditions plus 1,000 gpd for new employees) for the Scott Avenue/Scholes Street Truck to Rail TS, the small quantities of wastewater sent to the Newtown Creek WPCP would not significantly impact the sewage flow rate or the ability of the Newtown Creek WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 240.4 mgd in 2006, which would be well below the permitted capacity of 310 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

14.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 40 additional facility employees per day, 312 pounds of solid waste would be generated per week (52 lbs/day) and would represent an incremental increase of approximately 312 pounds per week (52 lbs/day) above current waste generation levels. This volume would be managed at the Scott Avenue/Scholes Street Truck to Rail TS and would not significantly impact the system.

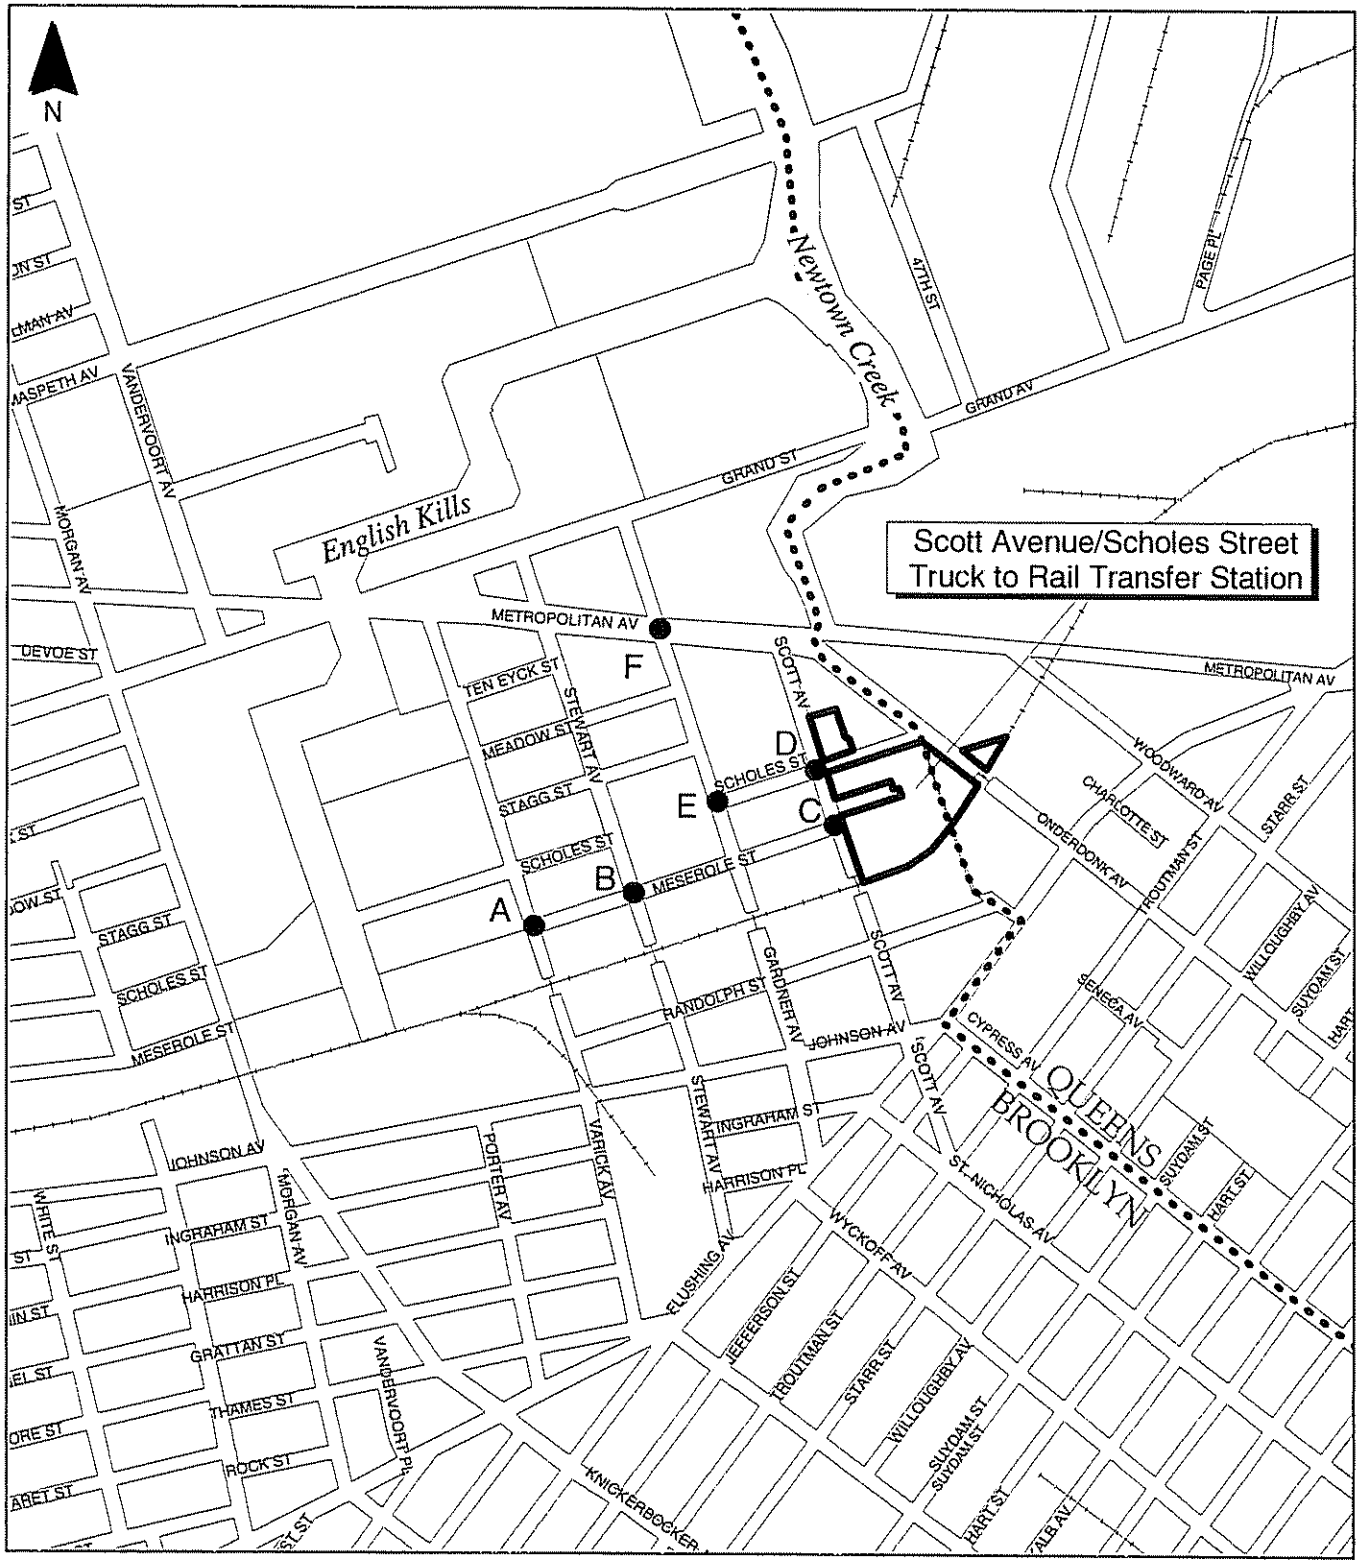
14.13.3.4 Energy

Detailed energy requirements based on the proposed renovations and changes for the Scott Avenue/Scholes Street Truck to Rail TS were not available at the time of this analysis. The renovations and changes are not expected to significantly change this facility's electrical and natural gas demands from Existing Conditions.

Additionally, Consolidated Edison has been notified of the power and natural gas requirements of the Greenpoint Converted MTS, a proposed facility in close proximity to the Scott Avenue/Scholes Street Truck to Rail TS. Consolidated Edison has stated that all demands

generated by the Greenpoint Converted MTS, which is not currently operational, could be met without an impact on the power and natural gas requirements of the surrounding community and without the need for additional power and natural gas generation capacity. Based on this statement, it is assumed that Consolidated Edison would also be able to meet all power demands without impacts of the Scott Avenue/Scholes Street Truck to Rail TS.

14.14 Traffic, Parking, Transit, and Pedestrians



14.14.1 Existing Conditions

The Scott Avenue/Scholes Street Truck to Rail TS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

14.14.1.1 Definition of Study Area

The traffic analysis study area is broad and includes the East Williamsburg neighborhood of Brooklyn. It includes the area bounded by Grand Street on the north, Flushing Avenue on the south, the dividing line between Kings County and Queens County on the east (which approximately follows Onderdonk Avenue in the area), and Varick Avenue and Vandervoort Avenue on the west. The traffic study area is predominantly light industrial in nature. There are no CEQR-defined areas of concern located within the study area. Figure 14.14-1 shows the locations of the intersections selected for analysis (locations A through F). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points more than ½-mile away in conjunction with local truck routes. Eastbound collection vehicles would approach the site along Flushing Avenue and turn northbound onto Varick Avenue. Collection vehicles would then turn east onto Meserole Street and then north onto Scott Avenue to access the facility. Alternatively, collection vehicles traveling eastbound could approach the facility on either Grand Street or Metropolitan Avenue. These vehicles would merge onto Metropolitan Avenue when crossing the bridge over English Kills and proceed east to Scott Avenue. The collection vehicles would then turn south onto Scott Avenue and proceed to the facility. Northbound and southbound collection vehicles could travel along the BQE or local designated truck routes to Flushing Avenue, Grand Street or Metropolitan Avenue, and then follow the same routes as eastbound collection vehicles. Westbound DSNY collection and other City agency vehicles are not expected to deliver DSNY-managed Waste to this facility.

14.14.1.2 Surface Network

One major highway, the predominantly north-south BQE, services the traffic analysis study area. Flushing Avenue, Grand Street and Metropolitan Avenue are local truck routes that provide access from east and west of the site. Varick Avenue is a local truck route that provides access from north and south of the site. A map showing all major truck routes and local truck routes in Brooklyn is provided in Section 3.16 (see Figure 3.16-3).

Flushing Avenue, Grand Street and Metropolitan Avenue are principal arterials that provide access to the BQE to the west of the facility. Varick Avenue is a collector road for local traffic and provides access for local and industrial traffic between Metropolitan Avenue and Flushing Avenue.

DSNY and other agency collection vehicles approaching the Scott Avenue/Scholes Street Truck to Rail TS from the south on the BQE would exit at Grand Street and travel east towards the facility. Other vehicles approaching the facility from the south would follow a designated truck route to Flushing Avenue and proceed east to Varick Avenue. DSNY and other agency collection vehicles traveling to the facility from the north would approach the area using local truck routes to Metropolitan Avenue and then proceed east towards the facility. Vehicles traveling along Metropolitan Avenue and Grand Street would merge onto Metropolitan Avenue when crossing the bridge over English Kills and proceed east to Scott Avenue. Collection vehicles approaching the site along Flushing Avenue turn northbound onto Varick Avenue, then east onto Meserole Street, and then north onto Scott Avenue. Collection vehicles gain access to the facility from Scott Avenue between Scholes Street and Meserole Street.

Exiting vehicles all turn west onto Scholes Street between Scott Avenue and Onderdonk Avenue, then north onto Gardener Avenue. DSNY and other agency vehicles then would turn west onto Metropolitan Avenue and return to their CD of origin. Trucks returning to the south of the facility would turn onto Grand Street from Metropolitan Avenue and proceed to the BQE or a local designated truck route running north-south in the area. Trucks returning to areas north of the facility would follow Metropolitan Avenue to the west to a local designated truck route running north-south in the area. Figure 14.14-2 depicts NYCDOT-designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

Site delineations are approximate.

14.14.1.3 Existing Traffic Operations

The six intersections listed below were identified for analysis because they are the most likely to be impacted by the Scott Avenue/Scholes Street Truck to Rail TS. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Meserole Street and Varick Avenue– Unsignalized Intersection (see Figure 14.14-1 – location A)
- Meserole Street and Stewart Avenue – Unsignalized Intersection (see Figure 14.14-1 – location B)
- Meserole Street and Scott Avenue – Unsignalized Intersection (see Figure 14.14-1 – location C)
- Scott Avenue and Scholes Street – Unsignalized Intersection (see Figure 14.14-1 – location D)
- Scholes Street and Gardener Avenue – Unsignalized Intersection (see Figure 14.14-1 – location E)
- Gardener Avenue and Metropolitan Avenue – Signalized Intersection (see Figure 14.14-1 – location F)

Metropolitan Avenue is a principal arterial that provides access to the BQE to the west of the facility. Varick Avenue is a collector road for local traffic and provides access for local and industrial traffic between Metropolitan Avenue and Flushing Avenue. Meserole Street, Stewart Avenue, Scott Avenue and Scholes Street are local streets that are not designated truck routes.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted on May 26, 2004, while ATR counts were conducted between May 24 and May 31, 2004. Figures 14.14-3, 14.14-4 and 14.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:30 a.m. and 8:30 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 4:45 p.m. and 5:45 p.m. Table 14.14-1 presents the v/c ratio, delay and LOS for the six intersections during the AM, Facility, and PM peaks.

LR = left right movement

L = left movement

TR = through right movement

Notes for Table 14.4-1 (continued):
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
NA = Not Applicable

Existing truck traffic through most of the intersections was relatively high. The percentages of trucks during the morning hours and Facility peak hours ranged between 32% and 61% at the study intersections and decreased to between 15% and 20% during the PM peak hours.

14.14.1.3.1 LOS at Signalized Intersections

Table 14.14-1 shows that the signalized intersection generally operates at an LOS of C or better with the following exception. At the intersection of Metropolitan Avenue and Gardener Avenue, during the AM peak hour the southbound movements have a delay of 40.7 seconds and operate at LOS D and during the Facility peak hour the northbound movements have a delay of 46.6 seconds and operate at LOS D.

14.14.1.3.2 LOS at Unsignalized Intersections

Table 14.14-1 shows that all of the unsignalized intersections generally operated at an LOS of C or better.

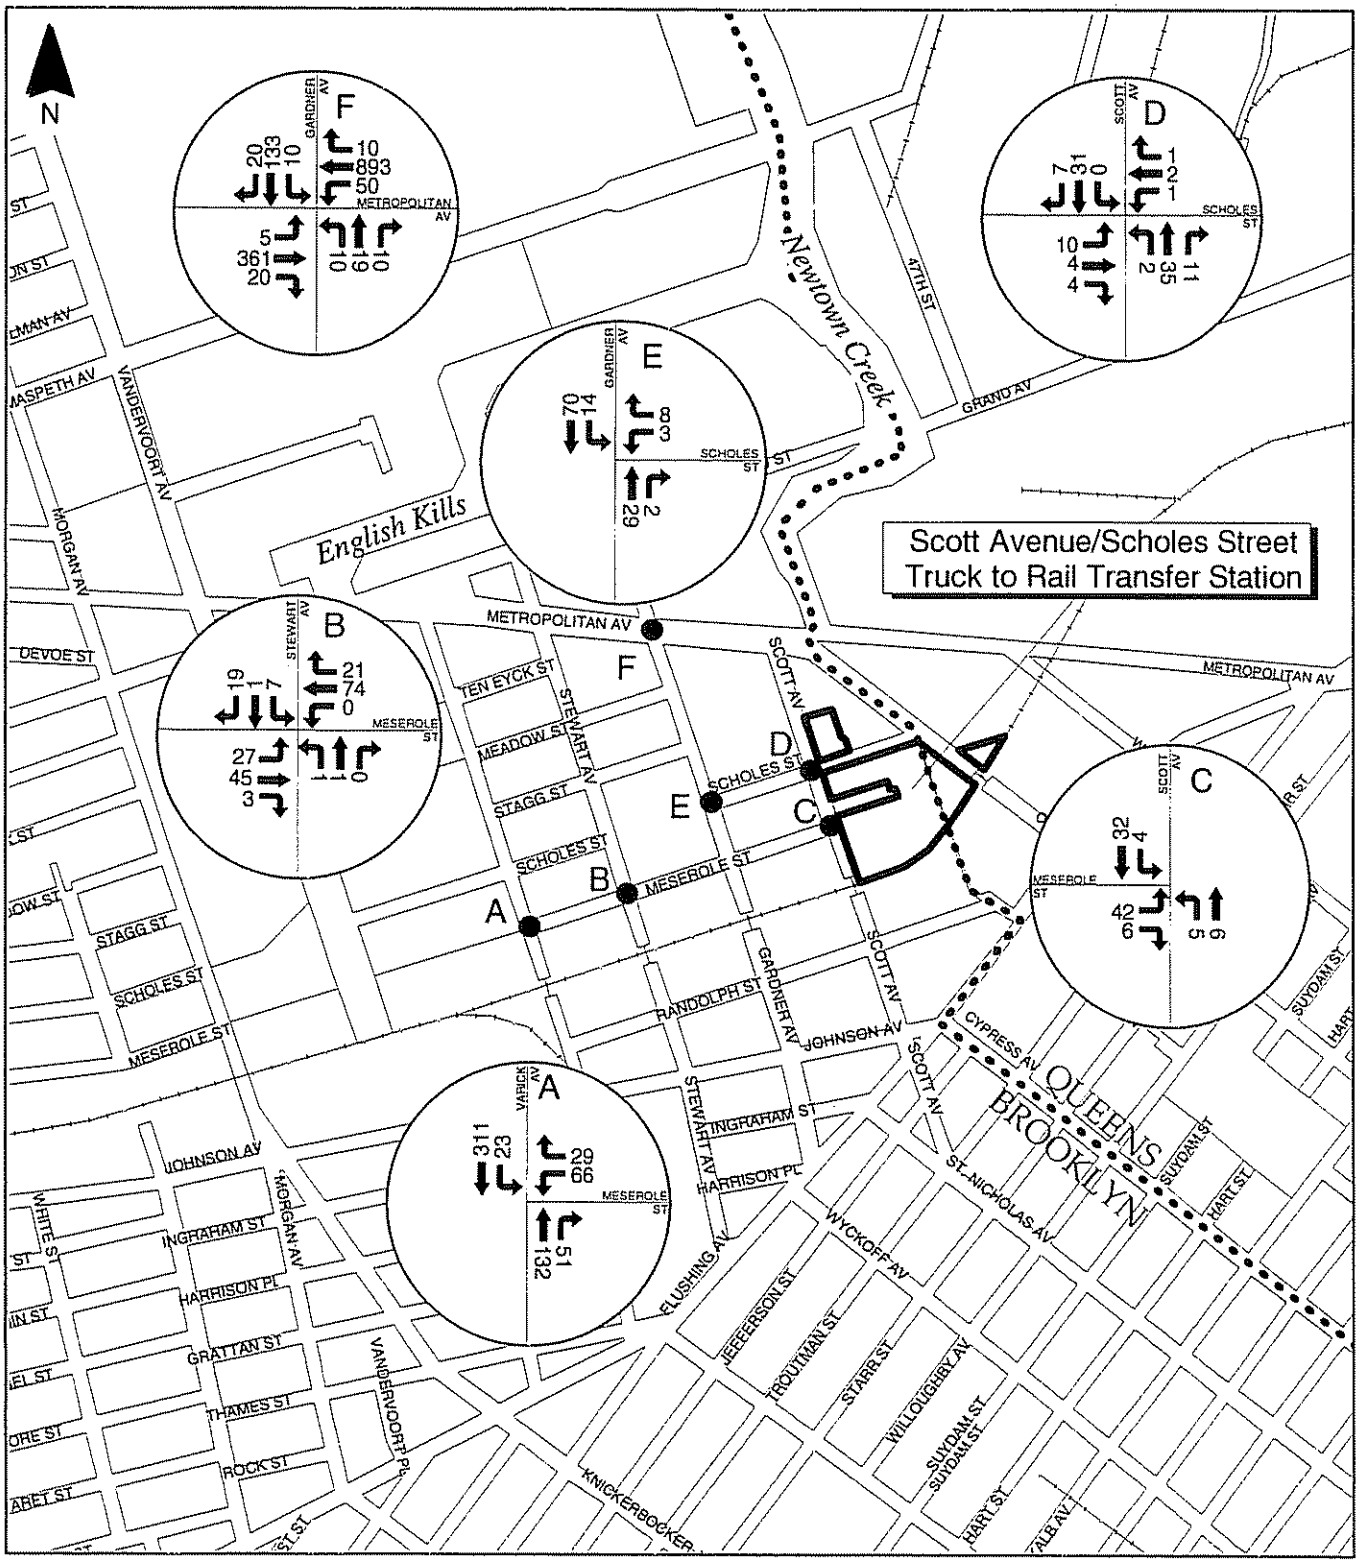
14.14.1.4 Existing DSNY-Related Traffic

Currently, the site contains a commingled recyclables facility, putrescible waste processing area and wastepaper baling plant, owned by BFI Waste Systems of New Jersey, Inc. The 598 Scholes Street site is currently permitted to handle 1,450 tpd of source-separated recyclables and 220 tpd of putrescible waste. The site is currently contracted to accept up to 220 tpd of DSNY-managed Waste under Interim Export.

14.14.1.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The "Jefferson Street" stop on the MTA's "L" subway line is located approximately three-tenths (3/10) of a mile southwest of the site at the Jefferson Street/Wycoff Avenue intersection. The MTA operates several Brooklyn and Queens bus lines that pass through the study area, but the closest bus stop to the facility is located over one mile away, next to the Linden Hill Cemetery by the intersection of Starr Street and Metropolitan Avenue in Queens.

14.14.1.6 Pedestrian Activity



Pedestrian activity is generally low within the study area. Striped crosswalks and pedestrian signals are provided at signalized intersections in the study area. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.

14.14.2 Future No-Build Conditions

14.14.2.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 25 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes in the study area.

Figures 14.14-6, 14.14-7 and 14.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 14.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their Existing Condition LOS.

14.14.2.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

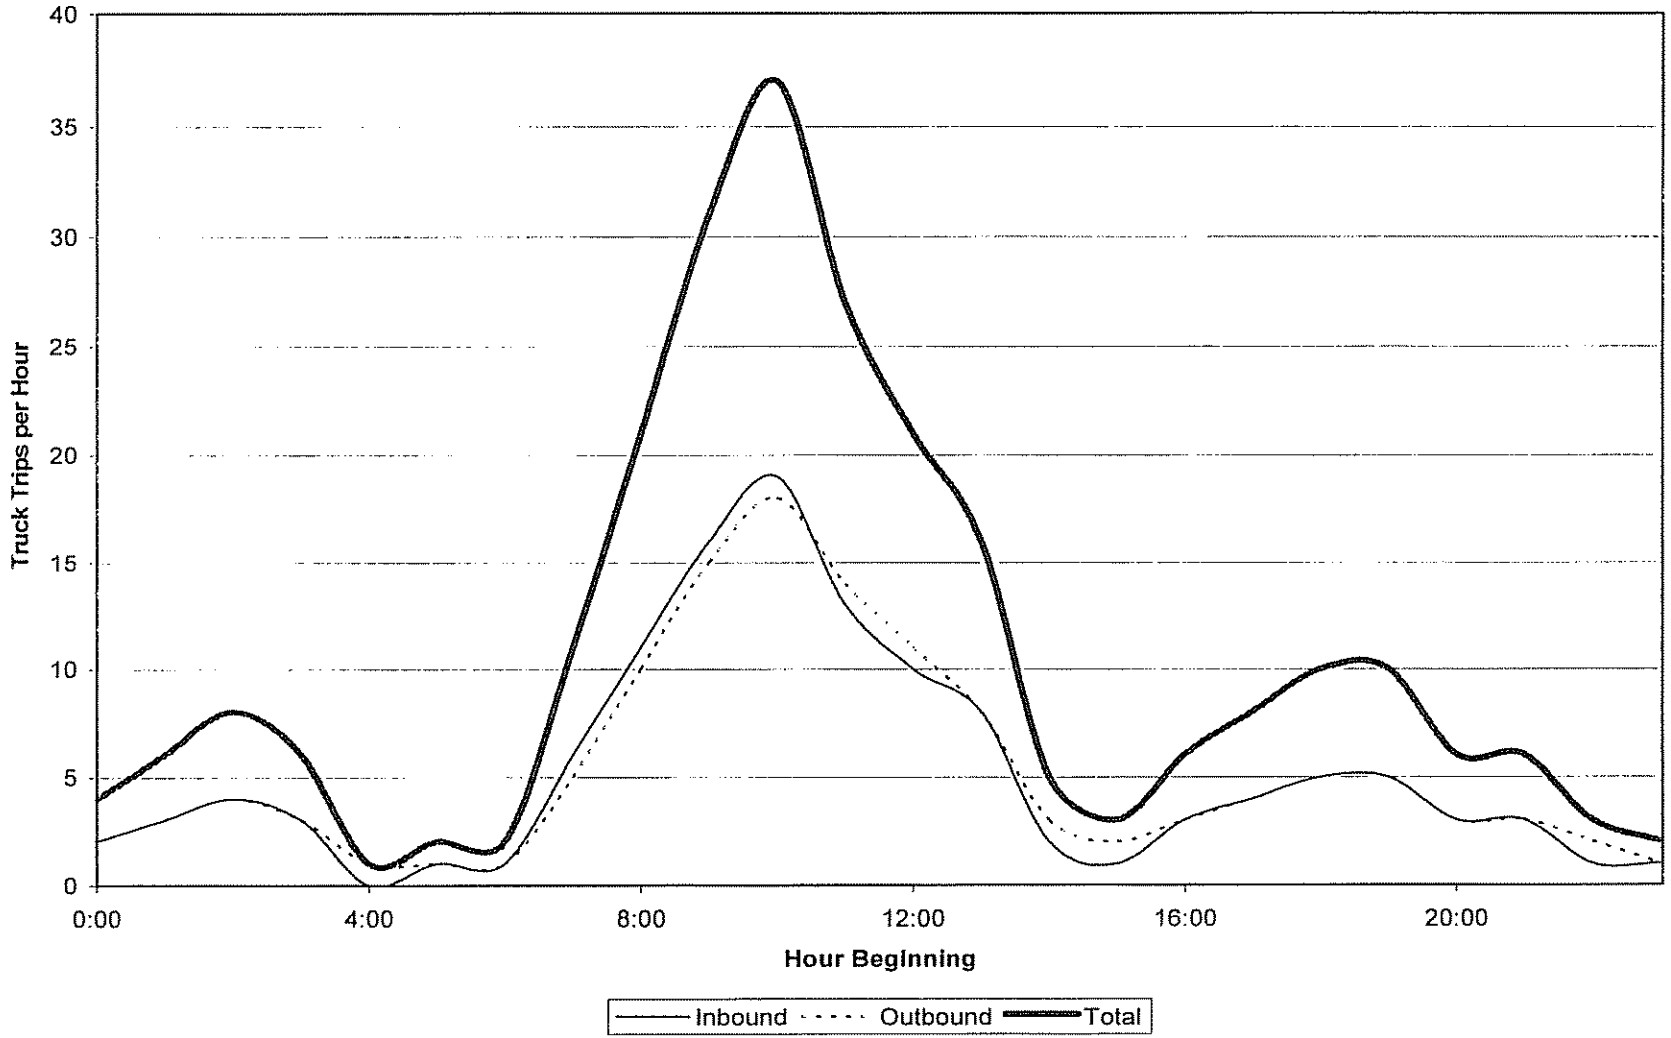
14.14.2.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

14.14.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

The Scott Avenue/Scholes Street Truck to Rail TS would receive waste from Brooklyn CDs 1, 3, 4 and 5 and the AFF. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Additionally, additional employee trips to and from the site may result in traffic impacts during the AM peak hour. The Scott Avenue/Scholes Street Truck to Rail TS would require an increase in the permitted putrescible waste capacity, and would add rail export to the facility's waste shipping capabilities. Rail export of containerized waste would be the preferred mode of operation, but some use of truck transfer during the transition period would be maintained. The capacity of the facility would be increased to 1,368 tpd, with a resulting additional 637 tpd of net waste (see Section 14.1).

14.14.3.1 2006 Future Build Traffic Conditions



2006 Future Build Conditions assume that the Scott Avenue/Scholes Street Truck to Rail TS would generate 125 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site or the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the Scott Avenue/Scholes Street Truck to Rail TS are shown in Figure 14.14-2.

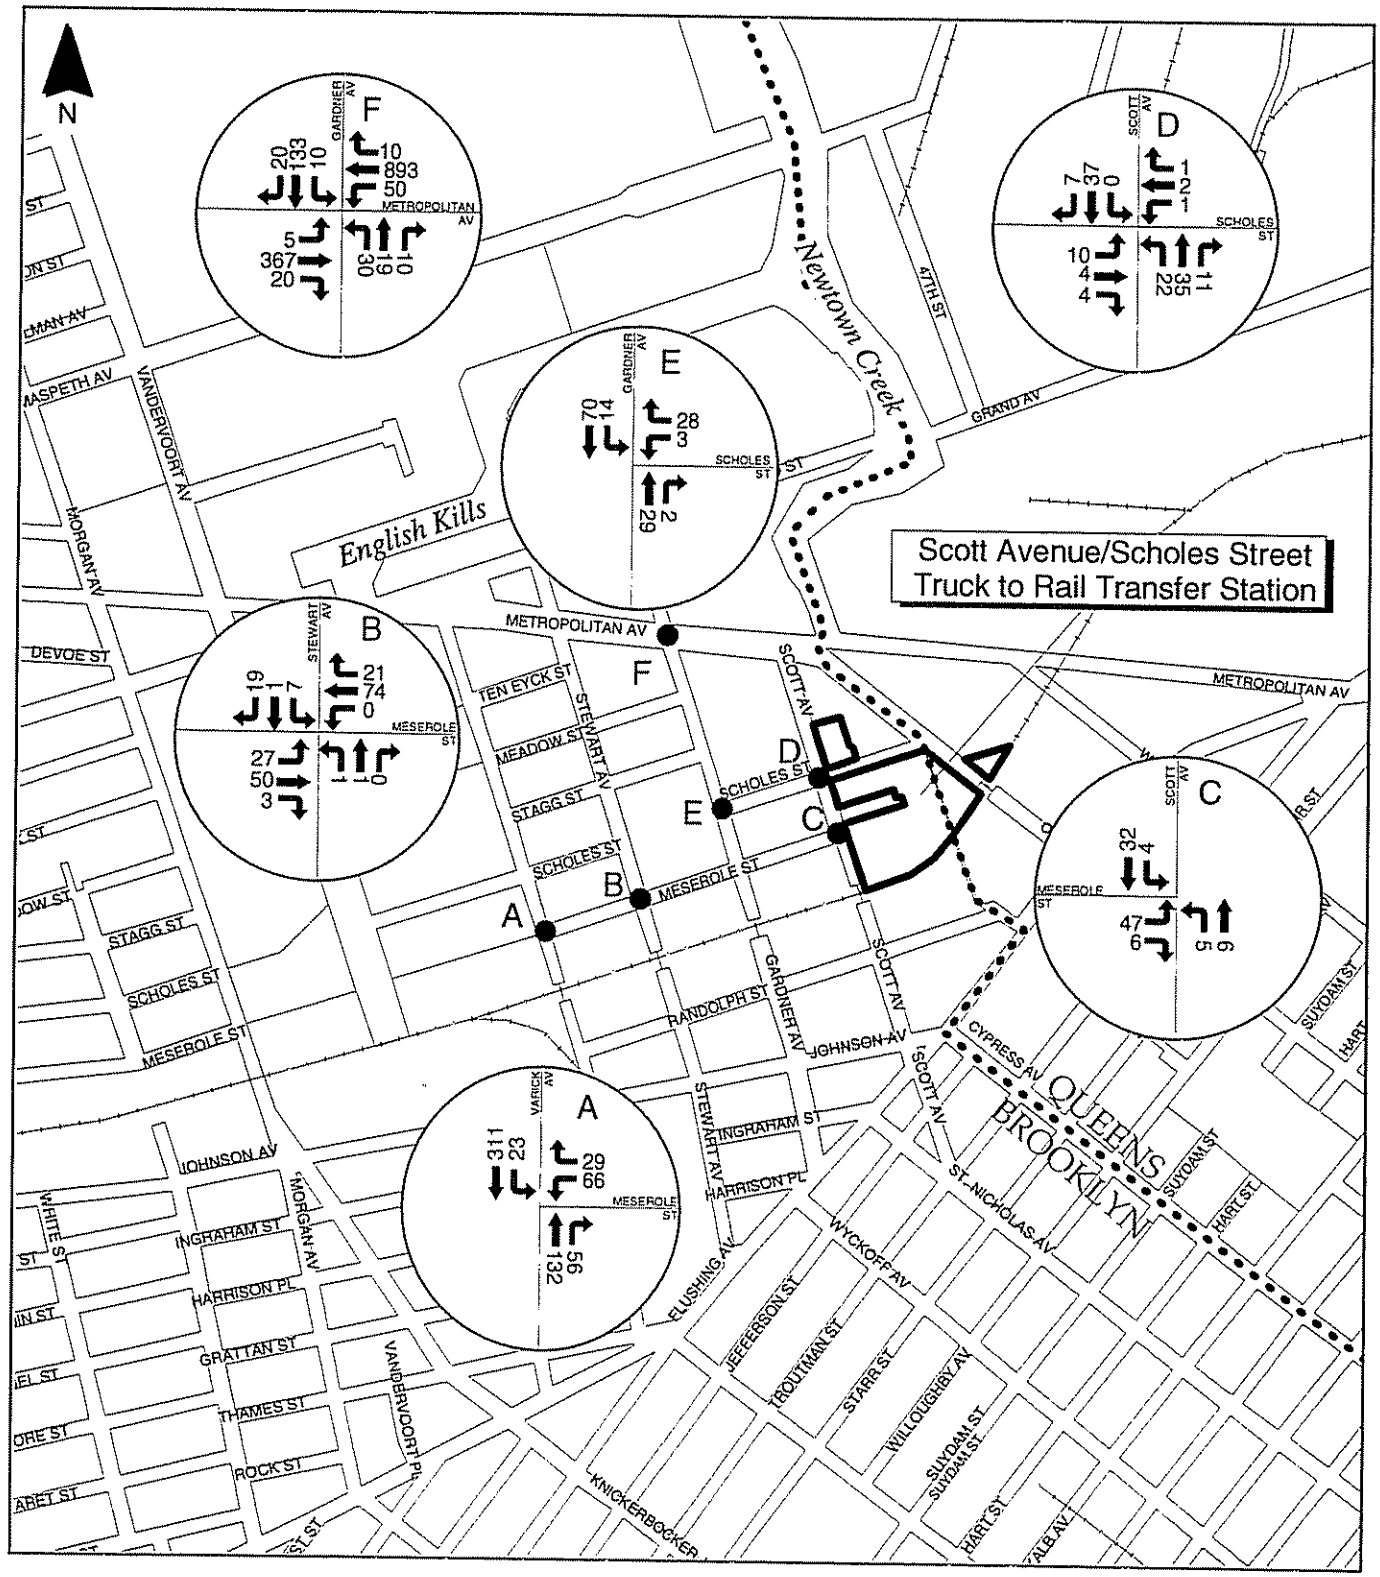


Figure 14.14-9 presents the average peak day temporal distribution of collection vehicles for the Scott Avenue/Scholes Street Truck to Rail TS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the Scott Avenue/Scholes Street Truck to Rail TS is expected to vary between approximately 2 to 8 truck trips per hour in the late evening/early morning, 5 to 37 truck trips per hour in the mid-morning/early afternoon, and 3 to 10 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (37) occurs at approximately 10:00 a.m.

Employee trips generated as a result of the Scott Avenue/Scholes Street Truck to Rail TS are expected to be about 30 per shift (15 arriving and 15 departing). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Therefore, during shift changes, employees would arrive within approximately 30 minutes before the start of a shift and leave within approximately 30 minutes after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m.

Because only the AM peak (7:30 a.m. to 8:30 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the Scott Avenue/Scholes Street Truck to Rail TS during the shift change (30) were considered as part of the net increase in site-generated traffic. Figures 14.14-10, 14.14-11 and 14.14-12 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 14.14-13, 14.14-14 and 14.14-15 show the intersections analyzed with only the net increase in site-generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the Scott Avenue/Scholes Street Truck to Rail TS. These projected net increases were routed through the intersections for each of the three peak hours. The highest net increase in trucks in the ingress or egress direction was 18. The highest net increase of collection vehicles at any one intersection was 28 trucks. Both of these net increases occurred at the intersection of Scott Avenue and Scholes Street.

DEPARTMENT OF SANITATION

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 75% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 82% of weekday traffic volumes. Table 14.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Scott Avenue/Scholes Street Truck to Rail TS would not operate on Sundays to receive DSNY-managed Waste. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 14.14-3
Weekday and Weekend Traffic
Scott Avenue/Scholes Street Truck to Rail TS

DSNY and Other Agency Collection Vehicle Traffic		**Background Traffic EB and WB on Metropolitan Avenue [1]**	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday average vehicles/Day	Weekend average vehicles/Day
125	94	10,691	8,715

Note:
[1] EB and WB traffic data collected from ATR counts taken on Metropolitan Avenue between Gardener Avenue and Stewart Avenue from June 13 to 20, 2003.

Table 14.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Scott Avenue/Scholes Street Truck to Rail TS. Over an average peak day, the intersections should not experience an extended increase in delay. The one intersection that may experience potentially significant impacts is discussed in Section 14.14.3.2 and summarized in Table 14.14-5.

14.14.3.2 Impacts and Mitigation

One of the six intersections may experience impacts great enough to be considered significant during one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines require mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below; their effectiveness is summarized in Table 14.14-5.

NA = Not Applicable

Gardener Avenue/Metropolitan Avenue – During the Facility peak hour a potential impact was identified on the northbound approach when the delay increased from 47.9 seconds to 69.4 seconds. An increase in green time of five seconds for the northbound and southbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract one second from the eastbound and westbound approach green time. The southbound approach delay would decrease by less than four seconds, the northbound approach delay would increase by less than three seconds, the eastbound approach delay would increase by less than four seconds and the westbound approach delay would decrease by less than one second, compared to Future No-Build Conditions. This mitigation should not generate any adverse impacts on the lane groups during other time periods.

14.14.3.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

14.14.3.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

14.15 Air Quality

14.15.1 Definition of Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Scott Avenue/Scholes Street Truck to Rail TS. The study area for the off-site air quality analysis is defined as the area or intersection listed in Section 14.15.4.65.1.

14.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 14.15-1. This data was compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 14.15-1
Representative Ambient Air Quality Data
Scott Avenue/Scholes Street Truck to Rail TS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO	Brooklyn	8-Hour	2,634 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	3,321 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	College Point Post Office	Annual	56 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}	Greenpoint	Annual	23 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	57 $\mu g/m^3$	150 $\mu g/m^3$
SO_2	Greenpoint	3-Hour	189 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	87 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	21 $\mu g/m^3$	80 $\mu g/m^3$

Note:
Source: NYCDEP, April 2003

14.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build Conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

14.15.4 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

14.15.4.1 On-site Emissions

On-site emissions related to the Department's use of this existing facility are considered only as part of total concentrations predicted for the Scott Avenue/Scholes Street Truck to Rail TS. Because the potential impacts from the operation of the Scott Avenue/Scholes Street Truck to Rail TS were estimated and found to be within applicable standards and guidelines for criteria pollutants, impacts of the DSNY-managed Waste contribution to the emissions from the Scott Avenue/Scholes Street Truck to Rail TS would also be within standards and guidelines, so an analysis of this alternative would likewise not result in a finding of significant impacts.

14.15.4.1.1 Sources considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table ~~7~~14.15-2. Figure ~~17.150-1~~14.15-1 shows the locations of these sources within the site.

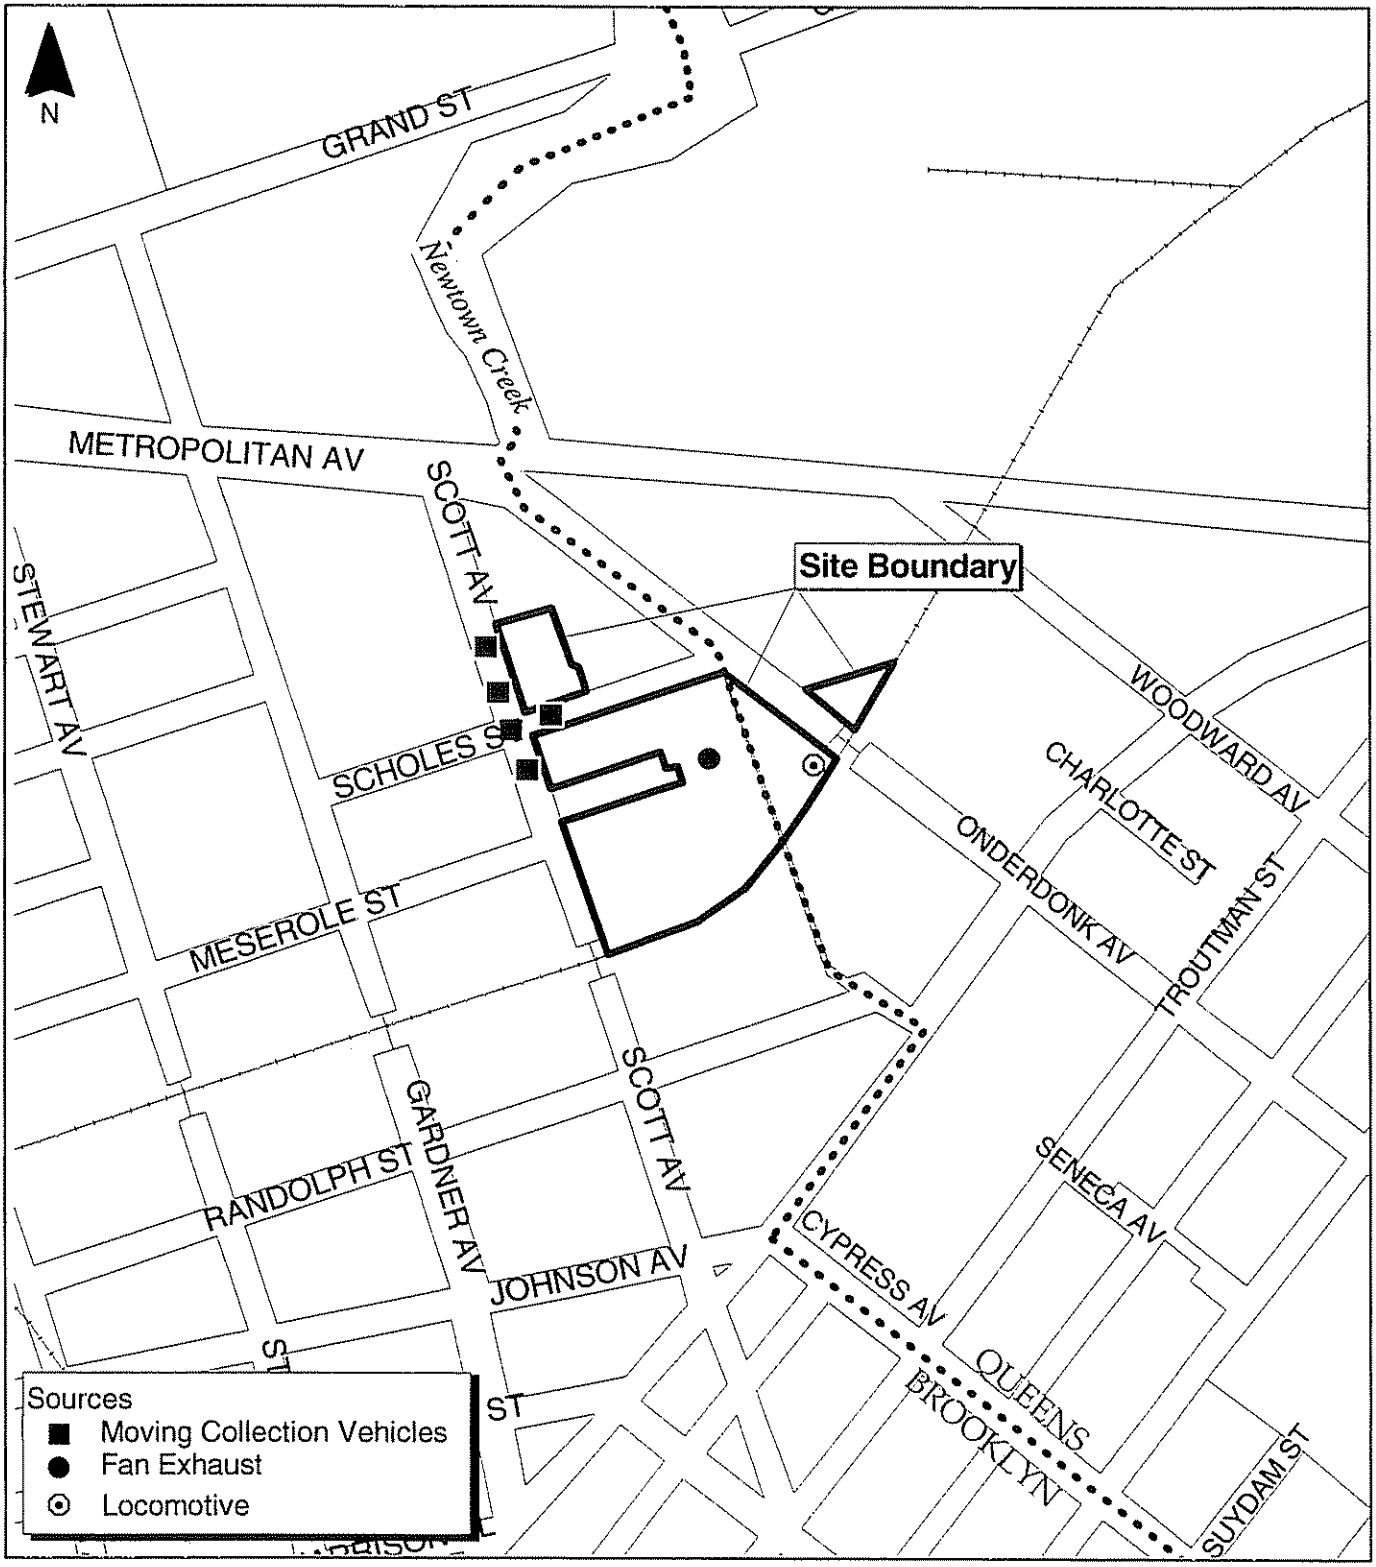

Table14.15-2
Emission Sources Considered for On-site Air Quality Analysis[1]
Scott Avenue/Scholes Street Truck to Rail TS

Type of Emission Source	Maximum Number of Sources Operated During a Single Peak Hour[2]	Number of Sources Operated During 24 Hour and Annual Average Period
Within Processing Building		
Moving/Queuing Collection Vehicles	47	6
Wheel Loaders	1	1
Track Loaders	1	1
Grapples	1	1
Moving Street Sweepers	1	1
Locomotives	1	1
Outside Processing Building	None	None

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in Technical Backup to be provided upon request.

(2) Peak 24-hour average number of moving collection vehicles: 13.
Peak 24-hour average number of queuing collection vehicles: 1.

14.15.4.3 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any one of the receptor sites considered are provided in Table 14.15-3. These values are compared with the applicable standards for the appropriate averaging time periods. Based on the results presented in Table 14.15-3, operations proposed at this facility would not adversely impact air quality in the area. The total predicted concentrations (including appropriate background concentrations) are below the national and state ambient air quality standards.

14.15.4.4 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 14.15-4.[7] The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by USEPA as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Scott Avenue/Scholes Street Truck to Rail TS are not considered to be significant.

[7] These concentrations have been estimated according to the methodology discussed in Section 3.11.2.2.

Table 14.15-3
Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions
Scott Avenue/Scholes Street Truck to Rail TS

Pollutant	Averaging Time Period	Maximum Impacts from On-Site Emission Sources [1]	Background Pollutant Concentrations [2]	Highest Estimated On-Site Pollutant Concentrations	NAAQS[3]	STV[4]
Carbon Monoxide (CO), $\mu g/m^3$	1-hour[6]	~~1,836~~1,730	~~2,635~~3,321	~~4,471~~5,051	40,000	NA
	8-hour[6]	~~1,048~~987	~~3,322~~2,635	~~4,370~~3,622	10,000	NA

Sulfur Dioxide (SO_2), $\mu g/m^3$	3-hour[6]	~~112~~81	~~189~~186	~~301~~267	1,300	NA
	24-hour[6]	~~21~~20	~~87~~107	~~108~~127	365	NA
	Annual	~~2~~1.6	~~2~~118	~~23~~20	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~memorandum dated February 18, 2005.

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

Notes to Table 14.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC.

(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.

(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

NA = Not Applicable

14.15.4.5 Off-Site ~~Emissions~~Analysis

~~14.15.4.6 Off-Site Emission Sources~~

14.15.4.65.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other collection agency's collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, mobile source analyses were conducted at the following locations for the applicable (i.e., worst-case) time periods:

- The multiple intersections around Meserole Street and Varick Street and Scott Avenue at Scholes Street to determine whether facility-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and
- The multiple intersections around Meserole Street and Varick Street and Scott Avenue at Scholes Street to determine whether facility-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 14.15-2.

14.15.4.5.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 14.15-5, are all within (less than) the applicable state and federal ambient air quality standards and STVs (for $PM_{2.5}$). Therefore, the off-site operations of the Scott Avenue/Scholes Street Truck to Rail TS, therefore, are not considered to be significant.

Site delineations are approximate

NA = Not Applicable

~~*14.15.4.6.2 Results of the Off-Site Analysis*~~

~~Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 14.15-5, are all within (less than) the applicable state and federal ambient air quality standards and STVs (for $PM_{2.5}$). Therefore, the off-site operations of the Scott Avenue/Scholes Street Truck to Rail TS, therefore, are not considered to be significant.~~

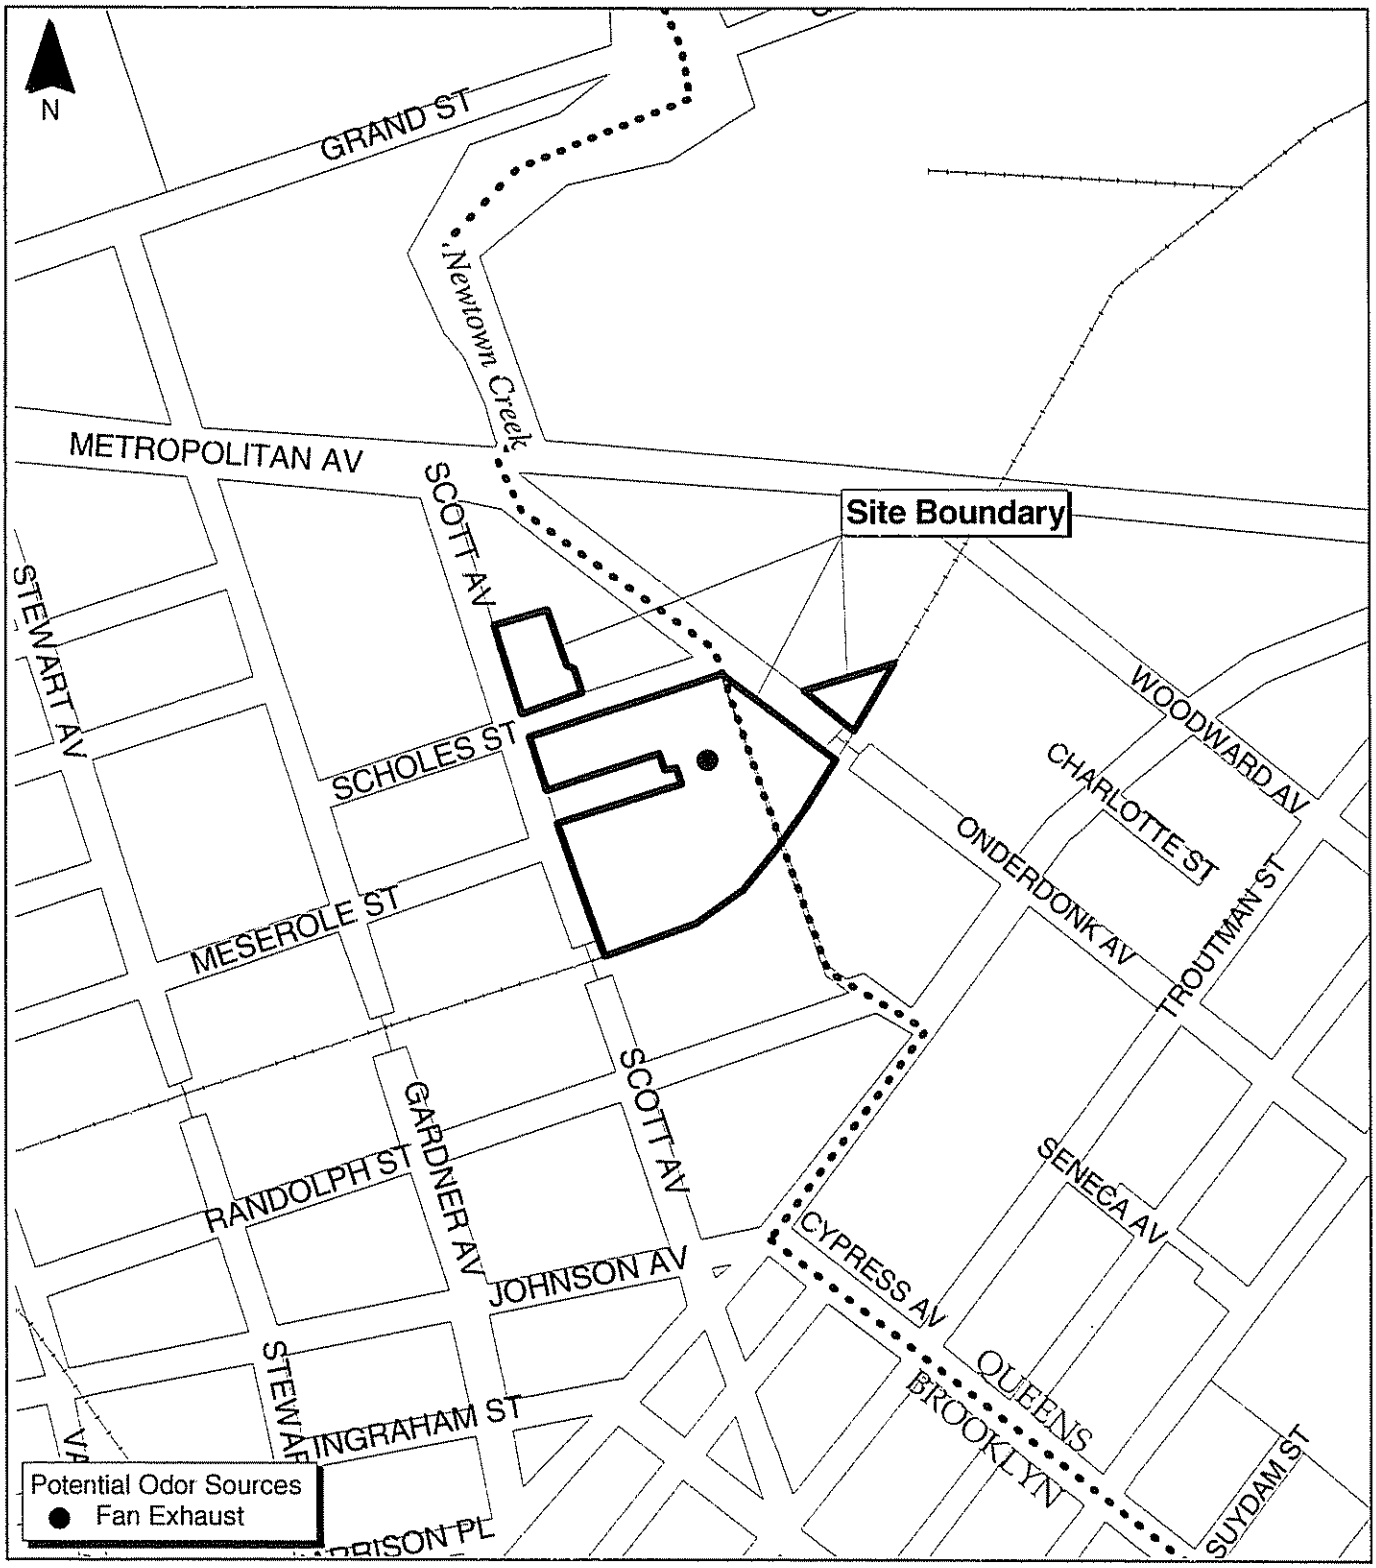
14.16 Odor

14.16.1 Existing Conditions

To evaluate all potential odors from the proposed Scott Avenue/Scholes Street Truck to Rail TS, the analysis assumes there are no existing sources of odor on site.

14.16.2 Future No-Build Conditions

No additional odor-producing sources are anticipated in the vicinity of the Scott Avenue/Scholes Street Truck to Rail TS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



14.16.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

14.16.3.1 Odor Source Types and Locations Considered in the Analysis

The number and type of odor sources assumed to be on-site with the Scott Avenue/Scholes Street Truck to Rail TS (while processing waste at proposed capacity for DSNY waste) are provided in Table 14.16-1. Figure 14.16-1 shows the locations of these sources within the project site.

Table 14.16-1
Odor Sources Included in Odor Analysis
Scott Avenue/Scholes Street Truck to Rail TS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity

300 0 300 Feet

Figure 14.16-1 Potential Odor Sources
Scott Avenue/Scholes Street
Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Scott Avenue/Scholes Street Truck to Rail TS.

14.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 14.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Scott Avenue/Scholes Street Truck to Rail TS at any nearby sensitive receptor is less than 1, so odors from the Scott Avenue/Scholes Street Truck to Rail TS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 14.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Scott Avenue/Scholes Street Truck to Rail TS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	0.57
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.016
Type of Receptor	~~Apartment Building~~Residential House
Distance to Receptor[2]	~~1,188~~535 Feet

Notes:
(1) Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.
(2) Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.
(3) Measured from the site boundary.
~~(3) Measured from the site property line.~~

14.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Scott Avenue/Scholes Street Truck to Rail TS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

14.17.1 Existing Conditions

14.17.1.1 Introduction

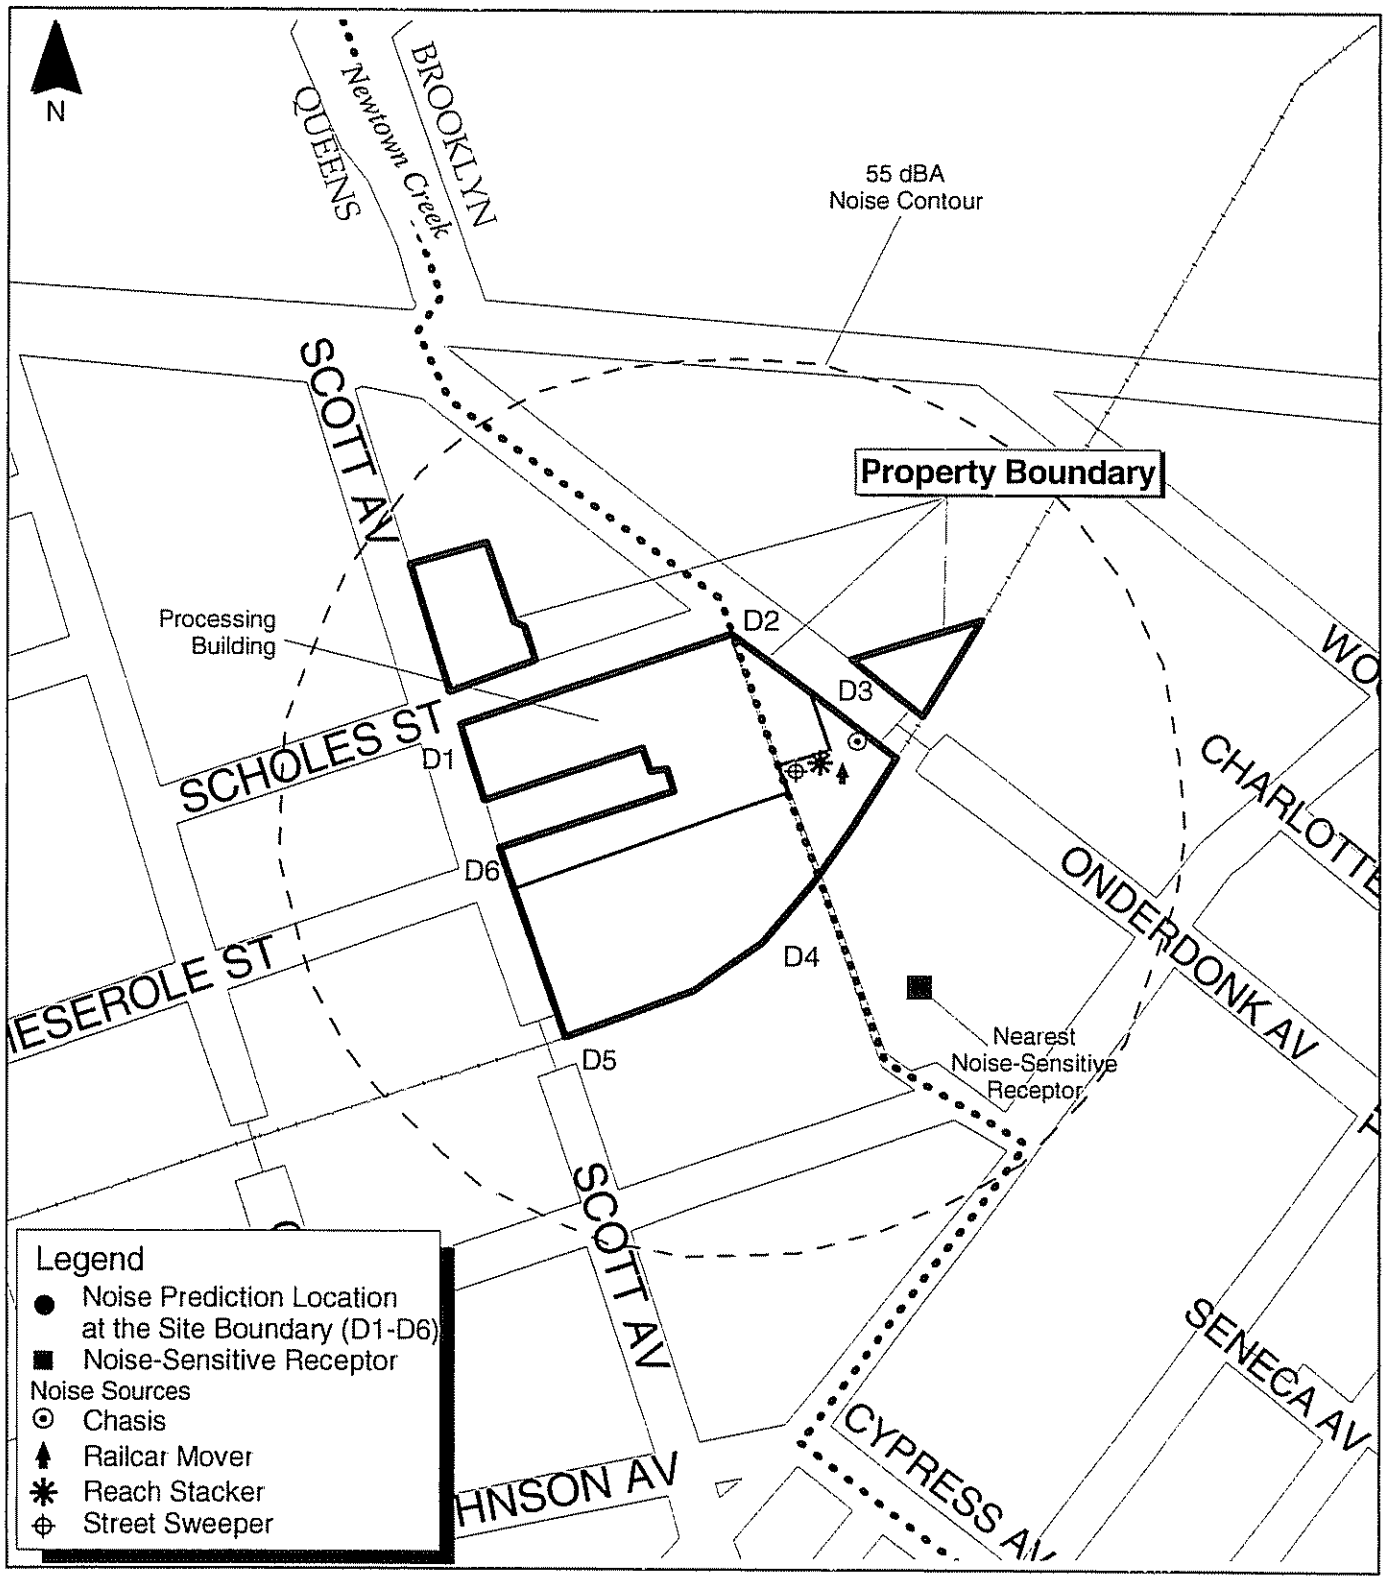

Figure 14.17-1 shows the location of the Scott Avenue/Scholes Street Truck to Rail TS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is the non-conforming residential house located on Flushing Avenue between Metropolitan Avenue and Woodward Avenue, approximately 163 meters (535 feet) southeast of the site boundary.

14.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the non-conforming house. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[8] and the statistical metrics of L_5, L_{50} and L_{90}.[9] Table 14.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 3:00 a.m. and 4:00 a.m. and had an $L_{eq(1)}$ of 59.3 dBA on June 25, 2004. Activities and events that contribute to the on-site noise levels include:

- Transportation of railcars on the adjacent Railroad line; and
- Other noise sources associated with activities in the surrounding industrial areas.

[8] Terms $L_{eq(1)}$, L_{min} and L_{max} are explained in Section 3.19.2.
[9] Terms L_{10}, L_{50} and L_{90} are explained in Section 3.19.2.

Site delineations are approximate

7:00-8:00 a.m.	65.7	60.9	63.8	70.2	58.2	82.5
8:00-9:00 a.m.	68.0	62.5	64.6	71.3	60.7	86.4
9:00-10:00 a.m.	67.7	62.0	64.6	72.6	60.3	86.2

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

14.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the Scott Avenue/Scholes Street Truck to Rail TS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required, and therefore, off-site noise monitoring was not conducted.

14.17.2 Future No-Build Conditions

14.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

14.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 14.17-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) based on the first-level screening.

Table 14.17-2
Off-Site Noise Traffic Volume
Scott Avenue/Scholes Street Truck to Rail TS

Location	Hour	Existing Traffic Volume [1] (Vehicles/Hour)	Future No-Build Traffic Volume [2] (Vehicles/Hour)
Metropolitan Avenue between Olive St. and Catherine St.	10:00 a.m.	763	786
Grand Avenue between Olive St. and Catherine St	2:00 a.m.	128	132
Flushing Avenue between Vandevoort and Knickerbocker Avenue	2:00 a.m.	156	159

Notes:
(1) Existing traffic volumes are based on ATR data.
(2) Future No-Build traffic volumes are based on CEQR annual traffic growth rates.

14.17.3 Potential Impacts with the Scott Avenue/Scholes Street Truck to Rail TS

14.17.3.1 On-Site Noise Levels

Proposed equipment assumed to be operating at the Scott Avenue/Scholes Street Truck to Rail TS and its reference noise levels used in the CEQR analysis are shown in Table 14.17-3. The number and types of equipment assumed for this analysis were based on the Scott Avenue/Scholes Street Truck to Rail TS's average design capacity. Shown earlier, Figure 14.17-1 indicates the Scott Avenue/Scholes Street Truck to Rail TS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 14.17-3
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Scott Avenue/Scholes Street Truck to Rail TS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Wheel Loader (1)	80.6
Track Loader (1)	80.6
Excavator 450PC (1)	75.4
~~Moving/Queuing Collection Vehicle (15)~~	~~73~~
~~**Outdoor**~~	
Reachstacker (Container Handler) (1)	76.2
Yard Jockey (1)	73.8
Shuttle Wagon (1)	76.3
Sweeper (1)	81.8
Moving/Idling Collection Vehicles (15)	79

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

14.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Scott Avenue/Scholes Street Truck to Rail TS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 186 meters (610 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is approximately 163 meters (535 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (See Figure 14.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 14.17-1 above. Table 14.17-4 below identifies the existing background noise level during the quietest hour. The table shows the distance from the Scott Avenue/Scholes Street Truck to Rail TS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, Scott Avenue/Scholes Street Truck to Rail TS-related predicted noise level at the noise-sensitive receptor, and the predicted noise level with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptor. This difference represents the predicted incremental change in noise level from the Scott Avenue/Scholes Street Truck to Rail TS. Because this incremental change is less than the CEQR threshold of 3 dBA during nighttime hours at the nearest noise-sensitive receptor, there is no predicted impact that would be caused by the Scott Avenue/Scholes Street Truck to Rail TS on-site operations.

Table 14.17-4
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
Scott Avenue/Scholes Street Truck to Rail TS

Noise-Sensitive Receptor ID	Distance from Facility (meters/feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
House	163/535	73.4	~~51.9~~ 28.8	73.4	0	No

Notes:
(1) Twenty-minute noise level readings measured at the nearest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.
(2) Existing noise levels measured on July 2, 2003 at 3:00 a.m.
(3) Predicted noise level calculations at the noise-sensitive receptor include on-site and off-site shielding from structures.
(4) According to CEQR, an increase of 3 dBA at nighttime is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the Scott Avenue/Scholes Street Truck to Rail TS with the quietest background noise levels that occur during facility operation. The quietest hour of background noise levels occurred during the nighttime hours for the noise-sensitive receptor; therefore, only nighttime impact criteria are discussed in this analysis for this noise-sensitive receptor.

~~25~~14.17.3.3 *Off-Site Noise Levels*

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Scott Avenue/Scholes Street Truck to Rail TS. The assumed DSNY and other agency collection vehicles routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, a second-level screening was not required; therefore an off-site noise analysis and off-site noise monitoring was not required. Results of the first-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) are provided in Table 14.17-5.

~~25~~14.17.3.4 *Combined On-Site and Off-Site Noise Levels*

An on-site noise analysis was performed for the Scott Avenue/Scholes Street Truck to Rail TS. As a result of the off-site screening analysis, which is described above in ~~25~~14.17.3.3, no off-site noise analysis was required. Since an off-site analysis was not required, a combined noise analysis was not performed.

Table 14.17-5
Off-Site Noise Screening[1] Results
Scott Avenue/Scholes Street Truck to Rail TS

Location	Hour	Future No-Build PCEs[2]	Collection Vehicles	Employee Vehicles	Total Net Collection Vehicle PCEs[2][3]	Future Build PCEs[2][3]	Possible Impact[4]
Metropolitan Avenue between Olive and Catherine	2:00 a.m.	1,473	25	0	1,175	2,648	No
Grand Avenue between Olive and Catherine	2:00 a.m.	247	2	0	94	341	No
Flushing Avenue between Vandevoort and Knickerbocker	2:00 a.m.	254	2	0	94	348	No

Notes:

(1) Based on first-level screening since a second-level screening was not required.

(2) Total PCEs are rounded to the nearest whole number.

(3) Future Build PCEs include Scott Avenue/Scholes Street Truck to Rail TS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted using a factor of 1.

(4) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

This page intentionally left blank.

CHAPTER 15 ENVIRONMENTAL REVIEW – REVIEW AVENUE SITE

15.1 Introduction

The Review Avenue TS is currently permitted for receipt and processing of waste into outbound transfer trailers at 958 tpd, and an increase in permitted capacity to 1,200 tpd is proposed. A Part 360 permit application to modify the facility for barge transport (Review Avenue Truck to Barge Transfer Station) and a capacity expansion from 958 to 1,200 tpd was submitted to NYSDEC in January 2003. Review Avenue is currently contracted to accept up to 958 tpd of DSNY-managed Waste under Interim Export and receives, on an average peak day, approximately 934 tons. The facility was subject to EAS review for Interim Export in June 2000, which did not consider $PM_{2.5}$. The facility would be modified to enable lidding of containers and transport of containerized waste by barge. Since Review Avenue was evaluated in the 2000 SWMP FEIS as a truck to barge operation at a planned average peak capacity of 1,200 tpd (37 collection vehicles during the peak hour), no on or off-site analysis is required, except for $PM_{2.5}$ (which was not evaluated in the 2000 SWMP FEIS).

The Review Avenue Truck to Rail TS would containerize DSNY-managed Waste and then dray the containers to the Maspeth Rail Yard in Queens CD 2, where the containers would be loaded onto rail cars. The 2000 SWMP FEIS analyzed a truck-to-rail design for this site at a capacity of 2,300 tpd, which included off-site air quality (PM_{10} and CO), traffic and noise analyses assuming 56 collection vehicles during the peak hour. The 56 collection vehicles assumption is equivalent to operating at 1,200 tpd and draying containers to Maspeth. The 2000 SWMP FEIS will be referred to as sufficient for evaluating impacts associated with the current proposal, except for $PM_{2.5}$, which will need to be reported in the New SWMP FEIS. Supplemental analyses will be conducted, as required, as detailed designs are developed, if the Review Avenue ~~Transfer Station~~TS is included in the Proposed Plan.

The RFP procurement issued by the City requires that proposers commit to exporting all waste (both DSNY and commercial) processed at their facility by rail or barge. The Maspeth Rail Yard will be permitted as an intermodal yard subject to DSNY's new rules, as a non-discretionary

action, and thus not subject to environmental review. An off-site traffic, air quality (including $PM_{2.5}$) and noise impact analysis for the Maspeth Rail Yard will be performed for the equivalent of 1,200 tpd in round-trip truck traffic.

The results of the environmental analyses of the facility options at the Review Avenue Site are presented in the following sections:

15.2 Land Use, Zoning, and Public Policy
15.3 Socioeconomic Conditions
15.4 Community Facilities and Services
15.5 Open Space
15.6 Cultural Resources
15.7 Urban Design, Visual Resources, and Shadows
15.8 Neighborhood Character
15.9 Natural Resources
15.10 Hazardous Materials
15.11 Water Quality
15.12 Waterfront Revitalization Program
15.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
15.14 Traffic, Parking, Transit, and Pedestrians
15.15 Air Quality
15.16 Odor
15.17 Noise

A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3.

The facility options evaluated for this site are:

- Review Avenue Truck to Barge TS;
- Review Avenue Truck to Rail TS; and
- Maspeth Rail Yard.

Section 2.2.12 provides a summary description of the site and important characteristics of the design and operation of these options. Supplemental information on the site or the study area is provided in the following sections when appropriate.

15.2 Land Use, Zoning, and Public Policy

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the land use, zoning, and public policy impacts.

15.3 Socioeconomic Conditions

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the socioeconomic impacts.

15.4 Community Facilities and Services

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the community facilities and services impacts.

15.5 Open Space

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the open space impacts.

15.6 Cultural Resources

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the cultural resources impacts.

15.7 Urban Design, Visual Resources, and Shadows

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the urban design, visual resources, and shadows impacts.

15.8 Neighborhood Character

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the neighborhood character impacts.

15.9 Natural Resources

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the natural resources impacts.

15.10 Hazardous Materials

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the hazardous materials impacts.

15.11 Water Quality

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the water quality impacts.

15.12 Waterfront Revitalization Program

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the waterfront revitalization program impacts.

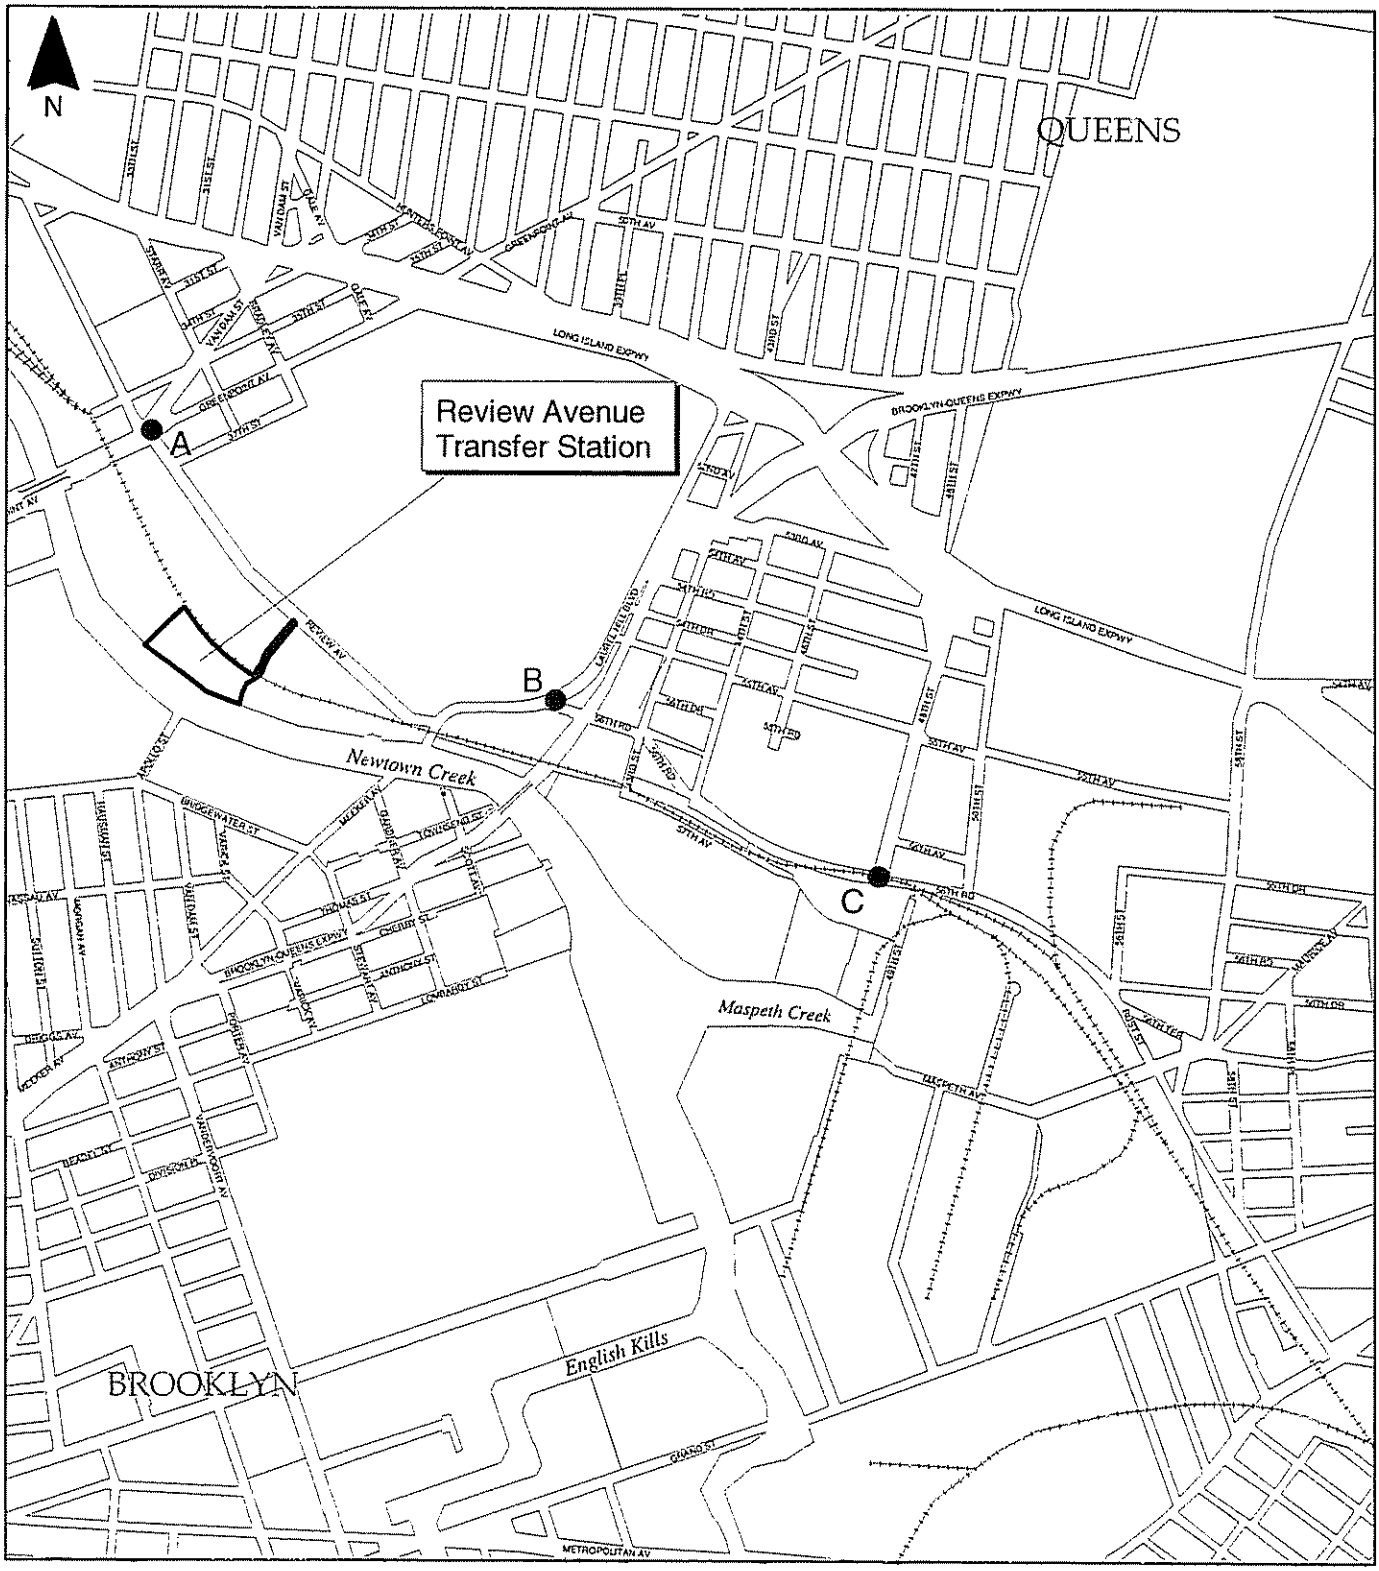
15.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the infrastructure, solid waste and sanitation services, and energy impacts.

15.14 Traffic, Parking, Transit, and Pedestrians

15.14.1 Introduction

The Review Avenue ~~Site~~ TS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles and other on-site-generated traffic in the study area. (See Section 3.16 for a discussion of CEQR analysis thresholds.)



15.14.2 Existing Conditions

15.14.2.1 Definition of Study Area

The traffic analysis study area is broad and includes the Greenpoint and Maspeth neighborhoods of Brooklyn and Queens, respectively. It includes the corridor along Review Avenue, Laurel Hill Boulevard, and 56th Road that is bounded by Greenpoint Avenue on the west and 48th Street on the east. The traffic study area is predominantly light industrial in nature. There are no CEQR-defined areas of concern located within the study area. Figure 15.14-1 shows the locations of the intersections selected for analysis (locations A through C). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicles routing to the site included highway access points more than ½-mile away in conjunction with local truck routes. Eastbound and southbound collection vehicles would approach the site along the BQE and Greenpoint Avenue and turn eastbound onto Review Avenue. Westbound collection vehicles would approach from the east via 56th Road, which turns into Laurel Hill Boulevard and then into Review Avenue.

~~The site is currently permitted to handle 558 tpd of solid waste and 400 tpd of recyclable materials as a truck transfer facility. Waste is exported from the site via transfer trailer. The site currently accepts up to 934 tpd of DSNY managed Waste under Interim Export.~~

Site delineations and study area boundaries are approximate.

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

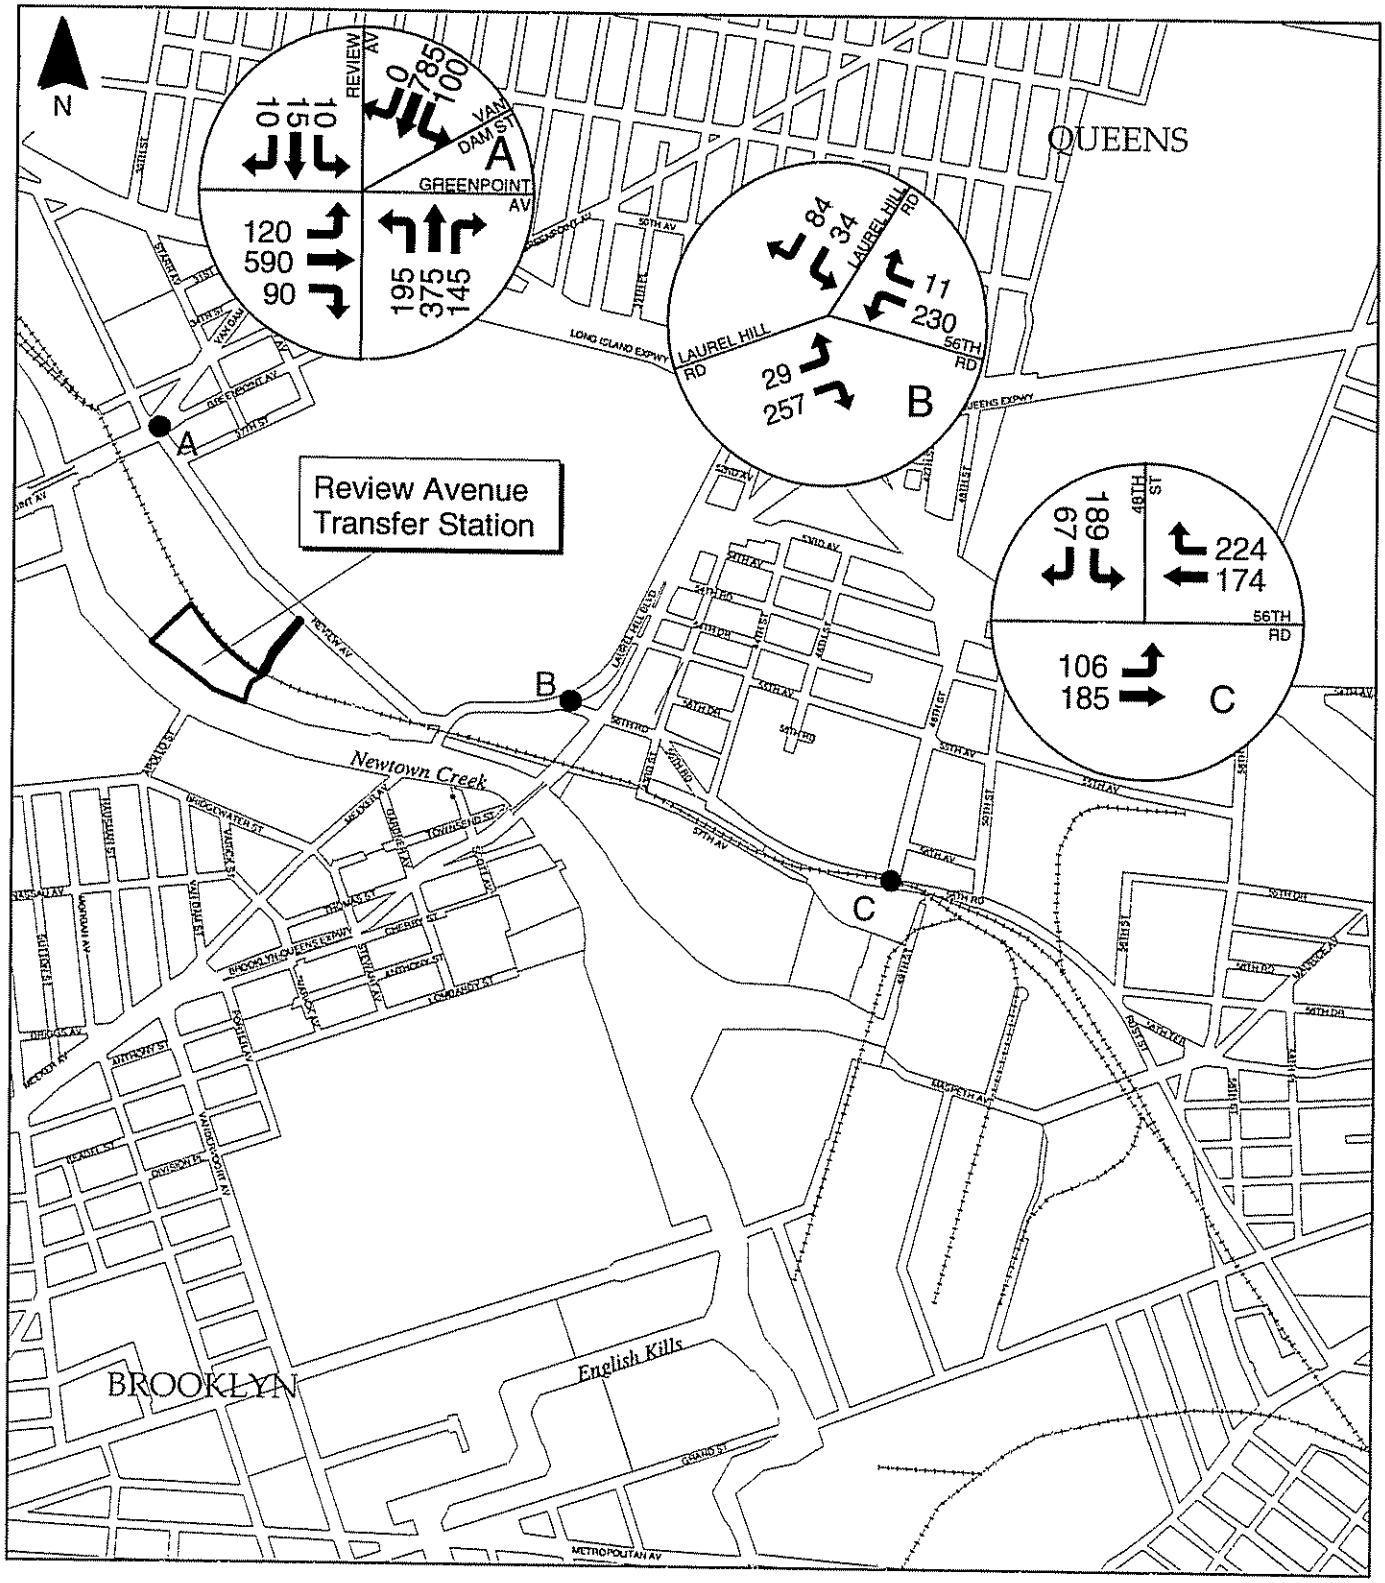
15.14.2.2 Surface Network

Two major highways, the predominantly east-west LIE and the predominantly north-south BQE, service the traffic analysis study area. 48th Street and Greenpoint Avenue are local truck routes that provide access from the north of the site. Laurel Hill Boulevard and 56th Road are local truck routes that provide access from south of the site. Review Avenue is a local truck route that provides access to the site from the west. Maps showing all major truck routes and local truck routes in Brooklyn and Queens are provided in Section 3.16 (see Figures 3.16-3 and 3.16-5).

Greenpoint Avenue (and Van Dam Street in Queens) is a principal arterial that provides access to the LIE. Review Avenue, Laurel Hill Boulevard, and 56th Road are minor arterials and designated truck routes that service the industrial areas adjacent to Newtown Creek. 48th Street is a collector that provides access from 56th Road to points north in Queens.

DSNY and other agency collection vehicles approaching the Review Avenue TS from the LIE would exit at Greenpoint Avenue and proceed to Review Avenue to access the facility. Other collection vehicles approaching the TS follow Van Dam Street and Greenpoint Avenue to Review Avenue. DSNY and other agency vehicles traveling to the Review Avenue TS from the west use 48th Street to access 56th Road. Collection vehicles follow 56th Road west, which turns into Laurel Hill Boulevard and then Review Avenue. All inbound DSNY and other agency collection vehicles converge at the intersection of the facility entrance and Review Avenue. At this intersection, all vehicles would proceed south into the TS. Exiting vehicles would follow the same truck routes back to their respective CDs.

Dray vehicles transporting waste containers to and from the Review Avenue TS would travel to and from the facility along Review Avenue, Laurel Hill Boulevard, and 56th Road between Maspeth Avenue and the facility entrance.



15.14.2.3 Existing Traffic Operations

The three intersections listed below were identified for analysis because they are the most likely to be impacted by the Review Avenue TS. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Greenpoint Avenue and Review Avenue and Van Dam Street – Signalized Intersection (see Figure 15.14-1 – location A)
- Laurel Hill Boulevard and 56th Road – Unignalized Intersection (see Figure 15.14-1 – location B)
- 48th Street and 56th Road – Signalized Intersection (see Figure 15.14-1 – location C)

Greenpoint Avenue (and Van Dam Street in Queens) is a principal arterial that provides access to the LIE. Review Avenue, Laurel Hill Boulevard, and 56th Road are minor arterials that service the industrial areas adjacent to Newtown Creek. 48th Street is a collector that provides access to 56th Road from points north.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between February 4 and February 6, 2003 and on June 10, 2004, while ATR counts were conducted between February 3 and February 7, 2003 and between June 9 and June 16, 2004. Figures 15.14-2, 15.14-3 and 15.14-4 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 8:00 a.m. and 9:00 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 4:45 p.m. and 5:45 p.m. Table 15.14-1 presents the v/c ratio, delay and LOS for the three intersections during the AM, Facility, and PM peaks.

NB = northbound
SB = southbound
EB = eastbound
WB = westbound
LT = left through movement
L = left movement
TR = through right movement
T = through movement

Existing truck traffic through most of the intersections was relatively high. The percentages of trucks increase steadily during the morning hours, remaining between 25% and 30% during mid-day hours, then decreases to 17% or lower during the PM peak hours.

15.14.2.3.1 LOS at Signalized Intersections

Table 15.14-1 shows that the signalized intersections generally operated at an overall LOS of B or C with the following exception. At the intersection of Greenpoint Avenue, Review Avenue, and Van Dam Street during the AM peak hour, the eastbound approach operated at LOS D. During the PM peak, the westbound approach operates at LOS E.

15.14.2.3.2 LOS at Unsignalized Intersections

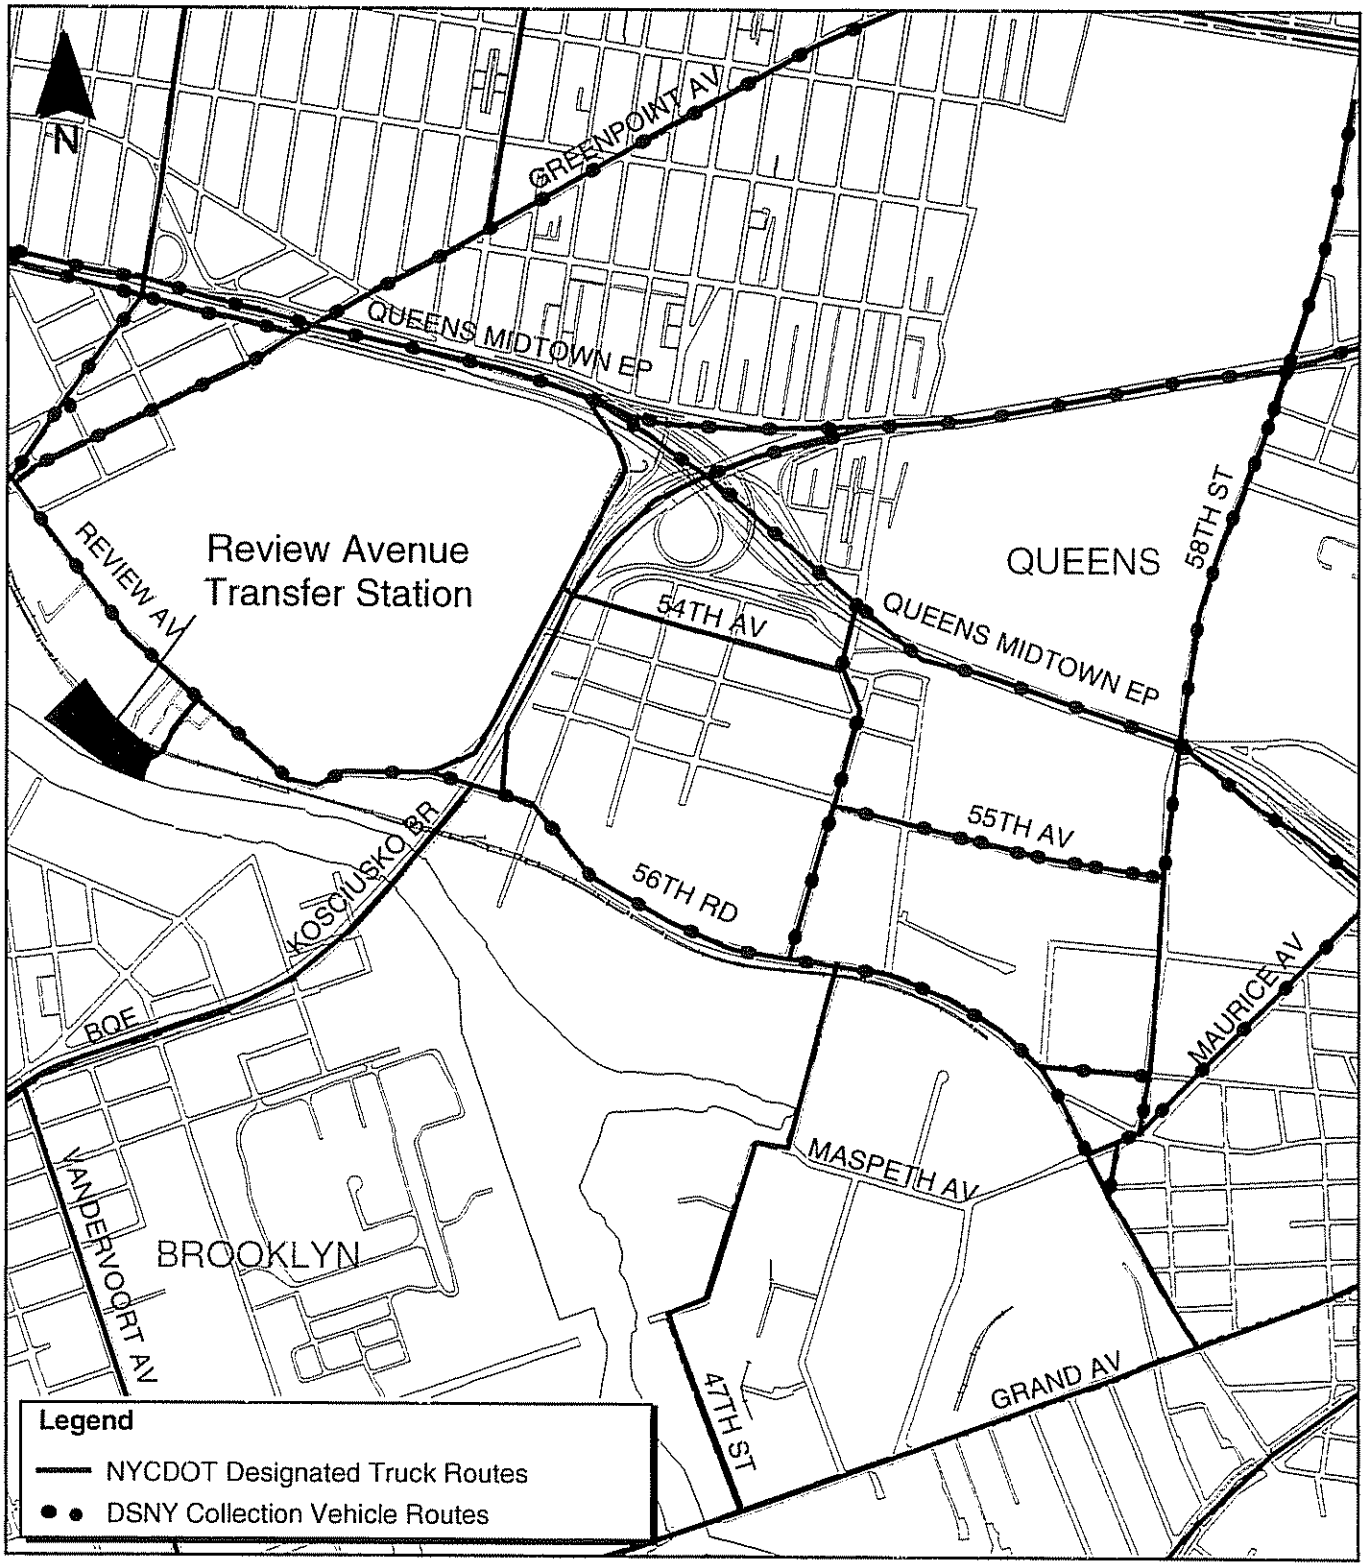

Table 15.14-1 shows that the unsignalized intersection generally operated at an overall LOS of B or C with the following exceptions. During the PM peak hour at the intersection of Laurel Hill Boulevard and 56th Road, the westbound approach operated at LOS D.

15.14.2.4 Existing DSNY-Related Traffic

The privately owned Waste Management Review transfer facility, located on Review Avenue in the West Maspeth section of Queens, currently accepts waste from Queens CDs 2, 3, 4, 5, 6 and 14 under the Interim Export Program. The existing DSNY-related traffic in the vicinity of the existing Review Avenue TS is generated by the Review Avenue facility. Within the study area, DSNY-related traffic is primarily routed along Greenpoint Avenue, Review Avenue and Van Dam Street. The NYCDOT designated truck routes in the area are presented in Figure 15.14-5.

15.14.2.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The "Greenpoint Avenue" stop on the MTA's "G" subway line is located approximately one mile southwest of the site at the Greenpoint Avenue/Manhattan Avenue intersection. The MTA operates one bus line, B24, along Greenpoint Avenue. A bus stop is located at the Greenpoint Avenue/Review Avenue/Van Dam Street intersection and scheduled stops occur at various times during the day.

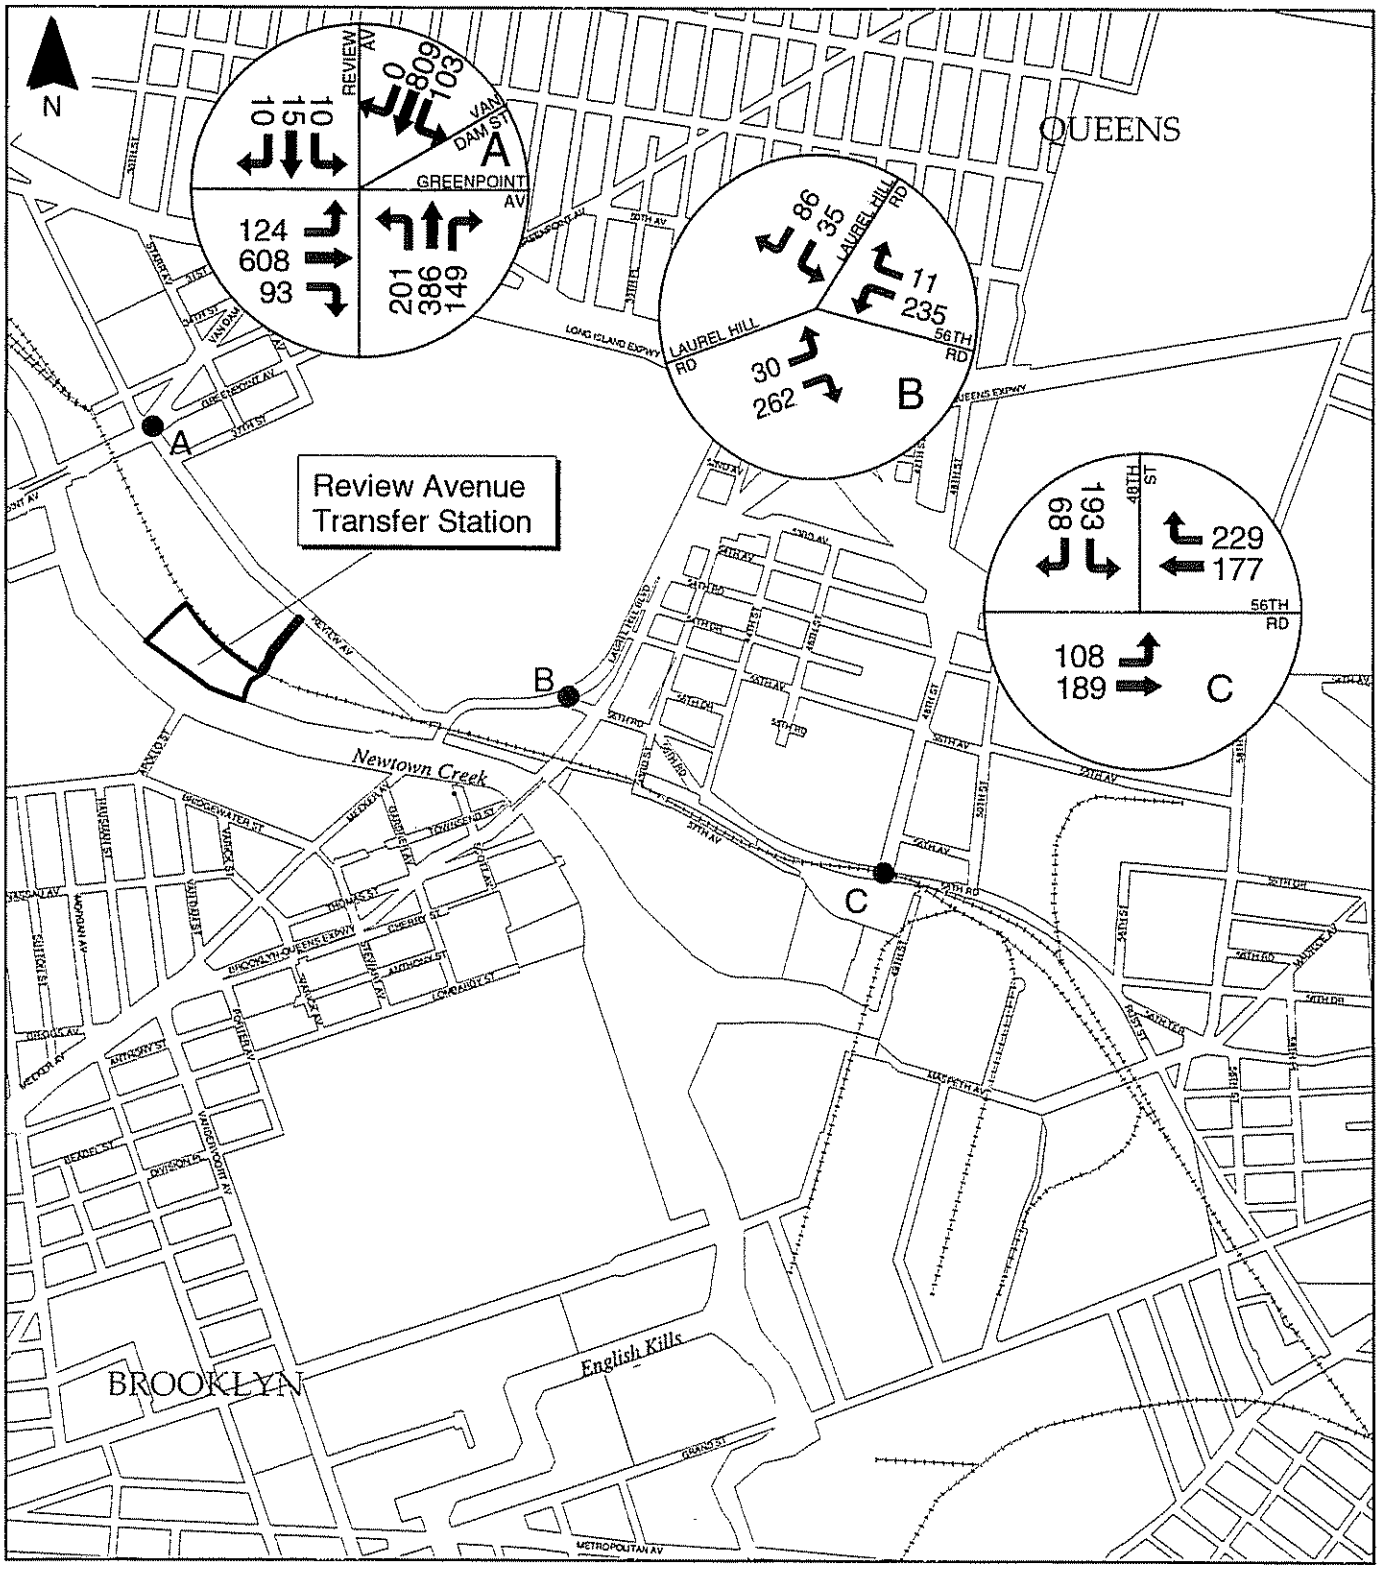
THE CITY OF NEW YORK DEPARTMENT OF SANITATION

15.14.2.6 Pedestrian Activity

Pedestrian activity is generally low within the study area. Striped crosswalks and pedestrian signals are provided at all signalized study intersections. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.



15.14.3 Future No-Build Conditions

15.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 100 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes in the study area.

Figures 15.14-6, 15.14-7 and 15.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 15.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, signalized intersections experienced relatively small increases in delay (less than 5 seconds) and are projected to remain at their Existing Condition LOS, with the following exceptions:

- During the AM peak hour, the delay of the eastbound approach at the intersection of Greenpoint Avenue and Review Avenue and Van Dam Street increased from 36.9 to 51.2 seconds (LOS D in both cases).
- During the PM peak hour, the eastbound and westbound approaches at the Greenpoint Avenue and Review Avenue and Van Dam Street intersection experienced an increase in delay (29.7 to 37.4 seconds, and 57.3 to 75.6 seconds, respectively). Also, the overall intersection delay increased from 34.5 to 44.3 (LOS C to LOS D).

~~Because analysis of traffic impacts was not required for the Review Avenue Site, as discussed in Sections 15.14.4, 15.14.5 and 15.14.6, Future No-Build Conditions were not estimated.~~

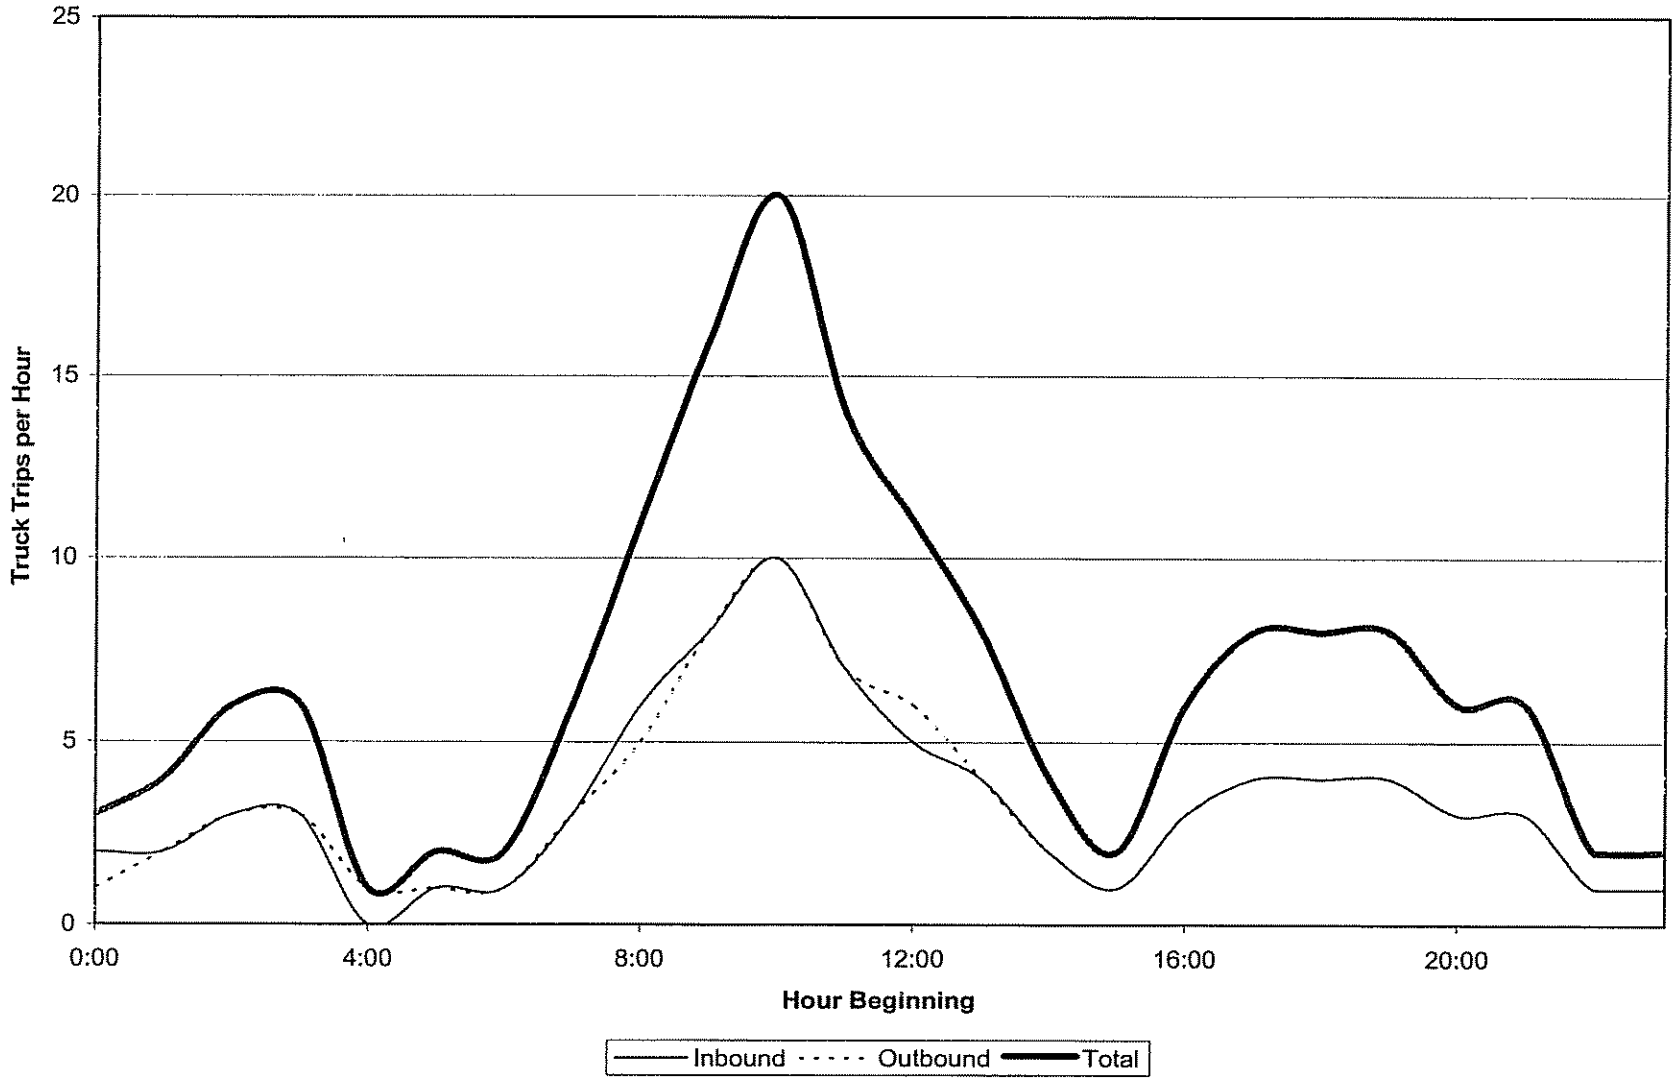
15.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

15.14.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions

15.14.4 Potential Impacts with the Review Avenue Truck to Barge TS



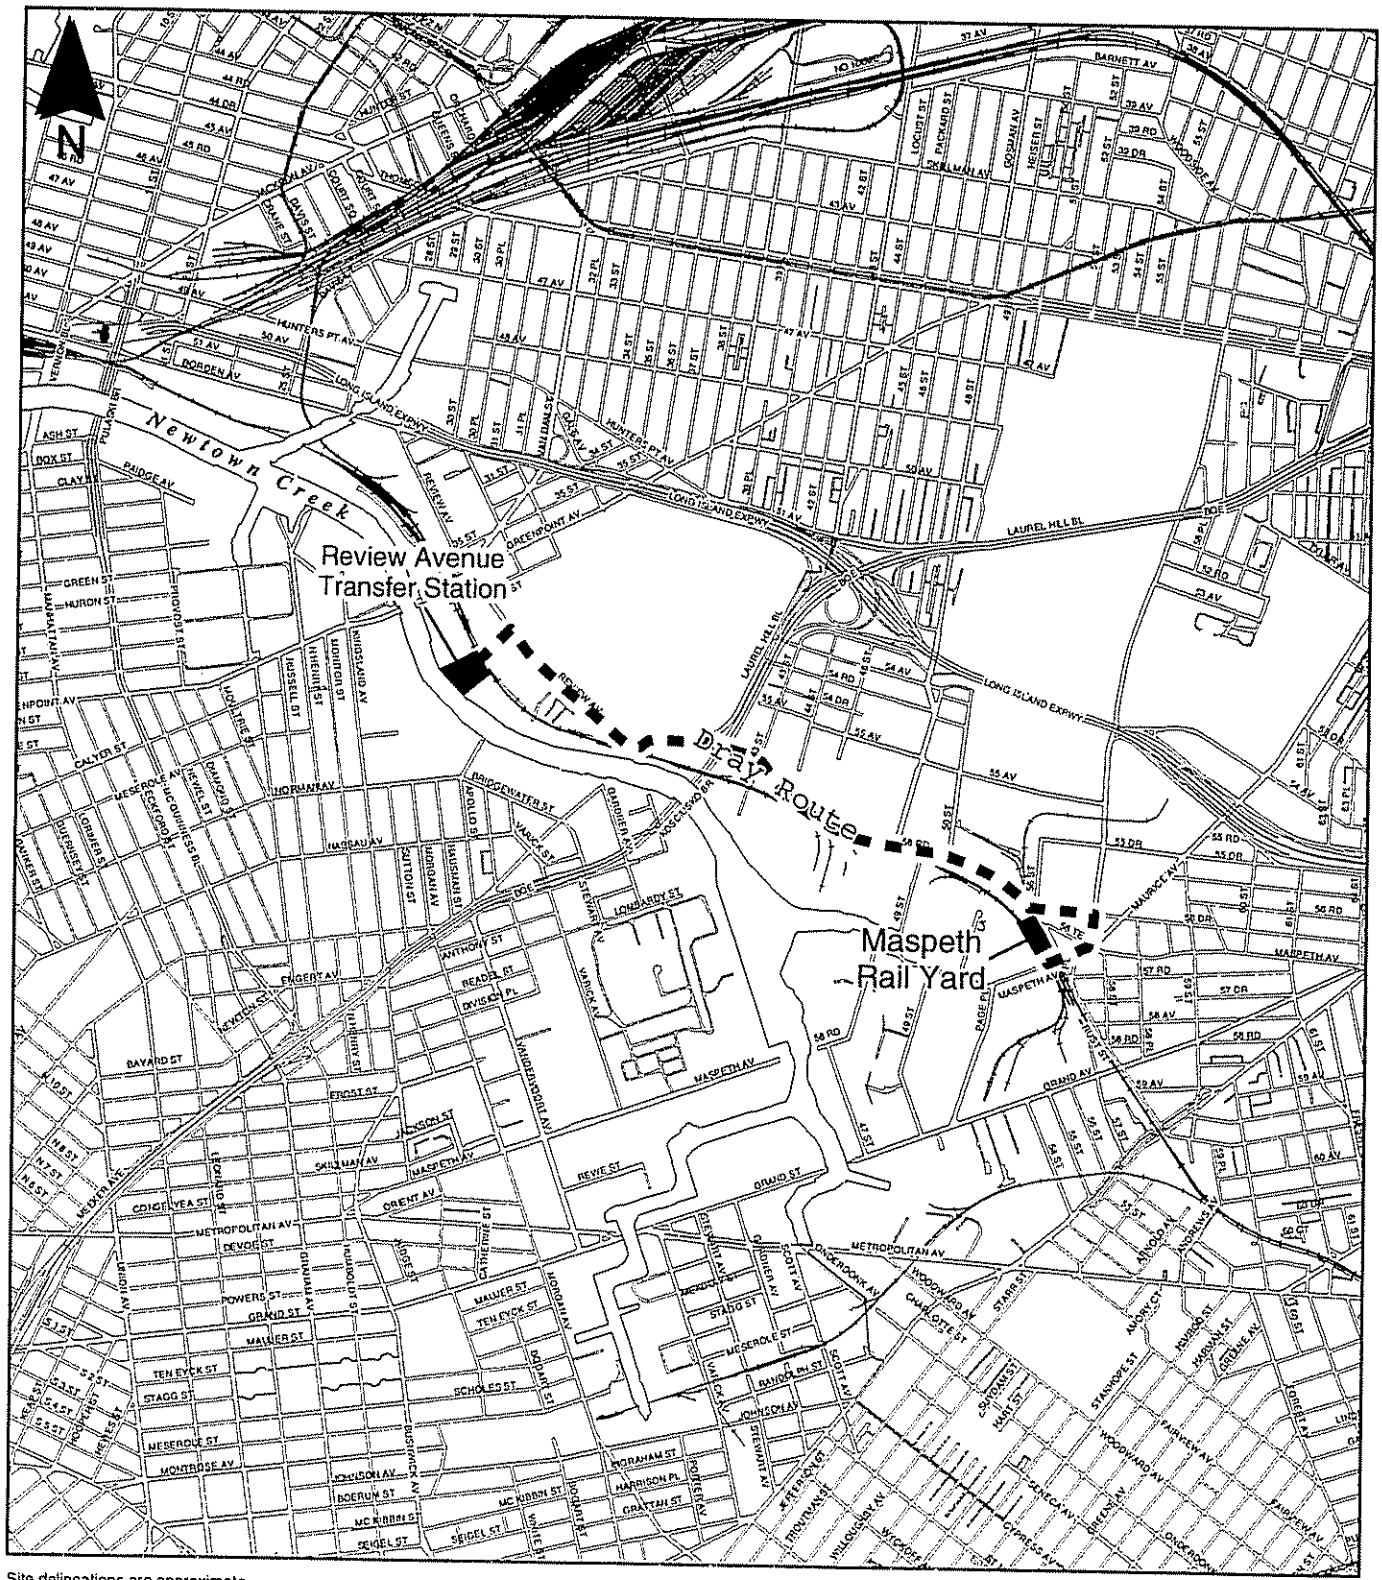
The Review Avenue Truck to Barge TS would receive waste from Queens CDs 1 through 6, (approximately 1,464 tons on an average peak day). The assumed 24-hour truck distribution to the Review Avenue TS Truck to Barge TS is depicted in Figure 15.14-9~~1~~. The assumed DSNY and other agency collection vehicle routes are depicted in Figure 15.14-5~~2~~.

Peak hour traffic generation for this facility is expected to be 30 PCEs, which falls below the CEQR screening threshold of 50 trip ends per hour. (See Table 3.16-2 in Section 3.16 for a listing of peak hour trip ends by facility.) Additionally, transfer trailer trips currently generated by the facility would be eliminated. Therefore, no additional traffic analysis is required at this site for this option.

15.14.5 Potential Impacts with the Review Avenue Truck to Rail TS

The Review Avenue TS would potentially receive waste from Queens (CDs 1, 2, 3, 4, 5 and 6). Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. The Review Avenue TS would also generate new trips from dray trucks transporting waste containers to and from the Maspeth Railyard located by the intersection of 56th Road, Rust Road, and Maspeth Avenue. Additionally, employee trips to and from the site may result in traffic impacts during the AM peak hour.

Figure 15.14-~~9~~1
Truck Trips per Hour
Review Avenue Truck to Barge ~~Rail~~ TS



15.14.5.1 2006 Future Build Traffic Conditions

2006 Future Build Conditions assume that the Review Avenue TS would generate 81 net inbound collection vehicles per average peak day. The facility would also generate 144 inbound dray truck trips per day transporting waste containers to the facility from the Maspeth Railyard. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site or the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the Review Avenue TS are shown in Figure 15.14-5. The proposed dray truck route to Maspeth Rail Yard from the Review Avenue Transfer Station is shown in Figure 15.14-10.

Figure 15.14-11 presents the average peak day temporal distribution of additional collection vehicles for the Review Avenue TS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the additional number of collection vehicles generated by the Review Avenue TS is expected to vary between approximately 2 to 18 truck trips per hour in the late evening/early morning, 18 to 42 truck trips per hour in the mid-morning/early afternoon, and 5 to 17 truck trips per hour in the late afternoon/early evening. The peak hourly net number of collection vehicle truck trips (42) occurs at approximately 10:00 a.m.

Increased employee trips generated as a result of the Review Avenue TS are expected to be about 12 per shift (6 entering and 6 departing). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Therefore, during shift changes, employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m.

Review Avenue Truck to Rail TS

ruck Trips per Hour

Because only the AM peak (8:00 a.m. to 9:00 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the Review Avenue TS during the shift change (6) were considered as part of the net increase in site-generated traffic. Figures 15.14-12, 15.14-13 and 15.14-14 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 15.14-15, 15.14-16 and 15.14-17 show the intersections analyzed with only the net increase in site generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the Review Avenue TS. These projected net increases were routed through the intersections for each of the three peak hours. The highest net increase in trucks in the ingress or egress direction was 13. The highest net increase at any one intersection was 26 trucks. Both of these net increases occurred at the intersection of Laurel Hill Boulevard and 56th Road.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 75% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 55% of weekday traffic volumes. Table 15.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Review Avenue TS would not operate on Sundays for receipt of DSNY-managed Waste. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 15.14-3
Weekday and Weekend Traffic
Review Avenue TS

DSNY and Other Agency Collection Vehicle Traffic		**Background Traffic EB and WB on Greenpoint Avenue [1]**	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday average vehicles/Day	Weekend average vehicles/Day
172	129	29,296	16,171

Note:
[1] EB and WB traffic data collected from ATR counts taken on Greenpoint Avenue between Kingsland Avenue and Monitor Street from September 11 to 17, 2003.

Table 15.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Review Avenue TS. Over an average peak day, the intersections should not experience an extended increase in delay.

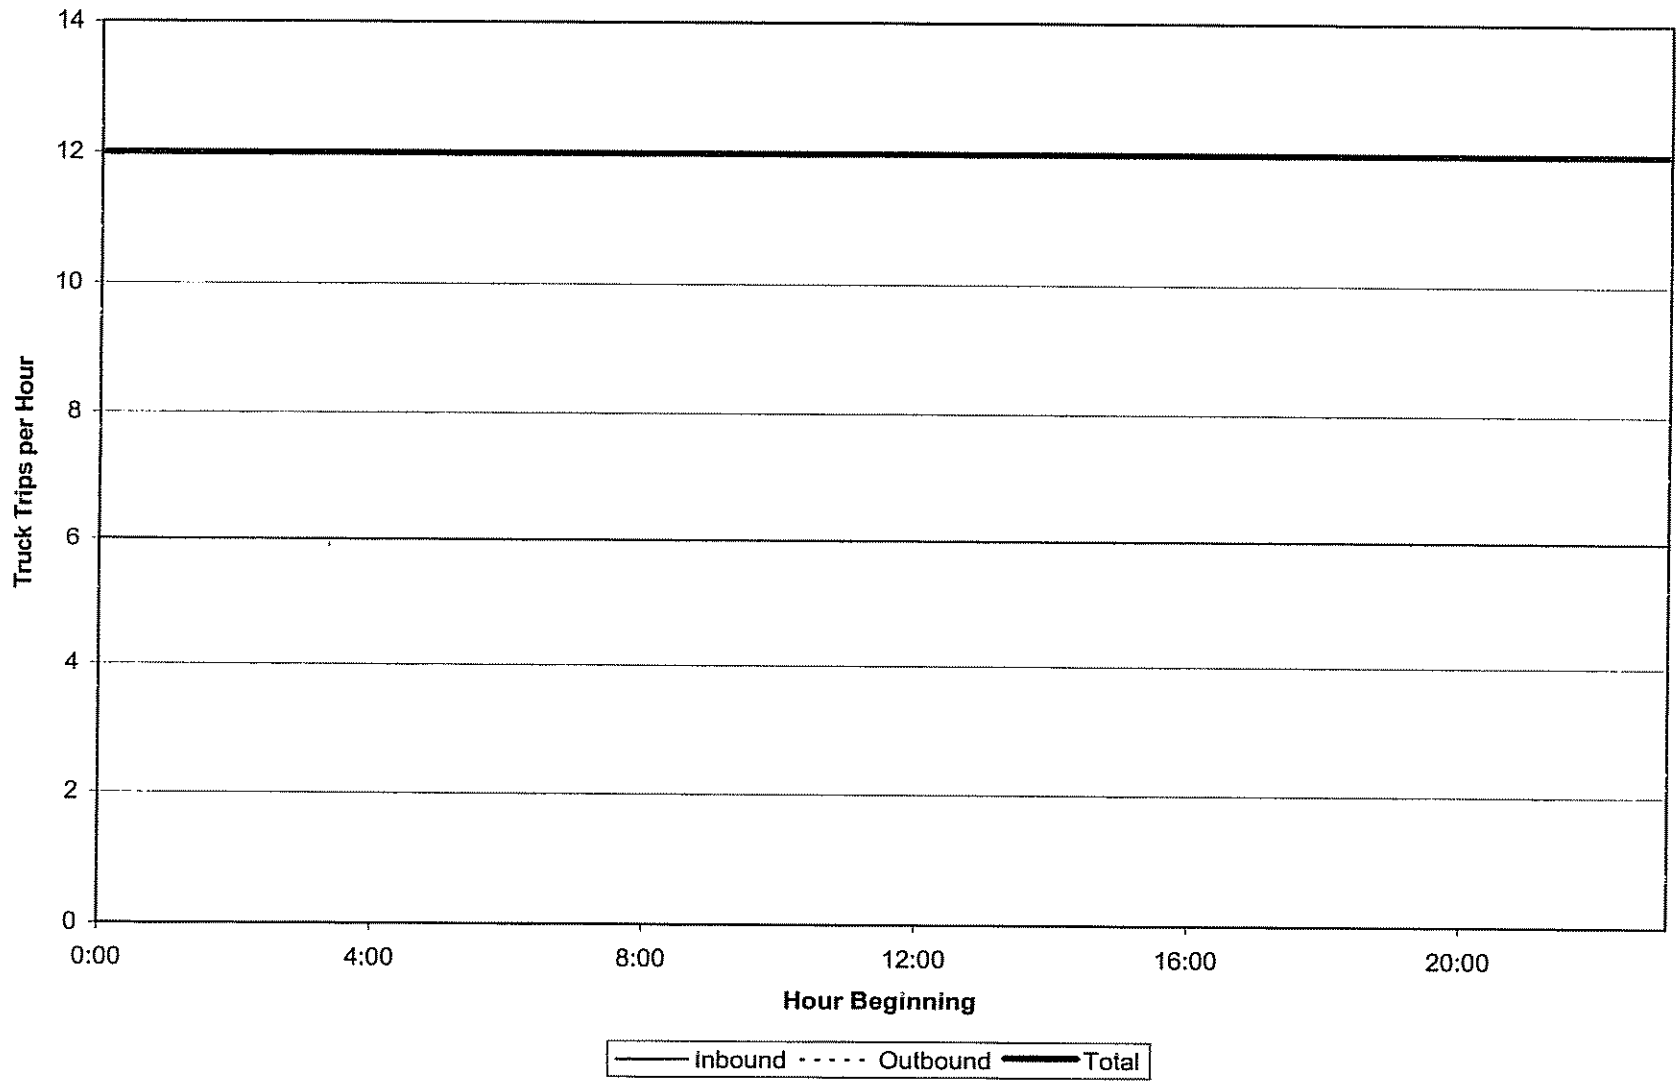
15.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

15.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.



~~The assumed 24-hour truck distribution to the Review Avenue Truck to Rail TS is depicted in Figure 15.14-3. The assumed 24-hour truck distribution included dray trucks used to transport containers between the Maspeth Rail Yard and Review Avenue Truck to Rail TS. . The assumed dray truck route to and from the Maspeth Rail Yard is depicted in Figure 15.14-4.~~

~~Peak hour traffic generation for this facility is expected to be 54 PCEs, which does not fall below the CEQR screening threshold of 50 trip ends per hour, which includes the outbound container dray trips. (See Table 3.16-2 in Section 3.16 for a listing of peak hour trip ends by facility.) However, no intersection in the study area would experience an increase of more than 45 PCEs, which falls below the CEQR screening threshold. The 2000 SWMP FEIS also contained an analysis of 56 peak trips per hour, with no unmitigatible significant adverse environmental impacts. Finally, an inspection of the intersections within the study area did not indicate that significant increases in delay would result from the addition of less than 50 PCEs, based on the type of traffic control and characteristics of the intersecting streets. Therefore, no additional traffic analysis is required at this site for this option.~~

15.14.5~~6~~ Potential Impacts with the Maspeth Rail Yard

Dray trucks would transport containers filled with waste to the Maspeth Rail Yard from the Review Avenue Truck to Rail TS and deliver empty containers from the Maspeth Rail Yard to the Review Avenue Truck to Rail TS. The Maspeth Rail Yard would receive an average of 1,200 tpd (or approximately 1,440 tpd with a 20% contingency) of containerized waste. The assumed 24-hour truck distribution to the Maspeth Rail Yard is depicted in Figure 15.14-5~~1~~8. The assumed dray truck route to and from the Maspeth Rail Yard is depicted in Figure 15.14-4-10 (shown earlier). Peak hour traffic generation for this facility is expected to be 24 PCEs, which falls below the CEQR screening threshold of 50 trip ends per hour. (See Table 3.16-2 in Section 3.16 for a listing of peak hour trip ends by facility.) Therefore, no additional traffic analysis is required at this site for this option.

Figure 15.14-~~5~~18
Truck Trips per Hour
Maspeth~~Review~~ Rail Yard ~~Truck to Rail TS~~

15.15 Air Quality

The 2000 SWMP FEIS evaluated this facility as a truck-to-barge and truck-to-rail operation and included an assessment of the on- and off-site air quality impacts, except for the analysis of $PM_{2.5}$.

15.15.1 Definition of Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Review Avenue Truck to Barge TS and Truck to Rail TS. The study area for the off-site air quality analysis is defined as the area or intersection listed in Section 15.15.5.2.

15.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 15.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

15.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build Conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

Table 15.15-1
Representative Ambient Air Quality Data
Review Avenue Truck to Barge TS and Review Avenue Truck to Rail TS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO	MTA, Flatbush Avenue Between Tillary Street and Johnson Avenue	8-Hour	3,436 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	4,695 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	College Point Post Office	Annual	56 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}	Greenpoint	Annual	23 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	51 $\mu g/m^3$	150 $\mu g/m^3$

		24-Hour	84 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	18 $\mu g/m^3$	80 $\mu g/m^3$

Notes:
Source: NYCDEP, April 2003 & USEPA Air data – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.
(2) Values are the highest pollutant levels recorded during the 1999 calendar year.

15.15.4 Potential Impacts with the Review Avenue Truck to Barge TS

15.15.4.1 On-Site Emissions

Based on the 2000 SWMP FEIS, at 1,200 tpd, the potential impacts from the operation of the Review Avenue Truck to Barge TS were estimated for criteria pollutants and found to be within applicable standards and guidelines, impacts under the Truck to Rail TS would also be within standards and guidelines, so an analysis of this facility would likewise not result in a finding of significant impacts.

15.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be operating during the peak hour and in an average hour are provided in Table 15.15-2. Figure 15.15.1 shows the locations of these sources within the site.

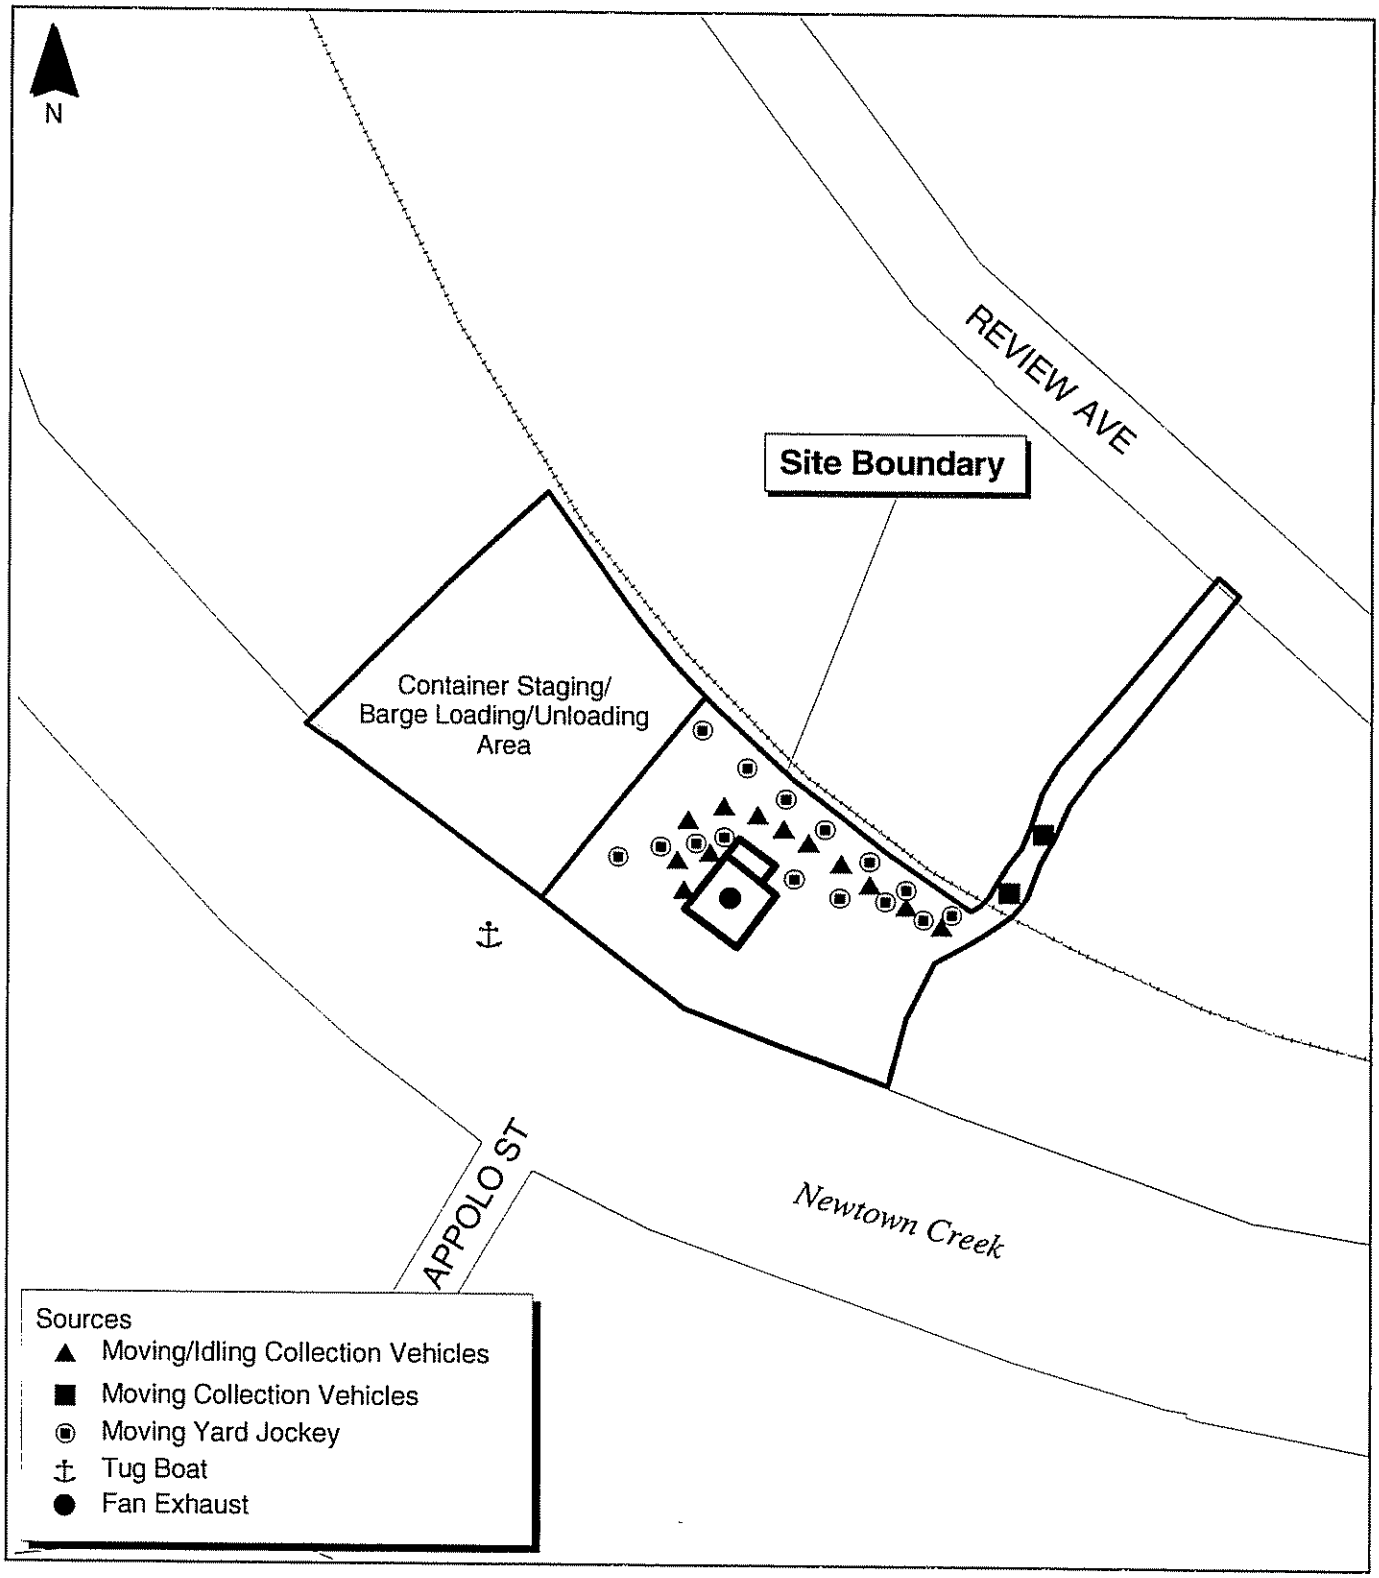

Table 15.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
Review Avenue Truck to Barge TS

Type of Emission Source	Maximum Number of Sources Operated During a Single Peak Hour	Number of Sources Operated During Annual Average Hour
Within Processing Building		
Moving/Queuing Collection Vehicles [2]	15	5
Wheel Loaders	1	1
Track Loaders	1	1
Grapples	1	1
Moving Street Sweepers	1	1
Outside Processing Building		
Moving/Queuing Collection Vehicles [2]	15	5
Moving Yard Jockey	6	3
Stick Crane	1	1
Container Handler	1	1
Tug Boat	1	1

Notes:
(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~to be provided upon request.
(2) Peak 24-hour average number of moving collection vehicles: 6.
Peak 24-hour and annual average number of queuing collection vehicles: 3.

15.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any one of the receptor sites considered are provided in 2000 SWMP FEIS. These values are compared with the applicable standards for the appropriate averaging time periods. $PM_{2.5}$ results are presented in Table 15.15-3. Based on the results presented in Table 15.15-3 and 2000 SWMP FEIS, operations proposed at this facility would not adversely impact air quality in the area. The total predicted concentrations (including appropriate background concentrations) are below the national and state ambient air quality standards.

Site delineations are approximate

(3) Incremental Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

15.15.5 Potential Impacts with the Review Avenue Truck to Rail TS

15.15.5.1 On-Site Emissions

Based on 2000 SWMP FEIS, at 1,200 tpd, the potential impacts from the operation of the Review Avenue Truck to Rail TS were estimated and found to be within applicable standards and guidelines for criteria pollutants, impacts under the Truck to Rail TS would also be within standards and guidelines, so an analysis of this facility would likewise not result in a finding of significant impacts.

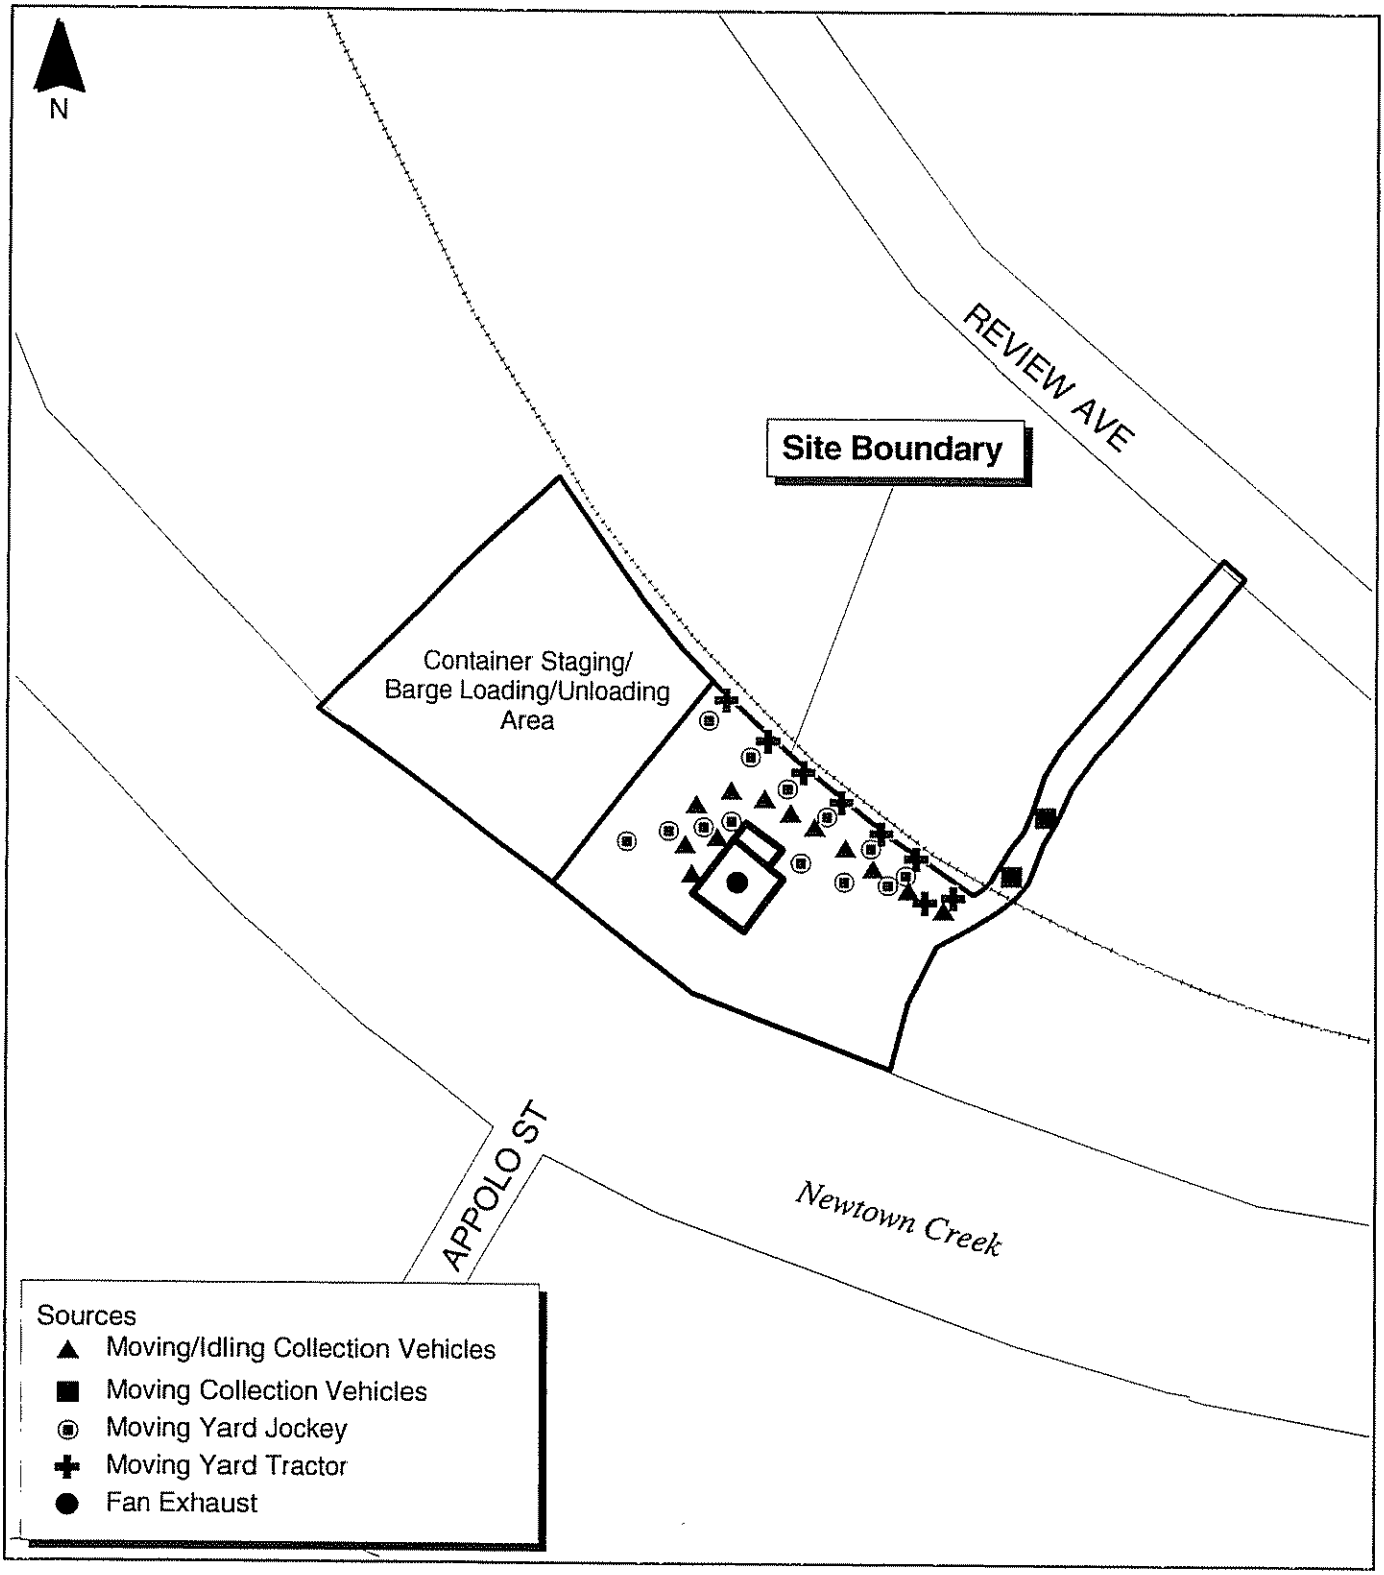
15.15.5.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be operating during the peak hour and in an average hour are provided in Table 15.15-4. Figure 15.15.2 shows the locations of these sources within the site.

Table 15.15-4

Emission Sources Considered for On-Site Air Quality Analysis[1]
Review Avenue Truck to Rail TS

Type of Emission Source	Number of Sources Operated During Peak Hour	Number of Sources Operated During Annual Average Hour
Within Processing Building		
Moving/Queuing Collection Vehicles [2]	15	5
Wheel Loaders	1	1
Track Loaders	1	1
Grapples	1	1
Moving Street Sweepers	1	1
Outside Processing Building		
Moving/Queuing Collection Vehicles [2]	15	5
Container Handler	1	1
Moving Yard Tractors	6	3
Moving Yard Jockey	6	3



Notes:
(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~to be provided upon request.
(2) ~~—~~Peak 24-hour average number of moving collection vehicles: 6.
~~—~~Peak 24-hour and annual average number of queuing collection vehicles: 3.

15.15.5.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any one of the receptor sites considered are provided in 2000 SWMP FEIS. These values are compared with the applicable standards for the appropriate averaging time periods. $PM_{2.5}$ results are presented in Table 15.15-5. Based on the results presented in Table 15.15-5 and 2000 SWMP FEIS, operations proposed at this facility would not adversely impact air quality in the area. The total predicted concentrations (including appropriate background concentrations) are below the national and state ambient air quality standards.

15.15.5.1.3 Results of the Toxic Pollutant Analysis

Based on 2000 SWMP FEIS, the potential impacts of the toxic pollutant emissions from the on-site operations of the Review Avenue Truck to Rail TS are not considered to be significant.

Site delineations are approximate

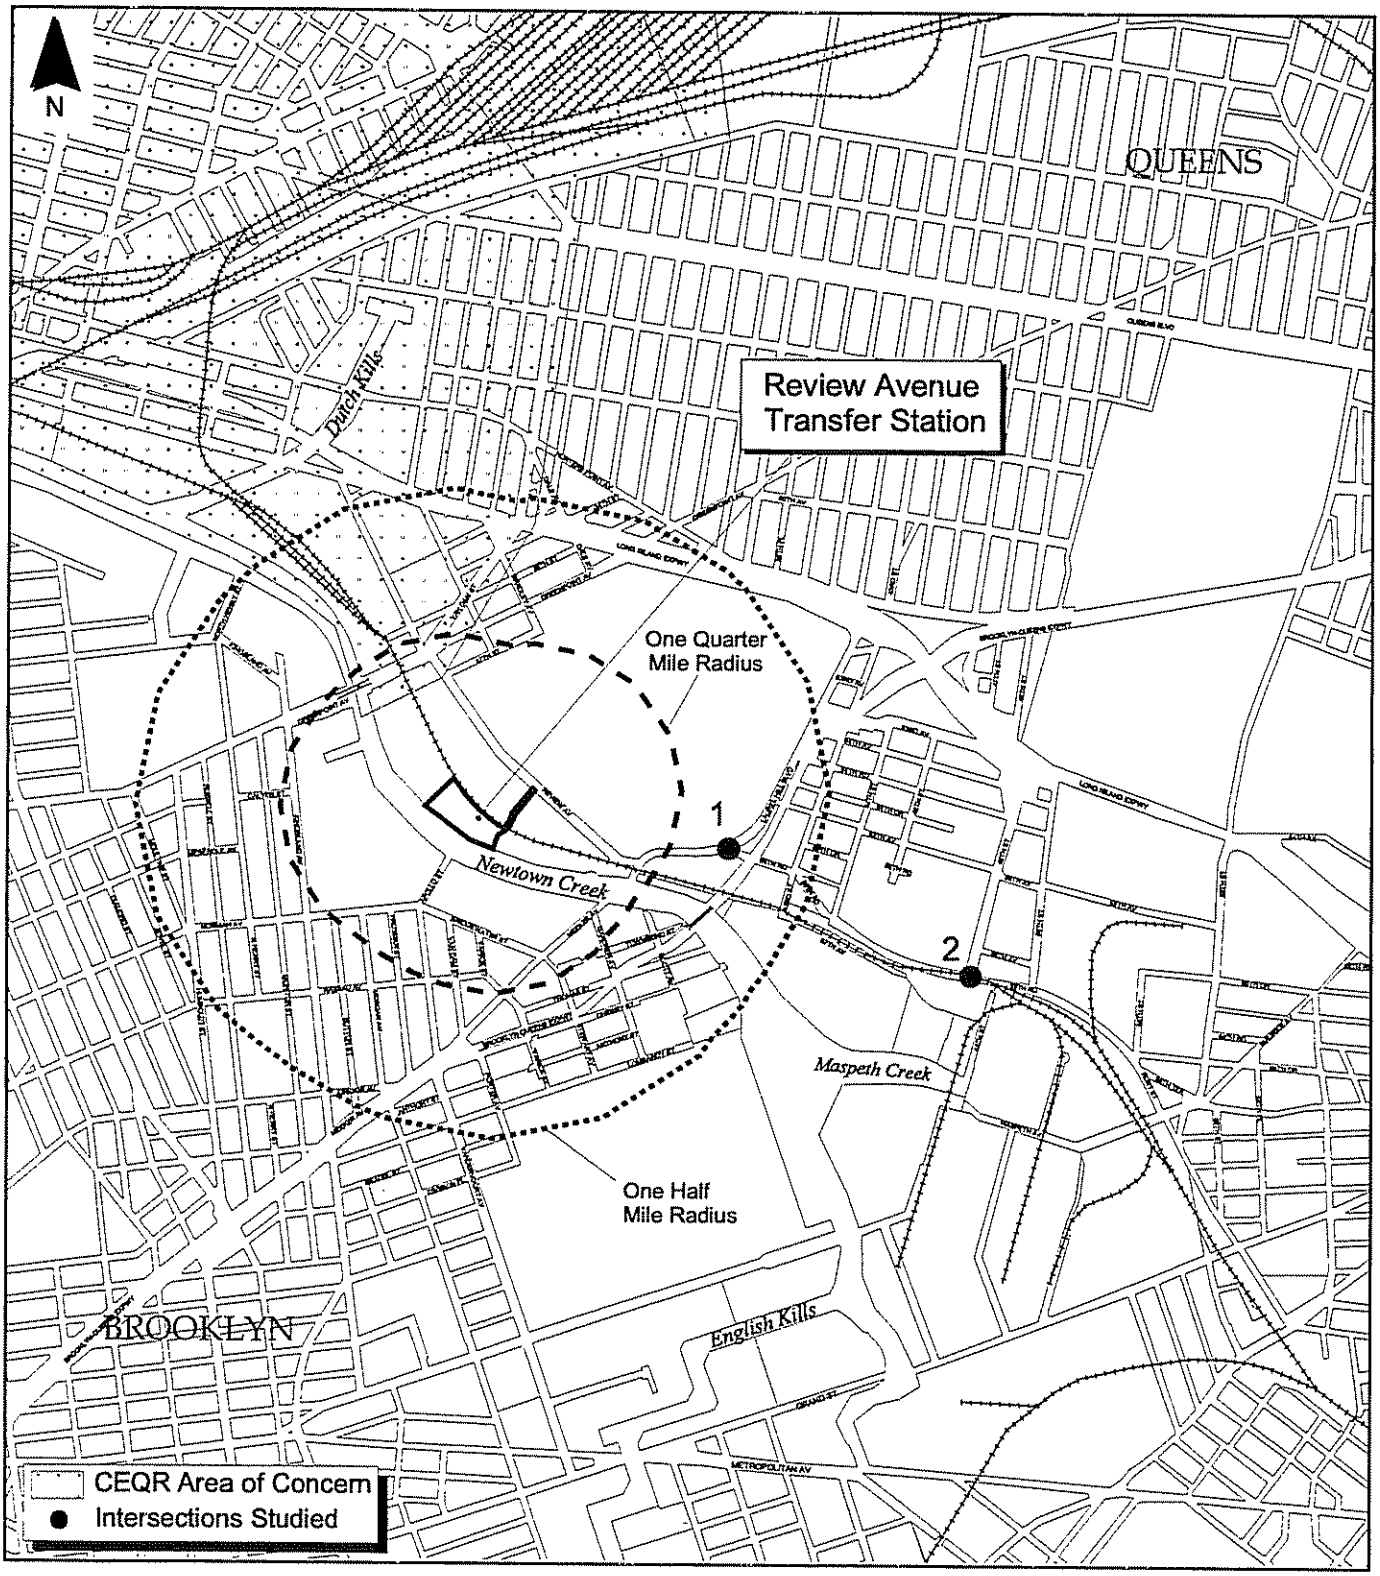
Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions
Review Avenue Truck to Rail TS

Pollutant	Averaging Time Period	Maximum Impacts from On-Site Emission Sources	STV[2]
Particulate Matter ($PM_{2.5}$), $\mu g/m^3$[3]	24-hour [1]	~~2.6~~4.3	5
	Annual Neighborhood Average	0.03	0.1

Notes:
(1) The highest estimated incremental pollutant concentrations found at any of the off-site receptor locations.
(2) Screening threshold value (STV) established by the NYCDEP and NYSDEC.
(3) Incremental a~~A~~verage $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.



15.15.5.2 Off-Site Emission Sources

15.15.5.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other collection agency's collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, mobile source analyses were conducted at the following locations for the applicable (i.e., worst-case) time periods:

- The intersections of Laurel Hill Boulevard west of the BQE and 48th Street at 56th Road to determine whether TS-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and
- The intersections of Laurel Hill Boulevard west of the BQE and 48th Street at 56th Road to determine whether TS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 15.15-3.

Site delineations and study area boundaries are approximate.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

15.15.5.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 15.15-6, are all within (less than) the applicable state and federal ambient air quality standards and STVs (for PM_{25}). The off-site operations of the Review Avenue Truck to Barge and Truck to Rail TS, therefore, are not considered to be significant.

Table 15.15-6
Estimated Pollutant Concentrations Near Selected Roadway Intersections
Review Avenue Truck to Barge and Truck to Rail TS

Air Quality Receptor Site	CO	PM_{10}		24-hr $PM_{2.5}$ Impacts			Max Annual Neighborhood $PM_{2.5}$ Impacts

Future Build Conditions	NA[5]	88	34						
Future Build Incremental				0.13	0.26	0.39	0.01	0.021	0.031
48th Street & 56th Road									
Existing Conditions	NA[5]	77	31						
Future No-Build Conditions	NA[5]	76	30						
Future Build Conditions	NA[5]	76	30						
Future Build Incremental				0.066	0.40	0.47	0.005	0.036	0.041

Notes for Table 15.15-6:

(1) PM_{10} concentrations are the maximum concentrations estimated using the AM, Facility, and PM peak traffic information plus background concentration (24-hr PM_{10} = 57 $\mu g/m^3$; Annual PM_{10} = 23 $\mu g/m^3$).

(2) The maximum incremental concentrations of the on-site emissions at the intersection considered.

(3) The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced [or Future Build] traffic only) estimated by taking the difference between the maximum $PM_{2.5}$ concentrations for the Future No-Build and Future Build scenarios at any receptor three meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.

(4) The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced [or Future Build] traffic only) estimated by taking the difference between the maximum $PM_{2.5}$ concentrations for the Future No-Build and Future Build scenarios at any receptor 15 meters from the edge of the roadways averaged over the mobile source analysis grid using AM, Facility, or PM peak traffic conditions.

NA = Not Applicable. Incremental 1-hour vehicular trips were below CEQR CO air quality screening thresholds.

ppm = parts per million

$\mu g/m^2$ = microgram per cubic meter

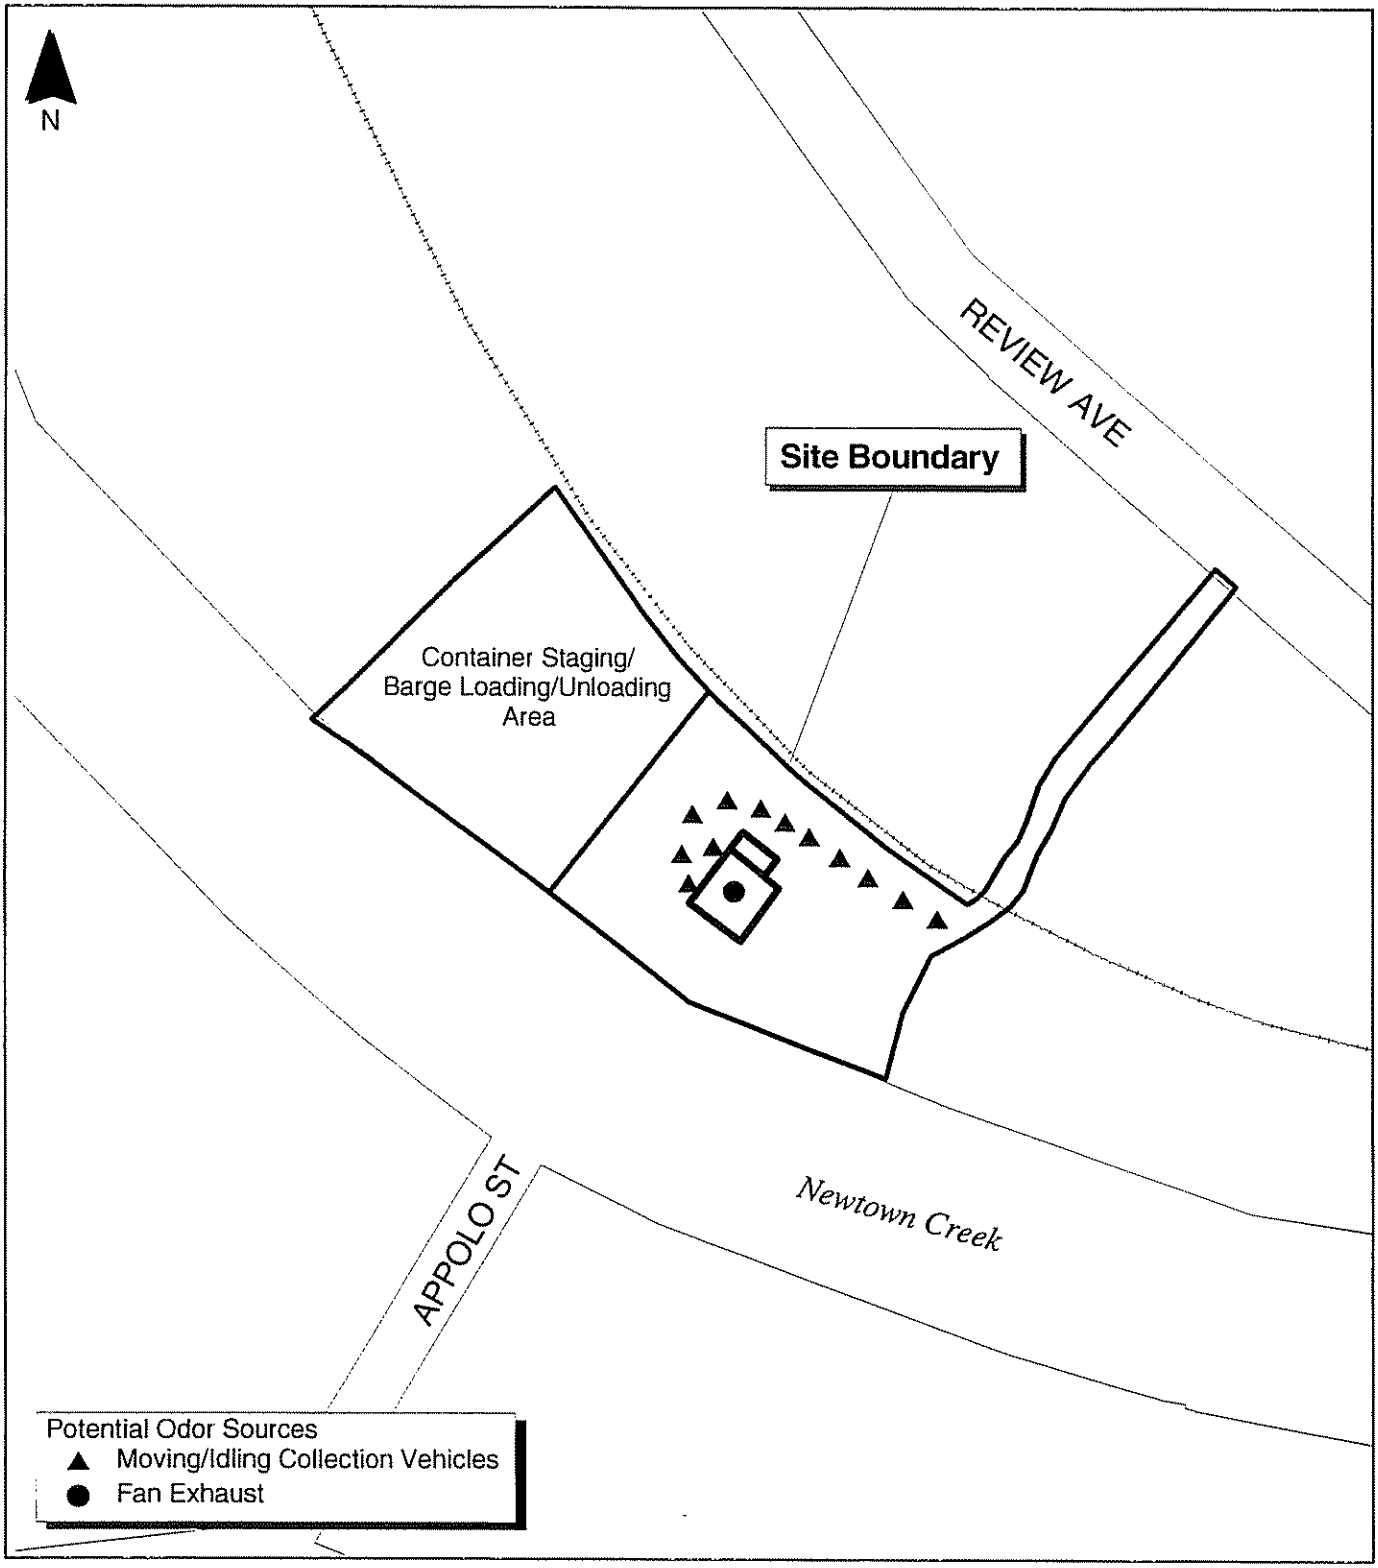
15.16 Odor

15.16.1 Existing Conditions

Although the existing Review Avenue TS is located at the site, the analyses of the Review Avenue Truck to Barge and Truck to Rail TS assume there are no existing on-site sources of odor. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is an apartment building at the intersection of Varick Street and Nassau Avenue, approximately, 312 meters (1,023) feet from the property boundary.

15.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the Review Avenue TS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



15.16.3 Potential Impacts with the Review Avenue TS~~South Bronx Converted MTS~~

15.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Review Avenue TS are provided in Table 15.16-1. The odor sources are the same for Review Avenue Truck to Barge and Truck to Rail TS. Figures 15.16-1 and 15.16-2 show the locations of these sources within the site.

Review Avenue Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Review Avenue TS.

15.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 15.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Review Avenue TS at any nearby sensitive receptor is less than 1, so odors from the Review Avenue TS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 15.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Review Avenue TS

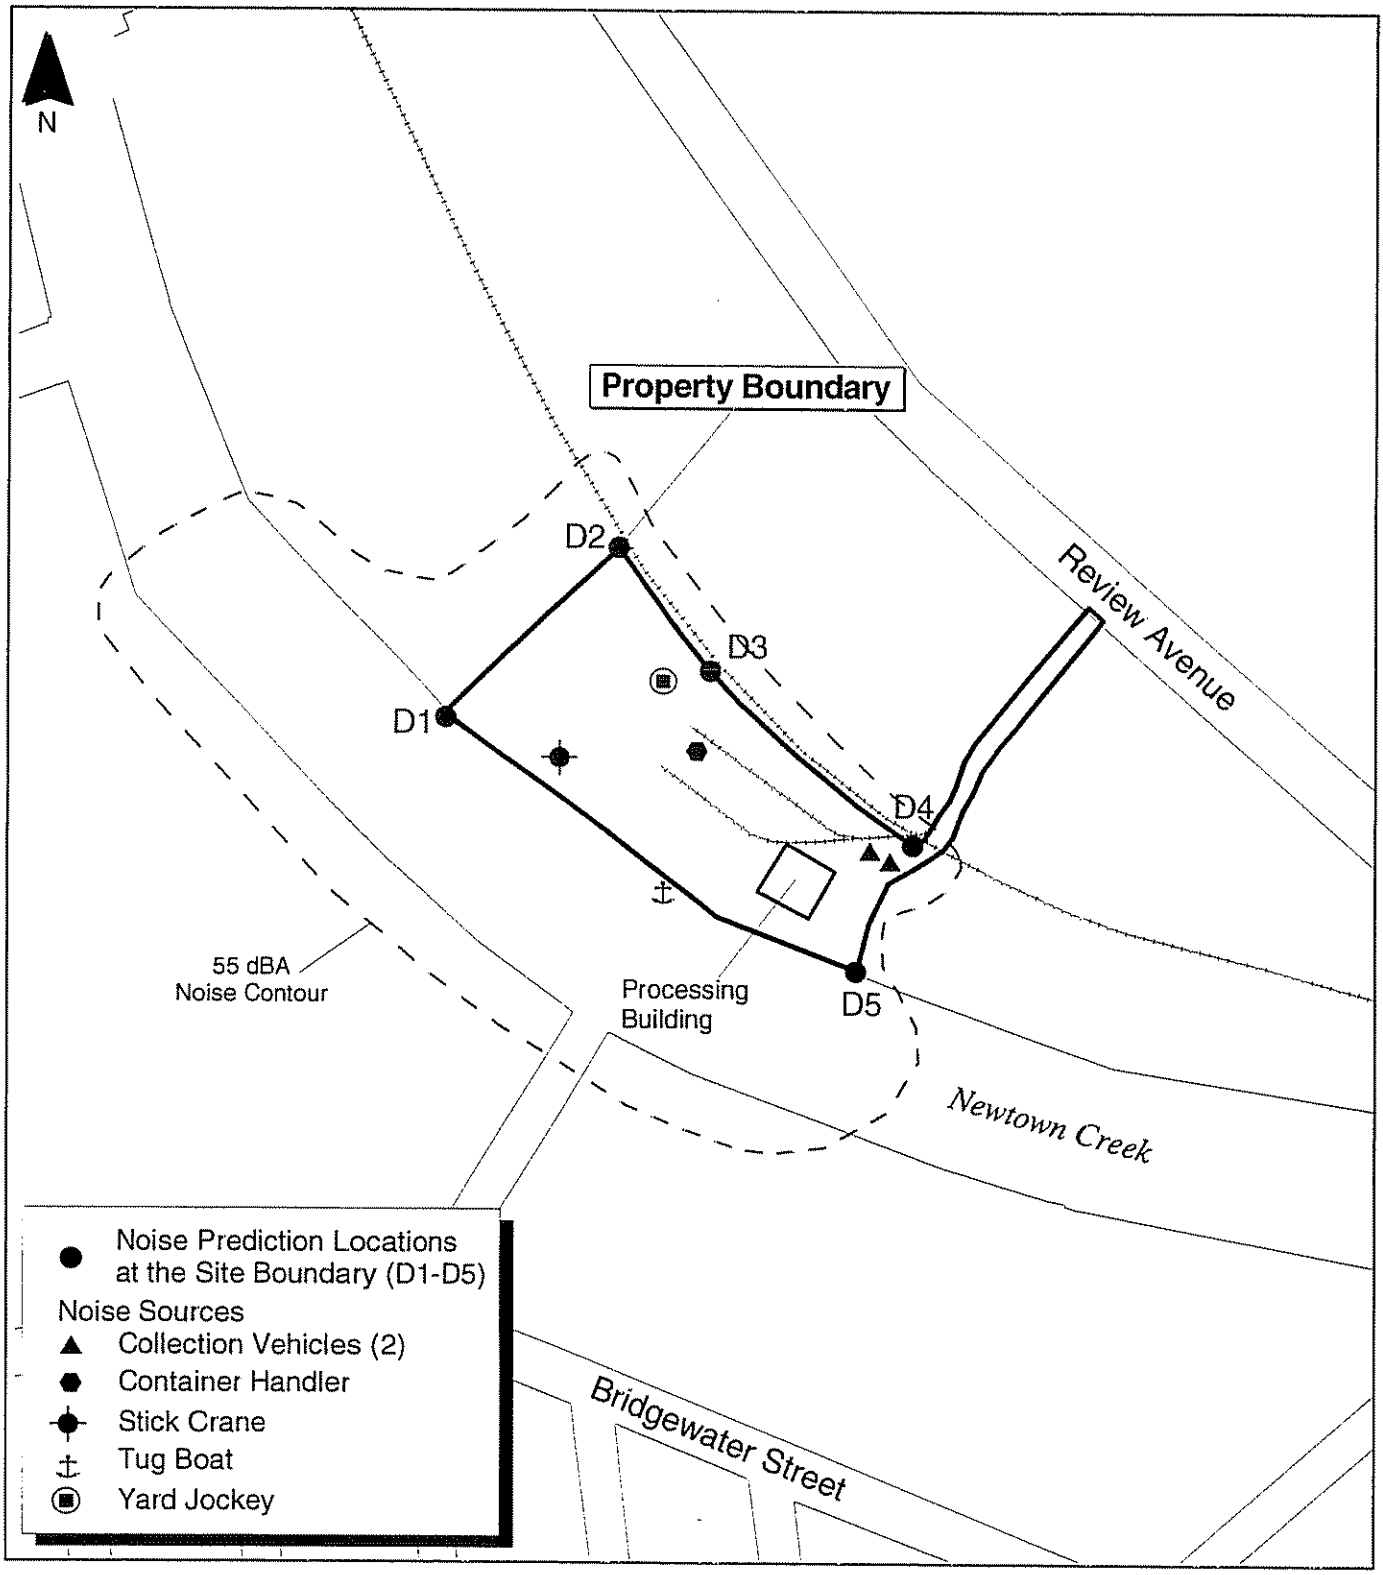
Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	0.27
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result[2]	0.03
Type of Receptor	Apartment Buildings
Distance to Receptor[3]	1,023 Feet

Notes:
(1) Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.
(2) Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.
~~(1) D/T ratio is dimensionless.~~
~~(2) Measured from the site boundary.~~
~~(3) Measured from the site property line.~~

15.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from the Review Avenue TS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for on-site and off-site sources for both the Review Avenue Truck to Barge TS option and the Review Avenue Truck ~~t~~To Rail TS option. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

15.17.1 Existing Conditions



15.17.1.1 Introduction

Figure 15.17-1 shows the location of the Review Avenue Truck to Barge TS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. Figure 15.17-2 shows the location of the Review Avenue Truck to Rail TS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is an apartment building at the intersection of Varick Street and Nassau Avenue, approximately, 312 meters (1,023) feet from the property boundary.

15.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptor. Noise monitoring data recorded hourly included: $L_{eq(1)}$, L_{min} and L_{max},[1] and the statistical metrics of L_{10}, L_{50} and L_{90}.[2]

[1] Terms $L_{eq(1)}$ L_{min} and L_{max} are defined in Section 3.19.2.
[2] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

Figure 15.17-2 Noise Sources and Receptors

Review Avenue Truck to Rail TS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Table 15.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 1:00 a.m. and 2:00 a.m. and had an $L_{eq(1)}$ of 49 dBA on March 10, 1999. Activities and events that contribute to the on-site noise levels include:

- Industrial activities across Newtown Creek and along Review Avenue;
- Train traffic on the LIRR tracks located between the Existing Review Avenue TS and Review Avenue;
- Commercial watercraft traffic on Newtown Creek; and
- Other noise sources associated with activities in the surrounding industrial areas.

15.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the Review Avenue TS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required, and therefore, off site noise monitoring was not conducted.

15.17.2 Future No-Build Conditions

15.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

15.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 15.17-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) based on the first-level screening.

Table 15.17-1
Existing Hourly (Monitored) Noise Levels On Site[1]

Location	Hour	Existing Traffic Volume [1] (Vehicles/Hour)	Future No-Build Traffic Volume [2] (Vehicles/Hour)
Greenpoint Avenue eEast of Bradley Avenue	3:00 a.m.	114	119
Van Dam Street between Star Avenue and Bradley Avenue	2:00 a.m.	87	89

Notes:
[1] Existing traffic volumes are based on ATR data
[2] Future No-Build traffic volumes are based on the CEQR annual traffic growth rates

15.17.3 Potential Impacts with the Review Avenue Truck to Barge TS

15.17.3.1 On-Site Noise Levels

Proposed equipment assumed to be operating at the Review Avenue Truck to Barge TS and its reference noise levels used in the CEQR analysis are shown in Table 15.17-3. The number and type of equipment assumed for this analysis was based on the Review Avenue Truck to Barge TS's average design capacity. Shown earlier, Figure 15.17-1 indicates the Review Avenue Truck to Barge TS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

15.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Review Avenue Truck to Barge TS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 65 meters (213 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is 312 meters (1,023 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (See Figure 15.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was not required.

Table 15.17-3
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Review Avenue Truck to Barge TS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Track Loader (1)	80.6
Overhead Crane (1)	70
Outdoor	
Yard Jockey (1)	73.8
Container Handler (1)	76.2
Stick Crane (1)	77.2
Tugboat (1)	73
Collection Vehicles (moving/idling) (2)	67

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

15.17.3.3 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Review Avenue Truck to Barge TS. The assumed DSNY and other agency collection vehicles routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, a second-level screening was not required; therefore an off-site noise analysis and off-site noise monitoring was not required. Results of the first-level screening for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) are provided in Table 15.17-4.

15.17.3.4 Combined On-Site and Off-Site Noise Levels

The on- and off-site screening analyses performed for the Review Avenue Truck to Barge TS, neither on- or off-site noise analyses were required; therefore, a combined noise analysis was not performed.

Table 15.17-4
Off-Site Noise Screening[1] Results
Review Avenue Truck to Barge TS

Location	Hour	Future No-Build PCEs[2]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicles PCEs[2][3]	Future Build PCEs[2][3]	Possible Impact[4]
Greenpoint Avenue East of Bradley Avenue	3:00 a.m.	222	4	0	188	410	No
Van Dam Street between Star Avenue and Bradley Avenue	2:00 a.m.	142	2	0	94	236	No

Notes:
(1) Based on first-level screening, since a second-level screening was not required.
(2) Total PCEs are rounded to the nearest whole number.
(3) Future Build PCEs include Review Avenue TS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted using a factor of 1.
(4) There is a possible impact if the Future Build PCEs are double the Future No Build PCEs or more.

15.17.4 Potential Impacts with the Review Avenue Truck to Rail TS

15.17.4.1 On-Site Noise Levels

Proposed equipment assumed to be operating at the Review Avenue Truck to Rail TS and its reference noise levels used in the CEQR analysis are shown in Table 15.17-5. The number and type of equipment assumed for this analysis was based on the Review Avenue Truck to Rail TS's average design capacity. Shown earlier, Figure 15.17-2 indicates the Review Avenue Truck to Rail TS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 15.17-5
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Review Avenue Truck to Rail TS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Track Loader (1)	80.6
Overhead Crane (1)	70
Yard Jockey (1)	73
Outdoor	
Container Handler (1)	76.2
Tractor (2)	80.6
Collection Vehicles (moving/idling) (2)	67

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

15.17.4.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Review Avenue Truck to Rail TS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 94 meters (307 feet) from the property line in the direction of the nearest

noise-sensitive receptor, which is 312 meters (1,023 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (see Figure 15.17-2); therefore, an on-site noise analysis, including noise monitoring, at the nearest noise-sensitive receptor, was not required.

15.17.4.3 Off-Site Noise Levels

The Review Avenue Truck to Rail TS option includes DSNY and other agency collection vehicles en route to and from the Review Avenue Truck to Rail TS, as well as trucks hauling loaded containers to the Maspeth Railyard for loading onto locomotives. Since noise-sensitive receptors are not located along the truck route from the Review Avenue Truck to Rail TS to the Maspeth Railyard, an off-site noise analysis was not required for those routes. Therefore, the off-site noise analysis for the Review Avenue Truck to Rail TS is the same as the off-site noise analysis for the Review Avenue Truck to Barge TS, which is presented in Section 15.17.3.3.

15.17.4.4 Combined On-Site and Off-Site Noise Levels

As a result of both the on- and off-site screening analyses performed for the Review Avenue Truck to Rail TS, neither the on- or the off-site noise analyses were required; therefore, a combined noise analysis was not performed.

CHAPTER 16 ENVIRONMENTAL REVIEW - COLLECTION VEHICLE TRANSPORT TO OUT-OF-CITY WASTE-TO-ENERGY FACILITIES

16.1 Introduction

The Essex County Resource Recovery Facility (RRF) is an existing permitted waste--to--energy (WTE) facility, and as such, the facility itself is not subject to environmental review in this FDEIS. It is currently utilized for Manhattan waste under Interim Export. Environmental analyses are limited to the evaluation of off-site impacts associated with vehicle traffic to the site in New Jersey, and this scenario is currently being evaluated under the Interim Export re-bid evaluation. The results of the environmental analyses of the Essex County RRF -are presented in the following sections:

16.2 Land Use, Zoning, and Public Policy
16.3 Socioeconomic Conditions
16.4 Community Facilities and Services
16.5 Open Space
16.6 Cultural Resources
16.7 Urban Design, Visual Resources, and Shadows
16.8 Neighborhood Character
16.9 Natural Resources
16.10 Hazardous Materials
16.11 Water Quality
16.12 Waterfront Revitalization Program
16.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
16.14 Traffic, Parking, Transit, and Pedestrians
16.15 Air Quality
16.16 Odor
16.17 Noise

Section 2.2.13 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

16.2 Land Use, Zoning, and Public Policy

Refer to Section 16.1 for an explanation of the analyses required for this site.

CHAPTER 17 ENVIRONMENTAL REVIEW: ~~MANHATTAN~~ BROOKLYN CURBSIDE RECYCLABLES TO 30TH STREET PIER AT SOUTH BROOKLYN MARINE TERMINAL

17.1 Introduction

The 30th Street Pier at South Brooklyn Marine Terminal (SBMT) is a complex of facilities that would be designed to receive and process DSNY Curbside Recyclables. Curbside Recyclables collected in Brooklyn would be delivered by truck to this facility. Curbside Recyclables from other boroughs would be delivered by barge. Once a design is developed, the 30th Street Pier at SBMT will be the subject of a future environmental review. The environmental review of trucking of ~~Manhattan~~Brooklyn Curbside Recyclables (~~MCR~~BCR) to the 30th Street Pier at the SBMT in this F~~D~~EIS is limited to off-site traffic, air quality and noise impacts, and impacts from the on-site waterfront construction activities that require USACE Section 10/404 permits and the NYSDEC Article 15/25 permits. ~~Pursuant to Title 6 of the NYCRR Sections 360-12.1 and 1.8 (h), the NYSDEC authorizes recycling facilities by registration – they are not subject to regulation as a solid waste facility~~. Recycling facilities are subject to regulation under NYSDEC regulation 6 NYCRR Part 360.

The results of the environmental analyses of the 30th Street Pier at SBMT are presented in the following sections:

17.2 Land Use, Zoning, and Public Policy
17.3 Socioeconomic Conditions
17.4 Community Facilities and Services
17.5 Open Space
17.6 Cultural Resources
17.7 Urban Design, Visual Resources, and Shadows
17.8 Neighborhood Character
17.9 Natural Resources
17.10 Hazardous Materials
17.11 Water Quality

17.12 Waterfront Revitalization Program

17.5 Open Space

See Section 17.1 for a description of the analysis required.

17.6 Cultural Resources

See Section 17.1 for a description of the analysis required.

17.7 Urban Design, Visual Resources, and Shadows

See Section 17.1 for a description of the analysis required.

17.8 Neighborhood Character

See Section 17.1 for a description of the analysis required.

17.9 Natural Resources

17.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from the 30th Street Pier at SBMT.

17.9.1.1 Definition of Study Area

The study area includes the site and the waterfront section that is bounded by the Gowanus Canal to the north (see Figure 2.3.1-1 in Chapter 2 of this FDEIS). The site is zoned M3-1 (heavy manufacturing) and was used for marine vessel loading and off-loading, long-term import/export cargo storage and processing, trailer inspection and repair, and office space. The upland portion of the study site is comprised of a parking lot with wrecked vehicles. The pier that extends from the site is essentially fill material with finger piers to the north and south. These finger piers were recently demolished, and now the main pier is surrounded by pile fields and debris. It is proposed that the facility be converted to a materials recovery facility (MRF) to accept and process the City's recyclables. To accomplish this, the pile field and debris must be removed; 40,000 cubic yards of dredge material must be removed from the site to accommodate the draft of working vessels; and two 400-foot-long, 60-foot-wide platforms, covering 48,000 square feet of water, will be constructed. The upland portions of the site and the surrounding neighborhood

parcels are fully developed and contain very limited terrestrial natural resources. Such resources that do exist are discussed in following sections. Because Future Build Conditions would include dredging of bottom sediments and construction of new platforms for the facility, a description of aquatic communities is included.

17.9.1.2 Geology

The borings taken for this project closest to the site were taken at the Existing Hamilton Avenue MTS, which is located northeast of the site on the Gowanus Canal. According to borings performed for the MTS Conversion Conceptual Design Report (2003), multiple strata of sediment are located beneath the Existing Hamilton Avenue MTS. The first layer, the surficial stratum, ranges in thickness from 10 to 25 feet and consists of loose fill material comprised of concrete, brick, glass, asphalt mixed with sand and gravel, and materials such as cinders, wood and vegetation.

A 10- to 20-foot-thick stratum of soft black to gray organic soil, with loose gray silty sand and loose gray poorly-graded sand with silt, underlays the fill. Shells and vegetation are also encountered in this layer. In addition, a one- to four-foot-thick layer of dark-brown-to-black peat is located in this layer.

A stratum of stiff gray silt with sand approximately 2 to 14 feet thick is located beneath most of the organic soil. A dense red-brown poorly- to well-graded sand with silt stratum 20 to 30 feet thick, with occasional gravel layers, is located beneath the silt with sand stratum.

A second stratum of silt is located beneath the sand with silt stratum. This silt stratum consists of stiff to very stiff gray silt sand layered with stiff gray lean clay. It ranges in thickness from 4 to 20 feet.

The deepest stratum encountered is a very dense red-brown poorly- to well-graded sand with silt layer with occasional layers of gravel. The thickness of the stratum is undetermined.

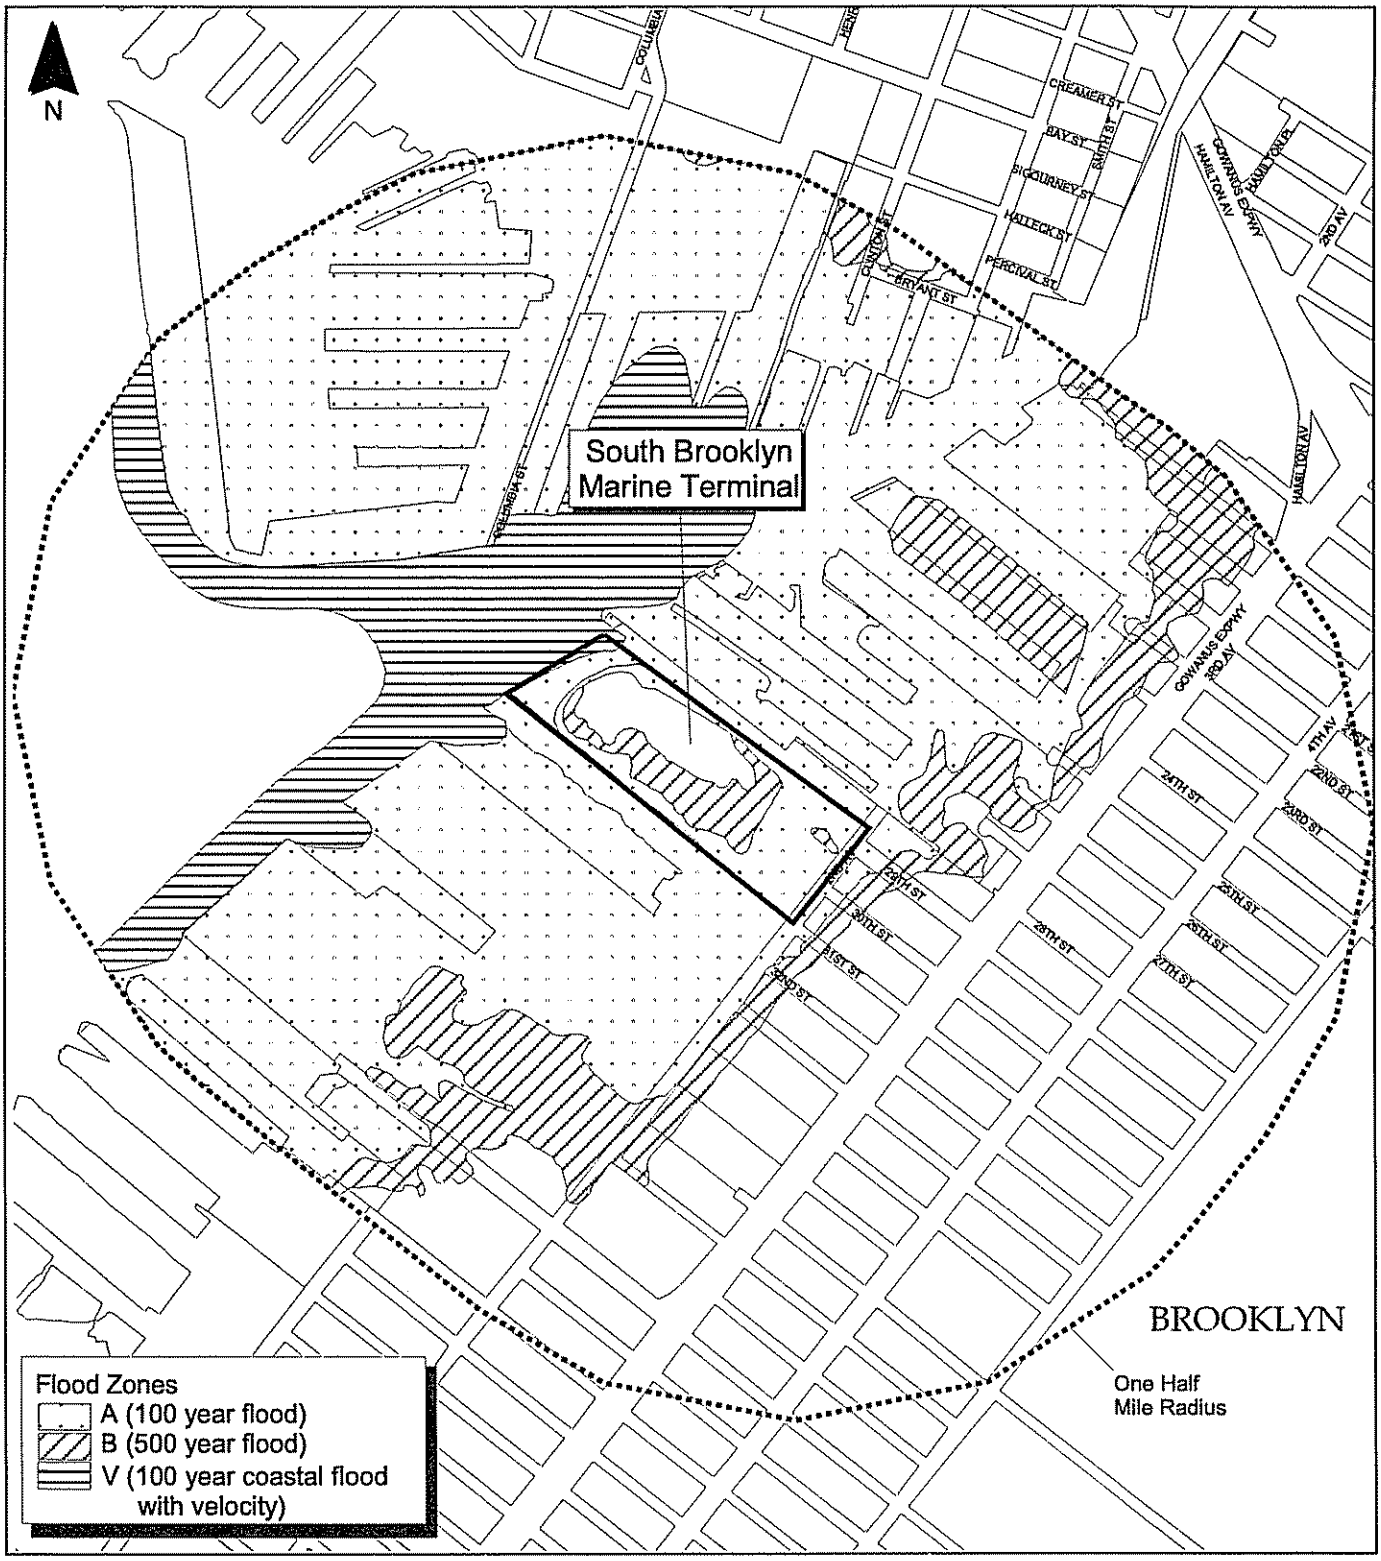
Based on information derived from a review of the Bedrock and Geologic Maps of New York County by Charles A. Baskerville, 1994, the bedrock lies 130 to 140 feet below surface sediment.[1] Surface sediment collected from the Existing Hamilton Avenue MTS, located just northeast of this site at the mouth of the Gowanus Canal, is mainly composed of fine-grained sediment and is somewhat degraded by contaminants.[2]

17.9.1.3 Floodplains

The site is within the 100-year coastal floodplain (sSee Figure 17.9-1). Just to the south of the pier is an area between the limits of the 100- and 500-year floodplain and an area of minimal flooding. No intertidal wetlands exist in the study area. Gowanus Canal, however, is a NYSDEC-designated littoral zone (see Figure 17.9-2). The site is located within the City's WRP boundaries and is a designated SMIA.

17.9.1.4 Ecosystems

The northwest portion of the SBMT site was investigated for plant species presence. The site is bordered by a chain-link fence along its southeast boundary, and by the Gowanus Bay along the remaining boundaries. The property on the opposite side of the southeastern boundary fence and the on-site parking lot is paved and devoid of vegetation. However, a band of vegetation occurs along the northeastern, northwestern and southwestern boundaries of the site between the pavement and the Gowanus Bay. The vegetated area varies from approximately 15 to 50 feet in width. Plant species observed in the vegetated areas include herbaceous plants, trees and shrubs. The herbaceous plants observed include poor-man's peppergrass (*Lepidium virginicum*), tall goldenrod (*Solidago altissima*), seaside goldenrod (*Solidago sempervirens*), lady's thumb (*Polygonum persicaria*), lamb's quarters (*Chenopodium album*), common mugwort (*Artemesia vulgaris*), wild carrot (*Daucus carota*), English plantain (*Plantago lanceolata*), spotted spurge (*Chamaesyce maculate*), black medic (*Medicago lupulina*), small white aster (*Aster vimineus*), common reed (*Phragmites australis*), horseweed (*Conyza canadensis*), Pennsylvania smartweed (*Polygonum pennsylvanicum*), white sweet clover (*Melilotus alba*), yellow sweet clover



[1] Baskerville, C.A., 1994. Bedrock and Engineering Geologic Maps of New York County and Parts of Kings and Queens Counties, New York and Parts of Bergen and Hudson Counties, New Jersey.

(*Melilotus officinalis*), panic grass (*Panicum* sp.), redroot pigweed (*Amaranthus retroflexus*), Kentucky bluegrass (*Poa pratensis*), green foxtail (*Setaria viridis*), common ragweed (*Ambrosia artemisiifolia*), common evening primrose (*Oenthera biennis*), annual wormwood (*Artemesia annua*), Asiatic bittersweet (*Celastrus orbiculatus*), pokeweed (*Phytolacca americana*), intermediate dogbane (*Apocynum medium*), common mullein (*Verbascum thapsus*), goose grass (*Eleusine indica*), field bindweed (*Convolvulus arvensis*), red clover (*Trifolium repens*), barnyard grass (*Echinochola crusgalli*), Canada thistle (*Cirsium arvense*), curly dock (*Rumex crispus*) and tufted lovegrass (*Eragrostis pectinacea*). The tree and shrub species observed on site were hackberry (*Celtis occidentalis*), cottonwood (*Populus deltoides*), princess tree (*Paulownia tomentosa*), smooth sumac (*Rhus glabra*), American basswood (*Tilia americana*), tree-of-heaven (*Ailanthus altissima*), black cherry (*Prunus serotina*), pin oak (*Quercus palustris*), black locust (*Robinia pseudo-acacia*) and rose (*Rosa* sp.). No species known as rare, threatened or endangered were observed on the site.

According to the USF&WS, except for occasional transients, there are no federally listed or proposed endangered or threatened species, or any "critical habitats," present on the site. According to the NYSDEC, there are no records of rare or state-listed animals or plants, significant natural communities or other significant habitats on or in the immediate vicinity of the site.

A field program conducted in 2003 was designed to fully characterize the marine biological resources of DSNY's eight existing MTSs. The program included monthly sampling for finfish eggs and larvae and water quality, and quarterly sampling for benthic organisms and sessile colonizing organisms. This site was not one of the locations extensively sampled; however, it is near the Existing Hamilton Avenue MTS (located at the mouth of the Gowanus Canal), which was thoroughly sampled. The physical and biological characteristics of the community at this site are expected to be similar to the communities at the Existing Hamilton Avenue MTS. These communities are described in the following paragraph.

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The dominant finfish larvae collected at the Existing Hamilton Avenue MTS were winter flounder (*Pleuronectes americanus*), anchovy spp. (*Anchoa* spp.), Atlantic menhaden (*Brevoortia tyrannus*) and goby spp. (*Gobiosoma* spp.). The dominant finfish eggs collected were cunner (*Tautogolabrus adspersus*), bay anchovy (*Anchoa mitchilli*), tautog (*Tautoga onitis*) and Atlantic menhaden. The species that have EFH listing (and the life stage collected) include windowpane (*Scophthalmus aquosus*) (eggs and larvae), winter flounder (larvae) and Atlantic herring (*Clupea harengus*) (larvae). The benthic invertebrates that were found at the Existing Hamilton Avenue MTS are similar to those found throughout New York Harbor. The most abundant species collected were worms – *Capitella capitata*, *Streblospio benedicti* and oligochaetes – all of which are tolerant of polluted areas. The dominant epibenthic colonizers found at the Existing Hamilton Avenue MTS were *Polydora* sp. (worms), *Molgula manhattensis* (sea grapes), *Balanus* sp. (barnacles), and hydrozoa, mud and algal film.[3]

17.9.2 Future No-Build Conditions

If the 30th Street Pier at SBMT was not developed, the study area would remain as is. The limited aquatic and terrestrial natural resources will remain and the study area will continue to be a stressed urban area with limited ecological productivity.

17.9.3 Potential Impacts with ~~MCR~~BCR to the 30th Street Pier at SBMT

It is proposed that this pier be used to accept and process the City's recyclables. The changes to the existing facility will include removal of piles and underwater debris in the area, dredging approximately 40,000 cubic yards of material, and the construction of two new piers. The piers would each be 400 feet long by 60 feet wide, and the supporting piles would penetrate the underlying sediment to approximately 120 feet.

[3] Ibid

17.9.3.1 Geology

The geology of the study area would not be impacted as a result of the 30th Street Pier at SBMT other than by potential dredging activity, which would remove layers of sediments deposited over time, and by the expansion of the land area of the facility by bulkheading and backfilling.

17.9.3.2 Floodplains

Potential development of the 30th Street Pier at SBMT would have no effect on the elevation of the site. The potential development does not include any provisions for raising any portions of the site over this level. The facility would be constructed within the 100-year floodplain and within the SMIA. The proposed activity, however, does not "substantially hinder" the area, and therefore, complies with New York State's CMP as expressed in the City's local WRP.

17.9.3.3 Ecosystems

Construction of the 30th Street Pier at SBMT would involve dredging 40,000 cubic yards of sediment from the site and the construction of two 400-foot-by-60-foot platforms that cover 48,000 square feet of water. Assuming normal operations, this procedure should not involve any permanent impacts to the aquatic or terrestrial natural resources. During the removal of the existing pier and pile fields, the upper organic silts lying beneath the structure would be disturbed to some degree, resulting in re-suspension of the sediments. However, the amount of re-suspended sediments is expected to be low, and the impacts, if any, highly localized. Turbidity and short-term lowered dissolved oxygen are possible, but not measurable, against the normal background fluctuations. The dredging activities in the area to accommodate tugboats and barges would result in an immediate, short-term destruction of the benthic invertebrates in the area; however, recolonization of the area by benthic invertebrates could be expected

within 6 to 12 months after cessation of dredging activities.[4] Given the relatively small size of the project and the existing impacts to the natural resources of the study area, minimal impact is expected from the disturbance of the environment associated with the 30th Street Pier at SBMT.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction; flatfish (flounders) are least sensitive. Finfish eggs and larvae are more sensitive to suspended sediment and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. In addition, larvae will be able to swim away from the impacted environments.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water, which results in shading that will block sunlight and hinder primary production. The total over-water coverage of the platforms is proposed to be 48,000 square feet. Recently, finger piers that were to the north and south of Pier 30 were demolished. Pier 30, which is essentially fill material, still remains. According to the conceptual site plan, the two proposed platforms appear to be smaller than the platforms that were recently demolished; however, the sizes of the demolished piers were not included in the site plan for comparison. If the new platforms truly cover less water than the platforms that were demolished, then there will be an overall increase in unshaded water on site allowing more sunlight to penetrate the water for primary production.

Any upland construction would not have significant impact on the few areas of vegetation present on the site. Existing on-site buildings and paved parking areas have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Vegetation

[4] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft – Phase I-II. During Construction and 1st Year Post-Construction Studies.

observed on the site was opportunistic weeds and plants, none of which were rare, endangered or particularly important from an ecological perspective. No significant terrestrial impacts would result from the 30th Street Pier at SBMT because the site is already fully developed.

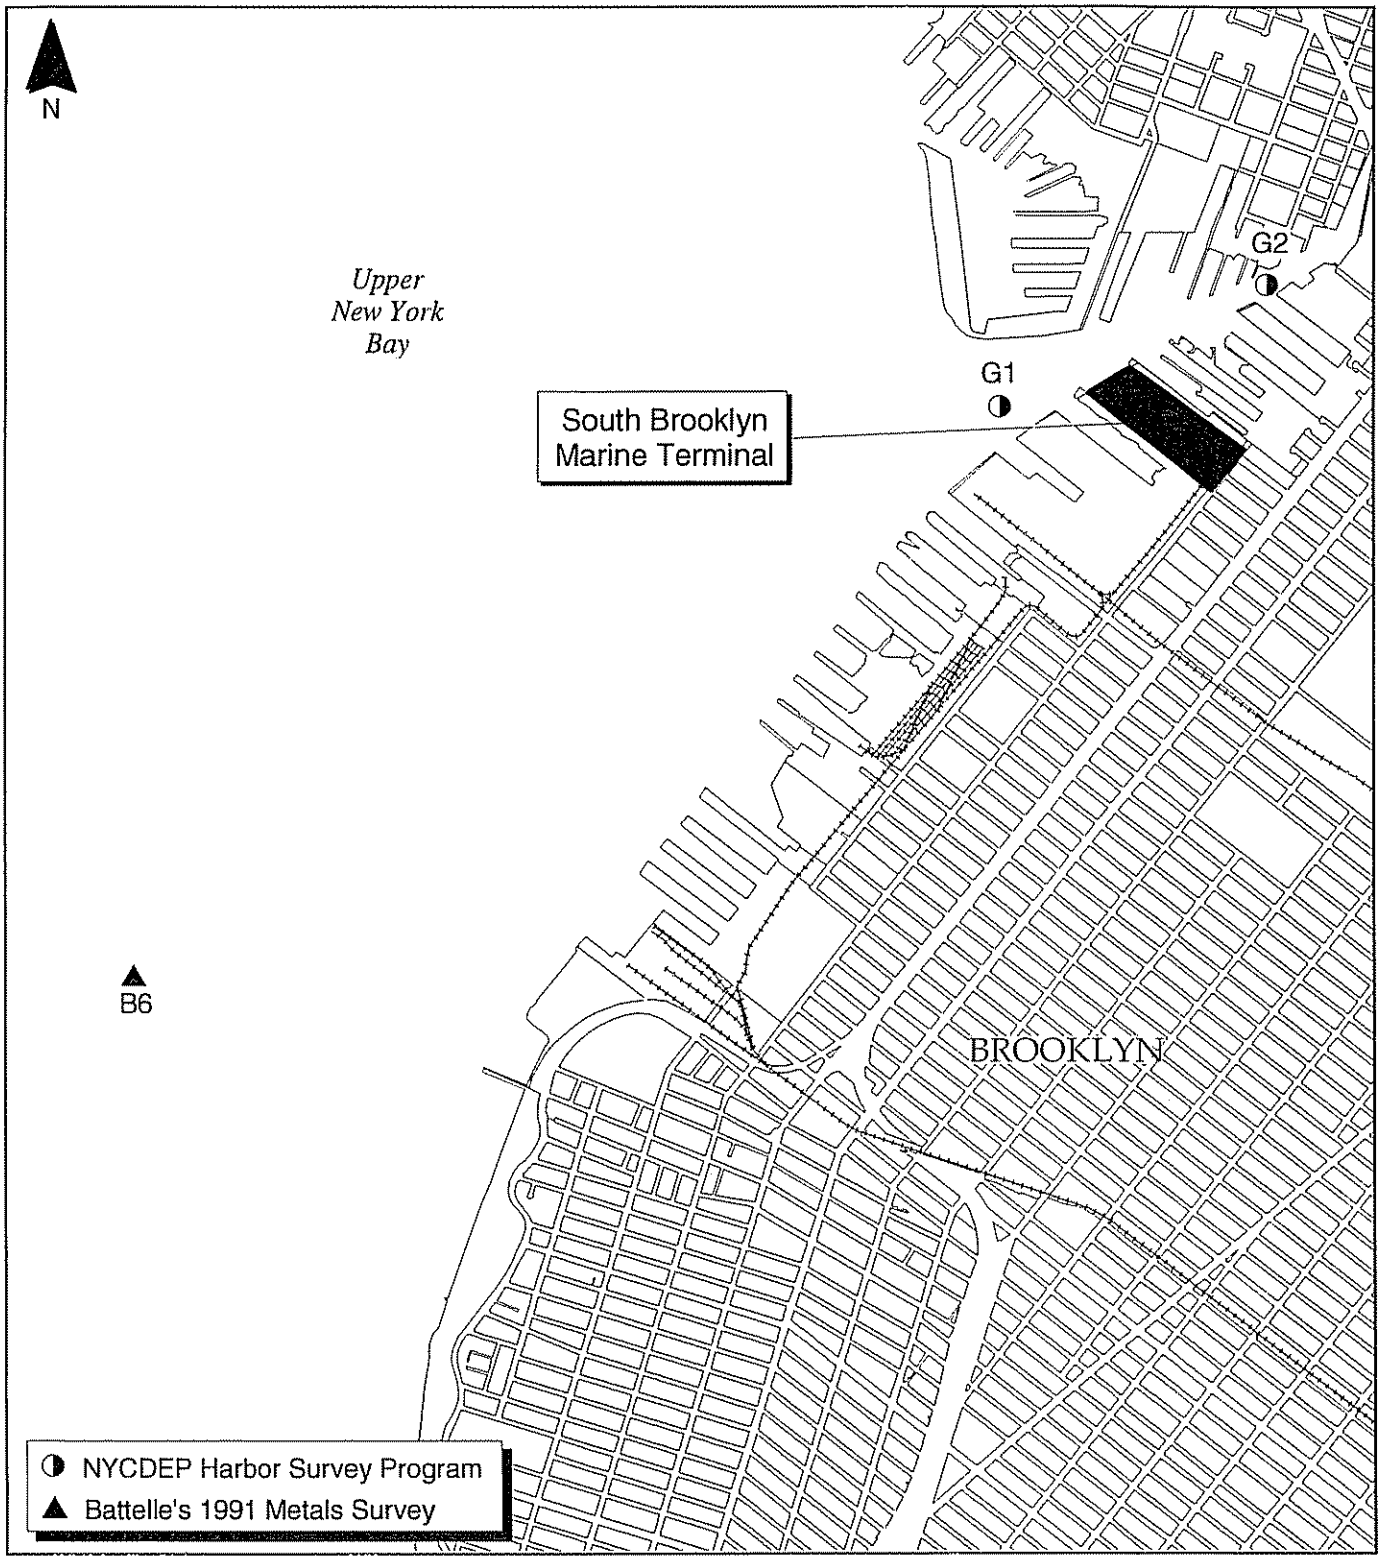
17.10 Hazardous Materials

See Section 17.1 for a description of the analysis required.

17.11 Water Quality

17.11.1 Existing Conditions

17.11.1.1 Definition of the Study Area



The water quality study area encompasses the Gowanus Bay, Gowanus Channel and Upper New York Bay and includes discharges from point sources and CSOs located within ½-mile of the site.

17.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 17.11-1, are generally representative of water quality conditions in the study area:

- NYCDEP Harbor Survey Program – Station G-1 in Gowanus Bay and Station G-2 at Gowanus Channel; and
- Battelle's 1991 Metals Survey – Station B-6 in Upper New York Bay.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 17.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class SD," which indicates fish survival only.

Site delineations are approximate

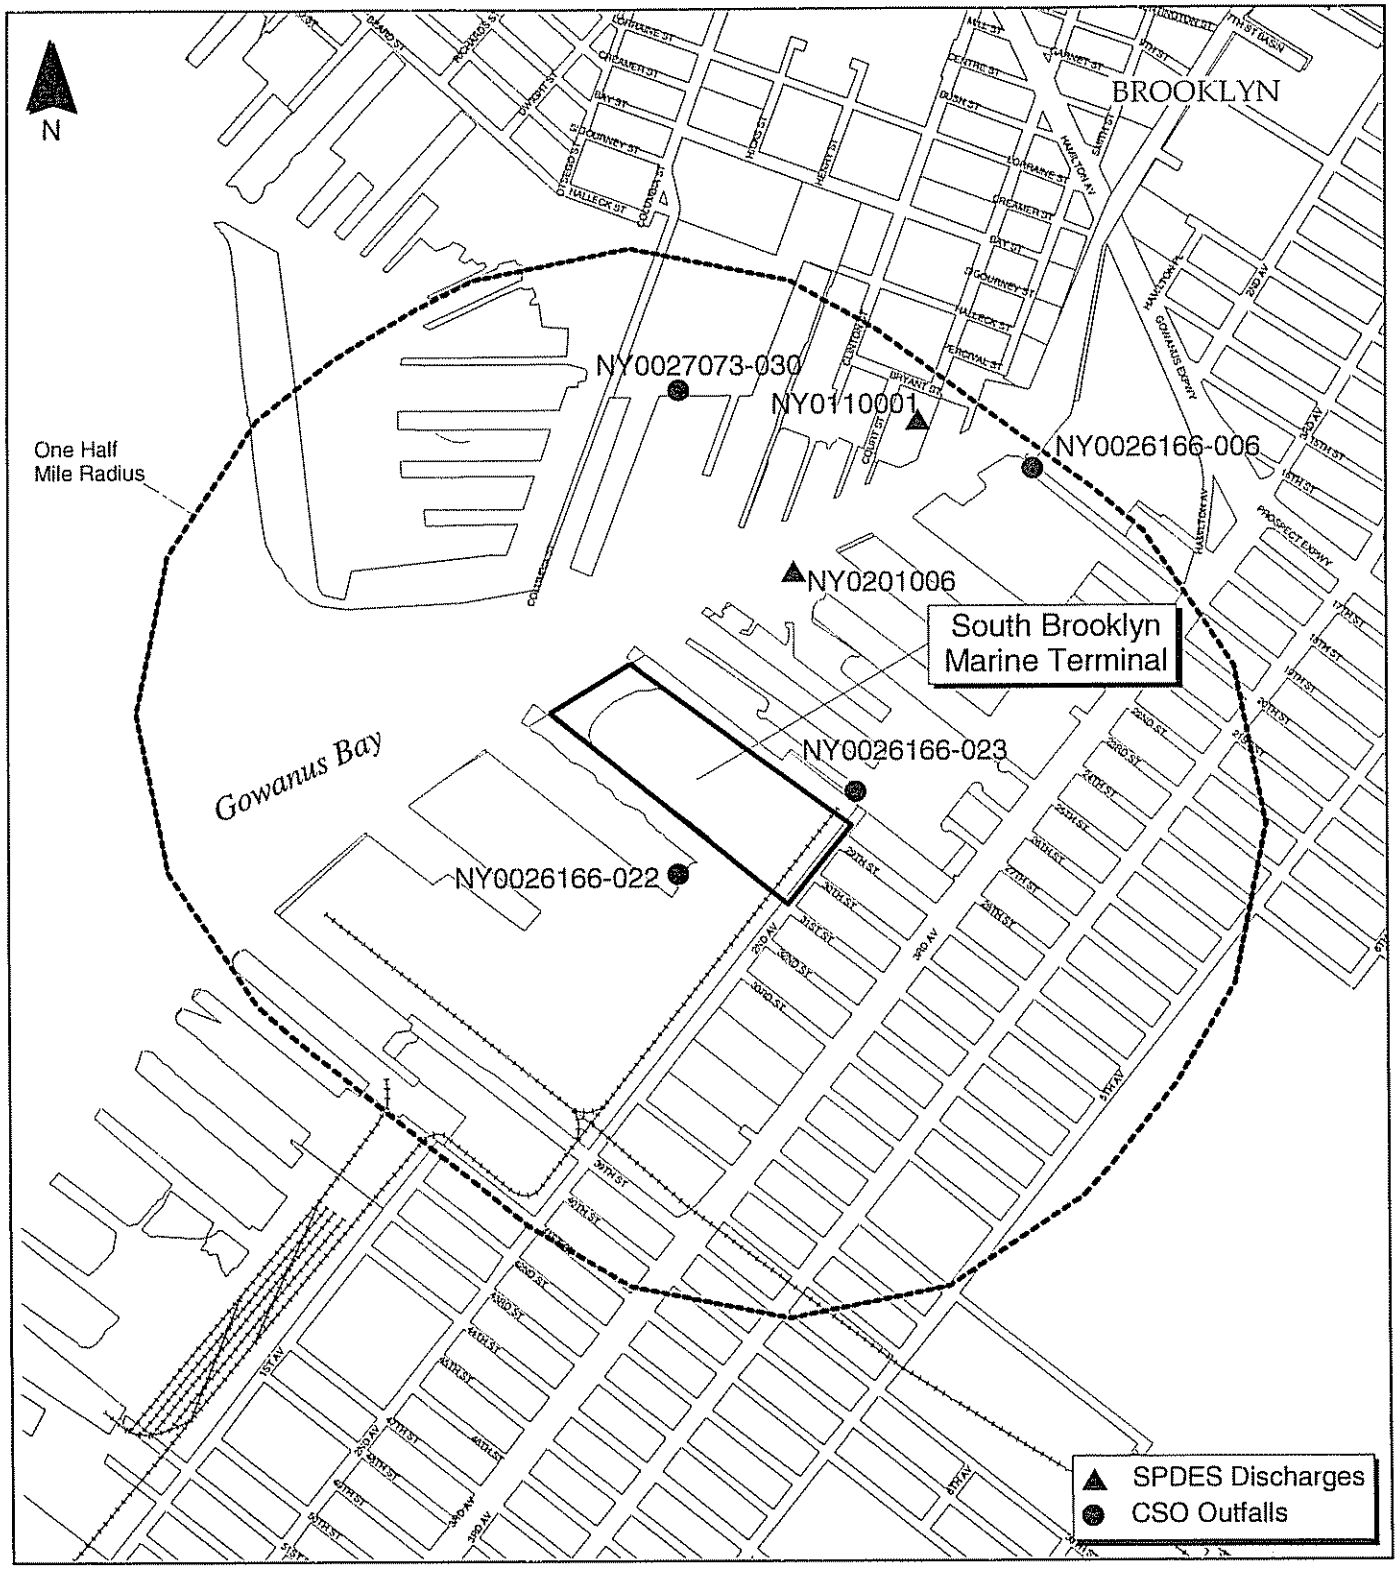
Notes:

[1] Average concentrations for 1999 NYCDEP Harbor Survey Station G-1, located in Gowanus Bay.
[2] Average concentrations for 2002 NYCDEP Harbor Survey Station G-2, located in the Gowanus Channel.
[3] Average concentrations for 1991 Battelle Ambient Survey Station B-6, located in Upper New York Bay.
[4] Represents average between February and December 1999.
[5] Minimum between June 1, 1999 and September 30, 1999.
[6] Represents average between January and December 2002.
[7] Minimum between June 1, 2002 and September 30, 2002.
[8] Represents average between February and October 1999.
[9] Represents average between June and December 2002.
[10] Latest available data 1997.
[11] Latest available data 1996.
[12] Latest available data 1999.
[13] Latest available data 1998.
[14] Guidance value and data are for dissolved metals.
[15] NYSDEC Guidance Value (NYSDEC TOGS 1.1.1, June 1998, errata sheet January 1999 and addendum April 2000).
[16] Site-specific chronic and acute criteria for dissolved copper in New York/New Jersey Harbor.

Notes for Table 17.11-1 (continued):
(17) Guidance value and data are for acid-soluble metal.
BOD = biochemical oxygen demand
NH_3-N = ammonia
NO_3 = nitrate; NO_2 = nitrite
PO_4 = phosphate
mg/L = milligrams per liter
MPN/100 ml = most probable number per 100 milliliters
MF = membrane filter
µg/L = micrograms per liter



As shown in Table 17.11-1, on average, NYSDEC standards and guidance values are met. For NYCDEP Harbor Survey Program Station G-2, however, the minimum surface and bottom dissolved oxygen between June 1, 2002 and September 30, 2002 did not meet the water quality standards for dissolved oxygen. In addition, the mercury concentration for Battelle Station B-6 did not conform to the water quality standard for mercury.

17.11.1.3 Permitted Discharges

A review of the most recently available NYSDEC and USEPA databases indicated that there are several permitted discharges in the vicinity of the site. Those within a ½-mile radius of the 30th Street Pier at SBMT site are listed in Table 17.11-2 and shown in Figure 17.11-2. The discharges consist of four CSOs and two industrial sites, all of which are permitted by the NYSDEC.

DEPARTMENT OF SANITATION

17.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, estimates of stormwater pollutant loadings were calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and/or infiltration. A runoff flow of 0.823 cfs was calculated using the impervious site area (13.6 acres), an average rainfall intensity per storm of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 17.11-3, represent the existing loads at the site.

Table 17.11-3
Estimated Existing Pollutant Loads and Runoff Flows
30th Street Pier at SBMT

Pollutant	Concentration	Pollutant Loading (lbs/day)
Fecal Coliform MPN/100 ml	34,000	150,757[1]
BOD mg/L	11	48.8
Heavy Metals		
Copper µg/L	35	0.155
Lead µg/L	28	0.124
Zinc µg/L	154	0.683
Total Impervious Area (acre) = 13.6		Runoff Coefficient (C) = 1.00
Average Rainfall Intensity per Storm (inch/hour) = 0.06[2]		Runoff Flow (cfs) = 0.823

Notes:
[1] Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
[2] Based on Central Park Rain Data (1969 – 2002); The National Climatic Data Center.

17.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to ongoing water improvement programs such as the NYCDEP CSO Abatement Program, which would reduce untreated discharges to the receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from the City WPCPs; and other programs. Stormwater loads from the site would not be expected to change, so no significant water quality impacts would be expected.

17.11.3 Potential Impacts with ~~MCR~~ BCR to the 30th Street Pier at SBMT

With the development of the 30th Street Pier at SBMT, the overall area of the site would be increased by 1.1 acres. Table 17.11-4 shows the existing impervious area, the change in impervious area and pollutant loads.

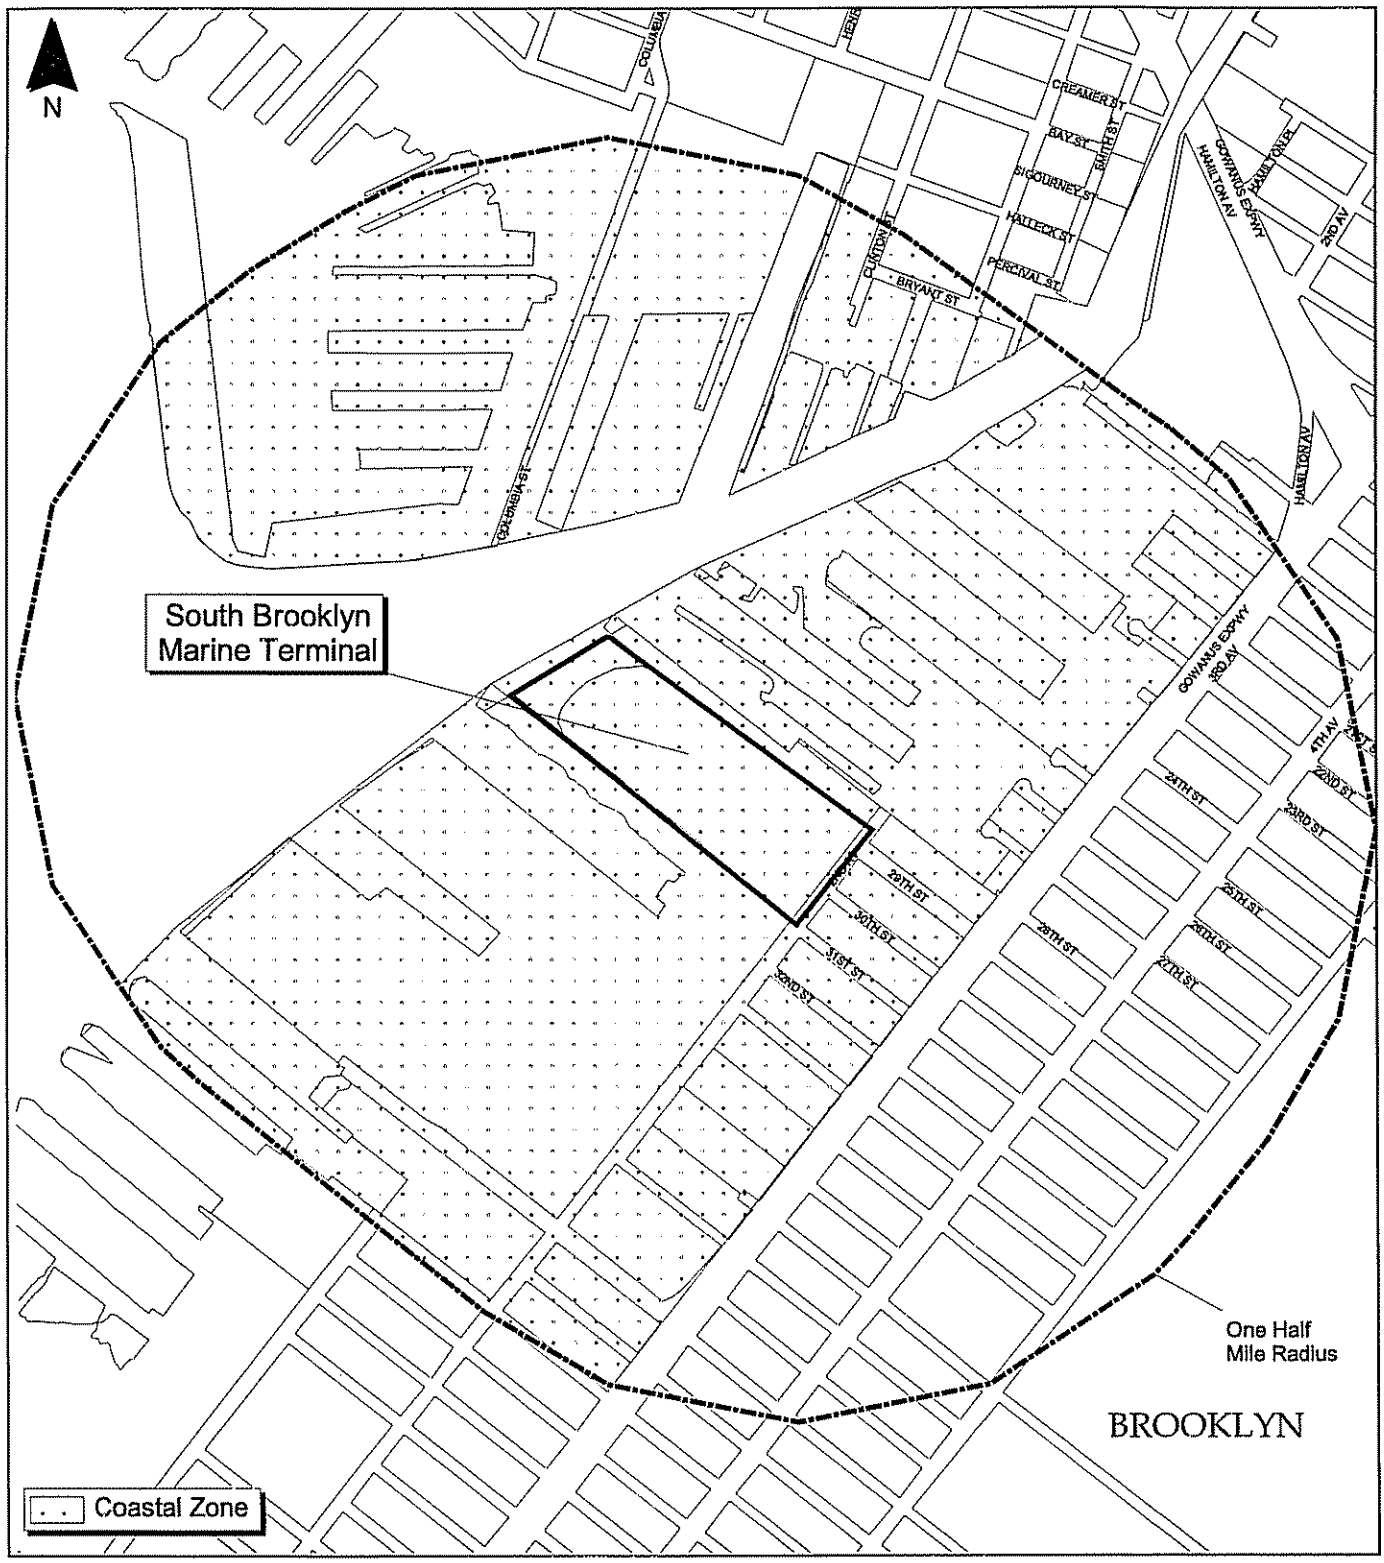
Table 17.11-4
Impervious Area and Estimated Pollutant Loads
30th Street Pier at SBMT

Impervious Area Change			Estimated Pollutant Loadings/Incremental Change [1]				
Condition	Total Impervious Area (acres)	Change in Impervious Area (acres)	Fecal Coliform[2]	BOD (lbs/day)	Copper (lbs/day)	Lead (lbs/day)	Zinc (lbs/day)
Existing Conditions	13.6	NA	150,757/NA	48.8/NA	0.155/NA	0.124/NA	0.68/NA
Future Build Conditions	14.7	1.1	162,847/12,090	52.7/3.9	0.168/0.013	0.134/0.01	0.74/0.06

Notes:
(1) Incremental change refers to the difference in pollutant loading between the Existing Conditions and the Future Build Conditions.
(2) Coliform loads are not shown in pounds/day. Loading comparable to MPN/100 ml.
NA = Not Applicable

The potential impact of the stormwater pollutant loadings on surface water quality was evaluated using the New York Harbor Seasonal Steady State Water Quality 208 Model (208 Model). This model was developed under Section 208 of the Clean Water Act to help state and local water quality management agencies integrate water quality activities and goals. The 208 Model was used to predict the incremental changes in BOD, fecal coliform, copper, zinc and lead that resulted from the stormwater loadings.

The 208 Model predicted no significant impact on existing surface water quality due to fecal coliform, BOD, copper, zinc and lead loadings from the 30th Street Pier at SBMT. Stormwater runoff from the 14.7 acres of the 30th Street Pier at SBMT area would not result in any further violation of water quality standards or guidance values beyond existing violations. Therefore, the development of the 30th Street Pier at SBMT would not affect water quality.



Unimpeded operation of the 30th Street Pier at SBMT may also require dredging activities to construct the waterfront structures and to improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired before any such activities commenced. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not be expected to result in any significant adverse long-term impacts.

17.12 Waterfront Revitalization Program

17.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the Gowanus Bay, the 30th Street Pier Material Recoveryycling Facility (MRF) at the ~~South Brooklyn Marine Terminal (~~SBMT~~)~~ would be within the City's coastal zone boundary (Figure 17.12-1). According to "The New Waterfront Revitalization Program," the 30th Street Pier MRF at the SBMT would be classified as a water-dependent, industrial use. The site is within the designated Sunset Park Significant Maritime and Industrial Area (SMIA). It would be located within Reach 14/East River and Upper New York Bay Sunset Park Subarea as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Brooklyn Waterfront." The 30th Street Pier MRF at the SBMT is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The 30th Street Pier MRF at the SBMT was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3, 8.1, 8.5, 9.2 and 10.2. All policies and subpolicies, including those identified as not applicable, are listed in Section 3.14.2. In instances where a component of the 30th Street Pier MRF at the SBMT required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below.

Site delineations and study area boundaries are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

17.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

Sufficient public services and facilities to support the new 30th Street Pier MRF at the SBMT are present in the vicinity of the proposed site. As part of the 30th Street Pier MRF at the SBMT, connections from the new facility to existing utilities (e.g., sewer connections, etc.) in the vicinity would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The 30th Street Pier at the SBMT would be located within the Sunset Park SMIA. The pier would be developed into a complex of facilities designed to receive and process DSNY curbside recyclables. Development of the 30th Street Pier would involve the conversion of the existing site, which was previously used for marine vessel loading and off-loading, long-term import/export cargo storage and processing, into a MRF that would accept and process the City's recyclables. Some recyclables from DSNY South Brooklyn collection districts would be delivered to the facility by truck, while recyclables from other boroughs would be brought to the facility by barge.

Development of the proposed 30th Street Pier at the SBMT would help to restore and revitalize industrial waterfront property and would be compatible with existing and neighboring heavy industrial uses. Construction activities would predominantly occur on the existing 30th Street Pier at the SBMT. Demolition activities associated with development of the pier would involve the removal of piling remnants and other underwater debris from previous demolition of finger piers that abutted the 30th Street Pier. Development of the 30th Street Pier would require the construction of two docks in order to support the proposed recycling operations. Development of the MRF would involve: (1) construction of a receiving building, which would include a tipping area, processing area and an enclosed barge unloading area; (2) two piers for barge loading and unloading; (3) loadout docks for truck transfers; (4) new fendering and bulkhead system; and (5) a three-story administration/visitor center with parking.

Operations at the MRF would include accepting curbside recyclables by barge or truck, processing the material in an enclosed facility, then transporting the processed recyclables to other locations by barge. Development of the 30th Street Pier at the SBMT would be consistent with the existing land uses in the vicinity of the site and with the "Plan for the Brooklyn Waterfront" which recommends the expansion and continued industrial use of the area. The proposed development of the 30th Street Pier would involve the development of a new industrial water-dependent use within an area of the Brooklyn waterfront that has been designated as an SMIA and an area suitable for waterfront industrial uses. The 30th Street Pier at the SBMT would, therefore, be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The proposed MRF would be located at the existing 30th Street Pier at the SBMT. Modifications to the existing pier would involve the construction of two additional docks that would be used for loading/unloading of incoming and outgoing barges servicing the proposed facility. To allow for the unimpeded

operation of the facility, piling remnants and other underwater debris from previous demolition of finger piers that abutted the 30th Street Pier would also need to be removed. In addition, new fendering systems and dredging would be required to improve existing water depths at and in the vicinity of the site and to allow for the unimpeded operation of barges and tugboats once the site became operational. All required dredging would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any proposed dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The development of the 30th Street Pier at SBMT would involve the reactivation of a historic waterfront use and would not interfere with any maritime industrial, commercial or recreational vessel activities in the area. Activities within Gravesend Bay resulting from the 30th Street Pier at SBMT would be limited to barge loading along the pier level and the periodic swapping of loaded barges at the slips. Four or five barges would be filled on a daily basis. These swapping activities would be similar to previous barge activities at the site. Therefore, no adverse impact to other uses within the water body would be anticipated. The 30th Street Pier at SBMT would be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

Development of the 30th Street Pier at SBMT would involve the conversion of the existing site, which was previously used for marine vessel loading and off-loading, long-term import/export cargo storage and processing, into a MRF where recyclables would be brought to the facility by either barge or truck and processed in an enclosed building prior to transport. All unloading, processing and

unloading would be conducted within an enclosed area and, therefore, would be protective of the aquatic environment and surrounding land and water uses.

In addition, inbound barges carrying mixed recyclables would be equipped with netting or fencing to prevent windblown litter from entering the surrounding environment. Litter control methods, such as fencing and regular housekeeping of the site perimeter, placement of booms and/or the use of a skimmer boat as needed, and operating personnel using dip nets to control litter in the enclosed barge unloading/loading area, would be implemented to minimize or eliminate the potential for litter entering surface waters. All process wastewaters generated on site (e.g., washdown waters, etc.) would be treated prior to their discharge to the municipal sewer system. In addition, any on-site storage of petroleum products related to the operation of the MRF at the 30th Street Pier, if required, would be done in accordance with applicable federal, state and local regulations. Therefore, the proposed 30th Street Pier would be consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs, as described in "The Waterfront Revitalization Program," as well as Recognized Ecological Complexes and SCFWH information, the 30th Street Pier at the SBMT is not located within a designated area. The proposed MRF would be a water-dependent use that would involve the unloading, processing and loading of materials largely within an enclosed structure. The proposed facility would not be anticipated to result in any long-term impacts to natural resources in the vicinity of the site. Development of the 30th Street Pier MRF would therefore, be consistent with this subpolicy.

4.2 *Protect and restore tidal and freshwater wetlands.*

A review of NYSDEC tidal and freshwater wetland maps was conducted to determine the presence of wetlands within the site. As noted in Section 17.9.3.3, sections of the proposed MRF would be situated on pilings within Gowanus Bay, a NYSDEC-designated littoral zone. No freshwater wetlands exist on site. The proposed development of the 30th Street Pier would not be anticipated to result in any significant long-term impacts to tidal wetlands.

Dredging would be required to remove accumulated sediments in order to provide adequate draft for barges and tugboats. In addition to dredging, piling remnants and other underwater debris from previous demolition of finger piers that abutted the 30th Street Pier would need to be removed. Potential impacts due to dredging and the removal of the pilings, however, would be minimal and all activities would be conducted in compliance with applicable federal, state and local regulations. Mitigation of potential impacts, as appropriate and applicable, would be proposed as part of the permitting of the MRF at the 30th Street Pier.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

A review of USF&WS and NYSDEC NHP databases indicates that no known species of concern were located in the vicinity of the site. The MRF at the 30th Street Pier would be largely situated on an existing pier with additional development activities within Gowanus Bay. Dredging and removal of existing underwater debris would be required prior to the operation of the facility. Dredging would result in limited impacts to water quality, which would be of short-term duration and highly localized. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer system. Stormwater runoff from the 30th Street Pier would be

managed in accordance with applicable federal, state and local regulations. The 30th Street Pier at the SBMT would not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The MRF at the 30th Street Pier would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, sanitary and process wastewaters would be conveyed to an on-site treatment system, which would discharge to the municipal sewer system. Stormwater runoff from the 30th Street Pier at the SBMT would be managed in accordance with all applicable federal, state and local regulations.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

BMPs would be used to the extent possible during the construction activities and during the operation of the proposed facility in order to minimize and nonpoint discharges. The MRF at the 30th Street Pier would comply with federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling of recyclables would be conducted within an enclosed processing building. During dredging and construction activities, non-structural, and if necessary, structural measures would be used to minimize nonpoint source pollution.

In addition, in-bound barges carrying mixed recyclables would be equipped with netting or fencing to prevent windblown litter from entering the surrounding environment. Litter control methods, such as fencing and regular housekeeping of the site perimeter, placement of booms and/or the use of a skimmer boat as needed, and the use of dip nets to control litter in the enclosed barge unloading/loading area, would be implemented to minimize or eliminate the

potential for litter entering surface waters. All process wastewaters generated on site (e.g., washdown waters, etc.) would be treated prior to their discharge to the municipal sewer system. In addition, on-site storage of petroleum products related to the operation of the MRF, if required, would be done in accordance with applicable federal, state and local regulations. Therefore, the proposed MRF would be consistent with this subpolicy.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

Dredging would be required to improve existing water depths at and in the vicinity of the site and to allow for the unimpeded operation of barges and tugboats once the site became operational. In addition, removal of existing piling remnants and other underwater debris from the previous demolition of finger piers that abutted the 30th Street Pier would be required prior to operation of the proposed facility. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired prior to any dredging activities. Applicable and appropriate measures, such as the use of closed clamshell buckets and silt curtains would be implemented during dredging activities to minimize and/or eliminate short-term impacts to local water quality. Dredging and the subsequent development of the proposed facility would not be expected to result in any long-term impacts to water quality. Development and operation of the 30th Street Pier at the SBMT would, therefore, be consistent with this subpolicy.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The 30th Street Pier at the SBMT would have no impact of the quality or quantity of surface or ground waters. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer or water supply. Process wastewaters would be conveyed to an on-site treatment system and then discharged to the municipal sewer system. Stormwater runoff from the 30th Street Pier at the SBMT would be managed in accordance with all applicable federal, state and local regulations. The proposed facility would, therefore, be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to a review of FEMA National Flood Insurance Program maps, portions of the proposed facility would be situated within the 100-year floodplain (Zone A). The proposed MRF would be located at the site of the existing 30th Street Pier, but would require the addition of two new piers. The piers would be equipped with a new fendering and sheet pile bulkhead to prevent erosion. The redevelopment of the site would not affect the potential for flooding or erosion. Construction of the facility would comply with applicable building code requirements. To the extent practicable, non-structural or structural measures would be implemented to minimize potential impacts from flooding or erosion.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The MRF at the 30th Street Pier would not involve the storage, treatment or disposal of hazardous waste. The proposed facility would, however, involve the processing of recyclables consisting of glass, metal and plastics. The development of the proposed 30th Street Pier would involve the conversion of the existing site, which was previously used for marine vessel loading and off-loading, long-term import/export cargo storage and processing, into a MRF that would accept and process the City's recyclables. The storage of petroleum products at the proposed facility, if required, would be conducted in accordance with applicable federal, state and local regulations. The proposed MRF would be constructed and

operated in a manner that would not result in adverse impacts to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

In-bound barges carrying mixed recyclables would be equipped with netting or fencing to prevent windblown litter from entering the surrounding environment. Litter control methods, such as fencing and regular housekeeping of the site perimeter, placement of booms and/or the use of a skimmer boat as needed, and the use of dip nets to control litter in the enclosed barge unloading/loading area, would be implemented to minimize or eliminate the potential for litter entering surface waters. Therefore, the proposed MRF would be consistent with this subpolicy.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

Due to the existing industrial uses at and in the immediate vicinity of the 30th Street Pier, public access would generally not be compatible. Therefore, this subpolicy is not applicable.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The 30th Street Pier would involve the development of a new water-dependent industrial use. Public access would not be compatible with the proposed 30th

Street Pier; however, its development would not preclude any future development of public access at other locations along the Gowanus Bay or Upper New York Bay waterfront.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

Development of the 30th Street Pier at the SBMT would involve the development of new facilities on an existing pier within a heavily industrialized area. The proposed facility would not be anticipated to impair existing visual access to coastal lands, waters or open space. The 30th Street Pier at the SBMT would not be anticipated to significantly impact visual access within the heavy industrial area. See also response to Subpolicy 9.1.

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

The proposed MRF at the 30th Street Pier would be located in a heavy industrialized area and does not have waterfront open space and recreation area in the immediate vicinity of the proposed site. A cluster of several small parks and open space collectively known as the Red Hook Recreation Area, is located northwest of the 30th Street Pier. There would be no impact to this area because the proposed facility would be are located across Gowanus Bay and would be approximately 2,000 feet, therefore, physically separated from the proposed site. There are no other mapped parklands or open space resources in the vicinity of the 30th Street Pier. Therefore, the proposed development of the 30th Street Pier would be consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 *Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.*

The 30th Street Pier at the SBMT would involve the development of a new MRF at the location of previous industrial uses and would, therefore, be compatible with the existing urban design context and visual conditions of this portion of the industrialized Gowanus Bay waterfront. The proposed 30th Street South Pier would, therefore, be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The 30th Street Pier would pose no new impact to scenic values associated with natural resources. It would be compatible with existing industrial uses in the vicinity of the site, which do not provide scenic views. Therefore, this subpolicy would not be applicable.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

There are no known designated historical or cultural resources at the proposed 30th Street Pier at the SBMT; therefore, the proposed facility would not have an adverse impact upon cultural or historical resources and would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No known archaeologically significant resources are located at the site. This subpolicy is, therefore, not applicable.

17.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

See Section 17.1 for a description of the analysis required.

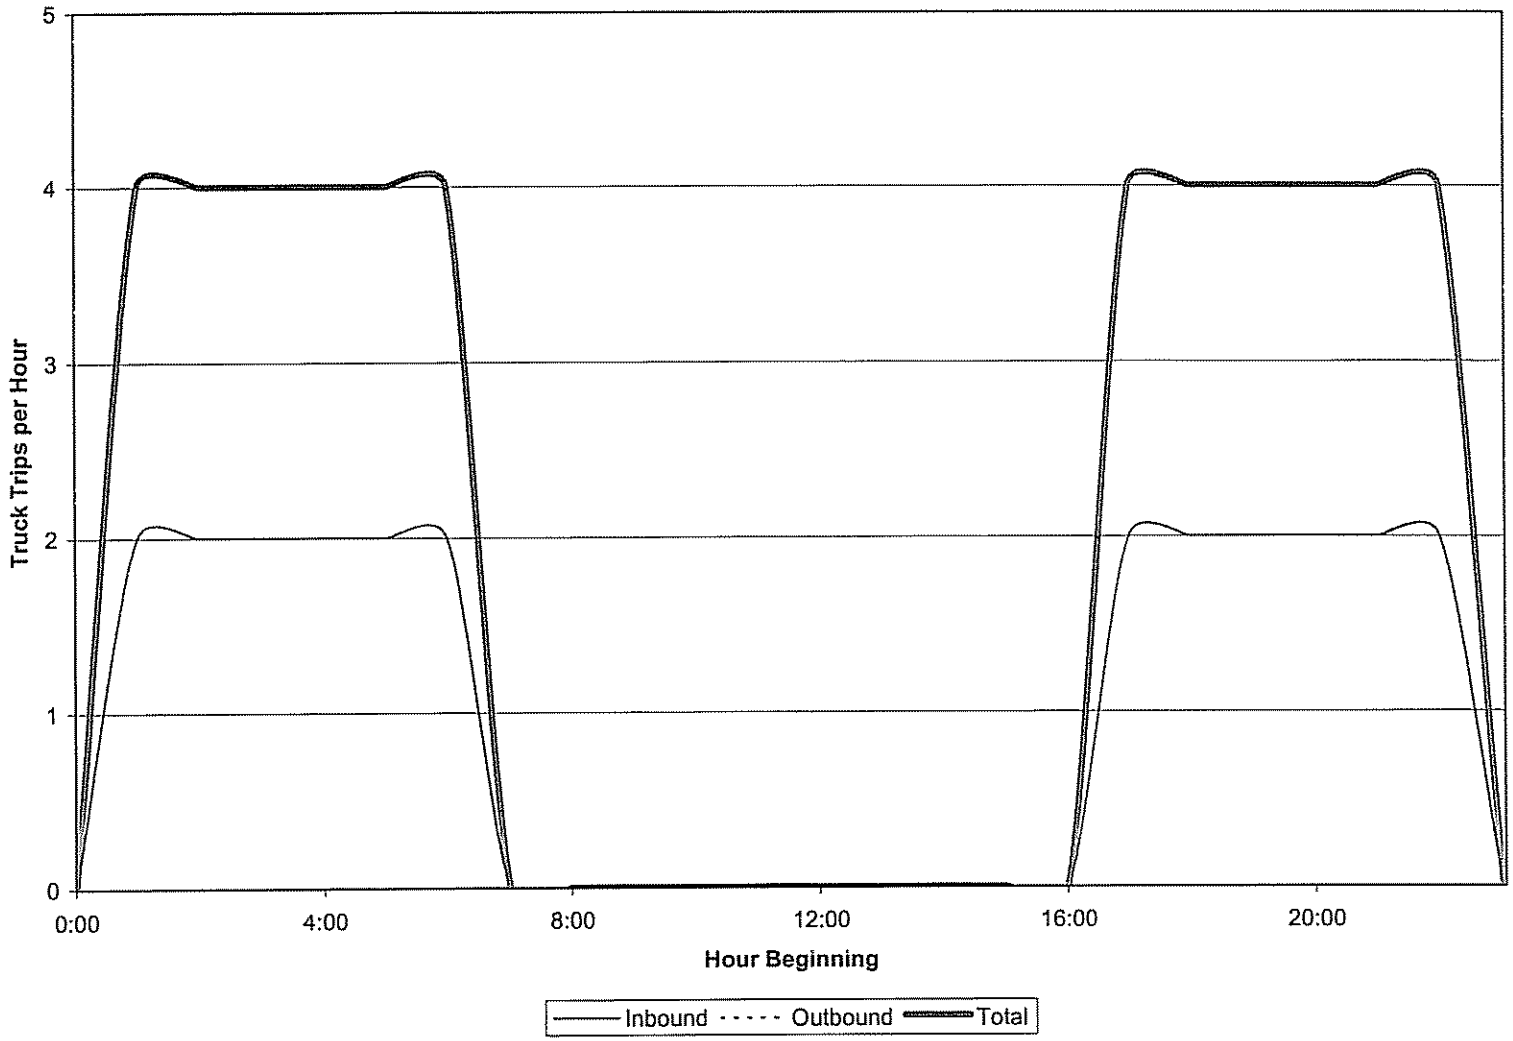
17.14 Traffic, Parking, Transit, and Pedestrians

17.14.1 Introduction

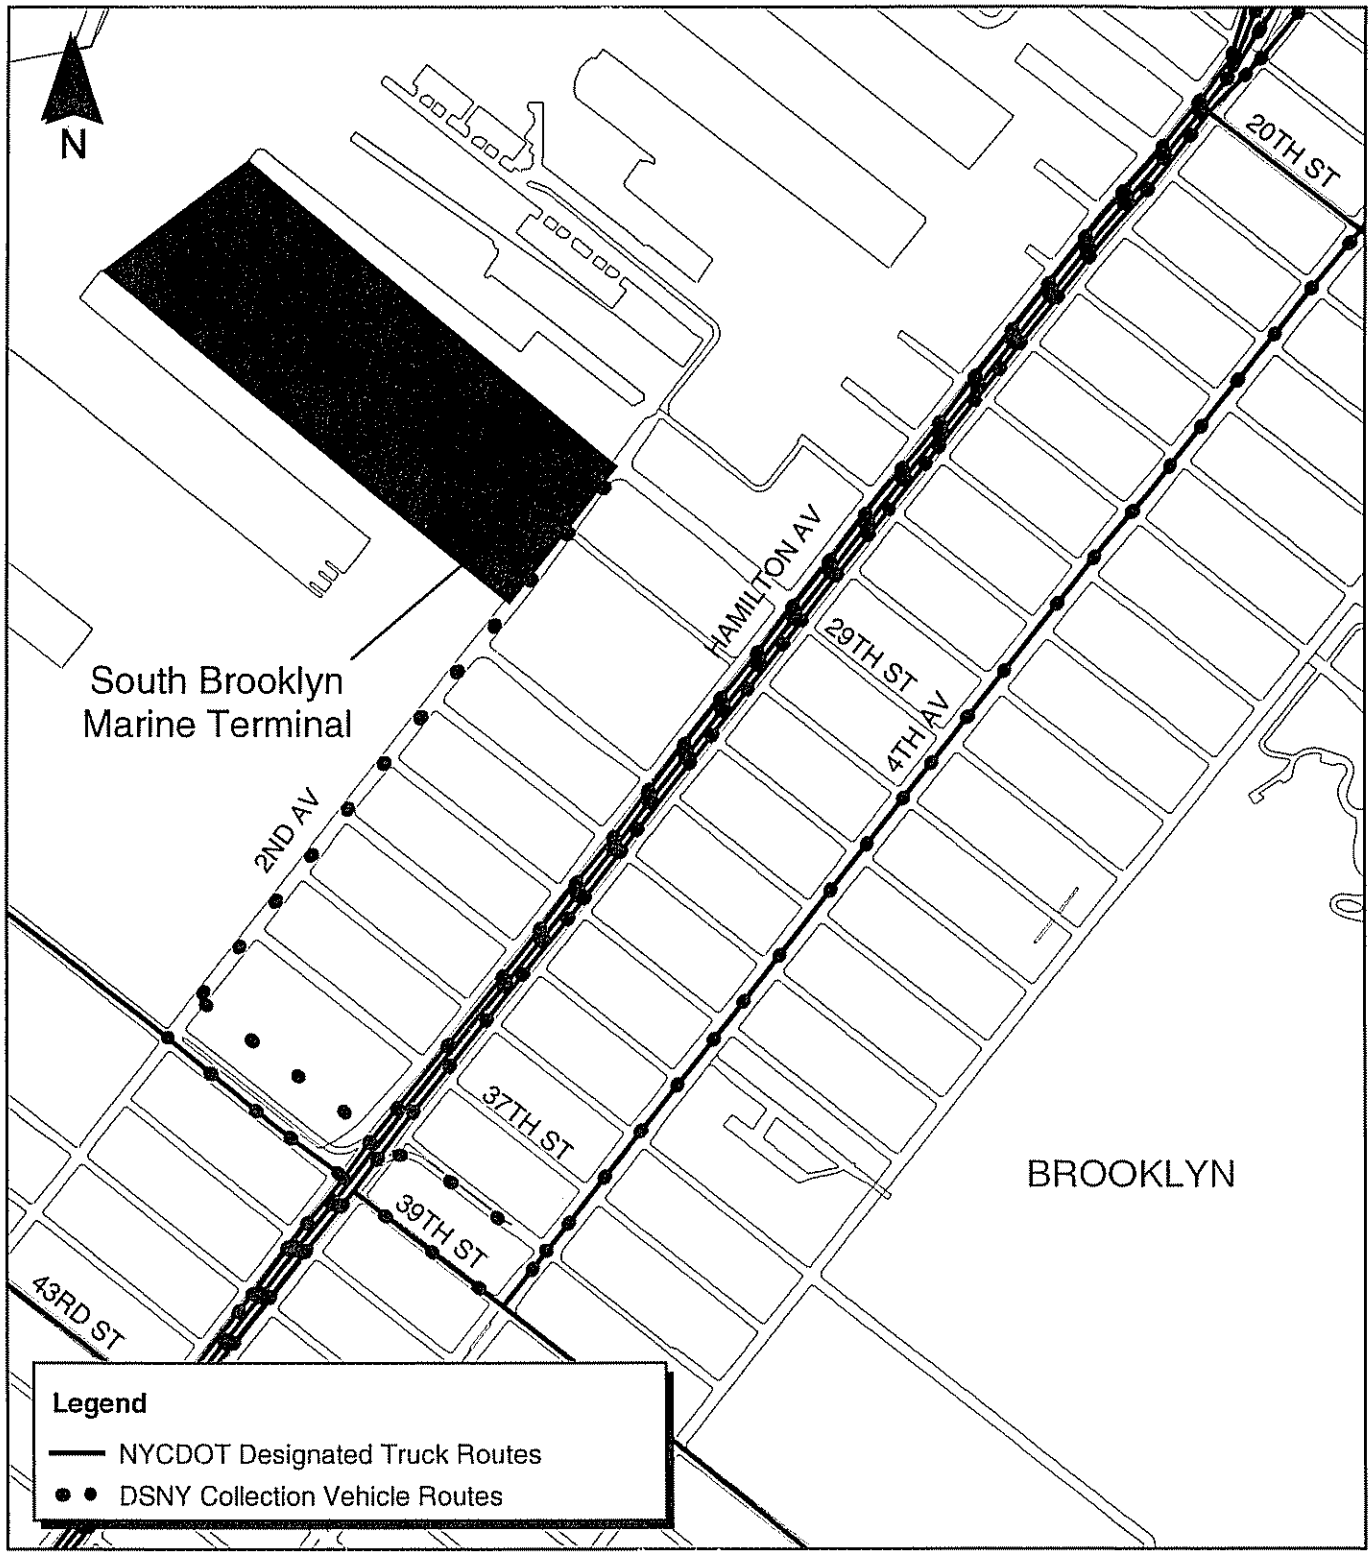
The 30th Street Pier at SBMT would receive recyclable materials from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

17.14.2 Existing Conditions

The site of the 30th Street Pier at SBMT was used for loading and off-loading marine vessels and long-term import/export cargo storage and processing, office space and trailer inspections and repair.



17.14.3 Future No-Build Conditions



Because analysis of traffic impacts was not required for the 30th Street Pier at SBMT, as discussed in Section 17.14.4, Future No-Build Conditions were not estimated.

17.14.4 Potential Impacts with ~~MCR~~ BCR to the 30th Street Pier at SBMT

The 30th Street Pier at SBMT would receive recycling materials from Brooklyn CDs 9, 14 and 15 ~~and Manhattan CDs 1 through 4~~. The assumed 24-hour truck distribution for the 30th Street Pier at SBMT is depicted in Figure 17.14-1. The assumed DSNY recycling collection vehicle routes are depicted in Figure 17.14-2. Peak hour traffic generation for this facility is expected to be ~~21~~ 17 PCEs (which includes 11 employee trips and 4 DSNY collection vehicles (6PCEs)), which falls below the CEQR screening threshold of 50 trip ends per hour. (See Table 3.16-2 in Section 3.16 for a listing of peak hour trip ends by facility.) Therefore, no additional traffic analysis is required at this site.

Figure 17.14-1
Truck Trips per Hour
30th Street Pier at SBMT

30th Street Pier at SBMT

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

17.15 Air Quality

See Section 17.1 for a description of the on-site analysis required.

Off-site air quality locations potentially affected by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, it was determined that the total number of collection vehicles generated by the facility during peak hours was well below the mobile source analysis screening thresholds for CO and $PM_{2.5}$. No appreciable increase in PM_{10} is expected due to the fact that the peak number of facility-generated collection vehicles added to major signalized intersections along 2nd Avenue during peak traffic hours accounts for only 1.4% of the total number of background vehicles at these intersections during these periods (a maximum of 10 facility-generated trucks versus 717 background vehicles during the peak hour at the intersection of 37th Street at 2nd Avenue). In addition, there were no PM_{10} impacts predicted at other intersections analyzed as part of this FDEIS that had a significantly higher number of collection vehicles at key intersections during peak background traffic conditions. Therefore, it was determined that the off-site air quality impacts from operations of the 30th Street Pier at SBMT are not considered to be significant.

17.16 Odor

See Section 17.1 for a description of the analysis required.

17.17 Noise

See Section 17.1 for a description of the on-site analysis required.

The noise analysis addresses off-site sources of noise emission from the 30th Street Pier at SBMT-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for off-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

17.17.1 Existing Conditions

17.17.1.1 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the 30th Street Pier at SBMT-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was not required; therefore, off-site noise monitoring was not conducted.

17.17.2 Future No-Build Conditions

17.17.1.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 17.17-1 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) based on the first-level screening.

Table 17.17-1
Off-Site Noise Traffic Volume
30th Street Pier at SBMT

Location	Hour	Existing Traffic Volume[1] (Vehicles/Hour)	Future No-Build Traffic Volume[2] (Vehicles/Hour)
39th Street between 5th Avenue and 6th Avenue	3:00 a.m.	108	110
39th Street between 3rd Avenue and 4th Avenue	3:00 a.m.	108	110
3rd Avenue between 22nd Street and 23rd Street	3:00 a.m.	193	199

Notes:
(1) Existing Traffic Volumes are based on ATR data.
(2) Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

17.17.3 Potential Impacts with ~~MCR~~BCR to the 30th Street Pier at SBMT

17.17.3.1 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the 30th Street Pier at SBMT. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis and off-site noise monitoring was not required. Results of the screening for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) are provided in Table in Table 17.17-2.

17.17.3.2 Combined On-Site and Off-Site Noise Levels

An off-site noise screening analysis was performed for the 30th Street Pier at SBMT. An on-site noise analysis was not required; therefore, a combined noise analysis was not performed.

Table 17.17-2
Off-Site Noise Screening Results
30th Street Pier at SBMT

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
39th Street between 3rd Avenue and 4th Avenue	3:00 a.m.	316	4	0	188	504	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include DSNY collection vehicles delivering ~~MCR~~BCR and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

CHAPTER 18 ENVIRONMENTAL REVIEW: MANHATTAN CURBSIDE RECYCLABLES TO GANSEVOORT RECYCLABLES ACCEPTANCE FACILITY

18.1 Introduction

The NYCEDC is in the planning stages for the Gansevoort Recyclables Acceptance Facility. Once a design is developed, the Gansevoort Recyclables Acceptance Facility will be the subject of a future environmental review. The environmental review of this Alternative in this FDEIS is limited to off-site impacts associated with traffic, air quality and noise.

The results of the environmental analyses of the Gansevoort Recyclables Acceptance Facility are presented in the following sections:

18.2 Land Use, Zoning, and Public Policy
18.3 Socioeconomic Conditions
18.4 Community Facilities and Services
18.5 Open Space
18.6 Cultural Resources
18.7 Urban Design, Visual Resources, and Shadows
18.8 Neighborhood Character
18.9 Natural Resources
18.10 Hazardous Materials
18.11 Water Quality
18.12 Waterfront Revitalization Program
18.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
18.14 Traffic, Parking, Transit, and Pedestrians
18.15 Air Quality
18.16 Odor
18.17 Noise

Section 2.3.2 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

18.2 Land Use, Zoning, and Public Policy

See Section 18.1 for a description of the analysis required.

18.3 Socioeconomic Conditions

See Section 18.1 for a description of the analysis required.

18.4 Community Facilities and Services

See Section 18.1 for a description of the analysis required.

18.5 Open Space

See Section 18.1 for a description of the analysis required.

18.6 Cultural Resources

See Section 18.1 for a description of the analysis required.

18.7 Urban Design, Visual Resources, and Shadows

See Section 18.1 for a description of the analysis required.

18.8 Neighborhood Character

See Section 18.1 for a description of the analysis required.

18.9 Natural Resources

See Section 18.1 for a description of the analysis required.

18.10 Hazardous Materials

See Section 18.1 for a description of the analysis required.

18.11 Water Quality

See Section 18.1 for a description of the analysis required.

18.12 Waterfront Revitalization Program

See Section 18.1 for a description of the analysis required.

18.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

See Section 18.1 for a description of the analysis required.

18.14 Traffic, Parking, Transit, and Pedestrians

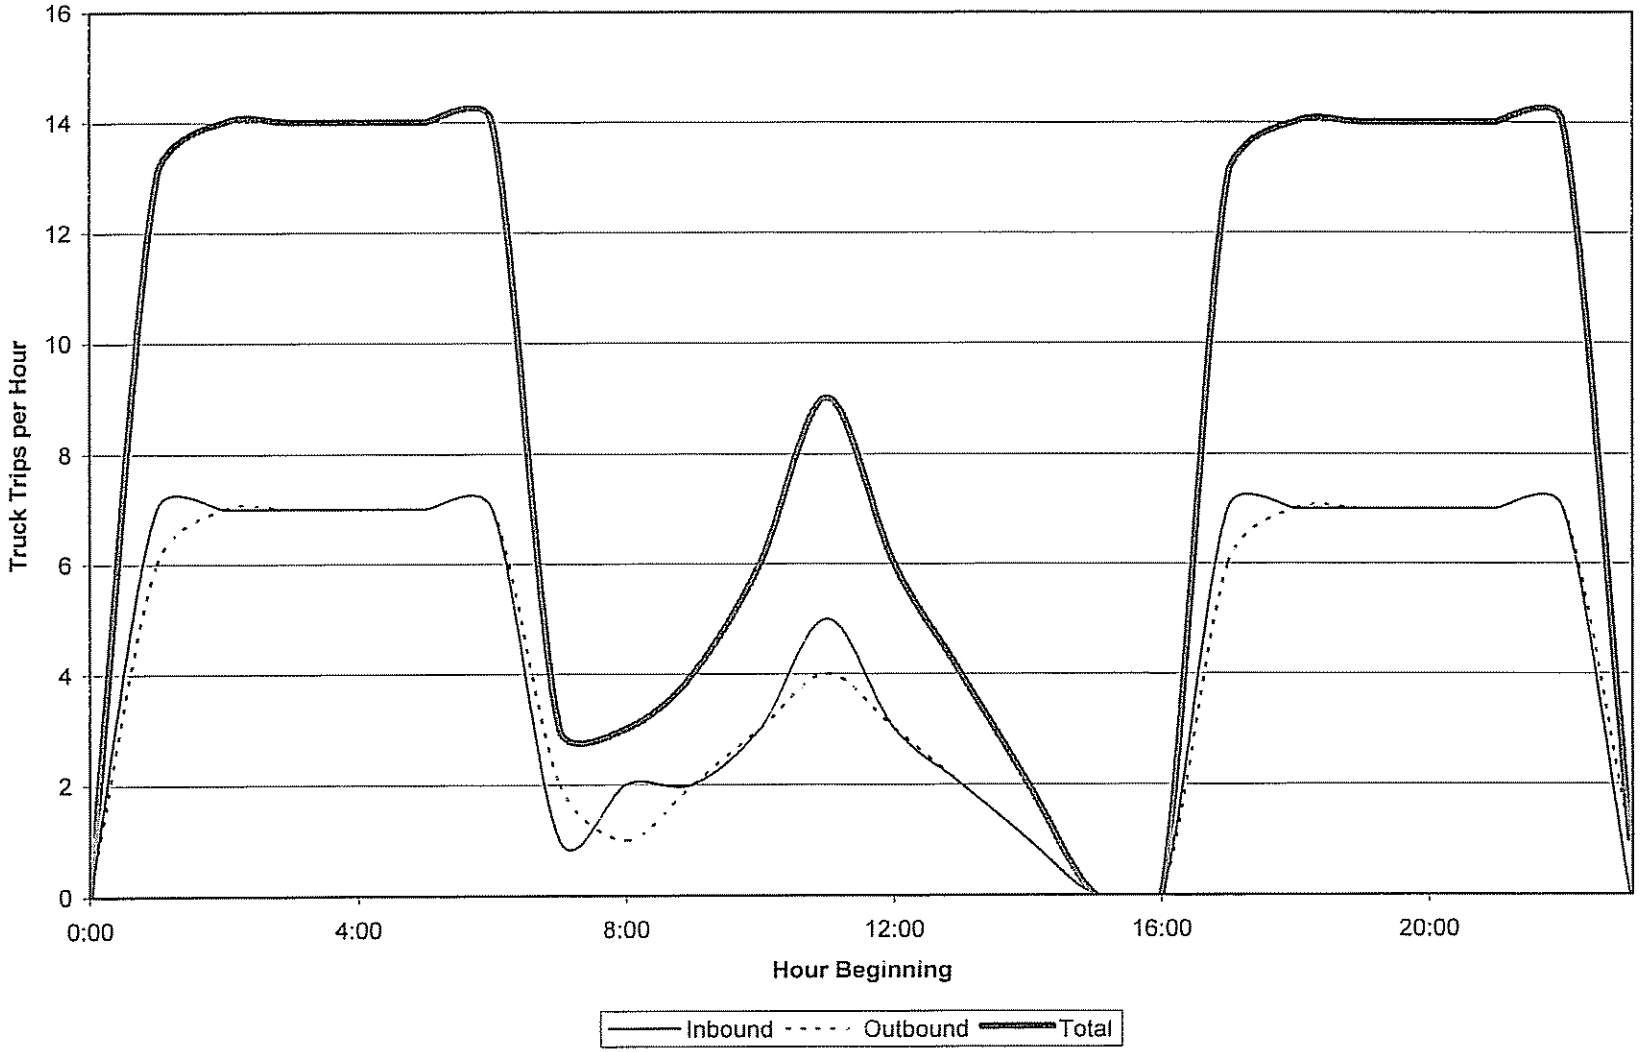
18.14.1 Introduction

The Gansevoort Recyclables Acceptance Facility would receive MCR delivered in DSNY collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on

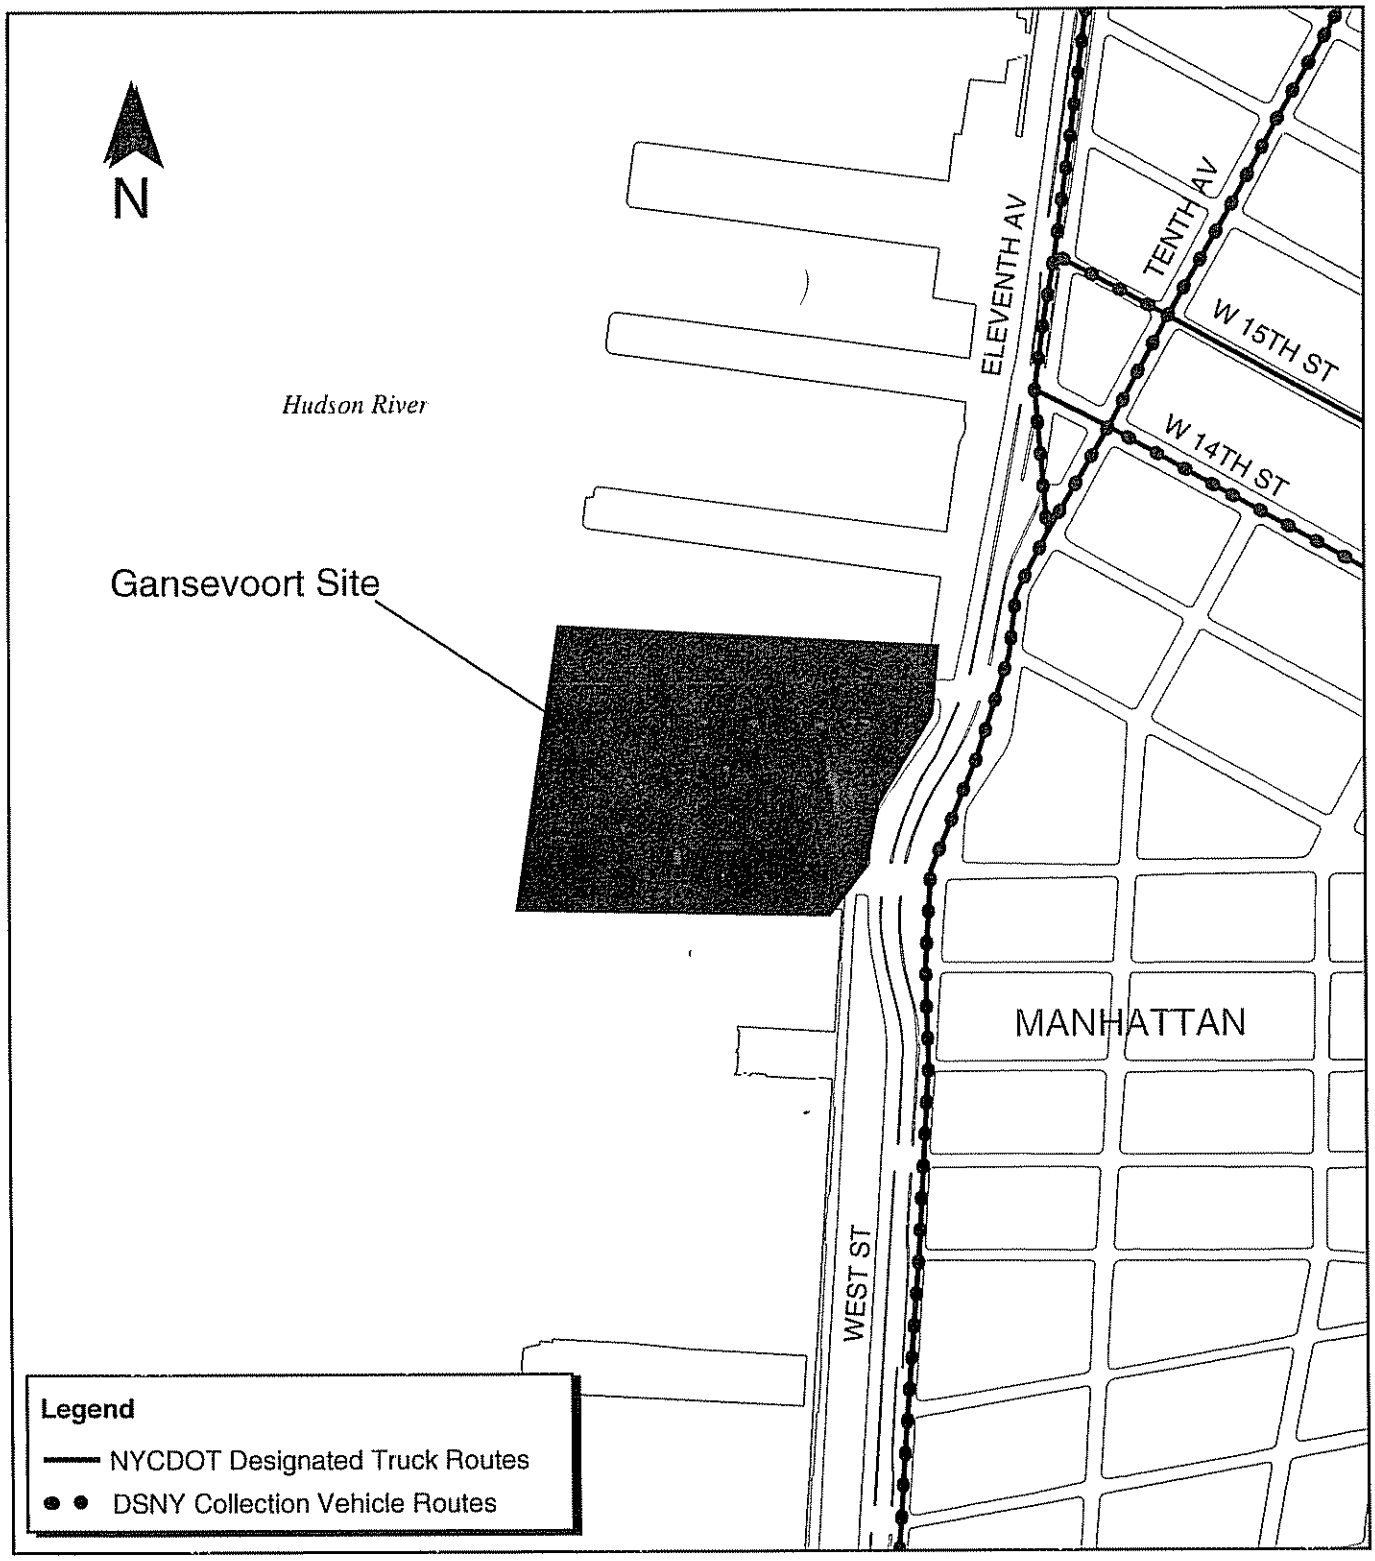
the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

18.14.2 Existing Conditions

The former Gansevoort Street MTS was used as an MTS, but has been closed since July 1991.



18.14.3 Future No-Build Conditions



The NYCEDC is currently in the planning stages for converting the Gansevoort property into parkland with recreational activities. Because analysis of traffic impacts was not required for the Gansevoort Recyclables Acceptance Facility, as discussed in Section 18.14.4, Future No-Build Conditions were not estimated.

18.14.4 Potential Impacts with MCR to the Gansevoort Recyclables Acceptance Facility

The Gansevoort Recyclables Acceptance Facility would receive MCR from Manhattan CDs 1 through 12. The assumed 24-hour truck distribution for the Gansevoort Recyclables Acceptance Facility is depicted in Figure 18.14-1. The assumed DSNY recycling collection vehicle routes are depicted in Figure 18.14-2. Peak hour traffic generation for this facility is expected to be 32 PCEs (including employee vehicles), which falls below the CEQR screening threshold of 50 trip ends per hour. (See Table 3.16-2 in Section 3.16 for a listing of peak hour trip ends by facility). Therefore, no additional traffic analysis is required at this site.

Figure 18.14-1
Truck Trips per Hour

DEPARTMENT OF SANITATION

18.15 Air Quality

See Section 18.1 for a description of the on-site analysis required.

18.15.1 Definition of Study Area

The study area for the off-site air quality analysis consists of the intersection of Route 9A and West 14th Street, as listed in Section 18.15.4.2.

18.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 18.15.1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

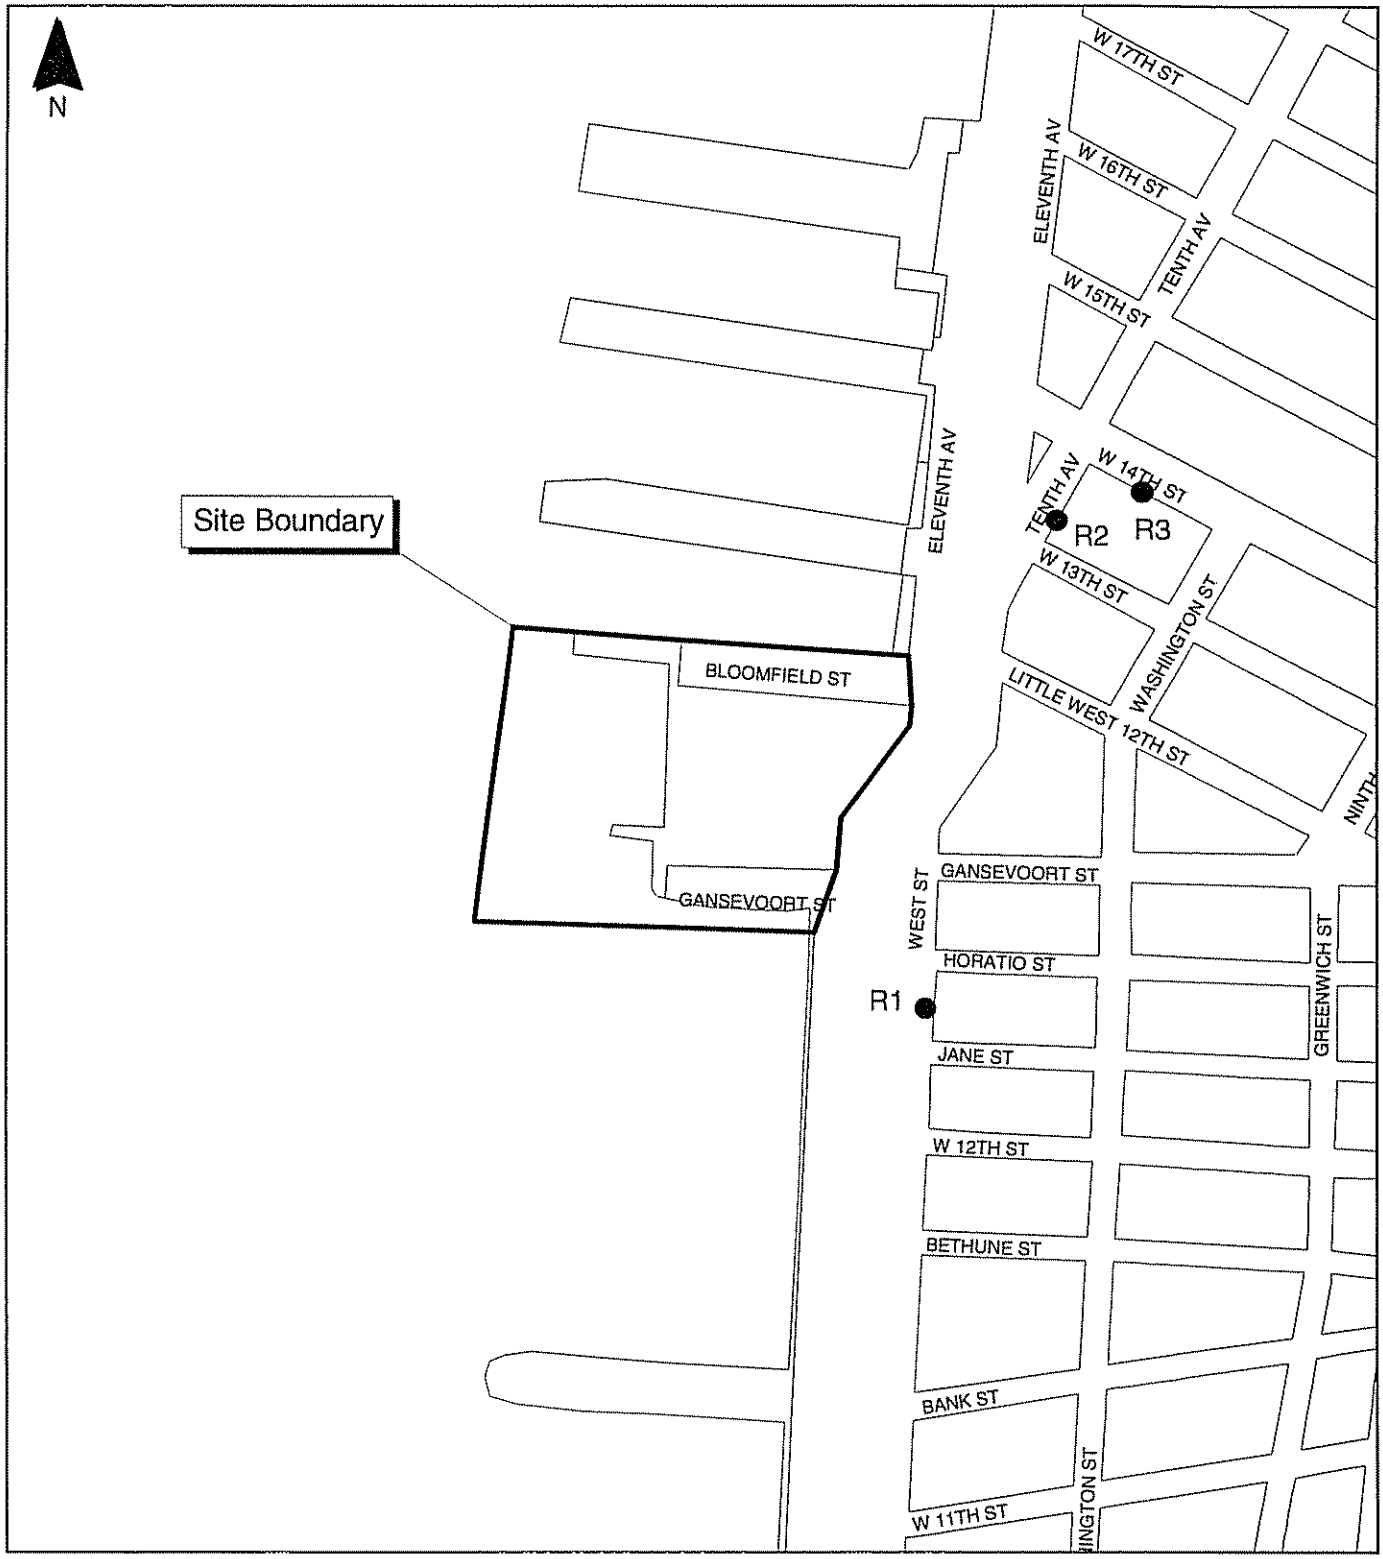
Table 18.15-1
Representative Ambient Air Quality Data
Gansevoort Recyclables Acceptance Facility

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO	225 East 34th Street between Second and Third Avenues	8-Hour	3.0 ppm	9 ppm
		1-Hour	4.0 ppm	35 ppm
NO_2	P.S. 59 (288 East 57th Street)	Annual	0.038 ppm	0.05 ppm
PM_{10}	1 Pace Plaza	Annual	27 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	80 $\mu g/m^3$	150 $\mu g/m^3$
SO_2	P.S. 59 (288 East 57th Street)	3-Hour	0.071 ppm	0.5 ppm
		24-Hour	0.047 ppm	0.14 ppm
		Annual	0.014 ppm	0.03 ppm

Notes:
Source: USEPA Airdata/NYCDEP, April 2003

18.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the 2006 analysis year. As such, no significant changes to air quality levels are anticipated, and Future No-Build Conditions are expected to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be reduced by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.



18.15.4 Potential Off-Site Air Quality Impacts with MCR to the Gansevoort Recyclables Acceptance Facility

18.15.4.1 Pollutants Considered and Analyses Conducted

Using 2001 CEQR Technical Manual guidelines for the selection of analysis locations, one intersection was identified as potentially having significant impacts by the proposed collection vehicles: the intersection of Route 9A and West 14th Street. Detailed mobile source analyses were then conducted at this location during the applicable (i.e., worst-case) time periods to determine whether the facility-generated traffic has the potential to cause exceedances of the PM_{10} NAAQS, or NYCDEP's and~~or~~ NYSDEC's 24-hour and annual $PM_{2.5}$ STVs. No CO analysis was conducted because the number of proposed vehicle trips to and from the facility is below CEQR CO screening thresholds. Figure 18.15-1 shows the location of the intersection analyzed.

18.15.4.2~~.2~~ Results of the Off-Site Analysis

Maximum PM_{10} concentrations and $PM_{2.5}$ project-related impacts estimated near the intersection of Route 9A and West 14th Street are provided in Table 18.15-2. These results show that all estimated concentrations are within (less than) the applicable state and federal ambient air quality standards and/or STVs for $PM_{2.5}$. As such, proposed recycling operations at this facility would not result in significant off-site air quality impacts.

Site delineations are approximate.

Notes:

(1) PM_{10} concentrations are the maximum concentrations estimated using the AM, Facility, and PM peak traffic conditions plus background concentration; 24-hr PM_{10} = 6188 $\mu g/m^3$; Annual PM_{10} = 2134 $\mu g/m^3$).

(2) ~~The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project induced [or Future Build] traffic only) estimated by taking~~ The difference between the ~~maximum~~ $PM_{2.5}$ concentrations under~~for the~~ Future No-Build and Future Build conditions~~scenarios~~ at ~~any~~ maximum slope walk receptors~~, three meters from the edge of the roadways~~ under ~~using~~ AM, Facility, or PM peak traffic conditions.

(3) ~~The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project induced [or Future Build] traffic only) estimated by taking~~ The difference between ~~the maximum~~ $PM_{2.5}$ concentrations under~~for the~~ ~~f~~Future No-Build and ~~f~~Future Build scenarios at maximum~~any~~ receptors 15 meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.

ppm = parts per million

$\mu g/m^3$ = microgram per cubic meter

18.16 Odor

See Section 18.1 for a description of the on-site analysis required.

18.17 Noise

See Section 18.1 for a description of the on-site analysis required.

The noise analysis addresses off-site sources of noise emission from the Gansevoort Recyclables Acceptance Facility-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for off-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

18.17.1 Existing Conditions

18.17.1.1 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the Gansevoort Recyclables Acceptance Facility-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was not required; therefore, off-site noise monitoring was not conducted.

18.17.2 Future No-Build Conditions

18.17.2.1 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 18.17-1 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) based on the first-level screening.

Table 18.17-1
Off-Site Noise Traffic Volume
Gansevoort Recyclables Acceptance Facility

Location	Hour	Existing Traffic Volume [1] (Vehicles/Hour)	Future No-Build Traffic Volume[2] (Vehicles/Hour)
Route 9A between Horatio and Jane Streets	3:00 a.m.	751	763
Route 9A Between West 13th and West 14th Streets	3:00 a.m.	751	763
West 14th Street Between Washington Street and Route 9A	4:00 a.m.	~~335~~336	341

Notes:
(1) Existing Traffic Volumes are based on ATR data.
(2) Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

18.17.3 Potential Impacts with MCR to the Gansevoort Recyclables Acceptance Facility

18.17.3.1 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Gansevoort Recyclables Acceptance Facility. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis and off-site noise monitoring was not required. Results of the screening for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) are provided in Table 18.17-2.

18.17.3.2 Combined On-Site and Off-Site Noise Levels

An off-site noise screening analysis was performed for the Gansevoort Recyclables Acceptance Facility. An on-site noise analysis was not required; therefore, a combined noise analysis was not performed.

Table 18.17-2
Off-Site Noise Screening Results
Gansevoort Recyclables Acceptance Facility

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
Route 9A between Horatio and Jane Streets	3:00 a.m.	1159	14	0	658	1817	No
Route 9A Between West 13th and West 14th Streets	3:00 a.m.	1159	7	0	329	1488	No
West 14th Street Between Washington Street and Route 9A	4:00 a.m.	932	7	0	329	1261	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include DSNY collection vehicles delivering MCR and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

CHAPTER 19 ENVIRONMENTAL REVIEW: SOUTH BRONX CONVERTED MTS

19.1 Introduction

The results of the environmental analyses of the South Bronx Converted MTS are presented in the following sections:

19.2 Land Use, Zoning, and Public Policy
19.3 Socioeconomic Conditions
19.4 Community Facilities and Services
19.5 Open Space
19.6 Cultural Resources
19.7 Urban Design, Visual Resources, and Shadows
19.8 Neighborhood Character
19.9 Natural Resources
19.10 Hazardous Materials
19.11 Water Quality
19.12 Waterfront Revitalization Program
19.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
19.14 Traffic, Parking, Transit and Pedestrians
19.15 Air Quality
19.16 Odor
19.17 Noise
19.18 Commercial Waste to the South Bronx Converted MTS

Section 2.4.1 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

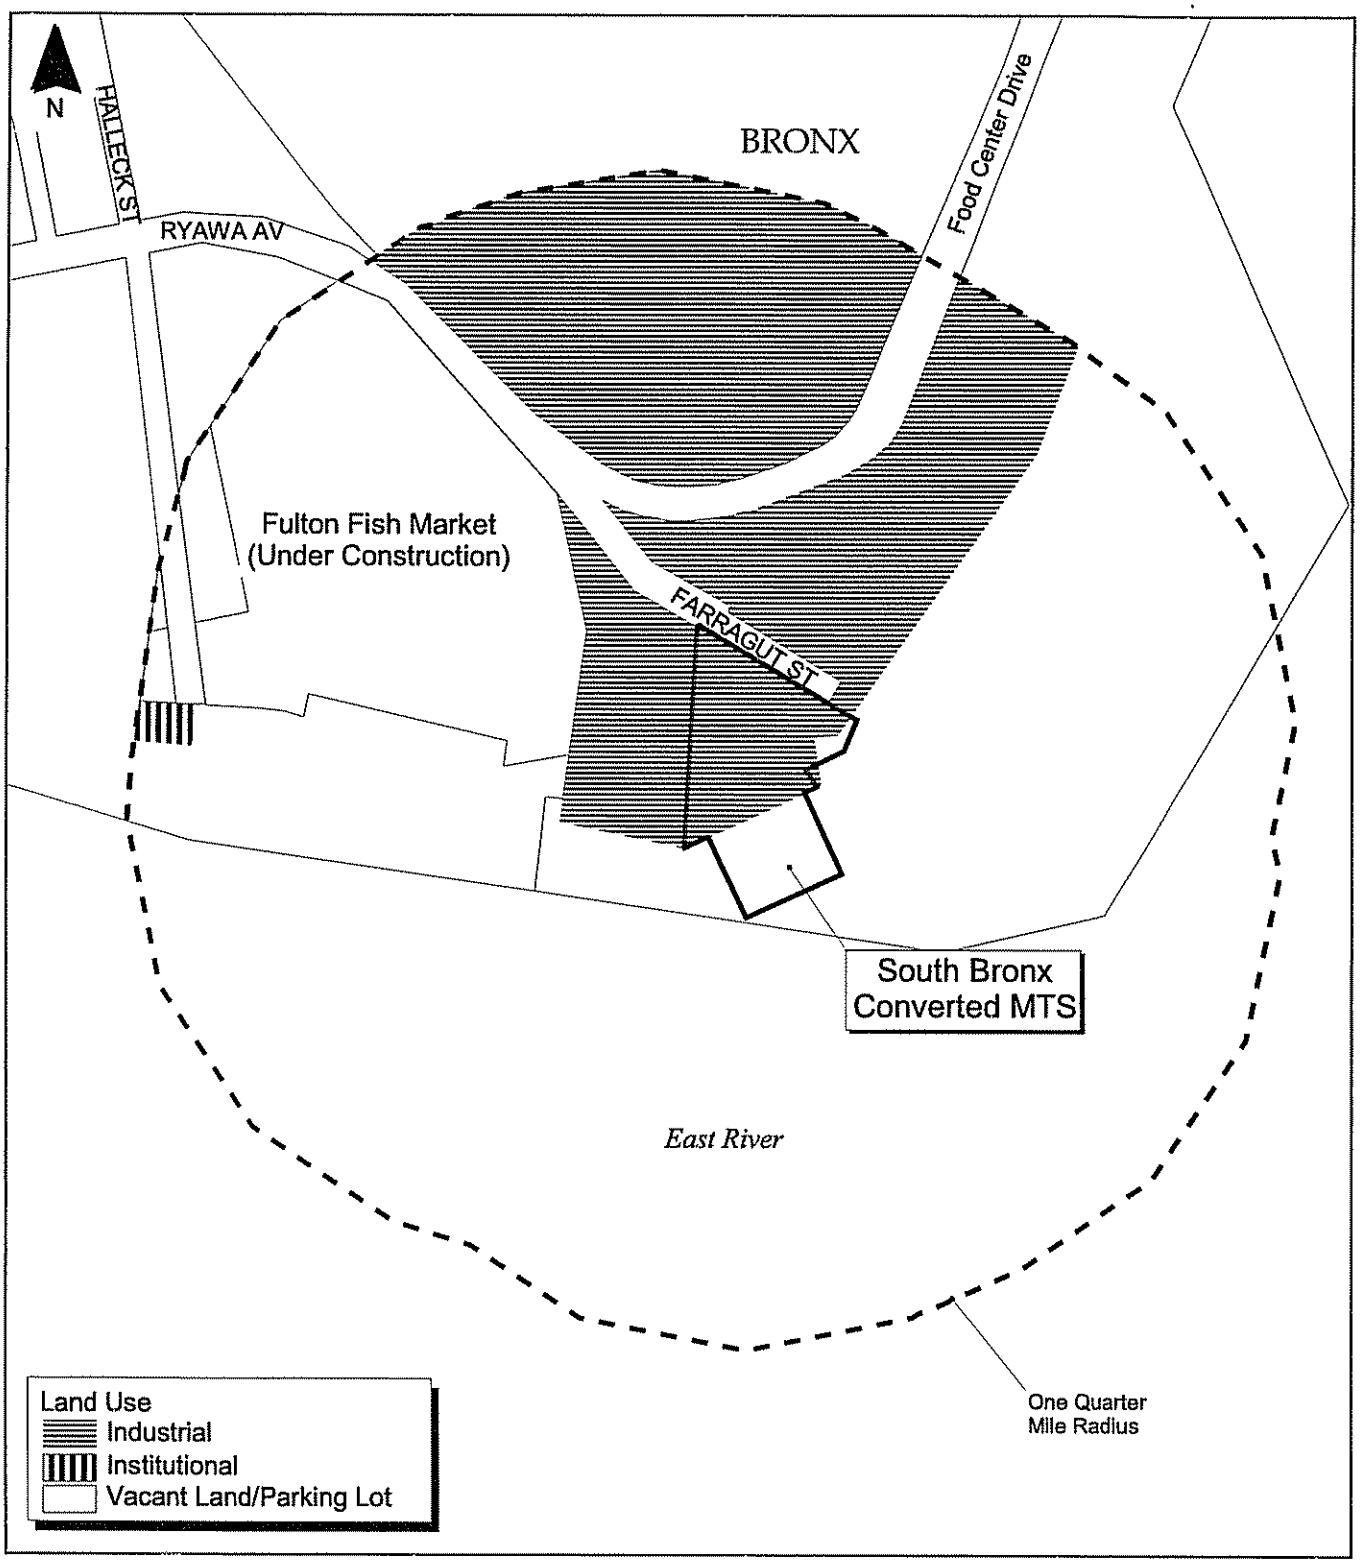
19.2 Land Use, Zoning, and Public Policy

19.2.1 Existing Conditions

19.2.1.1 Definition of the Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 19.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 19.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.4.1 provides information on existing land uses and operations on the site.

19.2.1.2 Land Use Patterns



19.2.1.2.1 General Context

The site is set on the industrial Hunts Point waterfront. A number of nearby City-owned properties and operations surround the site. The predominant use is the 329-acre Hunts Point Market, which is administered by NYCEDC.

19.2.1.2.2 Land Uses in the Primary Study Area

All property immediately adjacent to the site is owned by the City or its agencies (i.e., DSNY, Department of Correction, NYCDEP and NYCEDC). A small area with deteriorated paving that abuts the site near the East River's edge is used informally by local residents as a point of public access for fishing and viewing the water.

An active SHS on the site is comprised of a paved area surrounded by concrete walls topped with cyclone fencing. Accessed through a 30-foot sliding gate facing Farragut Street (formerly Hunts Point Avenue), the SHS accepts materials such as tires, metal, wood, C&D materials and glass from non-commercial vehicles. An office trailer is also located within this area.

Site delineations and study area boundaries are approximate

Figure 19.2-2 Land Use in the Secondary Study Area

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

A one-story, vacant goods distribution warehouse operated formerly by National Foods is located opposite the site, across Farragut Street. This facility is part of the City-owned Hunts Point Market, the wholesale food market and distribution center built in the 1970s that covers nearly the entire eastern half of the Hunts Point peninsula. The Hunts Point Market serves as the primary distribution point for meat and produce within the tri-state area. The meat market is located within the primary and secondary study areas, while the produce market extends north from East Bay Avenue.

Outdoor movement of meat occurs around the meat market buildings. Distribution and delivery to these buildings and some of the other facilities in the Hunts Point Market is by both truck and rail. The Hunts Point Rail Loop Spur extends into the primary study area, following Food Center Drive, a loop roadway serving the market.

The City Department of Correction's prison barge, known as the Vernon C. Bain Center (City Correctional Facilities Maritime Facility III), is located at 1280 Ryawa Avenue to the west of the site. The land area adjacent to the barge is fenced off from the site and is undeveloped and partly wooded. The prison barge is one of the Department of Correction's reserve facilities that is closed or opened on an as-needed basis in response to inmate population fluctuations. It is an 80-bed facility currently in use at full capacity. The 30-acre parcel vacant upland of the prison barge is currently being graded for construction of the relocated Fulton Fish Market.

19.2.1.2.3 Land Uses in the Secondary Study Area

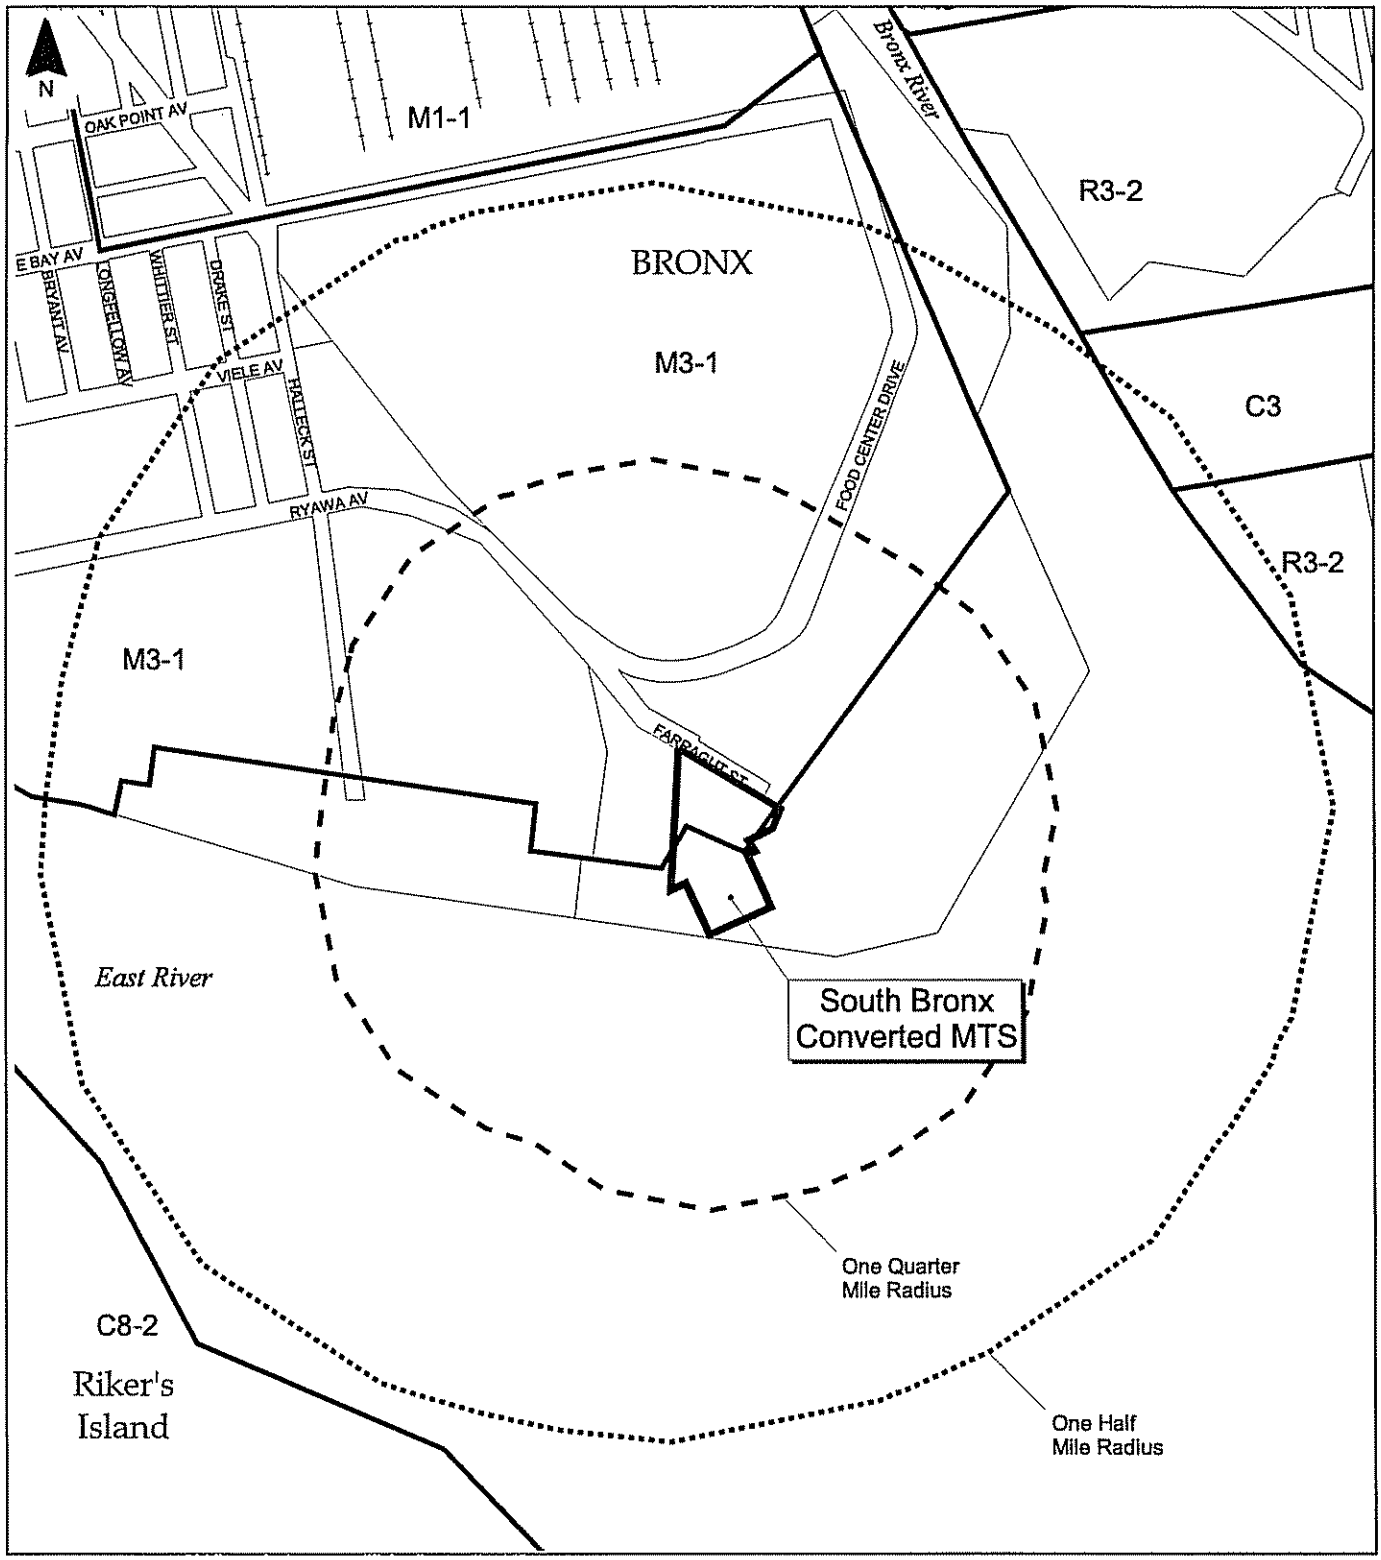
Several one-story market buildings and a two-story cold storage warehouse building are located in the secondary study area, north-northeast of the site within the Hunts Point Market. Paved storage and parking areas that surround these distribution warehouses are separated from Farragut Street by wire fencing. Major food distribution businesses including National Foods, Krasdale Foods, and Bazzini Nut Corporation are located off Food Center Drive.

Additional Department of Correction vacant property is to the west of the site. Further west, just within the ½-mile secondary study area is the Hunts Point WPCP operated by NYCDEP. Private industrial and heavy commercial uses, such as auto salvage yards, are located on Ryawa Avenue, Halleck Street, Drake Street and Whittier Street.

Beyond the secondary study area to the northwest and east, respectively, the Hunts Point peninsula contains additional industrial uses and the Hunts Point residential community (with approximately 11,400 residents).

19.2.1.3 Zoning On and Near the Site

19.2.1.3.1 Zoning Within the Primary Study Area



The site and surrounding properties within both the primary and secondary study areas fall within an M3-1 heavy industrial district that extends north to approximately East Bay Avenue and Randall Avenue, where it abuts an M1-1 light industrial district. Most of the Hunts Point peninsula is zoned for manufacturing, with the exception of the 20-block residential area located at the northeastern end (see Figure 19.2-3 and Table 3.4-1: Zoning District Characteristics), about one mile from the site.

19.2.1.3.2 Zoning Within the Secondary Study Area

North of the subject M3 district is an M1-1 light industrial zoning district that covers areas outside of the secondary study area surrounding Randall Avenue and east to approximately Longfellow Avenue.

19.2.1.4 Plans and Policies

In its FY 2004 CDNS, Bronx Community Board 2 (South Bronx) refers to the community's anticipated use of the Bronx River and shoreline areas outside the study area for recreational and educational purposes, but it refers to the designation of the Hunts Point waterfront as an SMIA, thus making it suitable for water-dependent industry. However, the document states that because the district perceives that it is unfairly burdened by private and public waste transfer facilities located in the district, the Community Board has adopted a policy of "zero tolerance for any proposed new waste transfer station in the district."

Site delineations and study area boundaries are approximate.
Base Map Source: New York City Department of Planning

500 0 500 Feet

Figure 19.2-3 Zoning

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The proposed Hunts Point Streetscaping and Transportation Enhancement Program is intended to improve the quality of life in residential areas on the Hunts Point peninsula. It includes traffic calming measures, landscaping and other improvements, including improving the industrial park with color-coded signage, lighting and streetscape improvements. Program recommendations include the decommissioning of certain truck routes. The Hunts Point Action Plan is a separate $20 million City initiative to pave streets and sidewalks and undertake bridge improvements on the peninsula.

Reach 7 of the NYCDCP's Plan for the Bronx Waterfront, which covers the South Bronx, makes several recommendations for the Hunts Point peninsula in the vicinity of the site. The plan recommends:

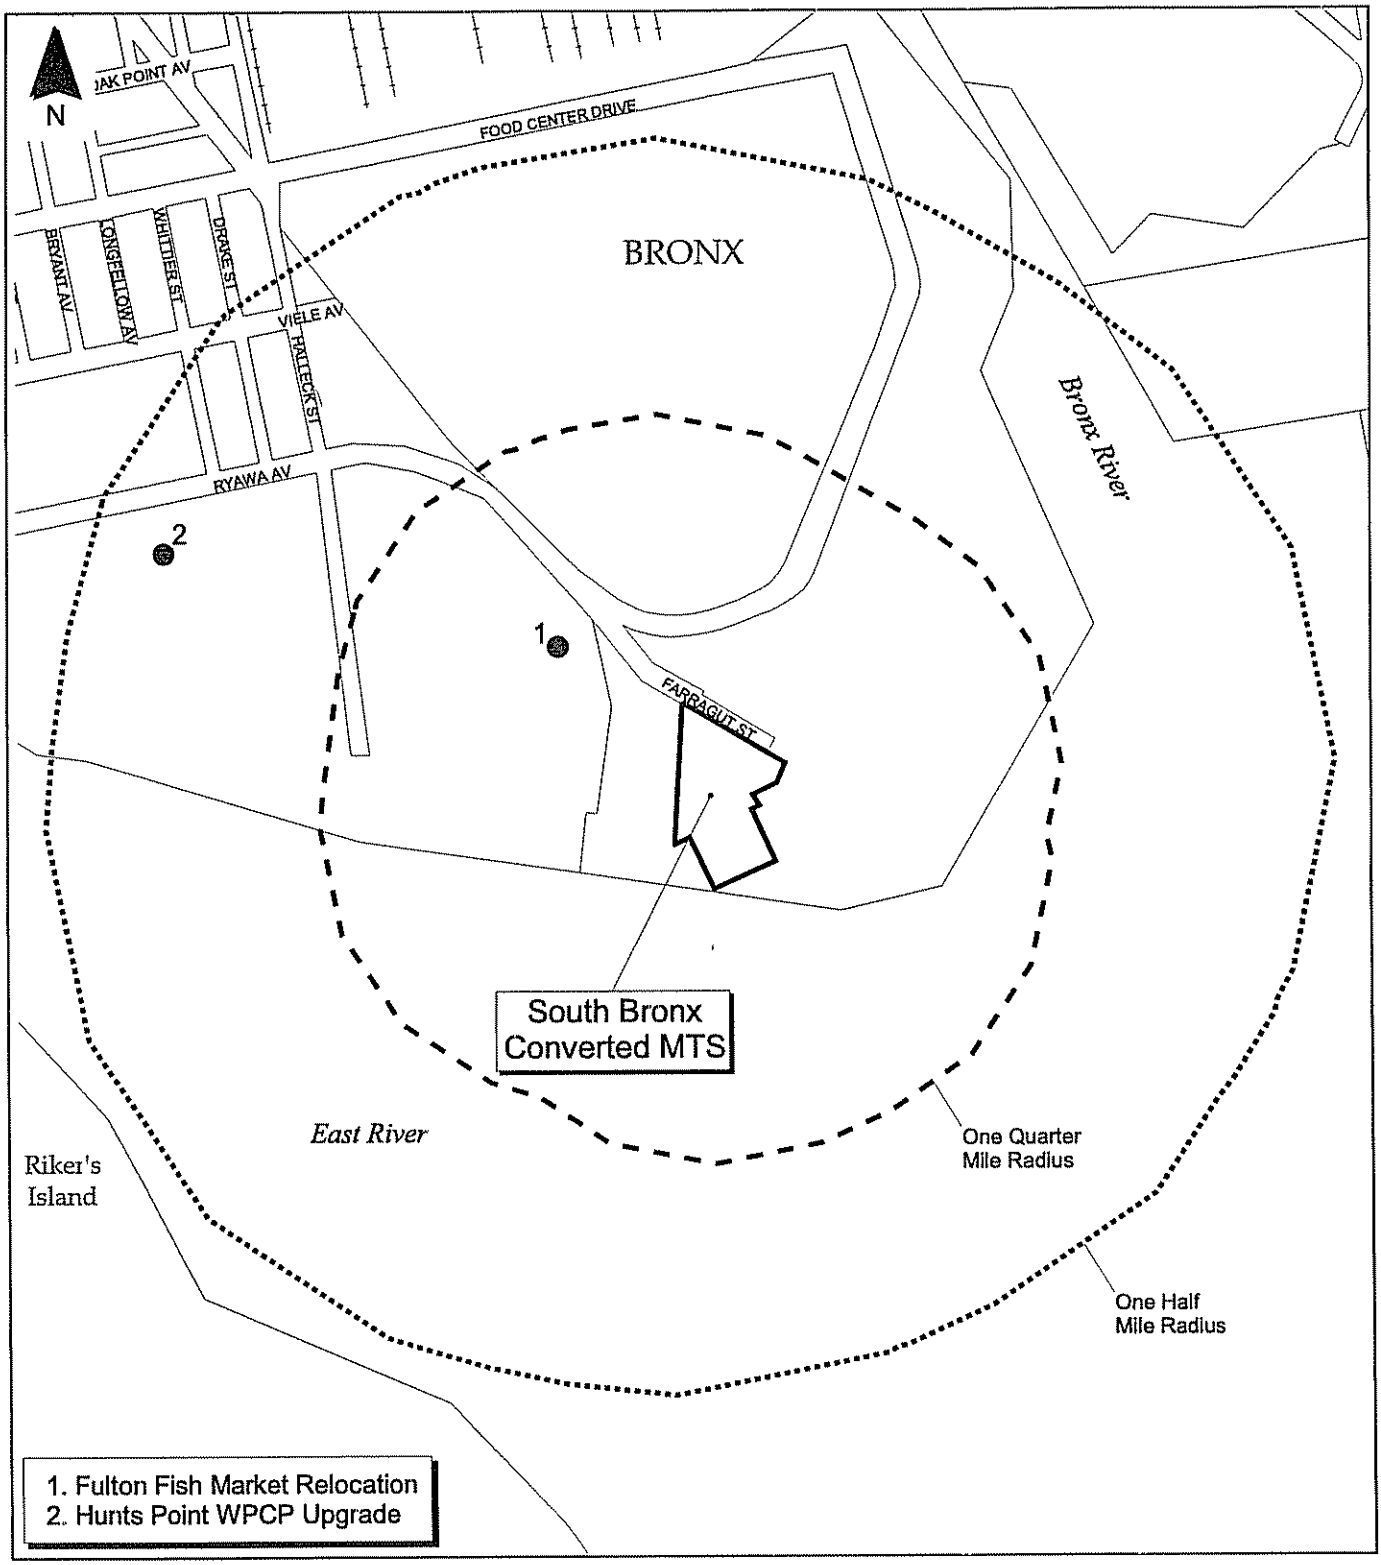
- Conservation of the existing natural edge along the waterfront for shoreline areas to the north of the site in order to soften the industrial character of the Hunts Point Market as seen from the East River and Soundview Park.
- Increased use of barge transport, including for solid waste transport. (Two sites within the Hunts Point Market food distribution center are cited as having barge access potential, including one point approximately ¼-mile northeast of the South Bronx Converted MTS site.)
- Waterfront public access improvements that emphasize sites within other parts of Hunts Point, such as the Tiffany Street Pier and Lafayette Street. However, a pedestrian access point is recommended at the end of Farragut Street adjacent to the South Bronx Converted MTS site, where local residents already access the waterfront informally for fishing.
- Exploring the reuse of the site as a waterfront park with an esplanade and fishing pier serving the Hunts Point community, in the event that it is vacated by DSNY.

The only element of the Reach 7 plan that is being implemented currently is the reconstruction of the Tiffany Street Pier as a public access pier with fishing and passive recreation facilities (see Section 19.12 for a review of consistency with the WRP).

19.2.2 Future No-Build Conditions

Two major developments are underway or proposed within ½-mile of the site. Figure 19.2-4 shows the planned development sites. Development plans include the following:

- The Fulton Street Fish Market will be relocated from Manhattan to the largest site, a 30-acre parcel site west of the South Bronx Converted MTS site, by the end of 2004. The newly constructed two-story 450,000-square-foot facility will house 55 businesses.
- The Hunts Point WPCP Expansion Project is currently underway. It encompasses a large waterfront site west of the South Bronx Converted MTS site and the prison barge, and will be substantially complete by 2006.



The Hunts Point Action Plan, developed in 1997 to improve signage on the peninsula and to address truck routing, will be in place by 2006.

The only element of the Reach 7 plan expected to be implemented is the reconstruction of the Tiffany Street Pier as a public access pier for fishing and passive recreation. This project will enhance waterfront public amenities on the greater Hunts Point peninsula. The site itself will remain DSNY property, and the existing MTS will remain standing. The associated DSNY salt storage facility and SHS will continue to be fully operational.

19.2.3 Potential Impacts with the South Bronx Converted MTS

19.2.3.1 Land Use and Zoning

The South Bronx Converted MTS represents a slight physical upgrading of the site. The existing MTS, which extends over water, would be demolished, and the new facility would be built in approximately the same location. The South Bronx Converted MTS processing operation would be designed to containerize waste and prepare containers for transfer to barges for disposal outside the City. The entrance to the facility would be moved slightly to the west. The existing salt shed and SHS would remain intact.

Site delineations and study area boundaries are approximate.
Base Map Source: New York City Department of City Planning

HDR HydroQual URBITRAN PB EEA Cambridge Environmental Inc

Figure 19.2-4 Planned Development Sites

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

The reactivation of waste transfer activities on the site would have no effect on land uses nearby and the truck traffic would be consistent with the heavy industrial character and zoning of the primary and secondary study areas.

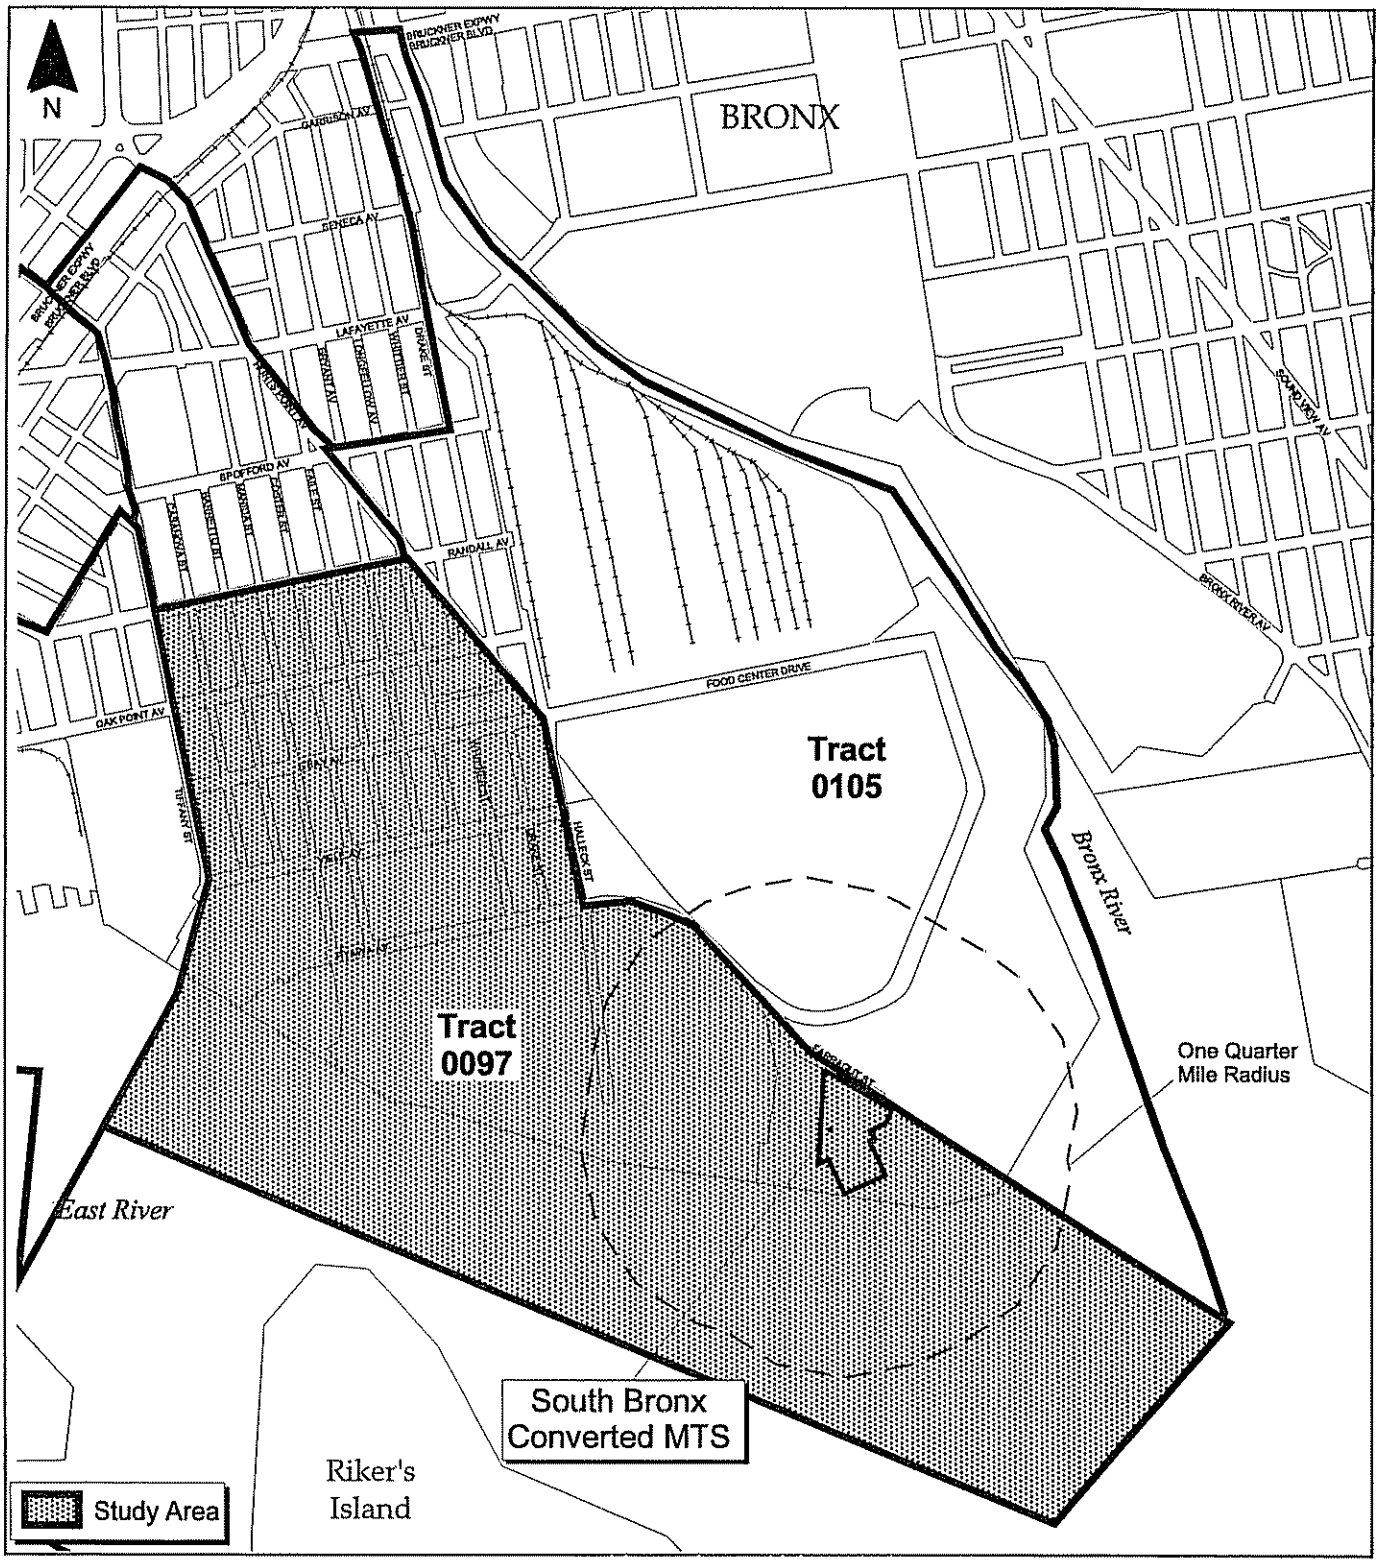
19.2.3.2 Consistency with Public Plans and Policies

The South Bronx Converted MTS is consistent with recommendations of the Reach 7 plan, which promote increased use of barge for solid waste transport. While the Reach 7 plan discussed a potential future Hunts Point waterfront park on the site, this is only recommended in the event that the site is no longer used by DSNY. Therefore, this recommendation does not conflict with the South Bronx Converted MTS. The South Bronx Converted MTS would not preclude use of land at the end of Farragut Street as a designated pedestrian waterfront access point, although it could detract from the enjoyment of that adjacent waterfront experience. It is reasonable to assume, however, that pedestrian waterfront access would be better accommodated by the new Tiffany Street Pier and Barretto Point Park, which will be in place west of the site by 2006. Although the presence of the South Bronx Converted MTS operations would be consistent with the SMIA designation, as the Community District (CD) 2 Statement of Needs says, it would be inconsistent with the Community Board's zero-tolerance policy.

19.3 Socioeconomic Conditions

19.3.1 Existing Conditions

19.3.1.1 Definition of the Study Areas



Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area consists of Census Tract 97 (see Figure 19.3-1). The tract encompasses predominantly industrial areas on the southern and eastern portions of the Hunts Point peninsula and contains some scattered residential areas. The study area for the assessment of potential impacts on economic conditions extends to approximately Viele Avenue.

19.3.1.2 Demographic Characteristics

Because the 2000 population of the study area consisted of only 92 individuals and 13 families, none of who would be directly displaced by the South Bronx Converted MTS, a detailed demographic review is not presented here. Socioeconomic data (comparing 1990 and 2000 census data for the study area, borough and City) were collected, however, and are provided in Appendix B.

19.3.1.3 Economic Conditions

The site is adjacent to the Hunts Point Market, a City-administered (NYCEDC) industrial park that is the main wholesale food distribution center for the New York region. A vacant one-story, canned food goods distribution warehouse formerly operated by National Foods is across Farragut Street from the site. Other business and institutional uses within ¼-mile north of the site include additional Hunts Point Market distribution and warehouse uses, including meat market buildings, and a City Department of Corrections property (prison barge). Several other one-story market buildings and a two-story cold storage warehouse building are between ¼- and ½-mile north-northeast of the site within the Hunts Point Market. Major food distribution

Site delineations and study area boundaries are approximate
Base Map Source: New York City Department of City Planning

Figure 19.3-1 Census Tracts

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

businesses, including Krasdale Foods and Bazzini Nut Corporation, are off Food Center Drive, a loop roadway serving the market. Industrial and heavy commercial uses, including auto salvage yards and waste transfer stations, are outside of the market in the industrially-zoned portions of Hunts Point. These industrial and heavy commercial uses are located at a distance of approximately ½-mile to the west of the site.

The Hunts Point EDZ extends beyond the boundaries of the ½-mile study area. The EDZ was developed to stimulate economic activity in distressed areas and encourage business development through targeted incentives and benefits to new and expanding commercial and industrial firms. State benefits are available through wage tax credits, investment tax credits, sales tax refunds on building/construction costs and financial assistance. Utility discounts and free security surveys are provided to relocating or expanding businesses. This is one of the City's most successful EDZs, with 130 businesses certified to participate in its programs. In 1998, 500 new jobs were created in the EDZ and $25 million in private investment was leveraged. The Hunts Point Local Development Corporation (LDC) is the local sponsor of the EDZ. It has been involved with planning and upgrading initiatives for the entire Hunts Point peninsula.

Current forecasts indicate that about 22,757 employees worked in Bronx CD 2 in 2005, which was about 8% of the borough's total employment.[1]

19.3.2 Future No-Build Conditions

19.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Bronx CD 2 will remain about the same as current conditions.[2]

The Department of Correction's prison barge adjacent to the site is currently fully occupied (800 inmates) and is expected to operate at this capacity in the Future No-Build Conditions.

---

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

[2] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

19.3.2.2 Economic Conditions

Regional projections indicate that employment in Bronx CD 2 will remain about 8% of the borough total.[3]

The near-term economic health of industrial areas, such as Hunts Point, may be supported by established City programs available through the IDA. The Industrial Incentive Program and the Small Industry Incentive Program provide business tax incentives for capital renovation and expansion projects.

Hunts Point is part of the South Bronx portion of the Harlem/South Bronx EZ. The EZ is one of six such designated zones in the country where state and federal matching funds and tax incentives are available to attract private investment, generate job growth, stimulate business openings and expansions, construct new housing, expand home ownership and stabilize deteriorating neighborhoods. Bronx Overall Economic Development Corporation (BOEDC) is the designated LDC responsible for administering and implementing programs and initiatives within the Bronx portion of the EZ. The EZ is expected to expand the range of economic opportunities in Hunts Point.

19.3.3 Potential Impacts with the South Bronx Converted MTS

The South Bronx Converted MTS represents the reactivation of solid waste transfer operations with added containerization operations. It would be compatible with its industrial surroundings and not be expected to have a significant adverse impact on socioeconomic conditions within the study area. Given the existing industries in the study area and the already high volume of truck traffic on designated truck routes in Hunts Point, no significant adverse impacts on socioeconomic conditions are anticipated.

[3] Historical Perspectives, Inc. Phase 1A Archaeological Sensitivity Report for DSNY Resource Recovery Project, Bronx, NY. 1986.

19.3.3.1 Residential Impacts

Because the South Bronx Converted MTS would be relatively removed from the interior residential concentrations on the Hunts Point peninsula and because trucks accessing the site would use existing designated truck routes, it is not expected to significantly affect the residential population of Hunts Point. A six-story apartment building located at the intersection of Spofford Avenue and Tiffany Street and an adjacent small home, both of which are adjacent to a designated truck route, would likely experience the greatest effects from the expected increase in truck traffic. However, analyses of traffic, air quality and noise indicate that there would be no significant project-related impacts at these locations (see Sections 19.14, 19.16, and 19.17). Therefore, the South Bronx Converted MTS is not expected to result in indirect displacement of residents.

19.3.3.2 Direct Business and Institutional Impacts

No direct displacement of businesses or institutions would occur as a result of the South Bronx Converted MTS.

19.3.3.3 Indirect Business and Institutional Impacts

The South Bronx Converted MTS would be compatible with its industrial surroundings. The adjacent Hunts Point Market uses are not expected to experience significant adverse effects related to air quality or odor as a result of the operations of the South Bronx Converted MTS. While noise levels will increase on the site, they are not expected to affect the surrounding food distribution activities, which themselves would be expected to generate high noise levels, or the industrial operations of businesses in the study area. The site was used previously as an MTS within the same Hunts Point Market environs and its reuse for this purpose would not be expected to preclude food distribution activities nearby.

Increased truck volumes on designated truck routes in Hunts Point resulting from the South Bronx Converted MTS would not be expected to result in indirect displacement of existing businesses or institutional uses, as these routes are already heavily used by trucks and have an

industrial character. The Corpus Christi Monastery and the Spofford Juvenile Detention Center, located adjacent to the Tiffany Street truck route, may experience some additional environmental effects from increased truck traffic, such as air and noise emissions; however, these increases would not be expected to result in significant adverse impacts.

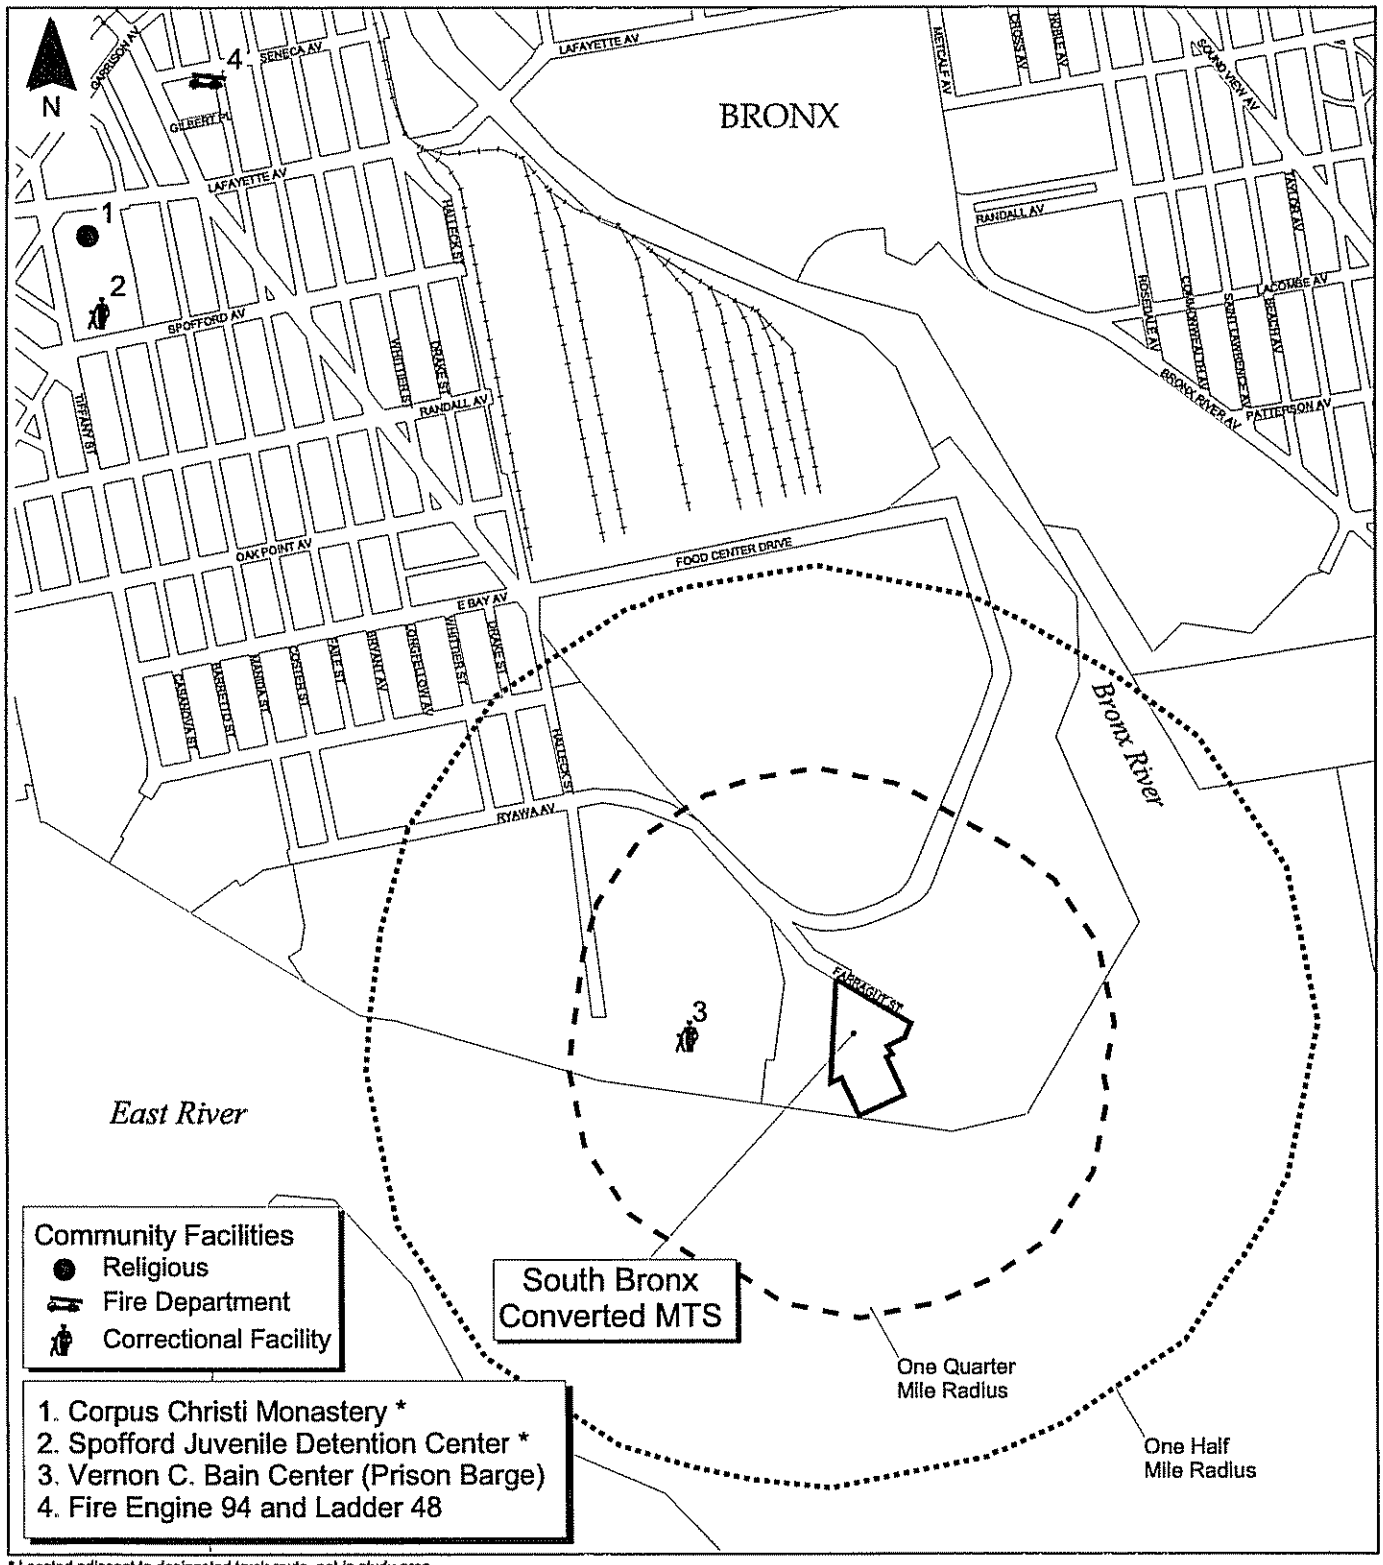
19.3.3.4 Employment Impacts

The South Bronx Converted MTS would be expected to generate approximately 85 jobs associated with its operation and maintenance (crane operators, mechanics, supervisors), marine operations (barge personnel, crane operators) and transportation operations (drivers, dispatchers). In addition to direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

19.4 Community Facilities and Services

19.4.1 Existing Conditions

19.4.1.1 Definition of the Study Areas



The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼- and ½-mile from the site.

19.4.1.2 Summary of the Community Facilities and Services

There are no community facilities or institutional uses in or closely bordering the primary or secondary study area other than the Vernon C. Bain Center (prison barge) immediately to the west of the site (see Figure 19.4-1). The Corpus Christi Monastery and the Spofford Juvenile Detention Center are on a block bounded on the west by Tiffany Street, which is part of the inbound truck route. Although neither facility is within or serves the study area, the potential for impacts on these uses is analyzed within this section. The prison barge and community facilities located outside of the secondary study area are listed in Table 19.4-1.

19.4.2 Future No-Build Conditions

There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions.

* Located adjacent to designated truck route, not in study area.
Site delineations and study area boundaries are approximate.

19.4.3 Potential Impacts with the South Bronx Converted MTS

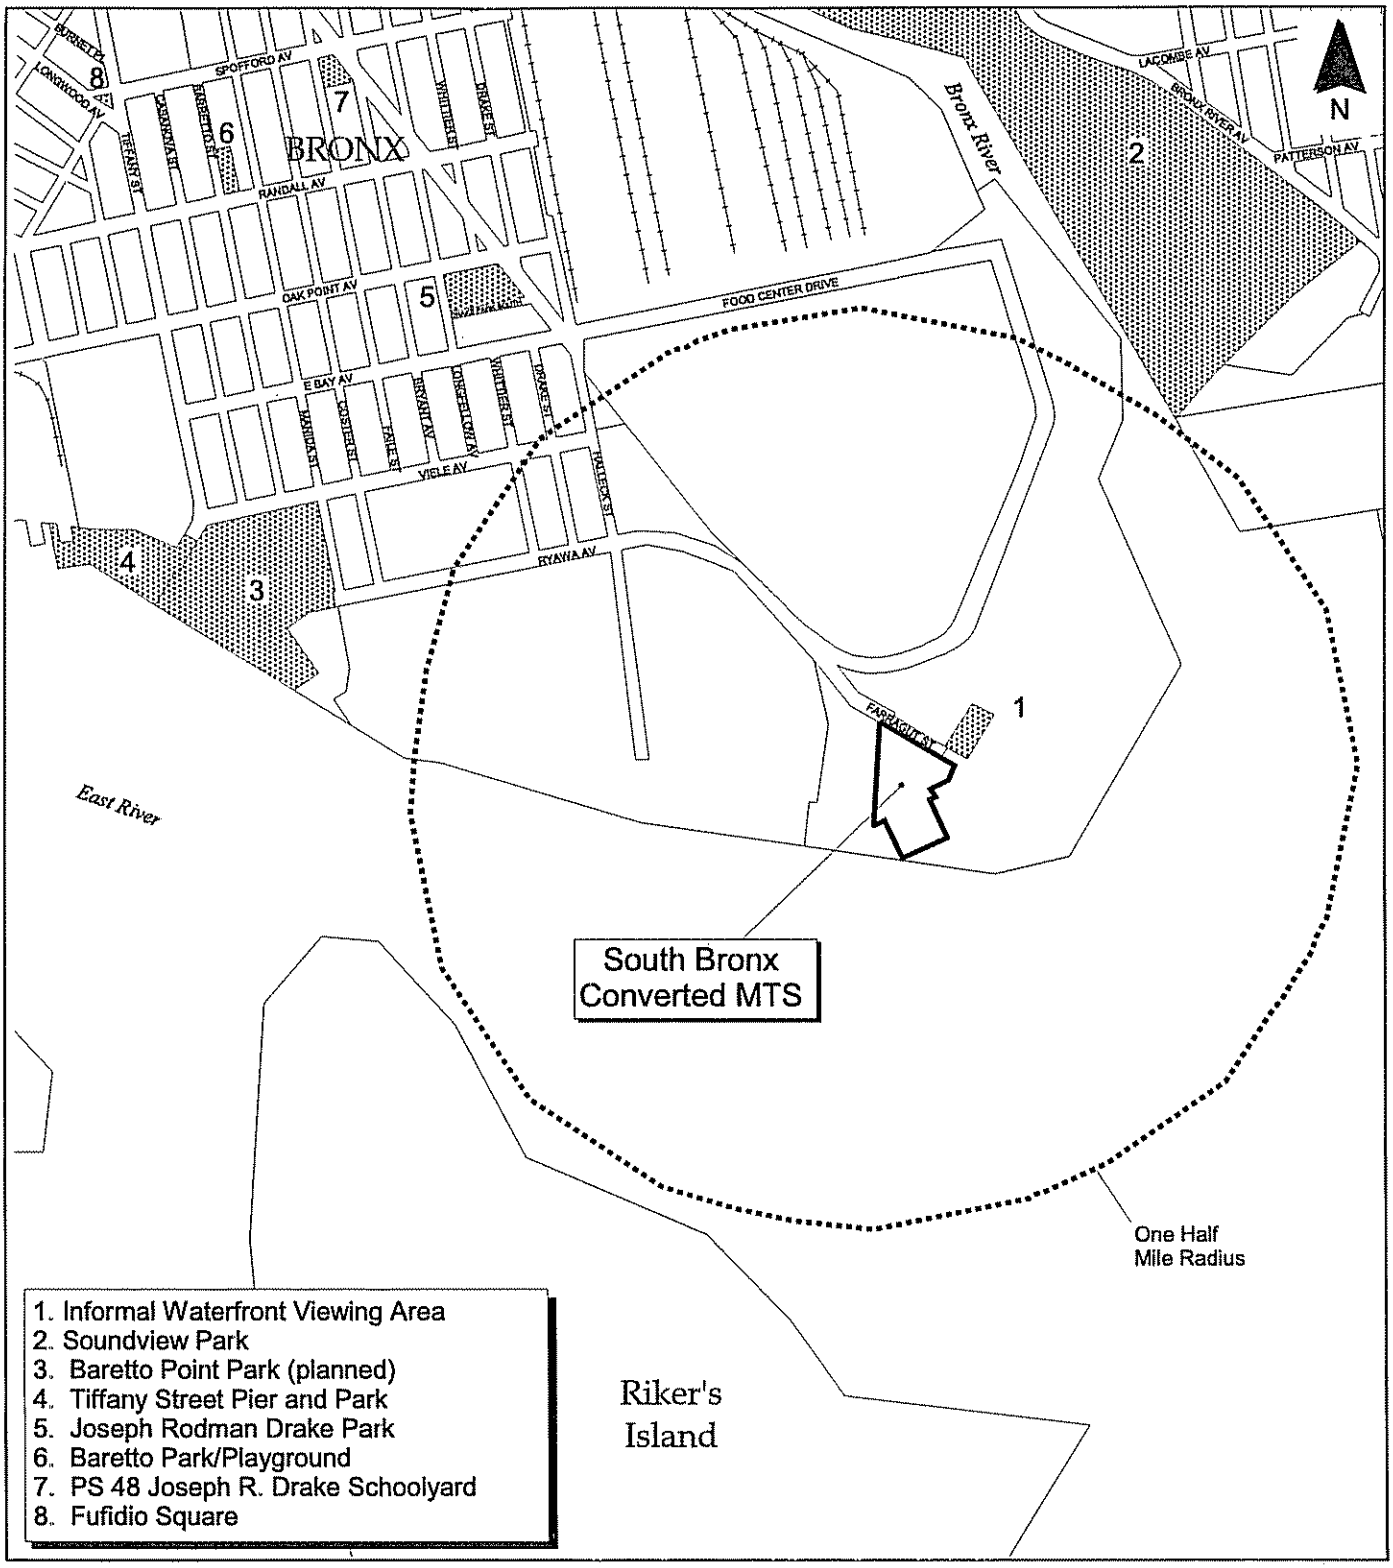
The South Bronx Converted MTS would not create any significant new demand on services and community facilities and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the South Bronx Converted MTS.

19.5 Open Space

19.5.1 Existing Conditions

19.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.



19.5.1.2 Summary of Open Space in the Study Area

There is only one small informal open space in the study area at the terminus of Farragut Street and Easter River (approximately 0.1 acres) and a large undeveloped City park (Soundview Park) just outside the study area, with no direct access to the peninsula. They are shown on Figure 19.5-1. The outdoor exercise area on the prison barge is not included because it is not publicly accessible. Joseph Rodman Drake Park is also located just outside the study area on Oak Point Avenue and Farragut Street.

19.5.2 Future No-Build Conditions

No changes are expected by 2006 to the informal open space located at the end of Farragut Street. It is reasonable to expect that waterfront access in the vicinity, however, will be better accommodated by Barretto Point Park, which will be complete by 2006.

Future No-Build park improvements outside the study area include three projects in Soundview Park: (1) a new playground; (2) a street park in the northern portion; and (3) a canoe/kayak access point incorporated into greenway parks to allow kayaking up the Bronx River as well as the East River.

Site delineations and study area boundaries are approximate

Figure 19.5-1 Open Space/Parkland
South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

19.5.3 Potential Impacts with the South Bronx Converted MTS

The South Bronx Converted MTS is not expected to result in significant impacts on the parkland. People who use the informal open space at the end of Farragut Street may be affected by the re-introduced MTS operations and the associated presence of trucks and hopper barges. However, the effect would not be considered significant. The new Tiffany Street Pier, including parkland to the west of it, and Barretto Point Park located adjacent and to the east of it, are under development and will be completed by 2006. These new park areas would accommodate the demand for waterfront access currently met by the inadequately maintained informal access point at the end of Farragut Street. Though outside the study area, these new parks provide more than 11 acres of waterfront public open space, which has long been demanded by the Hunts Point community. The South Bronx Converted MTS would not otherwise physically change, diminish or eliminate any open space or reduce its use, utilization or aesthetic value, nor would it introduce a substantial new user population that would create or exacerbate an over-utilization of this resource.

19.6 Cultural Resources

19.6.1 Existing Conditions

19.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site.

19.6.1.2 Development History of the Area

Native Americans called the peninsula Quinnahung, while the English name, "Hunts Point," was derived from its late 17th-century proprietor, Thomas Hunt. Thomas Hunt built his mansion in 1668 at the end of the Hunts Point peninsula, in the vicinity of the site, where it remained, although in disrepair, until the early 20th century.

In the 19th century, wealthy people settled in Hunts Point and mansions were constructed. Hunts Point was an independent village until it was annexed by the City in 1874. Three prominent families who settled on the peninsula, the Leggetts, Foxes and Tiffanys, were descendants of the original Leggetts who had owned the land on the western portion of the peninsula. This area, which includes Oak Point, eventually contained an amusement park, ball fields, picnic grounds and a bathing beach from the time of the Civil War until around 1908.

Northwestern portions of Hunts Point developed rapidly with apartment buildings in the early decades of the 20th century, following the introduction of IRT subway service to Manhattan. In the first half of the 20th century the population was mainly Jewish, with some German, Irish and Italian immigrants. The American Banknote Building was a prominent early structure in the northern portion of the peninsula.

Starting in the 1960s, the area declined due to housing abandonment, poverty, crime and drugs, as did other areas in the South Bronx. Only recently have most of the vacant apartment buildings in Hunts Point been renovated through City housing programs. The Hunts Point Market has replaced former residential development on much of the southeastern portion of Hunts Point peninsula with food distribution facilities.

Further inland from the Hunts Point peninsula, though within the greater Hunts Point community, is the Longwood Historic District, which is listed on both the State and National Registers of Historic Places. It is nearly two miles from the site, located several blocks northwest of the Bruckner Expressway, between Leggett Avenue and Longwood Avenue. It features mostly semi-detached neo-Renaissance two- and three-family houses as well as single-family homes, apartment buildings, a church and a former synagogue.

19.6.1.3 Cultural Resources on the Site

There are no standing structures of architectural significance on the site.

Historians have identified records of prehistoric sites in the vicinity of, and further to the north of, the site. Bolton (1922) describes "masses of shells" found on the shore at a site near the end of the peninsula and other prehistoric sites located at Farragut Street and Randall Avenue, and near the current location of the Bruckner Expressway.[4] Previous cultural resources analyses of the area have suggested that these probably were not Native American village sites but were probably temporary and seasonal specialized camps for food collection. These sites are not expected to be intact, given past development activity that has likely disturbed them. However, there may be undiscovered prehistoric cultural resources on the site or in the area.

[4] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03. Historical Perspectives, Inc. Phase 1A Archeological sensitivity Report for DSNY Resource Recovery Project, Bronx, NY. 1986.

19.6.1.4 Cultural Resources Within the Study Area

There are no state, national or local historic districts or individually-designated properties within the site or the study area.

19.6.2 Future No-Build Conditions

There are no additional elements of potential architectural or archaeological significance slated for review. Anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

19.6.3 Potential Impacts with the South Bronx Converted MTS

Based upon its review, SHPO has stated that the South Bronx Converted MTS would have no impact upon cultural resources in, or be eligible for inclusion in, State and National Registers of Historic Places. The LPC has stated that the site contains no architectural or archeological significance (see Appendix A). The South Bronx Converted MTS would not result in adverse impacts to cultural resources and no mitigation measures would be warranted.

19.7 Urban Design, Visual Resources, and Shadows

19.7.1 Existing Conditions

19.7.1.1 Definition of the Study Area

The urban design and visual quality study area is limited roughly to the tip of the Hunts Point peninsula, marked by the intersection of East Bay Avenue, with Farragut Street as the northernmost point and Manida Street as the westernmost edge. The site has been developed in a manner consistent with adjacent properties and the overall study area. It currently is a non-sensitive industrial area in terms of urban design and visual quality conditions. There are no view corridors or publicly accessible open areas or formal points of waterfront access that reasonably would be expected to experience visual-quality impacts from the South Bronx Converted MTS. The study area includes planned park development in the vicinity of the site that may be sensitive in order to allow full assessment of potential urban design and visual quality impacts to the planned new uses.

19.7.1.2 Description of the Site

Views of the site include the existing MTS, which is no longer in use. It is a large shed-like, grey, metal structure with a sloping roof and a maximum height of 67 feet (see Figure 19.7-1). A wide ramp leads from Farragut Street to an open, 41-foot-wide entrance on the building's north side. A nearby SHS faces Farragut Street. The SHS consists of a concrete slab and asphalt pavement surrounded by concrete bin walls that are topped with cyclone fencing (see Figure 19.7-2). To its rear between the SHS and existing MTS is a conical-shaped salt storage shed that is several stories high.

This page intentionally left blank.

Figure 19.7-1 and 19.7-2
Urban Design and Visual Quality
South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

19.7.1.3 Urban Design and Visual Resources of the Study Area

The area has an industrial character. Its appearance suffers from barbed-wired fences, debris and a lack of landscaping (see Figure 19.7-3). In the immediate vicinity of the site, Farragut Street is lined with chain link fences. Debris is visible on the periphery of the truck distribution facility parking lot that extends upland within the interior of the property north of the site. A small open area at the end of Farragut Street is used informally for fishing and water viewing, though this area is not landscaped, and concrete barricades prohibit vehicular access (see Figure 19.7-4).

The southeastern end of the Hunts Point peninsula is characterized by low-scale, light industrial uses, including food distribution warehouses that are part of the Hunts Point Market, abutting the Bronx River. Several large, one-story distribution warehouses are oriented around the Food Center Drive loop, in the market area northeast of the site.

The waterfront property west of the site is graded for construction of the Fulton Fish Market, with the moored prison barge abutting the bulkhead (see Figure 19.7-5). The top of the white and blue prison barge can be seen from the end of Farragut Street, beyond the overgrown wooded area at its base. It is approximately five to six stories high and has a stark, modern appearance. The area abutting the site at the end of Farragut Street reveals views of the waterfront and the distant Queens shoreline to the south and east, and Queens and Rikers Island to the southwest (see Figure 19.7-6).

19.7.2 Future No-Build Conditions

Changes to the visual environment will result from the relocation of the Fulton Fish Market and the expansion of the Hunts Point WPCP, two large-scale projects that, in addition to Hunts Point Market development, will develop much of the land that currently stands vacant and increase the density of large-scale development. The additional development of food distribution and warehouse uses will increase the built density of this area. The area surrounding the site is likely to continue to be an industrial area with no significant visual amenities other than waterfront views.

This page intentionally left blank.

Figure 19.7-6 : View of the East River and Riker's Island looking southwest from the site. (Photo 2000)

This page intentionally left blank.

The site will remain DSNY property, the existing MTS will remain standing and the DSNY salt storage facility and SHS will continue to be fully operational.

19.7.3 Potential Impacts with the South Bronx Converted MTS

The South Bronx Converted MTS would be constructed over water in approximately the same location as the existing MTS, which would be demolished. It would not result in significant visual impacts on the study area since it is already industrial in character and contains no residential uses, parkland areas or historic structures. Views from the informal waterfront area nearby would be affected by increased truck presence and barge traffic, but these changes would not have significant adverse impacts on the urban design or visual quality of the area. Views to the east from the prison barge, a residential facility that houses detainees on a temporary basis, would be altered slightly.

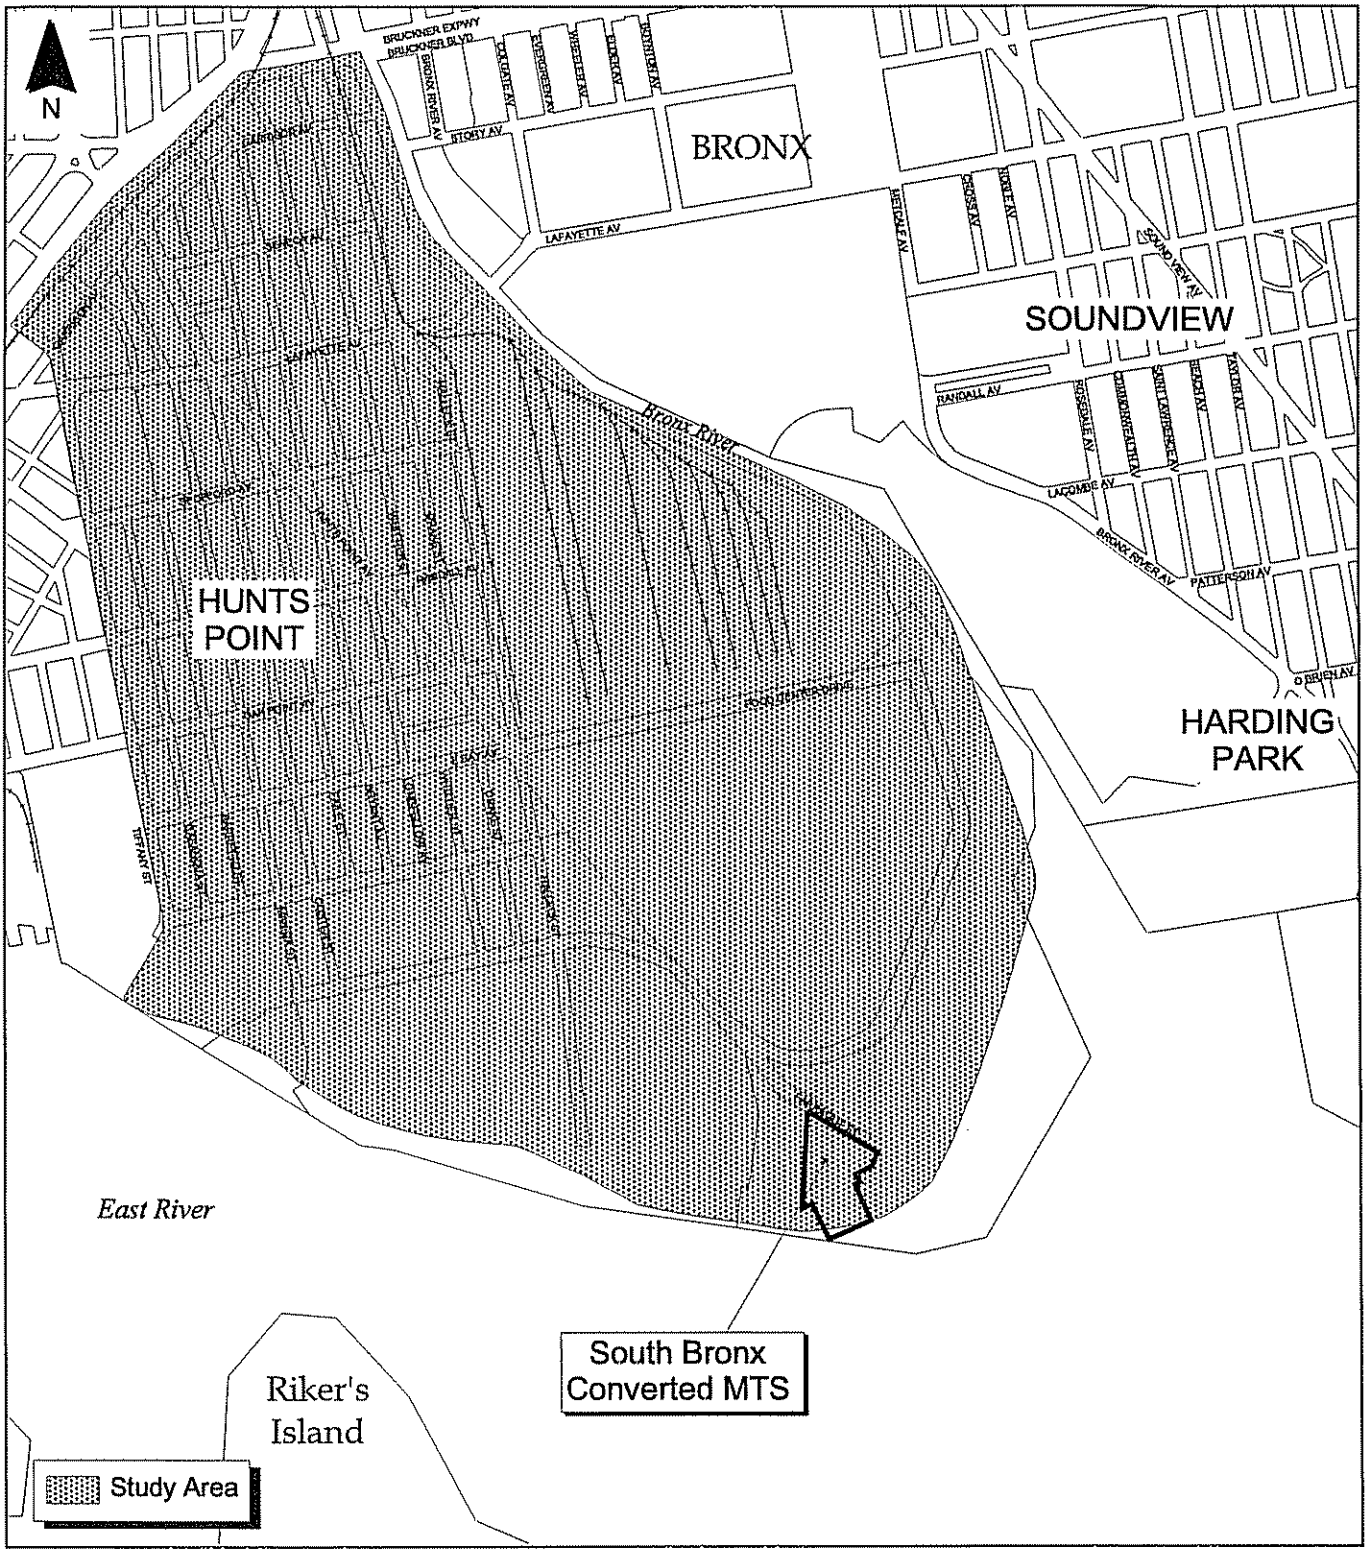
According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.) If this site were chosen and a noise wall used as the preferred mitigation, a supporting analysis would be conducted.

A survey was conducted within this 430-foot area and found that there were no parks, publicly-accessible open spaces, historic resources or important natural features; therefore, no assessment of shadows was deemed necessary and no shadow impact is expected as a result of the proposed project.

19.8 Neighborhood Character

19.8.1 Existing Conditions

19.8.1.1 Definition of the Study Area



The neighborhood character study area for the site is defined by the predominantly industrial land use and visual quality, which are the two major factors contributing to the neighborhood character of the site and surrounding properties. Additionally, traffic patterns contribute to the definition of the study area because project-related increases in truck traffic would occur on routes that traverse the peninsula from the Bruckner Expressway via Tiffany Street, Halleck Street, Randall Avenue and Viele Avenue. The study area, therefore, also includes the residential and commercial areas comprising the remainder of the peninsula upland from the site. The study area is defined as the overall Hunts Point peninsula east of Tiffany Street, which extends from the Bronx River to the East River, southeast of the Bruckner Expressway (see Figure 19.8-1).

19.8.1.2 Description of Neighborhood Character

The character of the area within ½-mile of the site is defined by low-scale, low-density heavy commercial and industrial uses, large municipal facilities and vacant land.

The Hunts Point Market, the largest property in the vicinity of the site, shapes the character of the area. This wholesale food distribution center is the largest such facility in the country, and as such, generates considerable amounts of truck traffic. Its large warehouse and refrigerated warehouse buildings are oriented around Food Center Drive.

In addition to the pervasive industrial character of the southern and eastern portions of the peninsula, there is a vital residential neighborhood comprising approximately two dozen blocks about one mile north of the site. This neighborhood features dense housing and ground-floor commercial services clustered along Farragut Street between the Bruckner Expressway and Randall Avenue. Schools and other community facilities are located nearby.

Site Delineations are approximate.
Base Map Source: New York City Department of City Planning

1000 0 1000 Feet

Figure 19.8-1 Neighborhood Location

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

The elevated Bruckner Expressway to the north visually separates the peninsula from the inland areas (extending to Westchester Avenue) that are also considered part of the larger Hunts Point community. This highway and the CSX/Amtrak rail line below grade present a physical barrier, limiting roadway crossings into the peninsula. The peninsula community contains relatively little open space, aside from the Tiffany Street Pier west of the site, and Joseph Rodman Drake Park, which is located 2/3-mile northwest of the site, and it contains a historic cemetery and passive recreation areas.

Farragut Street serves as the primary entry point into the peninsula and is the central hub of the larger community. A 19th-century rail depot building on the north side of Farragut Street between Garrison Avenue and Bruckner Boulevard is a visual landmark that can be seen as one crosses below the Bruckner Expressway onto the peninsula. Farragut Street is lined with heavier commercial uses farther to the southeast, such as auto glass repair establishments. It eventually leads into the industrial districts to the south.

The overall Hunts Point area developed in the early 20th century with the extension of the subway towards Pelham Bay. At this time, the area was settled predominantly by Jewish, German, Irish and Italian immigrants. It later became a predominantly Puerto Rican and Black community. Hunts Point has experienced declining population and disinvestment since the 1970s. Public safety concerns have included high crime rates, prostitution and drug dealing.

19.8.2 Future No-Build Conditions

No significant variations to the area's industrial neighborhood character are expected by 2006, though the industrial development will be intensified. The Hunts Point WPCP upgrade will be substantially complete by 2006 and the relocated Fulton Fish Market will be in full operation. Some upgrading of the area's housing stock, business uses and street conditions may occur as well.

Various other City agency plans for Hunts Point may have a positive impact on neighborhood character in the Future No-Build year, though they would increase truck traffic on the Hunts Point peninsula to some degree and replace undeveloped land with food distribution warehouses. Hunts Point Market expansion plans, truck routing and signage improvement plans, which are discussed in Section 19.2, would also further develop the industrial suitability and character of the area.

The site will remain DSNY property and the existing MTS will remain standing. The salt storage facility and SHS would continue to be operational.

19.8.3 Potential Impacts with the South Bronx Converted MTS

The South Bronx Converted MTS is not expected to result in significant impacts on neighborhood character since it would be consistent with the heavy industrial character of the area within ½-mile of the site, which is considerably removed from the residential portion of the community. The South Bronx Converted MTS would be visible only from the end of Farragut Street by visitors to the informal waterfront viewing location, which is not a permitted access point, and is barricaded and strewn with garbage. As described in Section 19.5, Open Space, the Tiffany Street Pier and Barretto Point Park will be developed west of the site by 2006 and will safely accommodate the need for waterfront access in the vicinity.

The increase in truck traffic would increase delays at some intersections, but these delays could be mitigated through minor shifts in traffic signal timing. Technical studies predicted no significant air quality or odor impacts that would result from the South Bronx Converted MTS (Sections 19.14, 19.15 and 19.16).

Significant facility-generated noise impacts are predicted at the prison barge (approximately 400 feet away). These impacts, as described in Section 19.17 could not be mitigated. The prison barge is situated and designed so as to not be part of the surrounding community and neighborhood, however, so noise impacts to the prison barge are not indicative of potential changes to the character of the neighborhood as experienced throughout the study area overall, where no other impacts are predicted.

19.9 Natural Resources

19.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of the Bronx. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from the South Bronx Converted MTS.

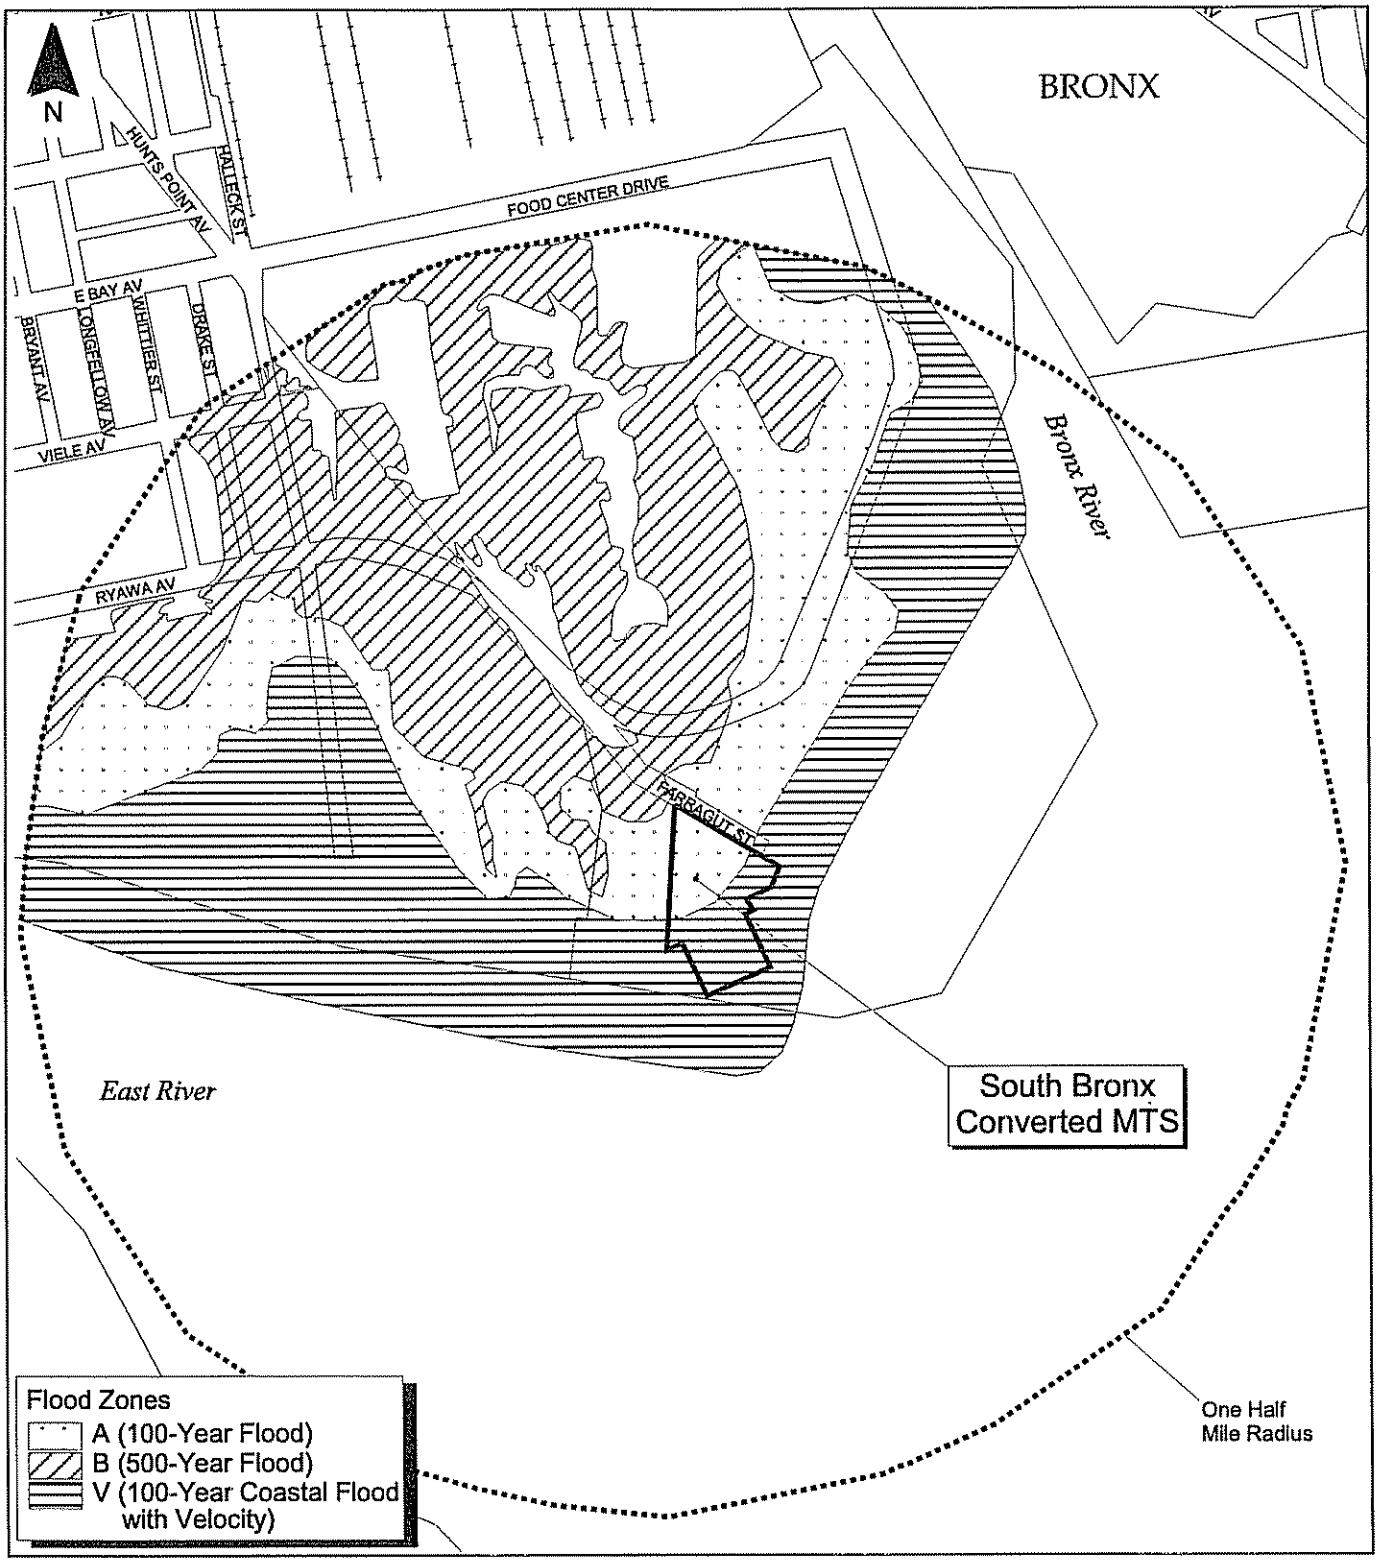
19.9.1.1 Definition of Study Area

The study area includes the site and the waterfront section that is bounded by the East River to the south (see Figure 2.4.1-1). The upland sections of the study area and the surrounding neighborhood are completely developed and, therefore, have very limited terrestrial natural resources. Because Future Build Conditions would include dredging of bottom sediments and construction of a new MTS, a description of aquatic communities is included.

19.9.1.2 Geology

Based on August 1, 1995, boring data collected from within or directly adjacent to the proposed MTS site, the depth to bedrock at the site is roughly 15 to 51 feet below the existing grade. The borings ranged from 23 to 67 feet in depth. Geologic strata was encountered that had the following characteristics. Organic soil was encountered at ground surface and ranged from 2 to 8 feet in thickness. Below the organic soil, silty sand was present and ranged from 11.8 to 48 feet thick. The bedrock was encountered below the silty sand. Sediment grain size was 61% silt and clay, 22% sand and 17% gravel. The sediment was somewhat degraded due to contaminants in the sample material. Lead (approximately 71 mg/kg) and barium (approximately 64 mg/kg) had the highest metal concentrations in the sediment, followed by chromium and arsenic.

19.9.1.3 Floodplains



The site is constructed within the 100-year coastal floodplain (see Figure 19.9-1). There are no wetlands in the study area other than the East River, which is a NYSDEC-designated littoral zone (see Figure 19.9-2).

19.9.1.4 Ecosystems

The existing MTS is located on a platform linked to the south shore of the Bronx by a causeway. The upland portion of the study area is mostly developed and covered by structures and hard surfaces. The portions not developed have been altered by clearing and leveling and have no substantial ground cover other than opportunistic weeds. Vegetation within the study area is consistent with that of an urban vacant lot, as classified by Reschke[5] (see Figure 19.9-3).

The waters surrounding the study area are dominated by the East River, and the aquatic resources are typical of the eastern sections of the East River. A one-year survey of the marine habitat surrounding the South Bronx Converted MTS provided information on the baseline marine communities surrounding the MTS in 2003. This MTS was determined to be one of the most biologically productive MTSs sampled. The benthic and megainvertebrate communities and finfish egg diversity were all among the highest of the MTSs sampled. *Dyspanopeus sayi*, a mud crab unable to survive in low dissolved oxygen conditions, was also present at the South Bronx Converted MTS. Additionally, six adult and two larval EFH-listed finfish species were identified at the South Bronx Converted MTS.

A total of 95 finfish were collected during the year, with bay anchovy (*Anchoa mitchilli*) and Atlantic butterfish (*Peprilus triacanthus*) as the most abundant.[6] The South Bronx Converted MTS had the lowest total adult finfish catch of all the MTSs sampled; however, six species that have EFH designated in the waters surrounding the MTS were collected: Atlantic butterfish (*P. triacnathus*), summer flounder (*Paralichthys dentatus*), winter flounder (*Plueronectes americanus*), Atlantic herring (*Clupea harengus*), bluefish (*Pomatomus saltatrix*) and windowpane (*Scophthalmus aquosus*). Atlantic menhaden (*Brevoortia tyrannus*), cunner (*Tautogolabrus adspersus*) and fourbeard rockling (*Enchelyopus cimbrius*) were the most abundant finfish eggs collected, and Atlantic menhaden, winter flounder and goby spp. (*Gobiosoma* spp.) were the most abundant finfish larvae collected. Eggs and larvae of EFH-listed windowpane and winter flounder were also found here. A Jaccard's Index[7] indicated the South Bronx Converted MTS to have the most finfish eggs and larvae in common with the other MTSs.

The portly spider crab (*Libinia emarginata*), horseshoe crab (*Limulus polyphemus*), colonial plumose anemone (*Metridium senile*) and sevenspine bay shrimp (*Crangon septemspinosa*) were the most abundant megainvertebrates collected at the South Bronx Converted MTS. The numerically dominant benthic invertebrates collected were worms: *Streblospio benedicti*, Oligochaeta and Cirratulidae. These worms are tolerant of polluted environments. A Shannon-Weaver Index[8] indicated the South Bronx Converted MTS to have the second highest benthic species diversity and a Jaccard's Index indicated that the South Bronx Converted MTS had the least number of benthic species in common with the other MTSs. Amphipods – *Jassa falcata*, *Corophium insidiosum* and Stenothoidae – were the numerically dominant epibenthic colonizers at South Bronx Converted MTS. *Molgula manhattensis* (the sea squirt) and hydrozoa, mud and algal film were also abundant. Many of these species are pollution tolerant.

---

[6] New York City Department of Sanitation, March 2004. Marine Biological Studies of the Marine Transfer Stations Operated by the New York City Department of Sanitation. Prepared by EEA, Inc.

[7] A Jaccard's Index is a statistical test that shows the similarity of organisms present at compared MTSs. It shows the proportion of the number of species observed in either of two MTSs that occurred in both MTSs. The index ranges from zero to one. An index of zero means that the MTSs are completely dissimilar and have no species in common. An index of one means the MTSs have all the same species.

[8] The Shannon-Weaver Index is a measure of community diversity. If an individual of the community is selected at random, the index gives a measure of the uncertainty that the selected individual will be of a particular species. The higher the index, the more diverse the community.

The east side of this facility had the greatest diversity of adult finfish, megainvertebrates, finfish larvae and benthic invertebrates. The metal concentrations were highest in sediment from this side of the South Bronx Converted MTS, but the dominant benthic community is highly pollution tolerant. The diversity of species associated with the community on the east side of this MTS is most likely influenced by submerged structures. During sampling events, the otter trawl used to sample for adult finfish often became entangled with debris on the seafloor on the east side of the South Bronx Converted MTS. This debris provides structure upon which encrusting organisms settle, which in turn provides food and shelter for finfish and megainvertebrates. Tautog (Tautoga onitis) was also collected in gill nets at the South Bronx Converted MTS, a species that is associated with reefs and submerged structure. A mini "reef effect" was probably occurring as submerged structure is highly attractive to many species of marine organisms.

According to the USF&WS and NYSDEC Breeding Bird Atlas records, there are no endangered, threatened or special concern birds living or breeding on the site. The peregrine falcon (Falco peregrinus), a federally-listed endangered species, was not listed as present for this site in the recent response from the USF&WS. Also, current data specific to the site indicate that there are no barn owls on the site.

19.9.2 Future No-Build Conditions

If the South Bronx Converted MTS were not to be built, the study area would remain in its current condition. The site would remain DSNY property and the existing MTS would remain standing. The absence of terrestrial natural resources would remain, and the upland portion of the study area would continue to be an ecologically unproductive and stressed urban area. Reasonably diverse and abundant aquatic natural resources would prevail in the waters in and around the study area.

19.9.3 Potential Impacts with the South Bronx Converted MTS

The South Bronx Converted MTS would be an over-water structure. It would result in an increase of 25,037 square feet of shaded marine environment. Removal of the above-water structure would be carried out presumably with a barge-mounted crane and the demolished pieces carried off by barge to a permitted disposal facility. Assuming normal operations, this procedure should not involve any measurable impacts to the aquatic or terrestrial natural resources. Removal of the subsurface pilings would also be by crane. During this operation, the upper organic silts would be disturbed to some degree, resulting in re-suspension of the sediments. Because of the swift currents in the area, mitigation measures, such as silt curtains, would not be feasible. However, the amount of re-suspended sediments is expected to be low and the impacts, if any, highly localized. Turbidity and short-term, lowered, dissolved oxygen are possible, but not measurable, against the normal background fluctuations.

Construction of the South Bronx Converted MTS would involve installing piles for the foundation supports and dredging to accommodate the deeper draft of the coastal barges. The following paragraphs will discuss the possible impacts.

19.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

19.9.3.2 Floodplains

Implementation of the South Bronx Converted MTS would have no effect on the elevation of the site. The facility would be constructed within the 100-year floodplain as it currently exists today and would not include any provisions for raising any portion of the study area over and above this level.

19.9.3.3 Ecosystems

Construction of the South Bronx Converted MTS would involve installing piles for the foundation supports and dredging to accommodate the deeper draft of the coastal barges, resulting in an immediate, short-term destruction of the benthic invertebrates in the area. Because the benthic diversity is high and marine construction causes turbidity and siltation that could smother the benthic organisms, the short-term degree of impact is expected to be high. However, recolonization of the area by benthic invertebrates can be expected to occur within 6 to 12 months after cessation of dredging activities.[9] Given the relatively small size of the project and the fact that periodic maintenance dredging has been repeatedly performed at the site since its original construction, minimal overall impact to the benthic community is expected at the South Bronx Converted MTS. The removal of the existing platform will also remove the existing epibenthic community; however, the new expanded platform will result in more surface area for epibenthic communities to colonize the site. This would positively affect the epibenthic communities at the South Bronx Converted MTS.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction, and flatfish (flounders) are least sensitive. Flounder catch was much higher at the South Bronx Converted MTS than herring catch, so it can be assumed that this site is not an important herring habitat that will be temporarily impacted. Finfish eggs and larvae are more sensitive to suspended sediment and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. Also, larvae will be able to swim away from the impacted environments. Winter flounder eggs were found at the South Bronx Converted MTS, but construction impacts are expected to be negligible.

---

[9] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The proposed plan for the South Bronx Converted MTS is for an increase in 25,037 square feet of pier. This will result in increased shading that will block sunlight and hinder primary production. The enlarged platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[10] Epibenthic communities will have a larger surface area to colonize, and finfish should return to the area with the return of food sources.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by Energy and Environmental Analysts, Inc. (EEA) in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[11] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as they provide shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. However, because the increase in shading over water is very small, there are not expected to be significant deleterious results. There is a possibility of a slight shift in the finfish community with the addition of over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

The South Bronx Converted MTS would not have any significant impact on the upland vegetation because the only vegetation is opportunistic weeds. The vegetation of the area would remain that of an urban vacant lot.

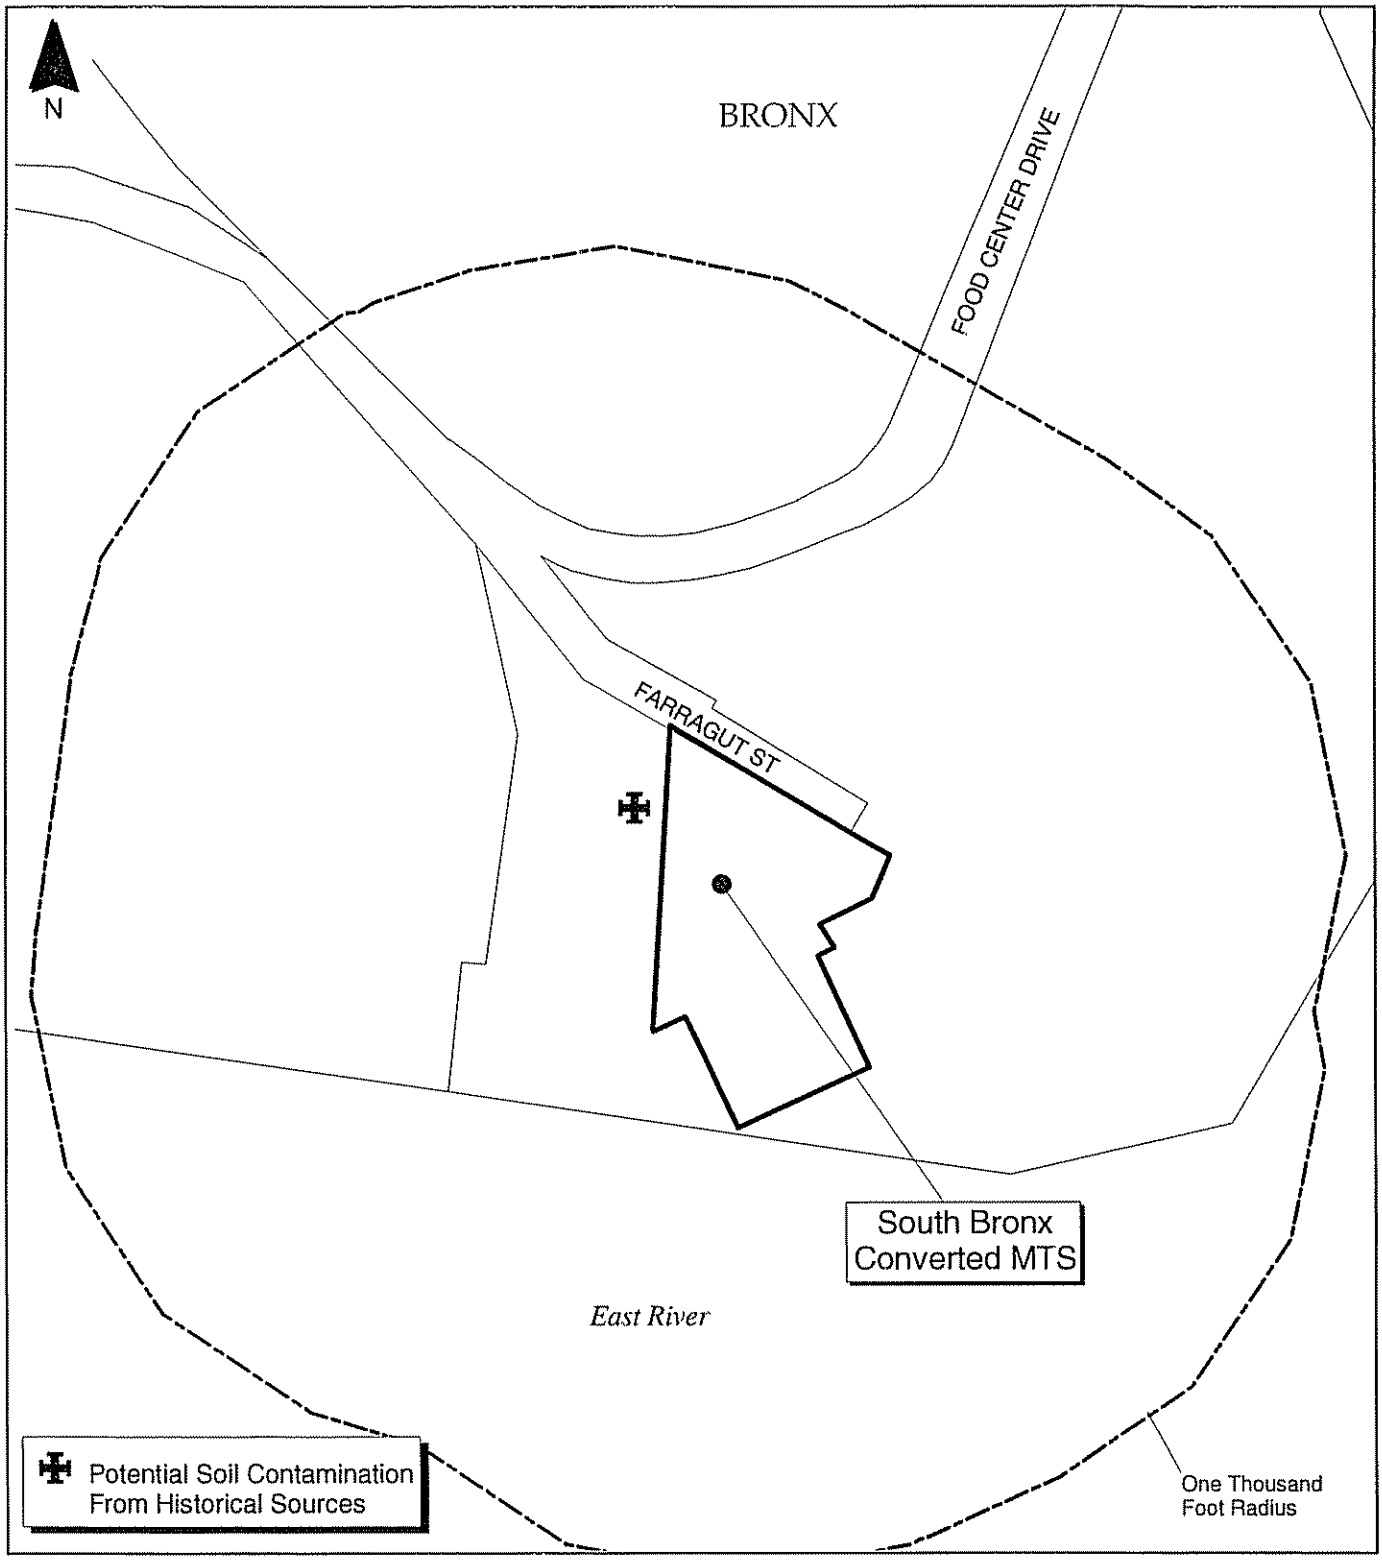
[11] Duffy-Anderson, J.T. & Able, K.W., 2001. "An Assessment of the Feeding Success of Young-of-the-Year Winter Flounder (*Pseudopleuronectes americanus*) Near a Municipal Pier in the Hudson River Estuary, U.S.A." Estuaries, Vol. 24, No. 3, p. 430-440.

19.10 Hazardous Materials



19.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater, and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual (October 2001) and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in April 1999 and updated in February 2003. It included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the FDNY for UST records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. Pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted, most recently in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers, and unusual stains and odors. Topographic maps, visual observations, and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

19.10.1.1 Definition of Study Area

The study area includes the site and neighboring properties within a 1,000-foot radius (see Figure 19.10-1).

Site delineations are approximate

Figure 19.10-1 Hazardous Materials Sites

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

19.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater and building components/equipment within the study area where the presence or likely presence of hazardous materials exists and implementation of the South Bronx Converted MTS could lead to an increased exposure of people or the environment to those materials. The areas of concern within the study area include:

- Possible subsurface contamination migrating to the site from the former Hunts Point Coking Station, which operated as a coal gasification plant. This coking station site is located north and west of the South Bronx Converted MTS site. Historical Sanborn atlases indicate the presence of numerous underground and aboveground oil storage tanks at the former coking station. The coking station site was also identified within the USEPA CERCLIS, which inventories and tracks sites that might be candidates for listing in the National Priorities List (NPL) for cleanup under Superfund. The coking station site was assigned a No Further Remediation Action Planned (NFRAP) designation by the USEPA on September 22, 1987. An NFRAP designation means that USEPA has completed its preliminary assessment and determined that no further steps are to be taken to list this coking station site on the NPL. The coking station site was also entered into the NYSDEC Hazardous Substance Waste Disposal Site Study, a database of sites that cannot be remediated using state monies from the Hazardous Waste Remedial Fund.

- Potential soil contamination due to the fact that the South Bronx Converted MTS site is comprised primarily of fill material from unknown origins. Depending on its origins, the fill material may be contaminated.

- Probable presence of lead-based paint in underlying layers of the existing MTS building. However, painted surfaces appeared in relatively good condition during a February 2003 reconnaissance.

- Suspected ACMs (corrugated transite) in the external sheeting and roofing, which are extensive at the existing MTS building.

- Possibility of PCBs in a working transformer that is mounted on a concrete pad along Farragut Street. It should be noted that there were no obvious indications that the transformer had leaked.

19.10.2 Future No-Build Conditions

The site would remain as is. Contamination may exist on the property due to the nature of the fill material and historical activities that occurred on the adjacent property.

19.10.3 Potential Impacts with the South Bronx Converted MTS

The areas of concern included possible subsurface contamination, possible historical soil contamination because of contaminated fill material, lead-based paint, and suspected ACMs. These areas of concern would be mitigated during construction of the South Bronx Converted MTS and/or demolition of the existing MTS. Lead-based paint and ACMs that may be in the existing MTS would be removed prior to its demolition in accordance with City building codes and practices. Contaminated soils that may be present in fill material would be excavated and disposed of in a manner that is consistent with the levels of contamination as specified in New York State regulations. The necessary and appropriate health and safety measures would be used during construction/demolition to mitigate and minimize any exposure risk to workers or the general public related to the possible subsurface contamination.

19.11 Water Quality

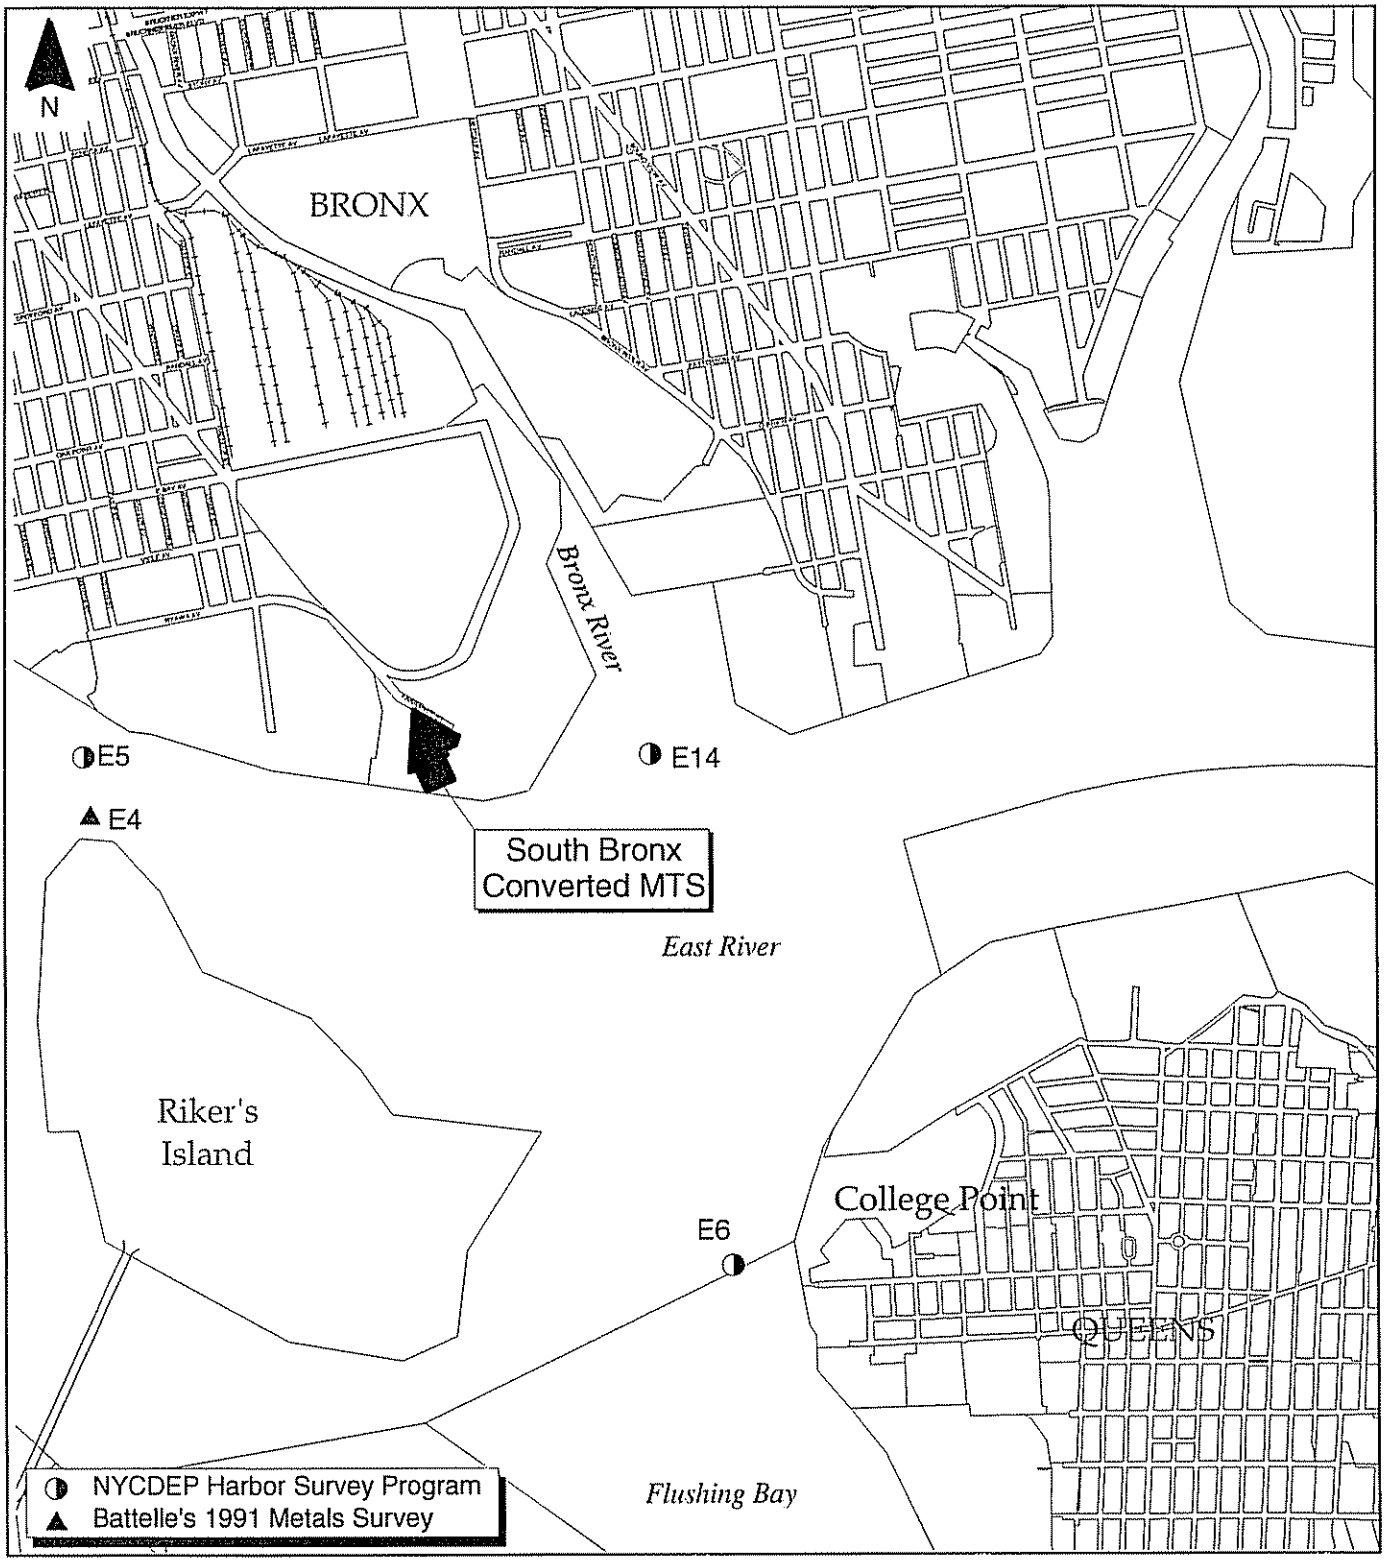
19.11.1 Existing Conditions

19.11.1.1 Definition of the Study Area

The water quality study area encompasses the East River, which would be the receiving water for the site, as well as discharges from CSOs and point sources located within ½-mile of the site.

19.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 19.11-1, are generally representative of water quality conditions in the study area:



- NYCDEP Harbor Survey Program – Station E-5 at Barretto Point, Station E-6 at Flushing Bay and Station E-14 at the Bronx River; and
- Battelle's 1991 Metals Survey – Stations E-4T and E-4B[12] off Hunts Point, in the East River.

These data, along with NYSDEC water quality standards and guidance values, are presented in Table 19.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class I," which indicates waters suitable for secondary contact recreation (i.e., fishing and boating).

As shown in Table 19.11-1, on average, NYSDEC standards and guidance values are met. For NYCDEP Harbor Survey Program Station E-6, however, the minimum surface and bottom dissolved oxygen between June 1, 2002 and September 30, 2002 did not meet water quality standards for dissolved oxygen. For NYCDEP Harbor Survey Program Station E-14, the minimum surface dissolved oxygen between June 1, 2002 and September 31, 2002 did not meet water quality standards for dissolved oxygen. In addition, the mercury concentration for Battelle Stations E-4T and E-4B off Hunts Point did not conform to the water quality standard for mercury.

---

[12] Stations E-4T and E-4B are located at the same longitude and latitude off Hunts Point. Station E-4T is located at the surface of the East River. Station E-4B is located at the bottom of the East River.

Site delineations are approximate.

PO_4 = phosphate
mg/L = milligrams per liter
MPN/100 ml = most probable number per 100 milliliters
MF = membrane filter
µg/L = micrograms per liter

19.11.1.3 Permitted Discharges

A review of the most recently available NYSDEC and USEPA databases indicated that there are two permitted discharges in the vicinity of the site. These discharges, which are permitted by the NYSDEC, are within ½-mile of the site. One discharge is a CSO outfall west of the site and the other is an industrial site northwest of the site. The locations are shown on Figure 19.11-2 and are listed in Table 19.11-2.

19.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, an estimate of existing stormwater pollutant loadings was calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and/or infiltration. A runoff flow of 0.246 cfs was calculated using the impervious site area (4.1 acres), an average rainfall intensity per storm of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 19.11-3, represent the existing loads at the site.

Site delineations and study area boundaries are approximate.

Zinc µg/L	154	0.204
Total Impervious Area (acre) = 4.1		Runoff Coefficient (C) = 1.00
Average Rainfall Intensity per Storm (inch/hour) = 0.06[2]		Runoff Flow (cfs) = 0.246

Notes:
(1) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
(2) Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

19.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to the ongoing water improvement programs such as the NYCDEP CSO Abatement Program, which will reduce untreated discharges to the receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from City WPCPs; and other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

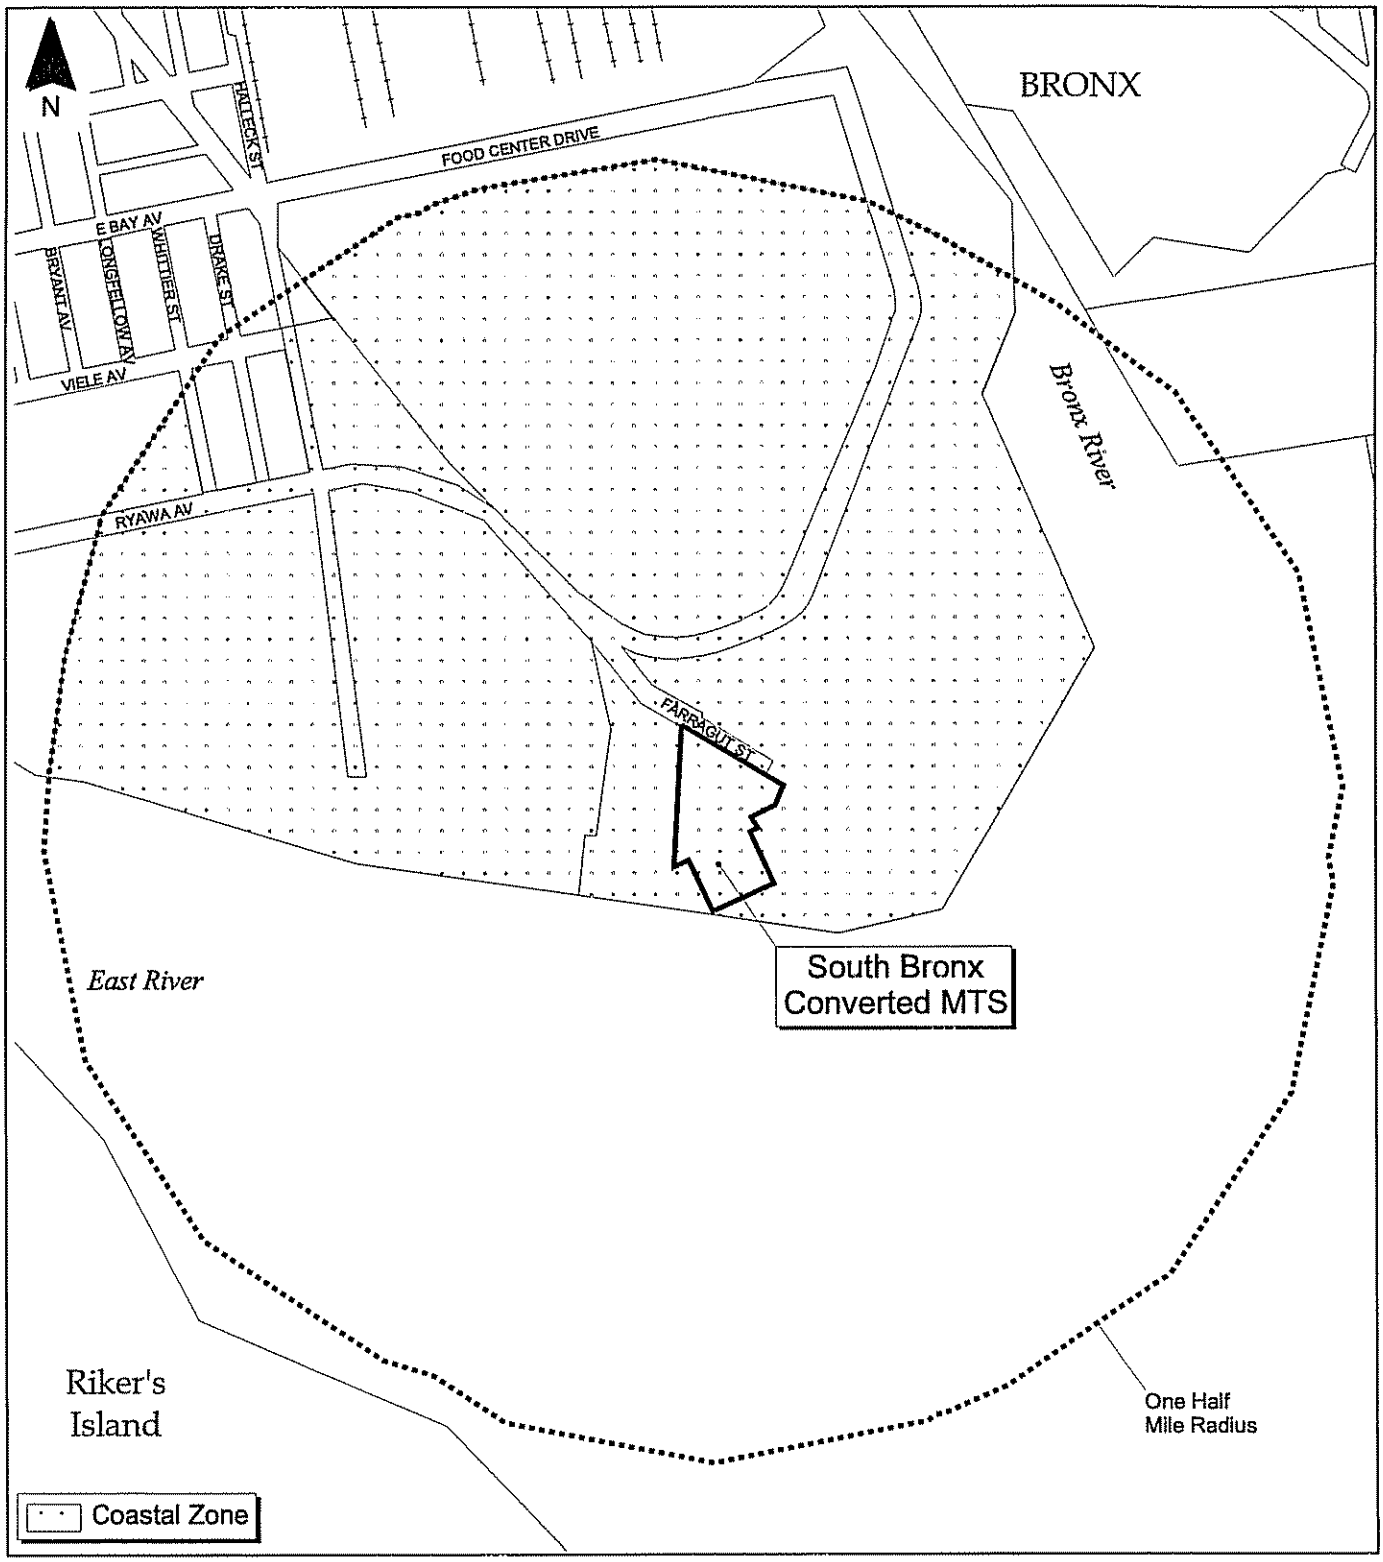
19.11.3 Potential Impacts with the South Bronx Converted MTS

An inoperative MTS that has been closed since July 1994 is on the site. With development and operation of the South Bronx Converted MTS, there would be an increase in the impervious area and, therefore, an increase in stormwater loadings. Water quality conditions would not be significantly different from Future No-Build Conditions and, as a result, no significant impacts to water quality would be anticipated. Table 19.11-4 shows the existing impervious area, the change in impervious area and pollutant loads. After treatment, the process wastewater would be discharged to the municipal sewer system and, ultimately, to the Hunts Point WPCP, where it would be treated prior to discharge to the East River and, therefore, would not adversely affect water quality.

Table 19.11-4
Impervious Area and Estimated Pollutant Loads
South Bronx Converted MTS

			Estimated Pollutant Loadings/Incremental Change[1]				
Conditions	**Total Impervious Area (acres)**	**Change in Impervious Area (acres)**	**Fecal Coliform[2]**	**BOD (lbs/day)**	**Copper (lbs/day)**	**Lead (lbs/day)**	**Zinc (lbs/day)**
Existing Conditions	4.09	0.0	45,008/NA	15/NA	0.046/NA	0.037/NA	0.204/NA
Future Build Conditions	5.67	1.58	62,391/17,383	20/5	0.064/0.018	0.051/0.014	0.283/0.079

Notes:
(1) Incremental change refers to the difference in pollutant loading between the Existing Conditions and Future Build Conditions.
(2) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable



Unimpeded operation of the South Bronx Converted MTS may also require dredging to refurbish the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired before such activities commenced. Applicable and appropriate measures (e.g., closed clamshell buckets, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant adverse long-term impacts.

19.12 Waterfront Revitalization Program

19.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of the East River, the South Bronx Converted MTS would be within the City's coastal zone boundary (see Figure 19.12-1). According to "The New Waterfront Revitalization Program," the South Bronx Converted MTS would be classified as a water-dependent, industrial use. It would be located within Reach 7/South Bronx, as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Bronx Waterfront," and within the South Bronx SMIA. The South Bronx Converted MTS is subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The South Bronx Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable, including subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3 and 8.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14-1. Further discussion is provided below for those policies or subpolicies needing more clarification or found to be inconsistent with a component of the South Bronx Converted MTS. A description of waste handling operations that would occur at the South Bronx Converted MTS is provided in Section 2.4.1.

Site delineations and study area boundaries are approximate

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

19.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the South Bronx Converted MTS. As part of the South Bronx Converted MTS, connections from the facility to existing utilities (e.g., sewer and electrical connections, etc.) in the vicinity would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The South Bronx Converted MTS would be located within the South Bronx SMIA. It would involve the conversion of the existing over-water MTS facility from a truck-to-barge waste transfer station to a TCB transfer station that would transport DSNY-managed Waste by marine transport to remote out-of-City disposal facilities. The proposed MTS would involve the removal of the existing MTS building and its support structures and the development of a new MTS, constructed over water on a pile-supported platform.

The South Bronx Converted MTS, as described in Section 2.4.1, would largely represent the continuation of an existing industrial and water-dependent use. Waterfront construction would involve four primary components: (1) elevated access ramps to the main structure; (2) an enclosed processing building, which would include the tipping floor, loading floor and pier level; (3) an outside gantry

crane system; and (4) a new bulkhead and fendering system. The South Bronx Converted MTS would serve to maintain this use while restoring and revitalizing industrial waterfront property. It would be consistent and compatible with surrounding industrial land uses and current zoning, and it would be consistent with the "Plan for the Bronx Waterfront," which recommends increased use of water-borne transportation for solid waste and other recyclables. Although the South Bronx Converted MTS would not encourage or facilitate the siting of any additional water-dependent uses, it would represent an expansion in building size of an existing water-dependent use and would be compatible with surrounding uses. The South Bronx Converted MTS would be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The South Bronx Converted MTS would involve the complete demolition of the existing MTS and the subsequent development of a new and expanded facility within the East River. It would allow for marine transport of solid waste to licensed out-of-City disposal facilities. Waterfront development would involve four primary components: (1) elevated access ramps to the main structure; (2) an enclosed processing building, which would include the tipping floor, loading floor and pier level; (3) an outside gantry crane system; and (4) a new bulkhead and fendering system. An existing salt shed and SHS would remain on the South Bronx Converted MTS site.

Based on historical information, navigable depths in the area have generally been maintained by natural scouring. However, dredging will be required to improve existing water depths at and in the vicinity of the site to allow for the unimpeded operation of barges and tugboats once the South Bronx Converted MTS became operational. All dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be acquired prior to any dredging activities.

Although the "Plan for the Bronx Waterfront" recommends that the parcel be converted to parkland serving the Hunts Point community should DSNY decide to vacate the site, expansion of the existing site by DSNY would be consistent and compatible with the plan, surrounding land uses and current zoning. The new facility would be consistent with existing industrial uses in the vicinity of the site and would be consistent with this subpolicy.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The South Bronx Converted MTS would be located within the East River and would be expanded from its existing footprint. In addition, the facility would be located within an existing, heavily industrialized area and would not interfere with any other maritime industrial, commercial or recreational vessel activities in the area. Activities within the East River resulting from the South Bronx Converted MTS would be limited to barge loading along the pier level and the periodic swapping of loaded barges at the slips. Four of five barges would be filled on a daily basis. These swapping activities would be similar to previous barge activities at the site. Therefore, no adverse impact to other uses within the water body would be anticipated. The South Bronx Converted MTS would be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The South Bronx Converted MTS would involve the conversion of an existing over-water facility truck-to-barge waste transfer station where loose waste was placed in open barges, into a TCB transfer station where waste would be transferred into containers that were sealed and placed into flat deck barges that would transport the DSNY-managed Waste to remote out-of-City disposal facilities. All waste would be placed in sealed containers before leaving the processing building. All solid waste handling would be done within an enclosed processing building and, therefore, would be protective of the aquatic environment and surrounding land and water uses. Litter control methods, such as routine sweeping and washing of the tipping floor, would also be implemented to minimize or eliminate the potential for litter entering surface waters. Building ventilation would be maintained under negative pressure, which would maintain dust inside the building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environment. All process wastewaters would be treated on site prior to being discharged to the municipal sewer system. In addition, any on-site storage of petroleum or hazardous materials related to the South Bronx Converted MTS would be managed in accordance with all applicable federal, state and local regulations.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs, Recognized Ecological Complexes, and SCFWHs, the South Bronx Converted MTS would not be located within any designated areas. It would represent an expansion in size of a previous use and

would not be anticipated to result in any long-term impacts to natural resources in the vicinity of the site. The South Bronx Converted MTS would be consistent with this subpolicy.

4.2 Protect and restore tidal and freshwater wetlands.

A review of NYSDEC tidal and freshwater wetland and National Wetland Inventory (NWI) maps was conducted to determine the presence of wetlands. As noted in Section 19.9.1, the site contains no freshwater wetlands. The South Bronx Converted MTS would be located within the East River, which is identified as a littoral zone, a state-designated wetland. The demolition of the existing MTS and subsequent development of the South Bronx Converted MTS would result in limited, short-term impacts to these tidal wetlands.

Impacts to littoral zones would be minimized due to previous and ongoing industrial activities at and in the vicinity of the site. Future Build Conditions would involve demolition and removal of the existing MTS and pile-supported structures, and construction of waterfront facilities for barge loading and mooring. Historical information indicates that natural scouring of sediments occurs in the immediate vicinity of the site, which has limited the need for ongoing dredging. However, dredging will be required to provide sufficient depths for barge and tugboat operations. Potential impacts due to dredging would be short-term and localized. All dredging would be conducted in accordance with applicable federal, state and local regulations. Mitigation for potential impacts, as appropriate and applicable, would be proposed during the environmental review and permitting of the South Bronx Converted MTS. Mitigation, if required, would be proposed to address any potential impacts to wetlands that may occur due to the development of the South Bronx Converted MTS. The South Bronx Converted MTS would, therefore, be consistent with this policy.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

There are no vulnerable plant, fish or wildlife species found in the vicinity of the site. A review of the USF&WS and NYSDEC Breeding Bird Atlas records indicates that there are no federally-listed endangered, threatened or special concern species found in the area surrounding the South Bronx Converted MTS.

The South Bronx Converted MTS would involve the demolition of the existing MTS facility. The proposed facility would remain as an over-water facility. Waterfront development would include elevated access ramps; an enclosed processing building, which includes a tipping floor, loading floor and pier level; a gantry crane system; and a fendering and bulkhead system. Although navigable depths in the area have historically been maintained by natural scouring, the development of the South Bronx Converted MTS will require dredging. However, potential impacts to plant, fish and wildlife species would be minimized and all dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be obtained prior to any dredging activities.

In addition, all handling and containerization of solid waste would be performed inside the processing building, thereby limiting the risk of an introduction of hazardous wastes or other pollutants into the environment that could impact surrounding fish and wildlife resources. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer system. Stormwater runoff from the South Bronx Converted MTS and the storage of any petroleum products would be managed in accordance with applicable federal, state and local regulations. The South Bronx Converted MTS would, therefore, be consistent with this subpolicy.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The South Bronx Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, the processing areas would be cleaned on a regular basis. All sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site treatment system, which would include an oil-water separator, and then discharged to the municipal sewer system. In addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. Stormwater runoff from the South Bronx Converted MTS would be managed in accordance with applicable regulations.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

During the development and operation of the South Bronx Converted MTS, BMPs would be used to the extent possible to minimize any nonpoint discharges. The South Bronx Converted MTS would comply with applicable federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be performed inside the processing building, thereby limiting the risk of an introduction of hazardous wastes or other pollutants into the environment. In addition, litter control methods would be implemented to minimize or eliminate the potential for litter to enter surface waters.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

The majority of the proposed demolition and construction would occur within the East River. The existing MTS structures and foundations would be removed. During removal of the existing pile-supported structure and over-water pier structures, disturbances to upper organic silts may occur, resulting in the temporary resuspension of sediment. Due to the swift currents in the area, mitigation measures (e.g., silt screens) would not be feasible; however, potential impacts would be short-term. Although navigable depths in the area have historically been maintained by natural scouring, dredging will be necessary to rehabilitate the existing bulkhead and to provide sufficient water depths for the unimpeded operation of barges and tugboats once the facility is operational. Potential impacts due to dredging would also be short-term and highly localized. All dredging would be done in compliance with applicable federal, state and local regulations and removed materials would be disposed of at a permitted facility.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The South Bronx Converted MTS would result in no adverse impact to the quality or quantity of surface waters at or in the vicinity of the site. Sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site treatment system and would then discharge to the municipal sewer system. Stormwater runoff from the South Bronx Converted MTS would be managed in accordance with federal, state and local regulations. No surface or ground waters in the vicinity of the site constitute a primary or sole source of water supply. The South Bronx Converted MTS would be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion

6.1 *Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.*

According to a review of the FEMA National Flood Insurance Program maps, the majority of the site is located within the 100-year flood plain boundary (Zone A). As part of the Future Build Conditions, the existing MTS would be demolished and a new MTS would be constructed within an expanded footprint that would encompass the existing site. The South Bronx Converted MTS would not affect the potential for flooding or erosion. All demolition and construction would comply with applicable building code requirements and, to the extent practicable, non-structural measures would be implemented to minimize damage from flooding or erosion.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 *Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.*

The South Bronx Converted MTS would not involve the storage, treatment or disposal of hazardous waste, but would involve the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Waste would be transported in airtight, waterproof sealed containers. All waste handling operations would occur within an enclosed processing building, which would minimize or eliminate the escape of litter into the surrounding water body. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours of tipping. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations

(6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the South Bronx Converted MTS. Litter control methods would be implemented at the facility to minimize or eliminate litter entering surface waters. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility.

On-site storage of petroleum or hazardous materials related to the operation of the South Bronx Converted MTS would be minimal. All storage would be in accordance with applicable federal, state and local regulations. The South Bronx Converted MTS would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8. Provide public access to and along New York City's coastal waters.

8.1 Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.

Due to the existing, heavy industrial uses at and in the immediate vicinity of the South Bronx Converted MTS, public access would generally not be compatible with the principal use of the site. Therefore, this subpolicy is not applicable.

8.2 Incorporate public access into new public and private development where compatible with proposed land use and coastal location.

Located at the end of Farragut Street and adjacent to the site, approximately where the Reach 7/South Bronx "Plan for the Bronx Waterfront" recommends waterfront public access be developed, is an informal and unimproved, City-owned area used for water viewing and fishing. While the operation of the South Bronx Converted MTS could detract from the enjoyment of the waterfront experience at the end of Farragut Street, it would not preclude this non-designated and informal use. The Reach Plan also recommends that if the site were abandoned by DSNY, its redevelopment as a waterfront park could be explored. Since the plan was prepared, however, waterfront park planning on Hunts Point has advanced other alternatives, and by 2006 waterfront access in the vicinity will be accommodated by Barretto Point Park, which will not be affected by the South Bronx Converted MTS (see Section 19.5). Therefore, the South Bronx Converted MTS is consistent with this policy.

The South Bronx Converted MTS would be a stand-alone, water-dependent facility within the East River. Public access would not be compatible with the South Bronx Converted MTS; however, its development would not preclude any future development of public access at other waterfront locations along the East River.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

Development of the South Bronx Converted MTS would be compatible with adjacent properties along the waterfront and would not obstruct or impair visual access to coastal lands, waters or open space. It would represent an expansion of an existing water-dependent facility. As discussed in Section 19.7.3, visual access to coastal lands would not be impacted. See also response to Subpolicy 9.1.

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

Located at the end of Farragut Street and adjacent to the site is the only existing open space resource in the study area. It is an informal and unimproved, City-owned area used for water viewing and fishing. The South Bronx Converted MTS would not be expected to result in significant impacts on this parkland resource. According to the plan for Reach 7/South Bronx in the "Plan for the Bronx Waterfront," it is recommended that this and the adjacent MTS site be incorporated into a large park. This park is only recommended in the event that DSNY no longer uses the site.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 *Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.*

The South Bronx Converted MTS would not result in a significant impact on visual quality, as noted in Section 19.7.3. Based on the information discussed in that section, the South Bronx Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The South Bronx Converted MTS would involve an expansion of an existing water-dependent use and would pose no significant new impacts to scenic values associated with natural resources. It would be compatible with surrounding industrial uses and would be constructed within the East River. The South Bronx Converted MTS would be consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

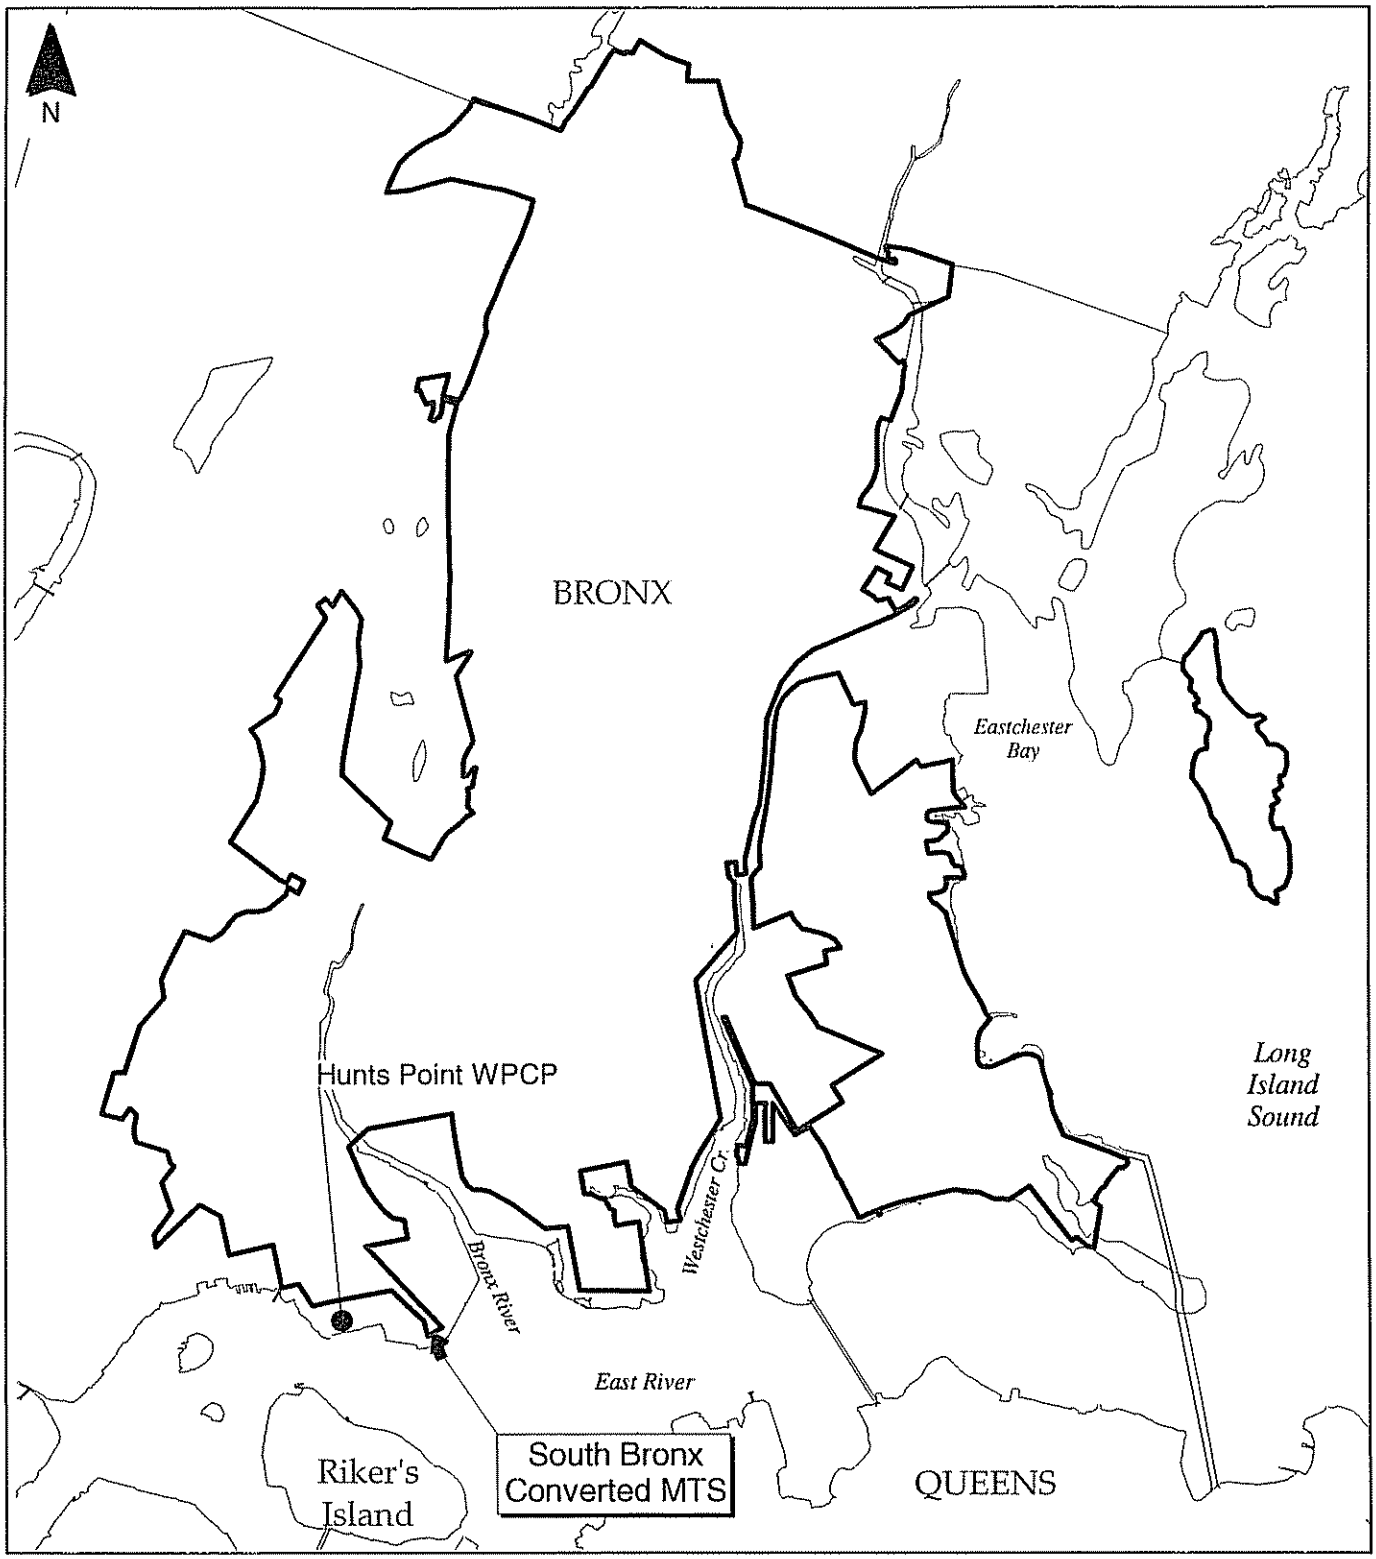
The South Bronx Converted MTS would have no effect on any cultural resources, as stated in Section 19.6.3. There are no historic structures listed or eligible for listing on the National or State Registers of Historic Places. Based on the information presented in Section 19.6.3, the South Bronx Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site, or in the immediate vicinity of the site. This subpolicy is, therefore, not applicable.

19.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

19.13.1 Existing Conditions



19.13.1.1 Water Supply

Water is supplied to the existing South Bronx MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. A 12-inch-diameter water line along Farragut Street provides potable water for both process and sanitary requirements. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

19.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Hunts Point WPCP, which serves the majority of the Bronx. The WPCP drainage area is illustrated in Figure 19.13-1. From July 2002 through June 2003, the WPCP treated an average of 99 mgd of wastewater under dry weather flow conditions and an average flow of 114 mgd, which includes the sanitary and stromwater flows received by the WPCP during wet weather (Table 19.13-1). The maximum dry weather flow during this period was 124 mgd in June 2003 and the maximum average flow was 144 mgd during June 2003. Effluent from the plant is discharged to the East River and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the Hunts Point WPCP is 200 mgd.

It is estimated that current on-site employee water usage is about 75 gpd. This estimate is based on three security employees (one guard per shift, three shifts per day) using 25 gallons per person per day (2001 CEQR Technical Manual). No additional potable water is used as the facility is currently not accepting waste, and no operational staff are currently assigned to the site. Sanitary wastewater generated at the facility is discharged to a 15-inch sanitary sewer line along Hunts Point Avenue. The 15-inch sanitary sewer line discharges to a pumping station from which wastewater is sent to the Hunts Point WPCP for treatment.

Site delineations are approximate.

March	103	121
April	101	115
May	89	100
June	124	144
Average Effluent	**99**	**114**

Notes:
(1) -Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

19.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each employee at the MTS produces approximately nine pounds of solid waste per week for a facility total of 27 pounds per week (approximately four pounds per day). As the facility is not currently accepting waste, no operational personnel are assigned to the site. Solid waste produced at the facility is collected by DSNY personnel and transported by truck to an appropriately licensed solid waste management facility.

19.13.1.4 Energy

Consolidated Edison of New York supplies electricity and gas to the facility. As the facility is currently not operating, the existing South Bronx MTS utilizes a negligible amount of energy due to the low staffing levels that supply only security for the site. The facility has no gas supply; however, a review of Consolidated Edison utility maps shows that gas mains are located in the vicinity of the facility along East Bay Avenue and currently serve the National Foods facility north of the site.

19.13.2 Future No-Build Conditions

The South Bronx MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would, therefore, be anticipated to remain at or near the Existing Conditions levels for security employees. Wastewater flows to the Hunts Point WPCP would continue to increase and would be projected to 113.5 mgd by 2006.

19.13.3 Potential Impacts with the South Bronx Converted MTS

19.13.3.1 Water Supply

The South Bronx Converted MTS would have a total of up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The South Bronx Converted MTS would have no impact on the existing system's ability to supply water reliably. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

19.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,300 gpd for the South Bronx Converted MTS, the small quantities of wastewater sent to the Hunts Point WPCP would not significantly impact the sewage flow rate or the ability of the Hunts Point WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 113.5 mgd in 2006, which would be well below the permitted capacity of 200 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

19.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the South Bronx Converted MTS and would not significantly impact the system.

19.13.3.4 Energy

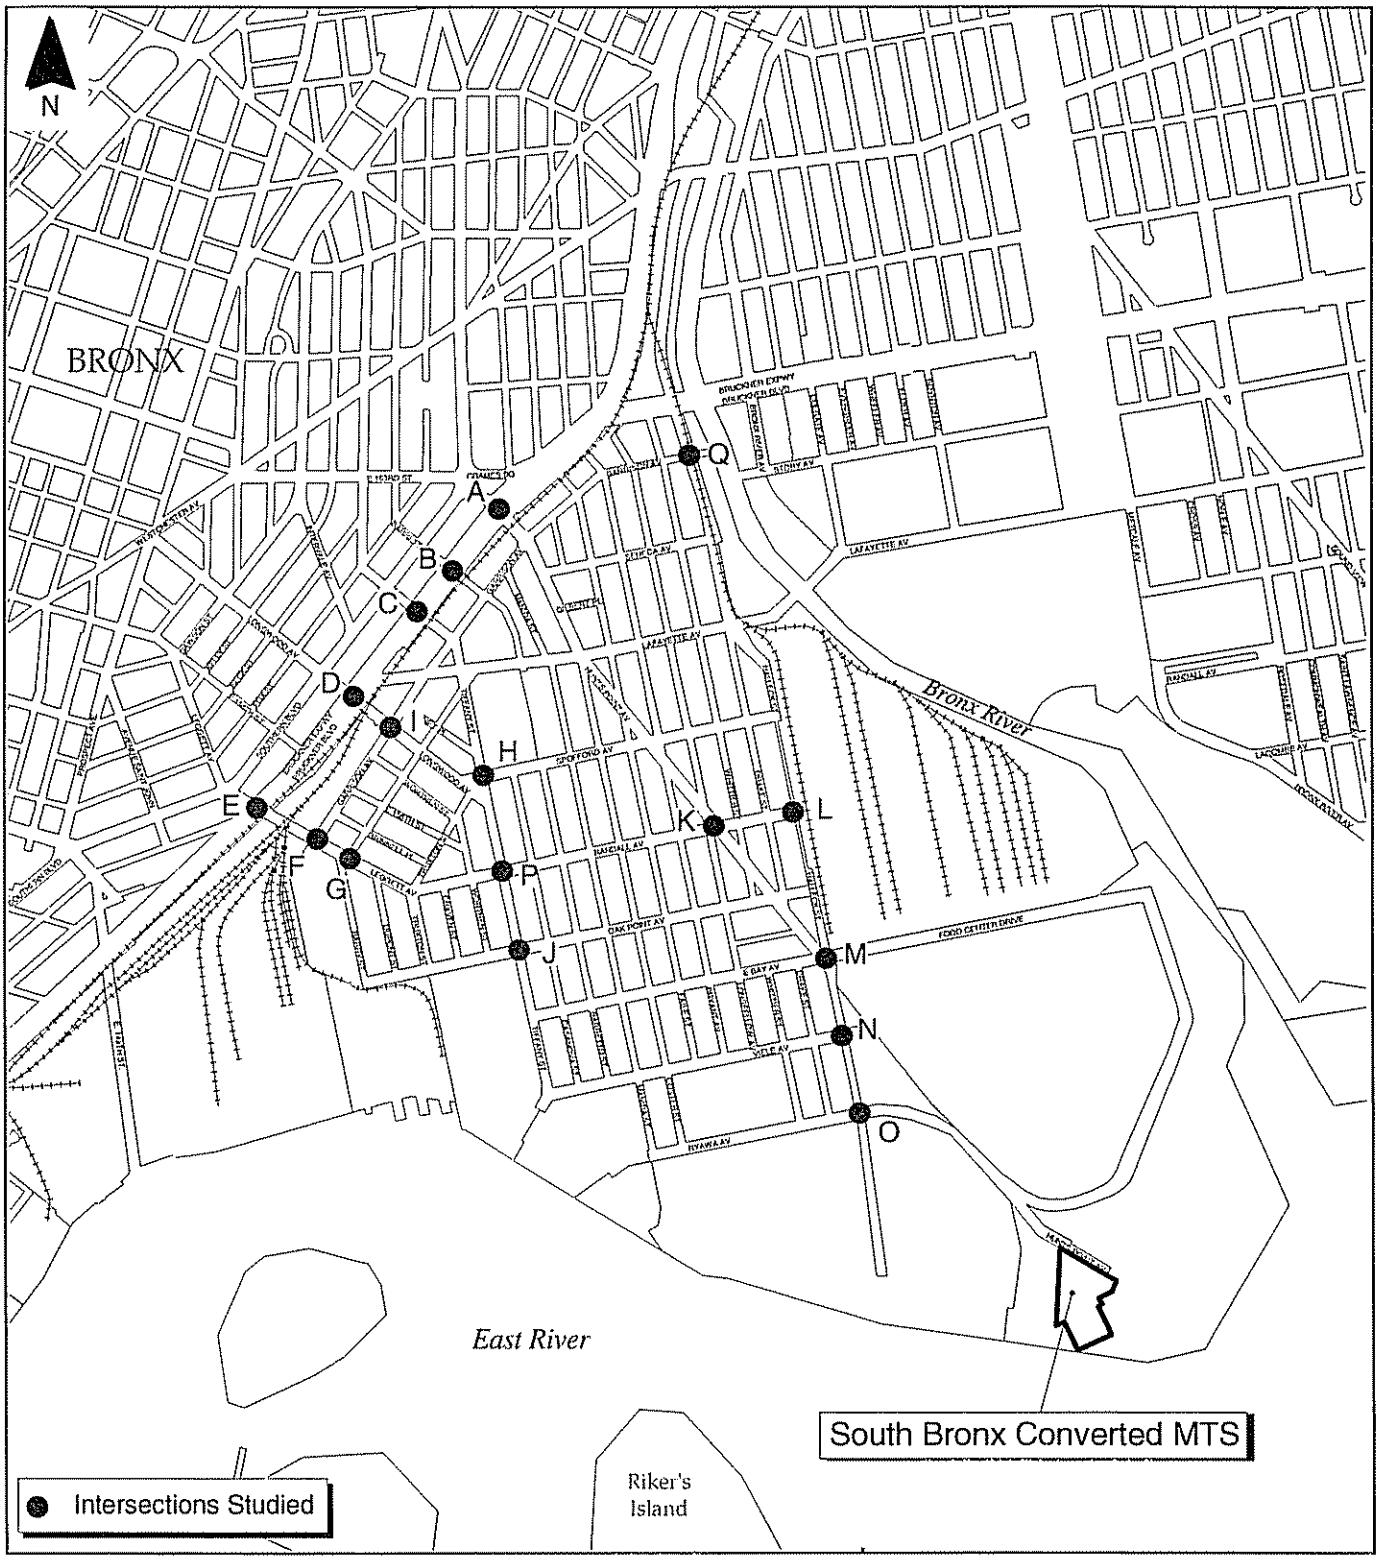
The South Bronx Converted MTS would require approximately 5.51E+10 BTU/year of electricity to operate the facility. Natural gas heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the South Bronx Converted MTS and has stated that all demands generated by the South Bronx Converted MTS could be met without any impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

Consolidated Edison was also notified of the natural gas requirements of the South Bronx Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts on the utility.

19.14 Traffic, Parking, Transit, and Pedestrians

19.14.1 Introduction



The South Bronx Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

19.14.2 Existing Conditions

19.14.2.1 Definition of Study Area

This site is located on the Hunts Point peninsula in the Bronx bounded on the land side by the elevated Bruckner Expressway, the depressed railroad right-of-way and the at-grade Bruckner Boulevard on the west, and the Bronx River and East River on the north, east and south. Thus, the peninsula and the adjacent Bruckner Boulevard provide a well-defined geographic boundary for the study area where concentrations of trips to and from the site would be expected to occur. The study area is characterized by a mixture of light industrial/manufacturing land uses with several residential areas. There are no CEQR-defined areas of concern located within the study area.

Bruckner Boulevard is a major corridor that extends from the Third Avenue Bridge in the Port Morris area of the Bronx west of the site to the interchange of the Bruckner and Sheridan Expressways. Vehicle trips into and out of the Hunts Points peninsula are limited to those portals where roadways bridge over the railroad right-of-way parallel to the Bruckner Expressway. Figure 19.14-1 shows the locations of the intersections selected for analysis (locations A through R). Intersections analyzed were selected using the procedures defined in Section 3.16. Section 19.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the South Bronx Converted MTS.

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

19.14.2.2 Surface Network

Trucks are required by NYCDOT Title 34 to travel on truck routes directly to the site or the intersection nearest the site if streets adjacent to the site are not designated truck routes. A map showing all major truck routes and local truck routes in the Bronx is provided in Section 3.16 (see Figure 3.16-2).

The primary truck access route to and from the Hunts Point peninsula is Bruckner Boulevard, a major arterial located at grade and below the Bruckner Expressway (I-278) for much of its length, with both express (mainline)- and service road-separated roadways. Through-truck routes connect the South Bronx with Queens via the Triborough, Bronx-Whitestone or Throgs Neck Bridges and with Manhattan via the Willis Avenue, Third Avenue or Madison Avenue Bridges.

Within the Hunts Point peninsula, NYCDOT is expected to implement several significant changes to the local truck route network by the end of 2003. These changes initially included the de-designation of a segment of Tiffany Street (from Bruckner Boulevard to Longwood Avenue), which is to be replaced with Longwood Avenue from Bruckner Boulevard to Tiffany Street, and the de-designation of Garrison Avenue from Longwood Avenue to Bryant Avenue. The analysis was based on these proposed modifications which were incorporated in Figure 3.16-2 and in all future truck routing considered in this analysis (not Existing Conditions). At the time of the analysis, DSNY and other agency collection vehicles would use Leggett Avenue and Longwood Avenue to enter the peninsula and proceed along Randall Avenue to Tiffany Street, which they would take to Viele Avenue, and from Viele take Halleck Street to Farragut Street. Leaving the site, trucks could utilize similar routing or a route following Halleck Street to Edgewater Road, then to the Bruckner Expressway and service road.

In addition, NYCDOT was expected to institute one-way travel westbound on Leggett Avenue (away from Bruckner Boulevard) between Southern Boulevard and Bruckner Boulevard. This modification would improve traffic operations on the westbound Leggett Avenue approach to

Bruckner Boulevard. Eastbound traffic from Leggett Avenue is expected to divert to alternate routes, including Longwood Avenue and Tiffany Street. This traffic diversion was also incorporated in the Future No-Build and Build Conditions described herein.

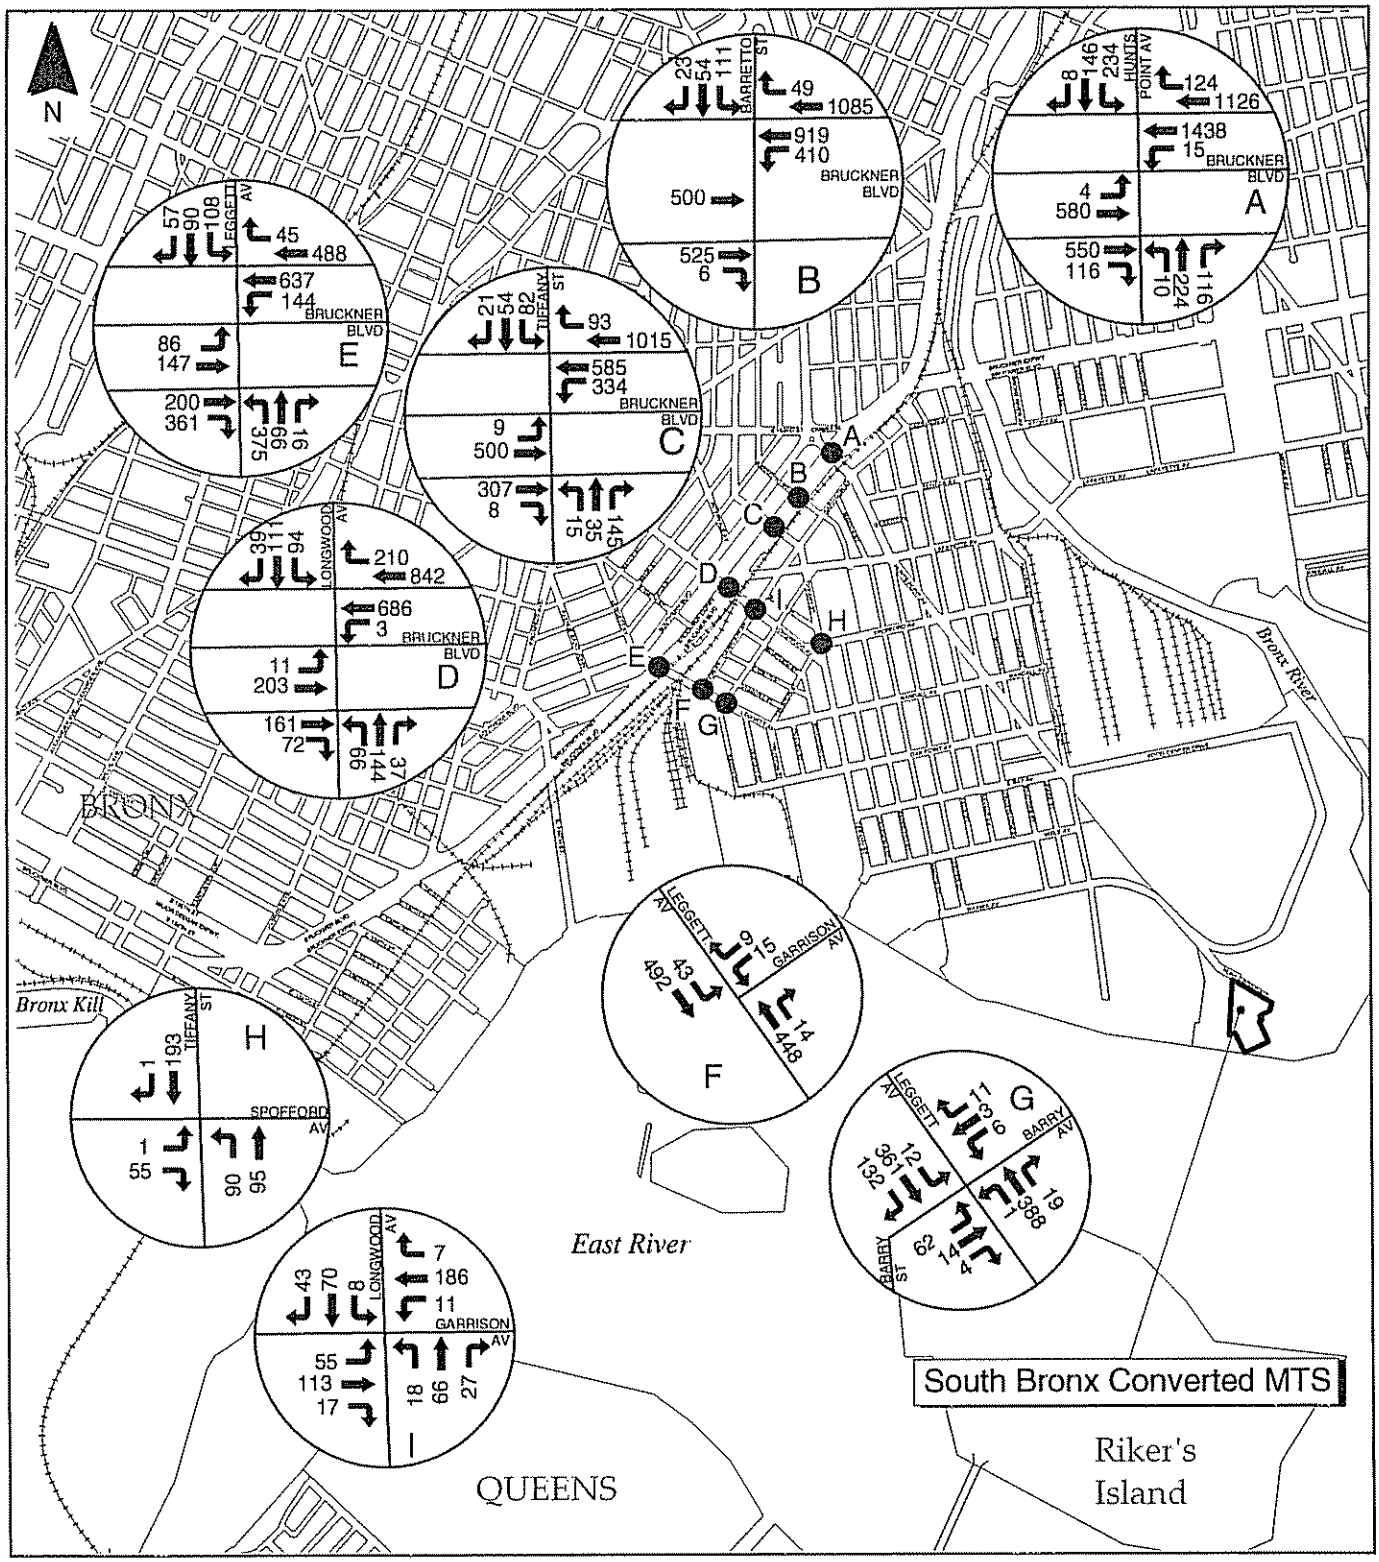
On July 21, 2004, the NYCDOT published the Updated Truck Routes in Hunts Point that no longer de-designated the segment of Tiffany Street from Bruckner Boulevard to Longwood Avenue and replaced it with Longwood Avenue from Bruckner Boulevard to Tiffany Street, as analyzed. The analysis presented herein will be updated in the FEIS if the South Bronx Converted MTS is included in the Proposed Plan.

DSNY and other agency collection vehicles would use Leggett Avenue and Longwood Avenue to enter the peninsula. Once on the Hunts Point Peninsula, DSNY and other agency collection vehicles would proceed to the South Bronx Converted MTS along using the a variety of different routes along the following designated truck routes: Randall Avenue, Tiffany Street, Viele Avenue, Halleck Street and Food Center Drive. All DSNY and other agency collection vehicles would turn from Food Center Drive onto Farragut Street, which is not a designated truck route, to access the South Bronx Converted MTS. Upon leaving the Converted MTS, DSNY and other agency collection vehicles would travel along the same designated truck routes as listed above, with the addition of Edgewater Street, to gain access to Bruckner Boulevard.

19.14.2.3 Existing Traffic Operations

The 18 intersections listed below were identified for analysis because they are most likely to be impacted from the South Bronx Converted MTS. Diagrams of these intersections were included in technical backup submitted to NYCDOT.

- Bruckner Boulevard and Hunts Point Avenue- Signalized Intersection (see Figure 19.14-1 - location A)
- Bruckner Boulevard and Barretto Street - Signalized Intersection (see Figure 19.14-1 - location B)
- Bruckner Boulevard and Tiffany Street - Signalized Intersection (see Figure 19.14-1 - location C)



- Bruckner Boulevard and Longwood Avenue - Signalized Intersection (see Figure 19.14-1 - location D)
- Bruckner Boulevard and Leggett Avenue - Signalized Intersection (see Figure 19.14-1 - location E)
- Leggett Avenue and Garrison Avenue - Signalized Intersection (see Figure 19.14-1 - location F)
- Leggett Avenue and Barry Street - Signalized Intersection (see Figure 19.14-1-location G)
- Longwood Avenue and Garrison Avenue - Unsignalized Intersection (see Figure 19.14-1 - location H)
- Longwood Avenue and Tiffany Street - Unsignalized Intersection (see Figure 19.14-1 - location I)
- Tiffany Street and Oak Point Avenue - Signalized Intersection (see Figure 19.14-1 - location J)
- Hunts Point Avenue and Randall Avenue - Signalized Intersection (see Figure 19.14-1 - location K)
- Randall Avenue and Halleck Street - Unsignalized Intersection (see Figure 19.14-1 - location L)
- East Bay Avenue, Hunts Point Avenue and Halleck Street - Signalized Intersection (see Figure 19.14-1 - location M)
- Halleck Street and Viele Avenue - Unsignalized Intersection (see Figure 19.14-1 - location N)
- Halleck Street and Ryawa Avenue - Unsignalized Intersection (see Figure 19.14-1 - location O)
- Tiffany Street and Randall Avenue - Signalized Intersection (see Figure 19.14-1 - location P)
- Edgewater Road and Garrison Avenue - Unsignalized Intersection (see Figure 19.14-1 - location Q)
- Tiffany Street and Spofford Avenue - Unsignalized Intersection (see Figure 19.14-1 - location R)

As noted above, Bruckner Boulevard is a major surface arterial in the South Bronx. Leggett Avenue, Longwood Avenue, Tiffany Street, Randall Avenue and Halleck Street currently serve, or will serve after the truck route changes are implemented, as the primary routes for trucks in the Hunts Point peninsula.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Counts were conducted in late February 2003. Figures 19.14-2, 19.14-3, 19.14-4, 19.14-5, 19.14-6 and 19.14-7 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 8:00 a.m. and 9:00 a.m., the Facility peak between 11:00 a.m. and 12:00 noon, and the PM peak between 5:00 p.m. and 6:00 p.m. Table 19.14-1 presents the v/c ratio, delay and LOS for the 18 intersections during the AM, Facility, and PM peaks.

For simplicity in this analysis, Bruckner Boulevard is described as north-south and Tiffany Street, Leggett Street, etc., as east-west. On Bruckner Boulevard, existing traffic volumes peak between 7:00 a.m. and 9:00 a.m., then decrease, but remain at a fairly high relative level throughout the Facility peak period. Traffic volumes peak again between 4:00 p.m. and 6:30 p.m. Throughout Hunts Point peninsula, traffic remains at a fairly consistent level from 6:00 a.m. through 4:00 p.m., and then begins to decrease through the late afternoon

The composition of vehicles in the traffic stream varies by location and time of day but is typically comprised of a high proportion of trucks. Along Bruckner Boulevard, trucks and buses comprise between 10% and 20% of the total traffic during the AM peak and slightly less during the PM peak. Trucks and buses typically comprise 15% to 25% of the total traffic volume during the Facility peak hour on Bruckner Boulevard. The proportion of trucks is higher within Hunts Point peninsula, where truck levels are well over 30% of total traffic during the AM and Facility peak periods and dip only slightly, typically to between 20% and 30%, during the PM peak.

LR = left right movement

19.14.2.3.1 LOS at Signalized Intersections

Table 19.14-1 shows the existing v/c ratio, delay and LOS for each analysis peak period. Overall, most signalized intersections operate at LOS A, B or C during each analysis period, except the intersections of Bruckner Boulevard at Hunts Point Avenue, Bruckner Boulevard at Barretto Street, and Bruckner Boulevard at Leggett Avenue. LOS D occurs northbound on both the mainline road and service road of Bruckner Boulevard at Hunts Point Avenue during all three time periods. LOS D also occurs during the PM peak hour on the mainline road of Bruckner Boulevard at Barretto Street as well as during both the AM and Facility peak hours on the mainline road of Bruckner Boulevard at Leggett Avenue.

Specific lane groups at study intersections typically operate at LOS C or better, but a number operate at LOS E or LOS F, specifically lane groups related to the above-mentioned intersections. These include the northbound through lane group and eastbound left turn lane group on the mainline intersection of Bruckner Boulevard at Hunts Point Avenue as well as the eastbound left turn lane group on the service road intersection during the PM peak hour. All of these lane groups operate at LOS E.

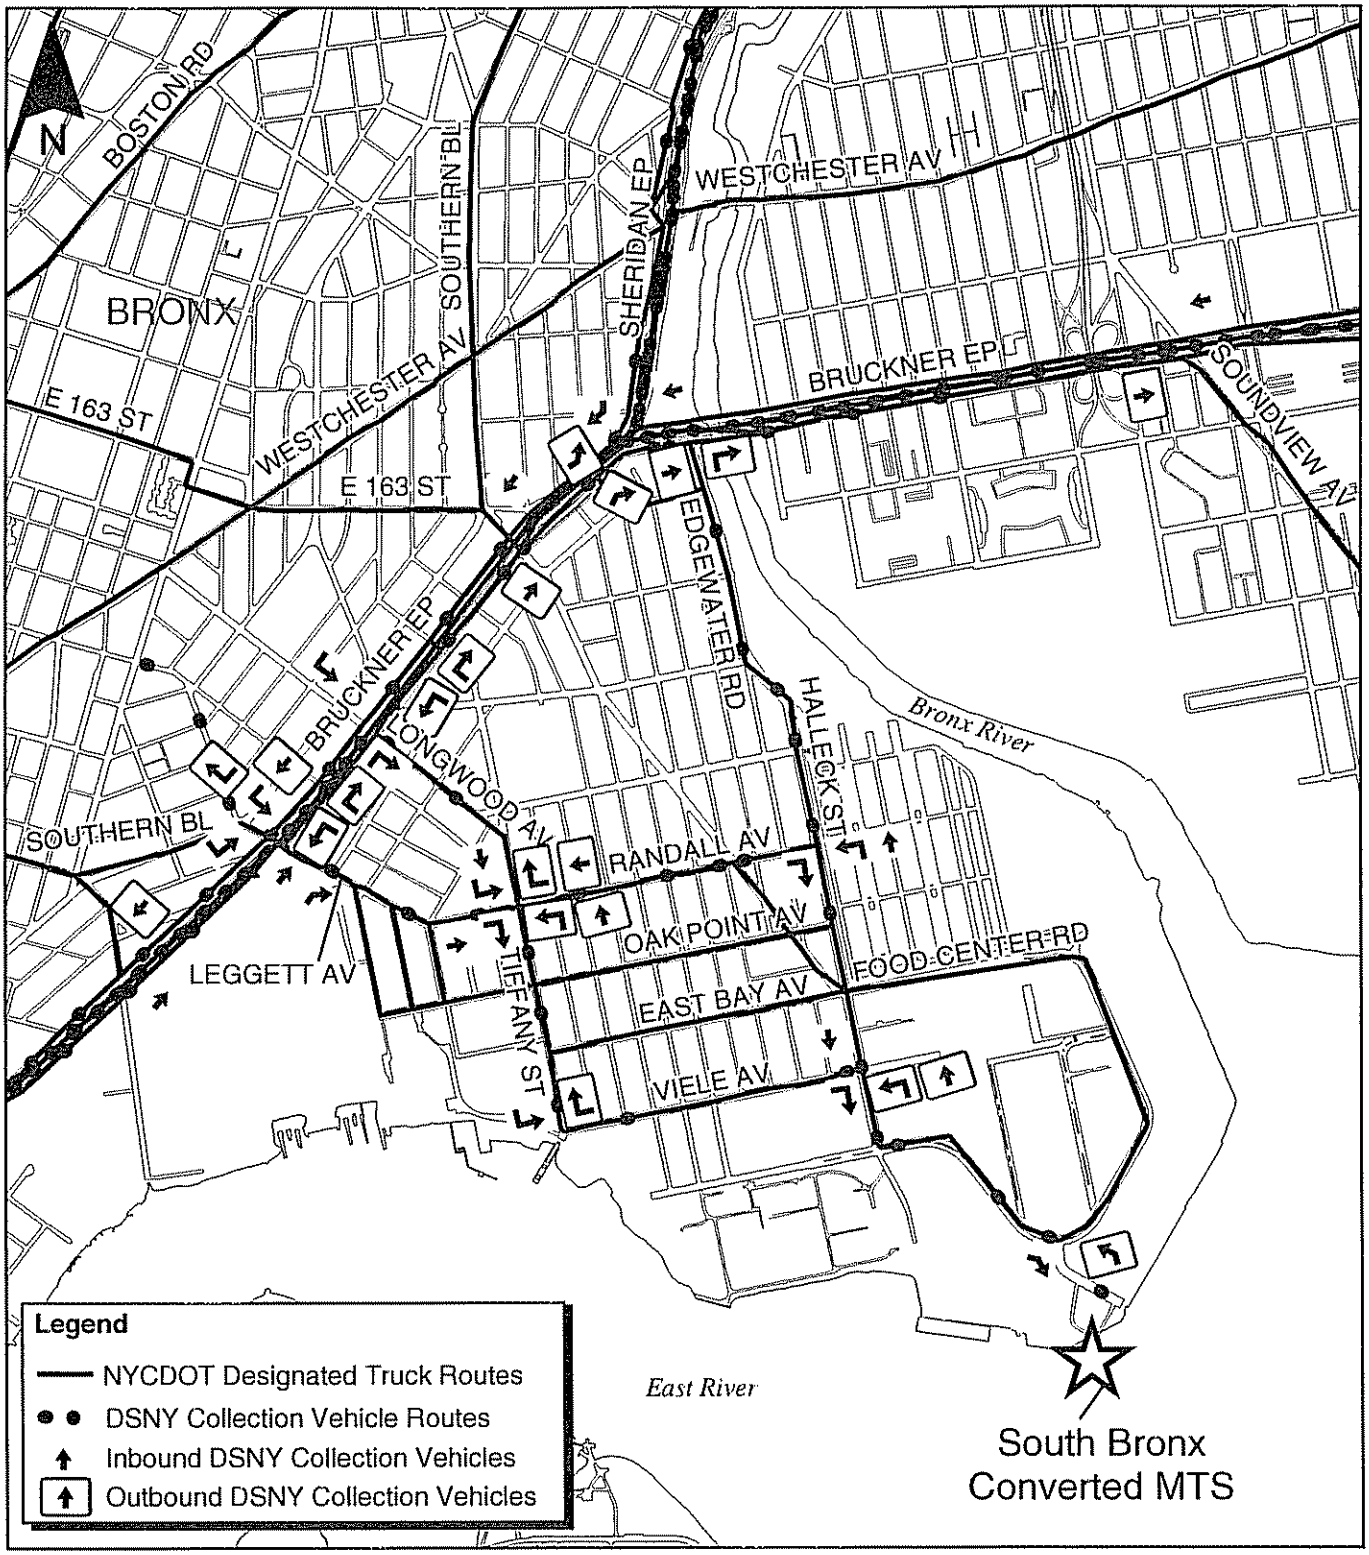
The intersection of Bruckner Boulevard at Barretto Street also has specific lane groups operating at LOS E or LOS F. On the mainline road intersection, the southbound left turn during the PM peak hour operates at LOS F, while the shared eastbound left and through lane group during the AM peak hour operates at LOS E. The shared eastbound through and right lane group on the service road intersection operates at LOS E as well during the AM peak hour. At the mainline road intersection of Bruckner Boulevard at Leggett Avenue, the westbound left turn is operating at LOS F during the AM peak hour. Lane groups operating at LOS E include the shared westbound left and through lane group during the AM peak hour, the westbound left turn during the Facility peak hour and the eastbound defacto left turn during the PM peak hour.

19.14.2.3.2 LOS at Unsignalized Intersections

Table 19.14-1 also indicates intersection operations at each of the unsignalized intersections analyzed. All unsignalized intersection movements analyzed operate at LOS A and LOS B with the exception of the eastbound left turn from Randall Avenue to Halleck Street, which operates

at LOS C during the AM and Facility peak hours. The shared eastbound left and through lane group from Garrison Avenue to Edgewater Road during the PM peak hour also operates at LOS C. (HCM output was included in technical backup submitted to NYCDOT.)

19.14.2.4 Existing DSNY-Related Traffic



MSW generated by Bronx CDs BX1 through BX8, BX11 and BX12 is currently transported under the Bronx interim export program to USA Waste Management of NY's Harlem River Yard facility, a commercial vendor located at 98 Lincoln Avenue in the Port Morris section of the Bronx. Municipal waste generated by CDs BX9 and BX10 is transported to the Waste Services of NY facility at 920 East 132nd Street, also in Port Morris. E-Z Pack loads from BX1 and BX6 are delivered to either the Waste Services facility or to Triboro Fibers, located at 770 Barry Street in the Bronx, as are all borough-wide collection activities. Existing DSNY collection vehicles in the traffic study area proceeding to and from these vendors are routed primarily along Bruckner Boulevard.

19.14.2.5 Public Transportation

Public transportation within the study area consists of the NYCT BX6 bus route with service along Hunts Point Avenue, Spofford Avenue, Halleck Street and Food Center Drive. The BX6 route crosses the Macombs Dam Bridge into Manhattan. No other transit service is available within ½-mile of the site.

19.14.2.6 Pedestrian Activity

There is little pedestrian activity in the study area. Most pedestrian activity is concentrated in the area of the commercial establishments near the intersection of Hunts Point Avenue and Garrison Avenue.

19.14.3 Future No-Build Conditions

19.14.3.1 Traffic Conditions

The following assumptions and traffic assignments were applied in the development of Future No-Build traffic volumes:

- Continued operation of the Bronx interim export program with MSW delivered to the vendors noted above;
- Discrete assignment of auto and truck trips generated by the relocation of the Fulton Fish Market at Hunts Point, as detailed in the 2001 FEIS prepared for the NYCEDC; and
- Background traffic growth of 0.5% per year in accordance with the 2001 CEQR Technical Manual.

In addition, background truck traffic was reassigned due to the changes expected to be implemented to the truck route network by NYCDOT and the one-way westbound restriction on Leggett Avenue between Bruckner Boulevard and Southern Boulevard, as described in Section 19.14.2.2.

- Due to the truck route changes assumed for 2006 Future No-Build Conditions, trucks traveling southbound on Bruckner Boulevard and turning left onto Tiffany Street will be re-routed to Longwood Avenue, thus turning left onto Longwood Avenue when traveling southbound on Bruckner Boulevard. As discussed with the NYCDOT, the installation of a southbound left turn lane on Bruckner Boulevard was assumed and the signal timing at the intersection of Bruckner Boulevard at Longwood Avenue was modified to accommodate the additional left turn volumes. The existing two-phase signal operation was modified to a three-phase operation.

Figures 19.14-9, 19.14-10, 19.14-11, 19.14-12, 19.14-13 and 19.14-14 provide the AM, Facility peak and PM peak-hour Future No-Build traffic volumes for the intersections analyzed in conjunction with this site.

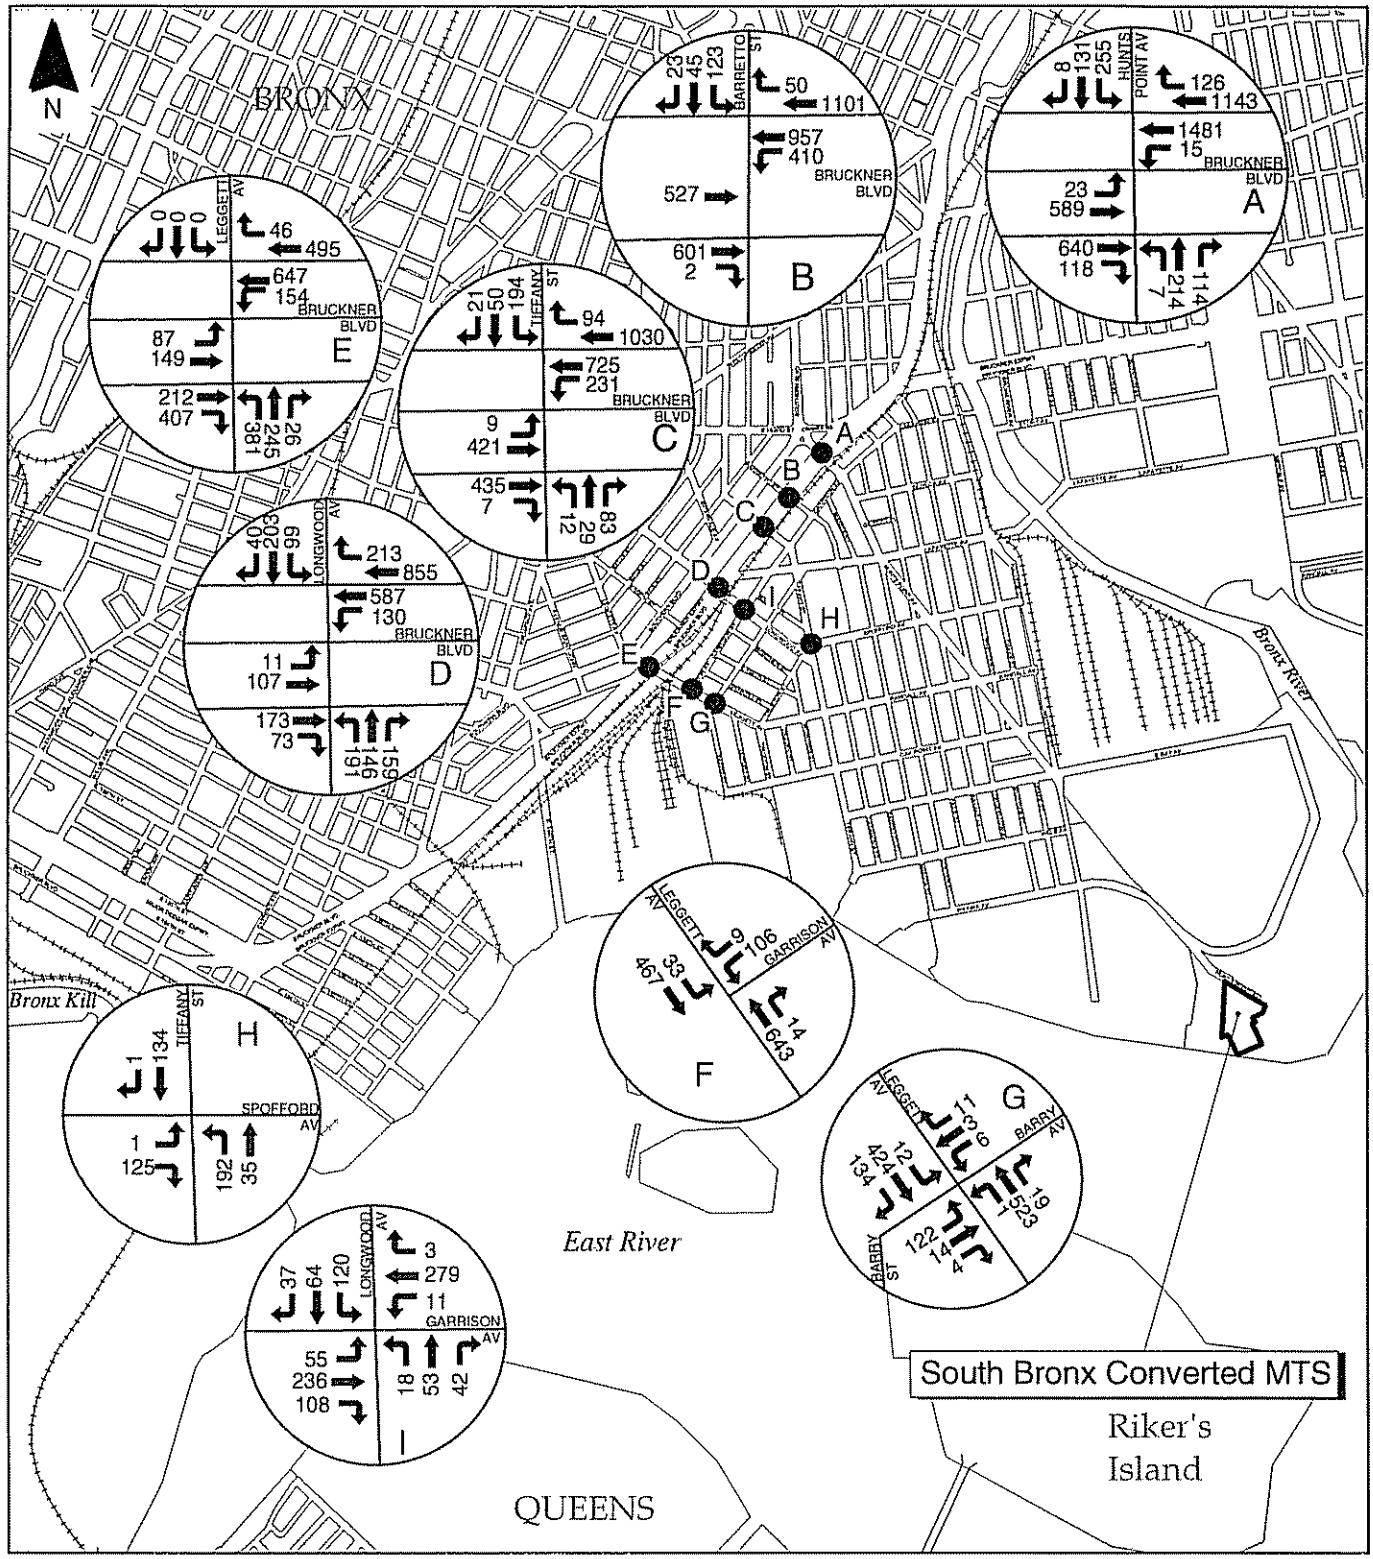

Table 19.14-2 provides the Future No-Build v/c ratio, delay and LOS for each study intersection. As shown, the majority of the intersections are forecast to operate at LOS B or LOS C, although a significant number are predicted to operate at LOS D. The additional volume of the background growth and new development did not significantly deteriorate any one intersection,

but, as expected, the re-routing of truck trips to Longwood Avenue would generate a LOS D at the mainline road intersection of Bruckner Boulevard at Longwood Avenue for both the AM and PM peak periods and on the service road for all three time periods.

During the PM peak period, the mainline road intersection of Bruckner Boulevard and Barretto Street would also operate at LOS D. Traffic operations during all three time periods on the northbound mainline road and service roads of Bruckner Boulevard at Hunts Point Avenue would also operate at LOS D, with the exception of the PM peak period on the northbound mainline road, which would operate at LOS E. Lastly, operations at the intersection of Bruckner Boulevard at Leggett Avenue was shown to improve slightly in comparison to existing conditions due to the elimination of conflicts for westbound left-turning vehicles.

Individual movements generally operate at LOS D or better, but a number operate at LOS E or F. During the PM peak hour, at the intersection of Bruckner Boulevard at Hunts Point Avenue, both the eastbound left and northbound through lane groups on the northbound mainline road intersection would operate at LOS E, as would the eastbound left turn lane group on the northbound service road intersection. The eastbound left turn lane group at the intersection of mainline Bruckner Boulevard at Tiffany Street would operate at LOS E, both during the AM and PM peak hours. LOS F was projected for the southbound left turn lane group on the mainline road at the intersection of Bruckner Boulevard with Barretto Street during the PM peak hour, while LOS E was projected for the shared eastbound left and through lane group during the AM peak hour. LOS E was also projected for the eastbound shared through and right turn lane group during the AM peak hour.

At the service road intersection of Bruckner Boulevard with Longwood Avenue, the westbound shared through and right turn lane group during the AM peak hour and the southbound shared through and right lane group during the PM peak hour would operate at LOS E. Lastly, the westbound left turn lane group and the westbound shared left and through lane group at the mainline road intersection of Bruckner Boulevard with Leggett Avenue and at the service road intersection shared through and right turn lane group would operate at LOS E during the AM peak period.

Notes:

[1] HCM output is included in technical backup submitted to the NYCDOT.

DFL = defacto left
EB = eastbound
LTR = left, through and right movements
ML = mainline
NB = northbound
SB = southbound
SR = service road
WB = westbound
LT = left through movement
L= left movement
TR = through right movement
R = right movement
T = through movement
LR = left right movement

Table 19.14-2 also indicates Future No-Build traffic operations at unsignalized intersections. As indicated, operations for all lane groups would remain at LOS A, LOS B or LOS C, with the exception of the eastbound left turn lane group from Ryawa Avenue to Halleck Street during the AM peak hour and the eastbound shared right and through lane group at the intersection of Garrison Avenue and Longwood Avenue. The additional traffic on Halleck Street is expected to be generated primarily by the Fulton Fish Market relocation and would result in the increased delay for the left turn from Ryawa Avenue to Halleck Street. Additionally, the re-routing of trucks onto Longwood Avenue will increase delay on both the Longwood Avenue and Garrison Avenue approaches.

19.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

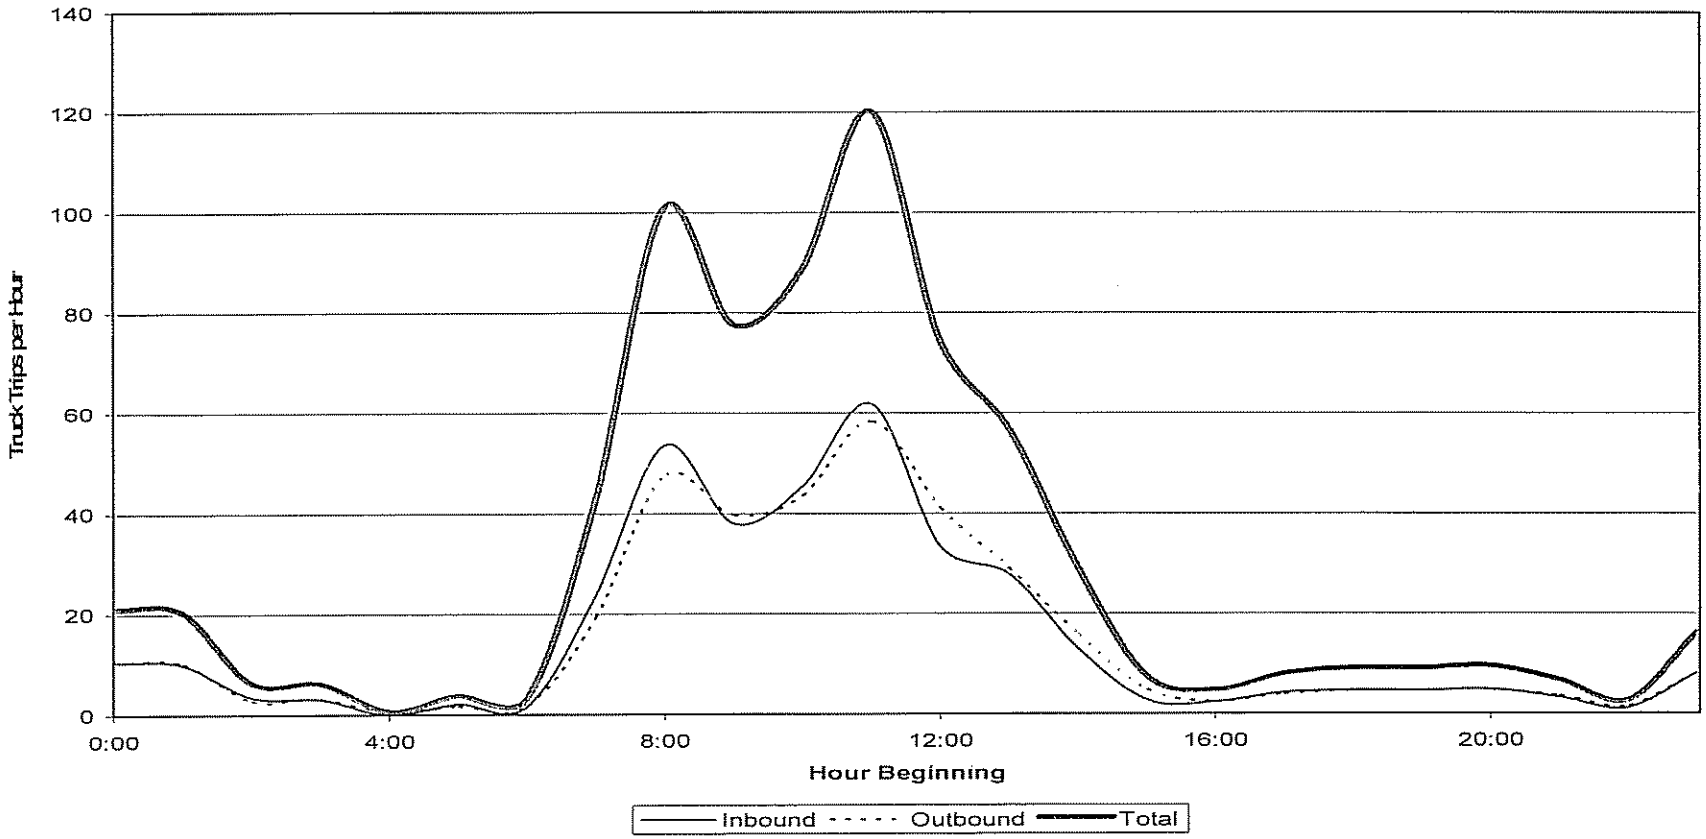
19.14.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

19.14.4 Potential Impacts with the South Bronx Converted MTS

The South Bronx Converted MTS would receive waste from all 12 CDs in the Bronx. Additionally, the waste collected via borough-wide collection activities would also be delivered to the South Bronx Converted MTS. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Additionally, employee trips to and from the site may result in traffic impacts during the AM peak hour.

19.14.4.1 2006 Future Build Traffic Conditions



2006 Future Build Traffic Conditions assume that the South Bronx Converted MTS would generate 363 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site

of the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the South Bronx Converted MTS are shown in Figure 19.14-8.

Figure 19.14-15 presents the average peak day temporal distribution of collection vehicles for the South Bronx Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicle trips generated by the South Bronx Converted MTS is expected to vary between approximately 2 to 20 truck trips per hour in the late evening/early morning, 30 to 120 truck trips per hour in the mid-morning/early afternoon, and 5 to 10 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (122) occurs from 11:00 a.m. to 12 noon.

Employee person trips generated as a result of the South Bronx Converted MTS are expected to be about 44 per shift (22 coming in and 22 leaving). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Most related trips would occur around shift changes when employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m. Because only the AM peak (8:00 a.m. to 9:00 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the South Bronx Converted MTS during the shift change (44) were considered part of the net increase in site-generated traffic.

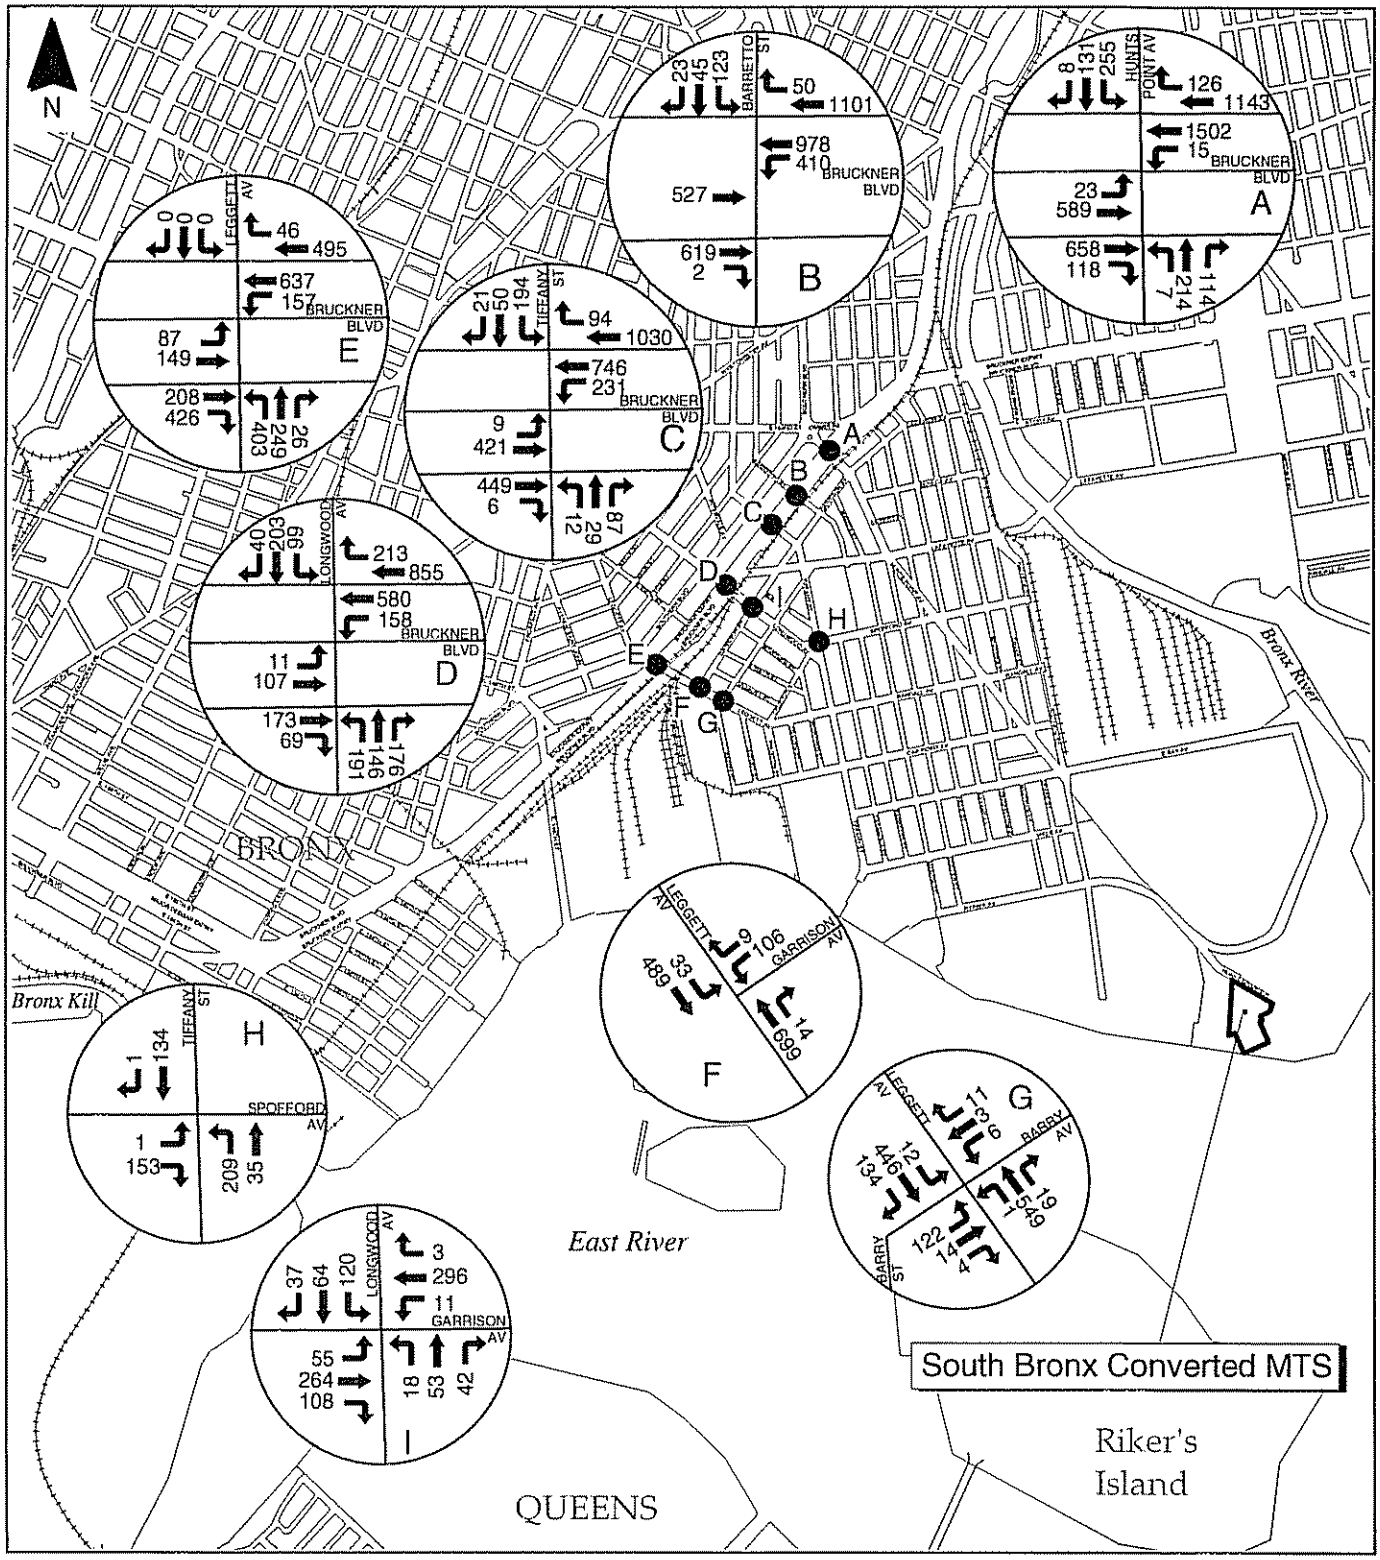


Figure 19.14-15
Truck Trips per Hour
South Bronx Converted MTS

Figures 19.14-16, 19.14-17, 19.14-18, 19.14-19, 19.14-20 and 19.14-21 provide the 2006 Future Build Condition traffic volumes, which are a combination of Future No-Build and South Bronx Converted MTS traffic volumes at the study intersections. These traffic volumes were derived using a two-stage process. First, the truck trips generated by existing interim export program were subtracted from the truck trips expected to be generated by the South Bronx Converted MTS. These net trips were added to the Future No-Build traffic volumes along the paths specified in Figure 19.14-8.

Figures 19.14-22, 19.14-23, 19.14-24, 19.14-25, 19.14-26 and 19.14-27 illustrate the resulting net change in traffic at each study intersection. A negative value indicates that the volume of existing DSNY-related collection vehicle trips to the interim export facilities removed from a movement would be greater than the volume of truck traffic added to the movement by the operation of the South Bronx Converted MTS. The highest net increase in truck trips on Bruckner Boulevard would occur at the southbound left turn at Longwood Avenue. An additional 33 truck trips are projected for this movement during the Facility peak hour. During the AM peak hour, the highest net increase in truck trips along Bruckner Boulevard would occur on this movement as well, resulting in an additional 28 truck trips. Within the Hunts Point peninsula, the highest overall increase in truck traffic would occur at the analysis intersections closest to the South Bronx Converted MTS, such as Halleck Street and Ryawa Avenue, through which an additional 122 site-generated truck and auto trips are projected during the Facility peak hour. At the intersection of Leggett Avenue with Tiffany Street, an increase of 106 site-generated trips is projected during the Facility peak.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 75% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 63% of weekday traffic volumes. Table 19.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the South Bronx Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Weekday and Weekend Traffic
South Bronx Converted MTS

DSNY and Other Agency Collection Vehicle Traffic		Background Traffic NB and SB on Bruckner Boulevard [1]	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday Average Vehicles/Day	Weekend Average Vehicles/Day
363	271	20,464	12,841

Note:
(1) NB and SB traffic data collected from ATR counts taken on Bruckner Boulevard between Tiffany Street and Barretto Street from September 17 to 22, 2003.

Table 19.14-4 provides the v/c ratios, delay and LOS for each signalized analysis intersection under the Future No-Build with Bronx Converted MTS traffic levels. Overall 2006 Future Build intersection traffic operations, expressed in terms of delay, would deteriorate slightly for certain intersections, but LOS would change only at the intersections of Bruckner Boulevard at Barretto Street (LOS C to LOS D) and at Bruckner Boulevard at Leggett Avenue (LOS D to LOS E) during the AM peak hour. The unsignalized intersection at Longwood Avenue and Garrison Avenue would also deteriorate (LOS C to LOS D) during both the AM and Facility peak hours. Significant traffic impacts, as defined by the 2001 CEQR Technical Manual and listed in Section 3.16, were identified for specific lane groups at the signalized intersections of Barretto Street/Bruckner Boulevard, Leggett Avenue/Bruckner Boulevard, Longwood Avenue/Garrison Avenue, and Ryawa Avenue/Halleck Street. These impacts and suggested mitigation are discussed below.

ML = mainline
NB = northbound
SB = southbound
SR = service road
WB = westbound
LT = left through movement
L= left movement
TR = through right movement
R = right movement
T = through movement
LR = left right movement

19.14.4.2 Impacts and Mitigation

Table 19.14-5 provides a comparison of v/c ratio, delay and LOS for the Future No-Build, Future Build before mitigation, and Future Build after mitigation scenarios at each intersection where impacts were identified. The following describes proposed mitigation and projected results with mitigation.

- During the AM peak hour, an impact was identified on the northbound approach at the intersection of Bruckner Boulevard at Barretto Street on the service road. LOS D deteriorated to LOS E with an increase in delay from 54.7 seconds to 61.4 seconds. The existing signal operates as a three-phase signal. The mitigation is as follows:
- Add one second of green time to the eastbound/westbound phase;
- Reduce the green time of the southbound exclusive left turn phase from 35 to 30 seconds; and
- Increase the green time of the northbound/southbound phase from 39 to 43 seconds.
- These changes would improve the approach of the northbound service road to LOS D with a delay of 46.5 seconds. There would be no impacts induced for either the eastbound/westbound lane group or the southbound exclusive left turn lane group. These changes would also continue to provide adequate clearance time for pedestrian crossings.
- During the AM peak hour, impacts were identified on the westbound approach at the mainline road intersection of Bruckner Boulevard at Leggett Avenue. At LOS E, delay would increase from 56.1 seconds to 61.1 seconds for the westbound left turn lane group, and from 75.9 seconds to 102.2 seconds for the westbound shared left and through lane group. On the service road, during the AM peak period, delay would increase from 64.1 seconds to 74.8 seconds for the westbound shared through and right turn lane group at LOS E.

OVERALL		22.2	C		29.0	D		12.3	B

Notes:

[1] HCM output is included in technical backup submitted to the NYCDOT.

DFL = defacto left
EB = eastbound
LTR = left, through and right movements
ML = mainline
NB = northbound
SB = southbound
SR = service road
WB = westbound
LT = left through movement
L= left movement
TR = through right movement
R = right movement
T = through movement

Currently, the existing signal operates as a three-phase signal. The mitigation is as follows:

- Provide a two-second increment in green time to the eastbound/westbound lane group by taking one second from both the southbound exclusive left turn phase and the northbound/southbound phase.

This change would decrease the delay of the westbound left turn lane group on the mainline from 61.1 seconds to 54.1 seconds and increase the LOS (LOS D to LOS C). The westbound shared left and through lane group delay would decrease from 102.2 seconds (at LOS F) to 75.5 seconds (at LOS E). Additional improvement would also be achieved for the westbound approach lane group on the service road. The westbound shared through and right turn lane group delay would reduce at LOS E from 74.8 seconds to 61.6 seconds. There would be no impacts induced for the northbound/southbound lane groups.

During the AM and Facility peak hour periods, impacts were identified on the eastbound left turn lane group at the intersection of Ryawa Avenue at Halleck Street. However, the traffic volume for this movement is very low (less than 25 PCEs during any peak hour in the Build Condition) and therefore does not qualify as an impact for unsignalized intersections under CEQR guidelines.

During the Facility peak, at the four-way STOP controlled intersection of Longwood Avenue and Garrison Avenue, impacts were identified at the eastbound shared through and right turn lane group. The first mitigation measure tested was to modify the intersection operations to two-way STOP control with Garrison Avenue as the minor street. This measure resulted in LOS F on Garrison Avenue. Therefore, the mitigation proposed is to signalize the intersection. A preliminary warrant analysis indicates that Traffic Signal Warrant 10, Peak Hour Delay would be satisfied. (There are 11 warrants that have been developed by the FHWA that are contained in the Manual on Uniform Traffic Control Devices. Traffic Signal Warrants are defined as minimum conditions under which signal installations may be justified. In this case, a traffic signal is warranted if for one hour of an average day the minor street traffic suffers undue delay in entering or crossing the major street.)

19.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

19.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

19.15 Air Quality

19.15.1 Definition of Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the South Bronx Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersections listed in Section 19.15.4.2.

19.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest the study area are shown in Table 19.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 19.15-1
Representative Ambient Air Quality Data
South Bronx Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO	200th Street and Southern Boulevard	8-Hour	2,519 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	4,695 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	200th Street and Southern Boulevard	Annual	51 $\mu g/m^3$	100 $\mu g/m^3$
PM_{10}	East 156th Street between Dawson and Kelly Streets	Annual	22 $\mu g/m^3$	50 $\mu g/m^3$
		24-Hour	60 $\mu g/m^3$	150 $\mu g/m^3$
SO_2	200th Street and Southern Boulevard	3-Hour	207 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	134 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	24 $\mu g/m^3$	80 $\mu g/m^3$

Note:
Source: USEPA Airdata, 2003 – Monitor Values Report (http://oaspub.epa.gov/airdata)

19.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the 2006 analysis year. Therefore, no changes to air quality levels are anticipated, and Future No-Build Conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

19.15.4 Potential Impacts with the South Bronx Converted MTS

19.15.4.1 On-Site Analysis

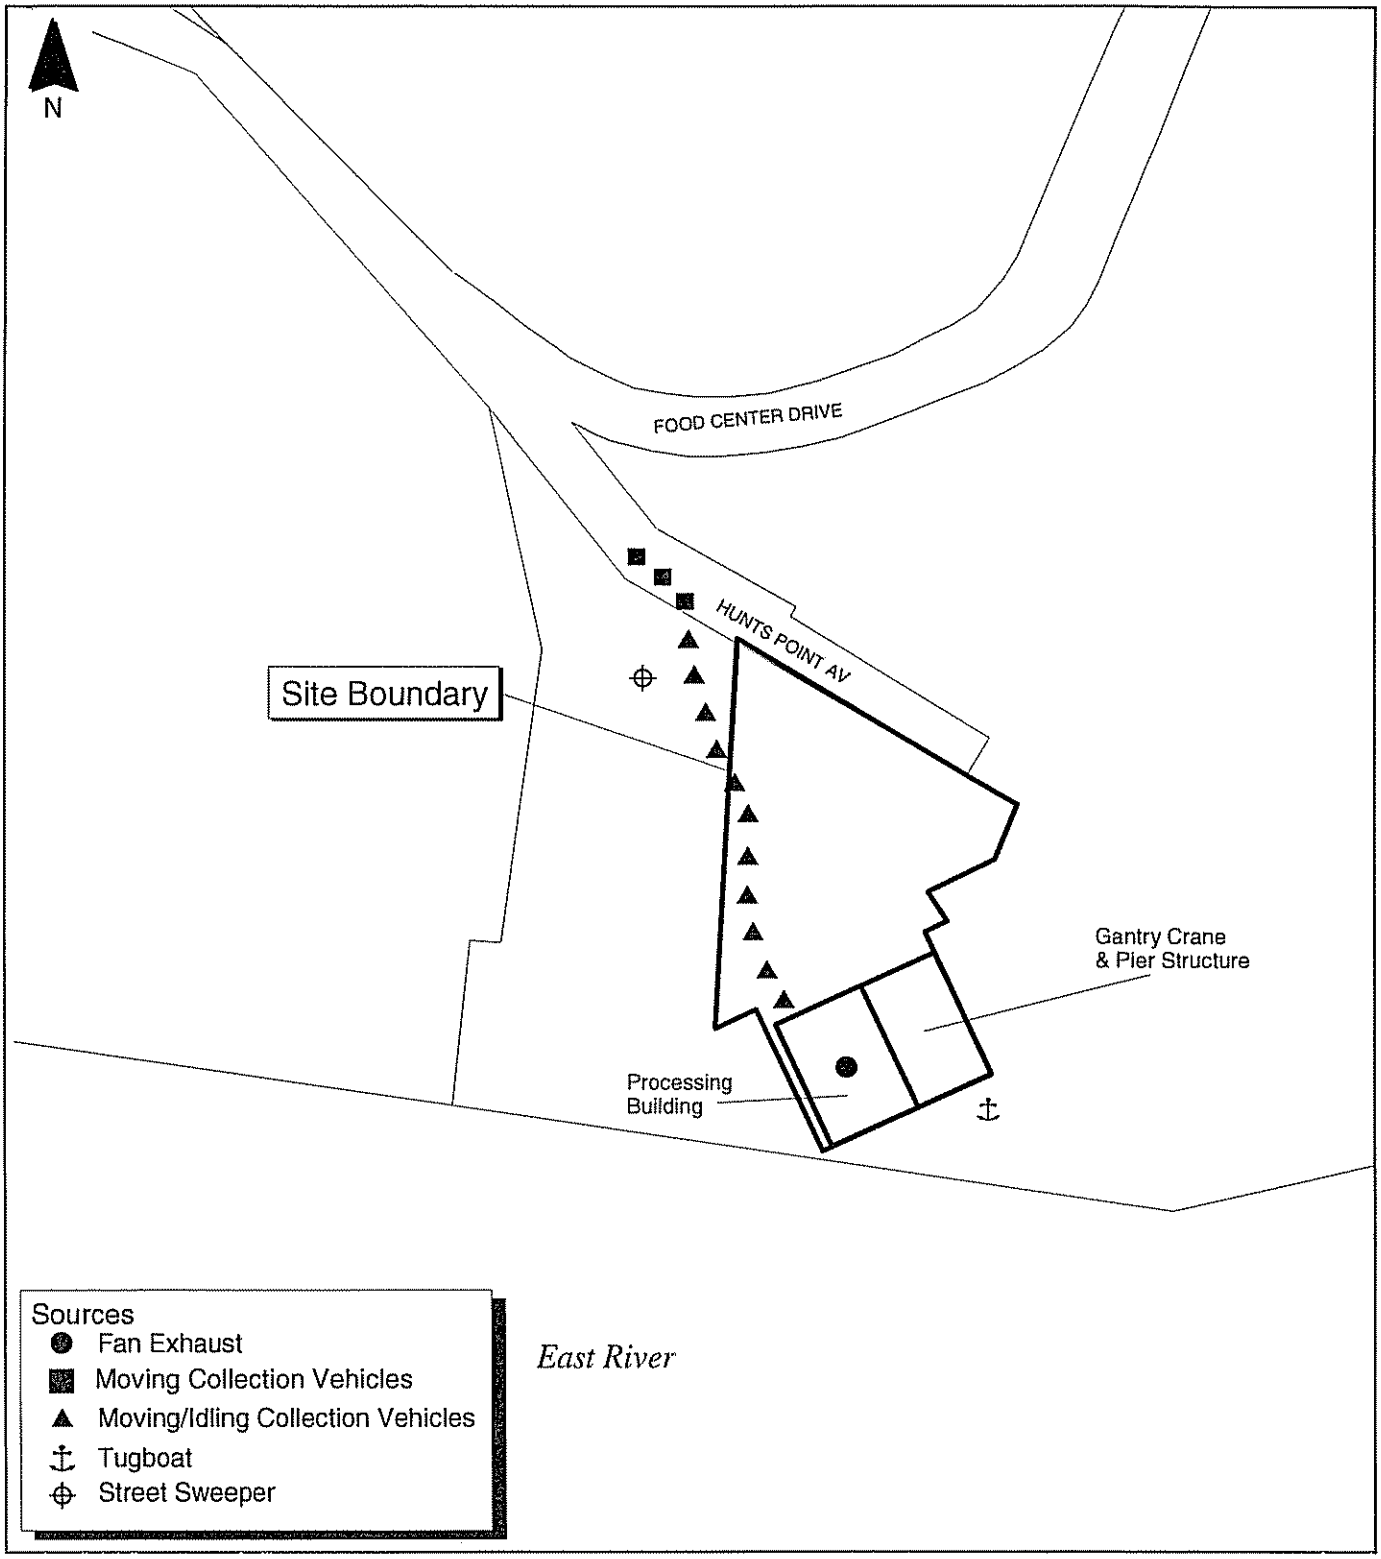
19.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that is anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 19.15-2. Figure 19.15-1 shows the locations of these sources within the site.

19.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 19.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from South Bronx Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 19.15-3, are below the STVs. The South Bronx Converted MTS would not, therefore, significantly impact air quality in the area.

Table 19.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
South Bronx Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	46	18
Space Heaters	10	10
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3]	17 in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (17), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

Site delineations are approximate.

	24-hour[6]	5	136	141	365	NA
	Annual	0.4	37	37	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~memorandum dated February 18, 2005.

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

19.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 19.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the South Bronx Converted MTS are not considered to be significant.

19.15.4.2 Off-Site Analysis

19.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines that are outlined in Section 3.17. Following these guidelines, the following detailed mobile source analyses were conducted for the applicable (i.e., worst-case) time periods:

- An analysis of the intersections of Tiffany Street and Randall Avenue, Halleck Street/East Bay Avenue and Hunts Point Avenue, and Bruckner Boulevard and Leggett Avenue to determine whether South Bronx Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 8-hour CO de minimus value or a violation of the 8-hour NAAQS;
- An analysis of the intersections of Bruckner Boulevard and Leggett Avenue, Bruckner Boulevard and Longwood Avenue, Tiffany Street and Randall Avenue, Halleck Street/East Bay Avenue and Hunts Point Avenue, and Halleck Street and Ryawa Avenue to determine whether South Bronx Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 24-hour and annual $PM_{2.5}$ STVs; and
- An analysis of the intersections of Bruckner Boulevard and Leggett Avenue, Bruckner Boulevard and Longwood Avenue, Tiffany Street and Randall Avenue, Halleck Street/East Bay Avenue and Hunts Point Avenue, and Halleck Street and Ryawa Avenue to determine whether South Bronx Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 19.15-2.

Notes to Table 19.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGCs) established by NYSDEC.

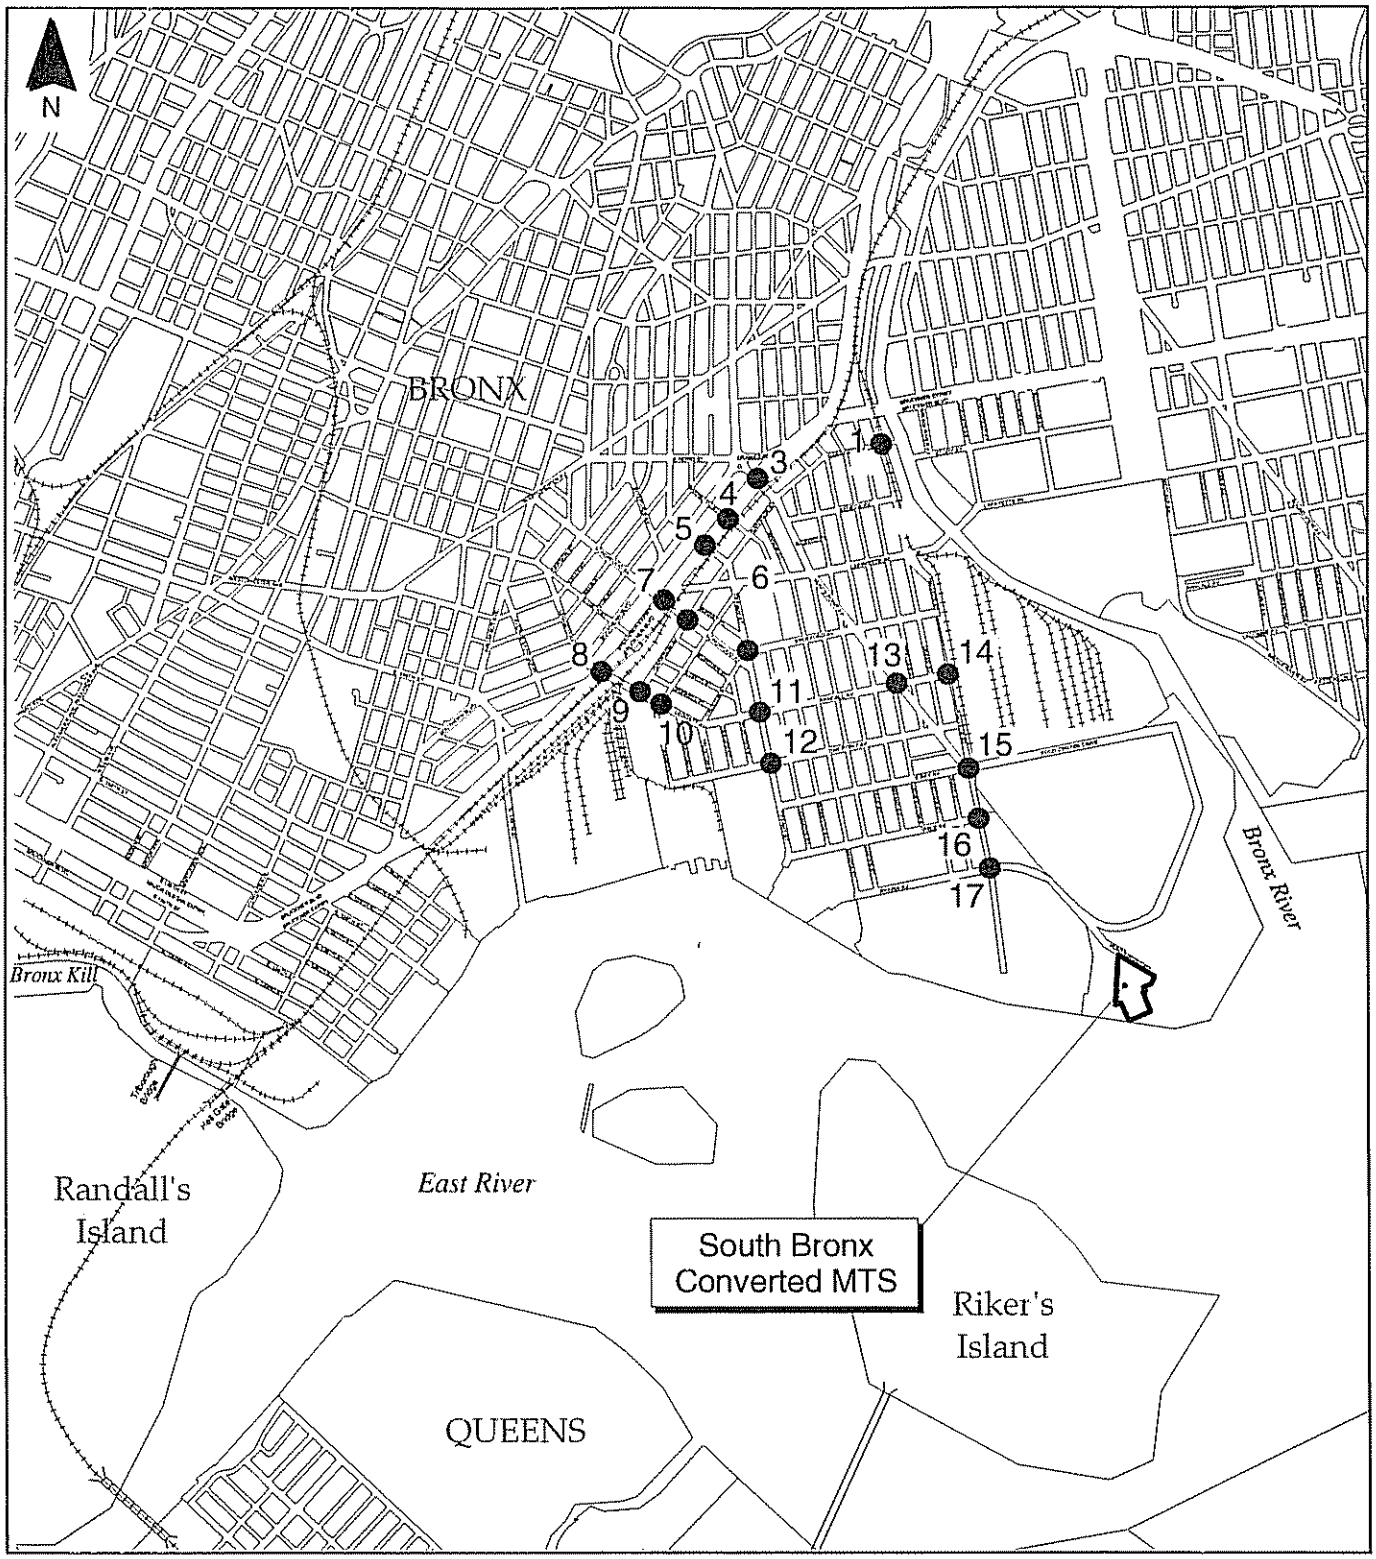
(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGCs) established by NYSDEC

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

19.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 19.15-5, are all within (less than) the applicable state and federal ambient air quality standards, STVs (for $PM_{2.5}$) and/or de minimus impact values (for CO). The off-site operations of the South Bronx Converted MTS are not, therefore, considered to be significant. (A Tier II analysis of the intersections at Tiffany Street and Randall Avenue, Halleck Street/East Bay Avenue and Hunts Point Avenue, and Halleck Street and Ryawa Avenue was necessary to determine the off-site annual impacts for $PM_{2.5}$.)

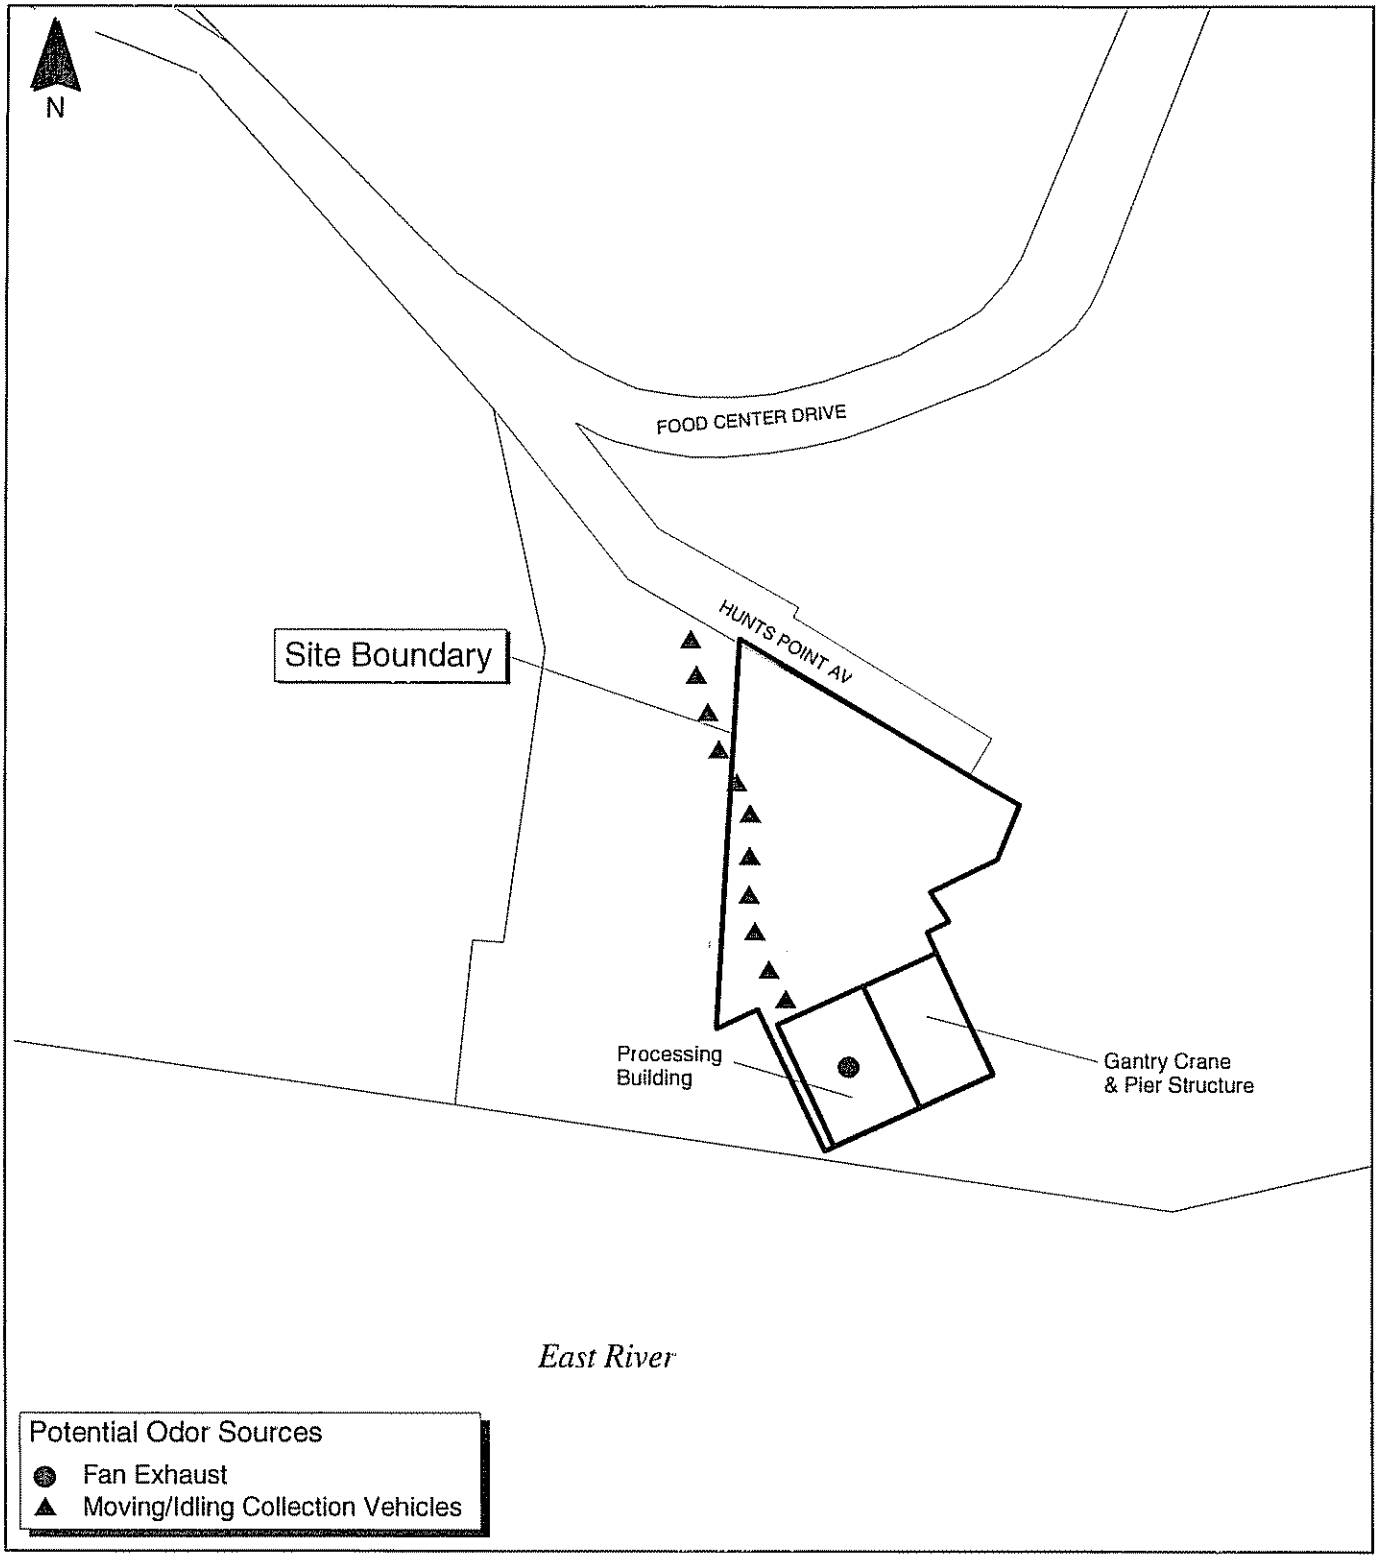
19.16 Odor

19.16.1 Existing Conditions

The existing MTS is currently not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations of sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is the Vernon C. Bain Center (prison barge), which is located approximately 645 feet from the site boundary.

19.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the South Bronx Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



19.16.3 Potential Impacts with the South Bronx Converted MTS

19.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the South Bronx Converted MTS are provided in Table 19.16-1. Figure 19.16-1 shows the locations of these sources within the site.

Table 19.16-1
Odor Sources Included in Odor Analysis
South Bronx Converted MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1

Figure 19.16-1 Potential Odor Sources

South Bronx Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the South Bronx Converted MTS.

19.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 19.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the South Bronx Converted MTS at any nearby sensitive receptor is less than 1, so odors from the South Bronx Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 19.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
South Bronx Converted MTS

Parameter	Resulting Odor Unit [1]
Estimated Detectable Concentration	5.0
Highest Result	0.25
Type of Receptor	Over-Water Receptor
Receptor	36 feet from the facility
Closest Sensitive Receptor Result [2]	0.03
Type of Receptor	Prison Barge
Distance to Receptor	645 Feet

Notes:
[1] Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.
[2] Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.

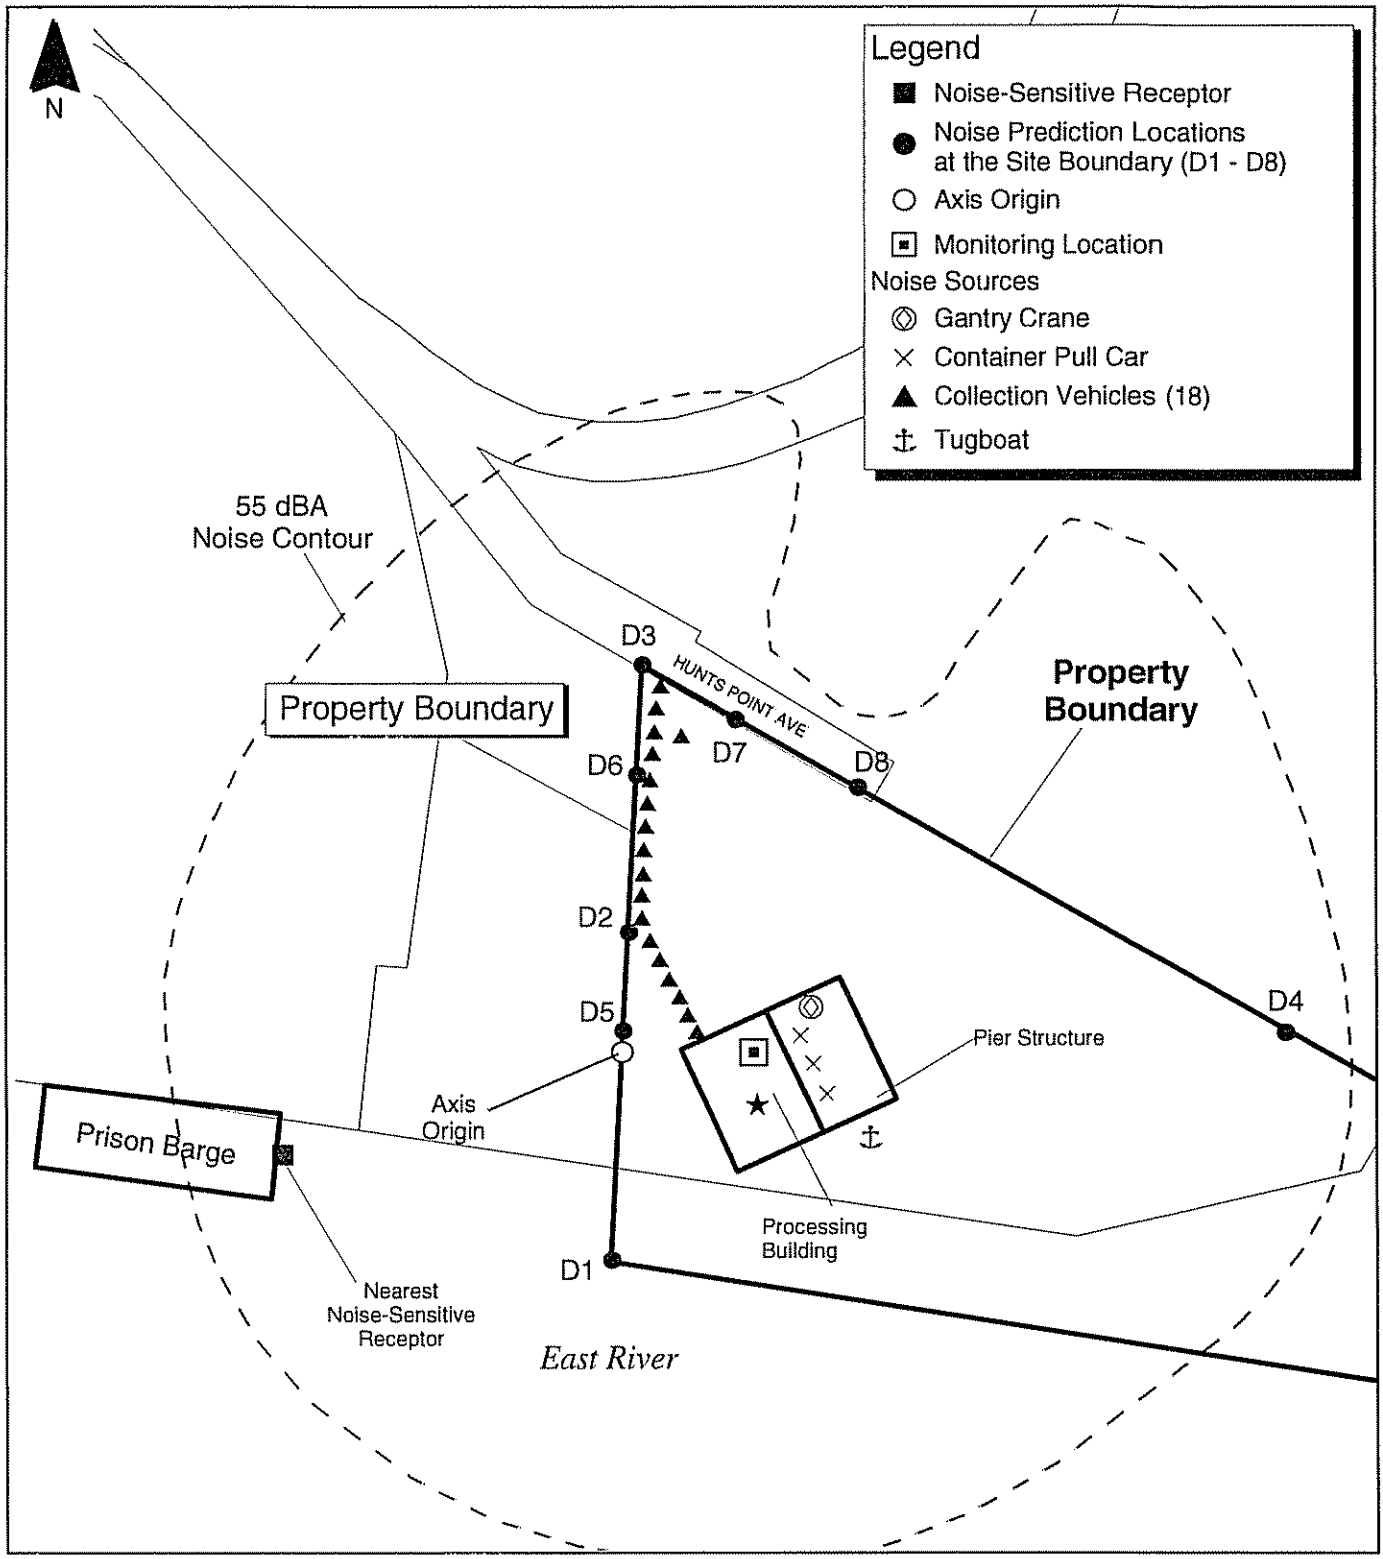
19.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from South Bronx Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

19.17.1 Existing Conditions

19.17.1.1 Introduction

Figure 19.17-1 shows the location of the South Bronx Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is the Vernon C. Bain Center (prison barge), which is moored off the East River shore, approximately 197 meters (645 feet) west of the site boundary.



19.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line nearest the prison barge. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[13] and the statistical metrics of L_{10}, L_{50} and L_{90}.[14] Table 19.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 2:00 a.m. and 3:00 a.m. and had an $L_{eq(1)}$ of 53.5 dBA on May 15, 2003. Activities and events that contribute to the on-site noise levels are as follows:

- Traffic on Hunts Point Avenue; and
- Other noise sources associated with activities in the surrounding industrial areas.

---

[13] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[14] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

Site delineations are approximate

11:00 p.m.-12:00 a.m.	55.6	52.5	53.5	55.1	50.9	72.8

Note:
(1) The 24-hour background noise levels were measured at site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

19.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if noise monitoring would be required along the South Bronx Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required. Therefore, no noise monitoring data were collected for off-site noise levels.

19.17.2 Future No-Build Conditions

19.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

19.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 19.17-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime and nighttime for locations where there is a possible impact based on the first-level screening.

19.17.3 Potential Impacts with the South Bronx Converted MTS

19.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the South Bronx Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 19.17-3. Spectral noise levels used in the Performance Standards analysis are shown in Table 19.17-4. The number and types of equipment assumed for this analysis were based on the South Bronx Converted MTS's peak design capacity. Shown earlier, Figure 19.17-1 indicates the South Bronx Converted MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 19.17-2
Off-Site Noise Traffic Volume
South Bronx Converted MTS

Location	Hour	Existing Traffic Volume [1] (Vehicles / Hour)	Future No-Build Traffic Volume [2] (Vehicles / Hour)
Randall Avenue between Manida Street and Coster Avenue	11:00 a.m.	545	553
Tiffany Street between Spofford and Randall Avenues	1:00 a.m.	135	137
Tiffany Street between Spofford and Randall Avenues	11:00 a.m.	564	573
Bruckner Boulevard between Longwood Avenue and Tiffany Street	11:00 a.m.	1,124	1,141
Longwood Avenue between Garrison and Barry Streets	1:00 a.m.	91	92
Longwood Avenue between Garrison and Barry Streets	10:00 a.m.	438	445

Notes:
(1) Existing Traffic Volumes are based on ATR data.
(2) Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

Notes:

(1) Instantaneous maximum number of pieces of equipment on site at any given time.

(2) Trucks and tugboats are not included in the Performance Standard analysis because they are transportation facilities.

(3) Noise level representative of each piece of equipment.

(4) Noise level will be specified for the gantry crane in DSNY's plans and specification for construction of the Converted MTS's.

Hz = Hertz
K = Thousand

19.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the South Bronx Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 214 meters (702 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is 197 meters (645 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. Since the background noise level at the receptor is 54.0 dBA, which is less than 55 dBA, the contour of the predicted facility L_{eq} equivalent to the background noise level is also shown in Figure 19.17-1. The results of the screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (see Figure 19.17-1). Therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 19.17-1 above. Table 19.17-5 below identifies the existing background noise level during the quietest hour. The table shows the distance from the South Bronx Converted MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, South Bronx Converted MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptor. This difference represents the predicted incremental change in noise level from the South Bronx Converted MTS. Because this incremental change is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, since the daytime noise level is 62 dBA or greater, there is a predicted impact that would be caused by the South Bronx Converted MTS on-site operations.

Table 19.17-5
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
South Bronx Converted MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
Prison Barge	197 / 645	~~54.0~~53.5	~~62.2~~62.0	~~62.8~~62.6	~~8.8~~9.1	Yes

Notes:
(1) Twenty-minute noise level readings measured at the nearest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.
(2) Existing noise levels measured on May 7, 2003 at 3:00 p.m.
(3) Predicted noise level calculations at the noise-sensitive receptor include on-site and off-site shielding from structures.
(4) According to CEQR, if the existing noise level is less than 60 dBA, an increase over 5 dBA during the daytime is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the South Bronx Converted MTS with the quietest background noise levels that occur during facility operation. The quietest hour of background noise levels occurred during the daytime hours for the noise-sensitive receptor; therefore, only daytime impact criteria are discussed in this analysis for this noise-sensitive receptor.

19.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points representative of the South Bronx Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (see Table 19.17-6). Based on this analysis, no exceedances to the Performance Standards are predicted.

Table 19.17-6
Zoning Code Analysis
Predicted Spectral Noise Levels (L_{max}) at the Property Boundary
South Bronx Converted MTS

Manufacturing District Regulation (M3)								
Frequency (Hz)	**63**	**125**	**250**	**500**	**1K**	**2K**	**4K**	**8K**

Notes:

Hz = Hertz
Lp = Sound pressure level
dB = Decibel
D1 through D8 are the points representative of the South Bronx Converted MTS boundary that are used in all noise analyses
K = Thousand

19.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the South Bronx Converted MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 19.17-7. Based on this analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 19.17-7
Current Noise Code Analysis
South Bronx Converted MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	63.8
D2	**76.32**
D3	**71.65**
D4	~~61.5~~60.4
D5	**70.8**
D6	**76.7**
D7	68.8
D8	65.3

Note:
D1 through D8 are the points representative of the South Bronx Converted MTS boundary that are used in all noise analyses.

Bold= Exceedence

19.17.3.5 Mitigation Measures

Mitigation measures available were limited to those that affect the source, the propagation path or the receiver. The typical mitigation measure for the path of noise between source and receiver is a noise wall. Noise walls can be designed to provide noise attenuation for noise-sensitive areas located relatively close to the wall. Noise attenuation provided by the wall decreases as distance from the wall increases. Receiver treatments may include the construction of noise walls at residential property lines or the installation of replacement windows and air conditioning. The latter two mitigation measures are suggested in the 2001 CEQR Technical Manual. Typical mitigation measures at the source include: (1) changes in operations schedules to reduce noise emissions; (2) reduction in DSNY collection vehicles; (3) using noise mufflers for the exhaust pipes of material handling equipment (e.g., side loaders, yard tractors, etc.) or other source noise reduction methods; and (4) maintaining the equipment through regularly scheduled maintenance and repairs.

The data presented in this section is for the analysis to date. If the South Bronx Converted MTS is included in the New SWMP, a supplemental analysis will be performed.

19.17.3.6 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the South Bronx Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime and nighttime are provided in Table 19.17-8.

Because the screening results presented above showed that the PCEs would not double on a roadway due to DSNY and other agency collection vehicles coming to or going from the South Bronx Converted MTS, a detailed off-site noise analysis was not required.

19.17.3.7 Combined On-Site and Off-Site Noise Levels

An on-site noise analysis was performed for the South Bronx Converted MTS. As a result of the off-site screening analysis, which is described above in 19.17.3.5, no off-site noise analysis was required. Since an off-site analysis was not required, a combined noise analysis was not performed.

Table 19.17-8
Off-Site Noise Screening Results
South Bronx Converted MTS

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
Randall Avenue between Manida Street and Coster Avenue	11:00 a.m.	5,106	54	7	2,538	7,644	No
Tiffany Street between Spofford and Randall Avenues	1:00 a.m.	2,093	9	0	423	2,516	No
Tiffany Street between Spofford and Randall Avenues	11:00 a.m.	8,530	54	4	2,538	11,068	No
Bruckner Boulevard between Longwood Avenue and Tiffany Street	11:00 a.m.	8,373	61	0	2,867	11,240	No
Longwood Avenue between Garrison and Barry Streets	1:00 a.m.	934	9	0	423	1,357	No
Longwood Avenue between Garrison and Barry Streets	10:00 a.m.	4,383	44	0	2,068	6,451	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include South Bronx Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

19.18 Commercial Waste to the South Bronx Converted MTS

19.18.1 Existing Conditions

No commercial waste is delivered to the South Bronx MTS site under Existing Conditions. Commercial waste generated in the Bronx is delivered to privately owned and operated transfer stations in the City, or taken directly out of the City to remote disposal locations.

19.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the South Bronx Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

19.18.3 Potential Impacts of Sending Commercial Waste to the South Bronx Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

19.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the South Bronx Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 19.15, 19.16 and 19.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

19.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the South Bronx Converted MTS were evaluated in Sections 19.14, 19.15 and 19.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 19.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 64 (inbound trip ends) per hour, which occurred during the AM peak. These 64 DSNY and other agency collection vehicles are more than the 23 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the South Bronx Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 64 DSNY and other collection agency vehicle trip ends at the South Bronx Converted MTS during the AM peak hour. Therefore, the addition of the 23 DSNY and other agency collection vehicles and commercial waste hauling vehicles at the South Bronx Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 64 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 64 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24 hour period at several analyzed intersections. Results showed there would be no unmitigatible significant adverse environmental impacts. Consequently, because the 23 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that could travel through these intersections during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed over a 24-hour period, there would be no significant adverse off-site air quality impacts.

For the intersections of Tiffany Street and Randall Avenue, Halleck Street/East Bay Avenue and Hunts Point Avenue, and Halleck Street and Ryawa Avenue, a Tier II analysis was required. The estimated actual hourly distribution over 24 hours included the estimated 23 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that could potentially be processed at the South Bronx Converted MTS, and no unmitigatible significant adverse environmental impacts were identified.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the South Bronx Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the South Bronx Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 1,611 tons (or 150 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

This page intentionally left blank.

CHAPTER 20 ENVIRONMENTAL REVIEW: GREENPOINT CONVERTED MTS

20.1 Introduction

The results of the environmental analyses of the Greenpoint Converted MTS are presented in the following sections:

20.2 Land Use, Zoning, and Public Policy
20.3 Socioeconomic Conditions
20.4 Community Facilities and Services
20.5 Open Space
20.6 Cultural Resources
20.7 Urban Design, Visual Resources, and Shadows
20.8 Neighborhood Character
20.9 Natural Resources
20.10 Hazardous Materials
20.11 Water Quality
20.12 Waterfront Revitalization Program
20.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
20.14 Traffic, Parking, Transit, and Pedestrians
20.15 Air Quality
20.16 Odor
20.17 Noise
20.18 Commercial Waste to the Greenpoint Converted MTS

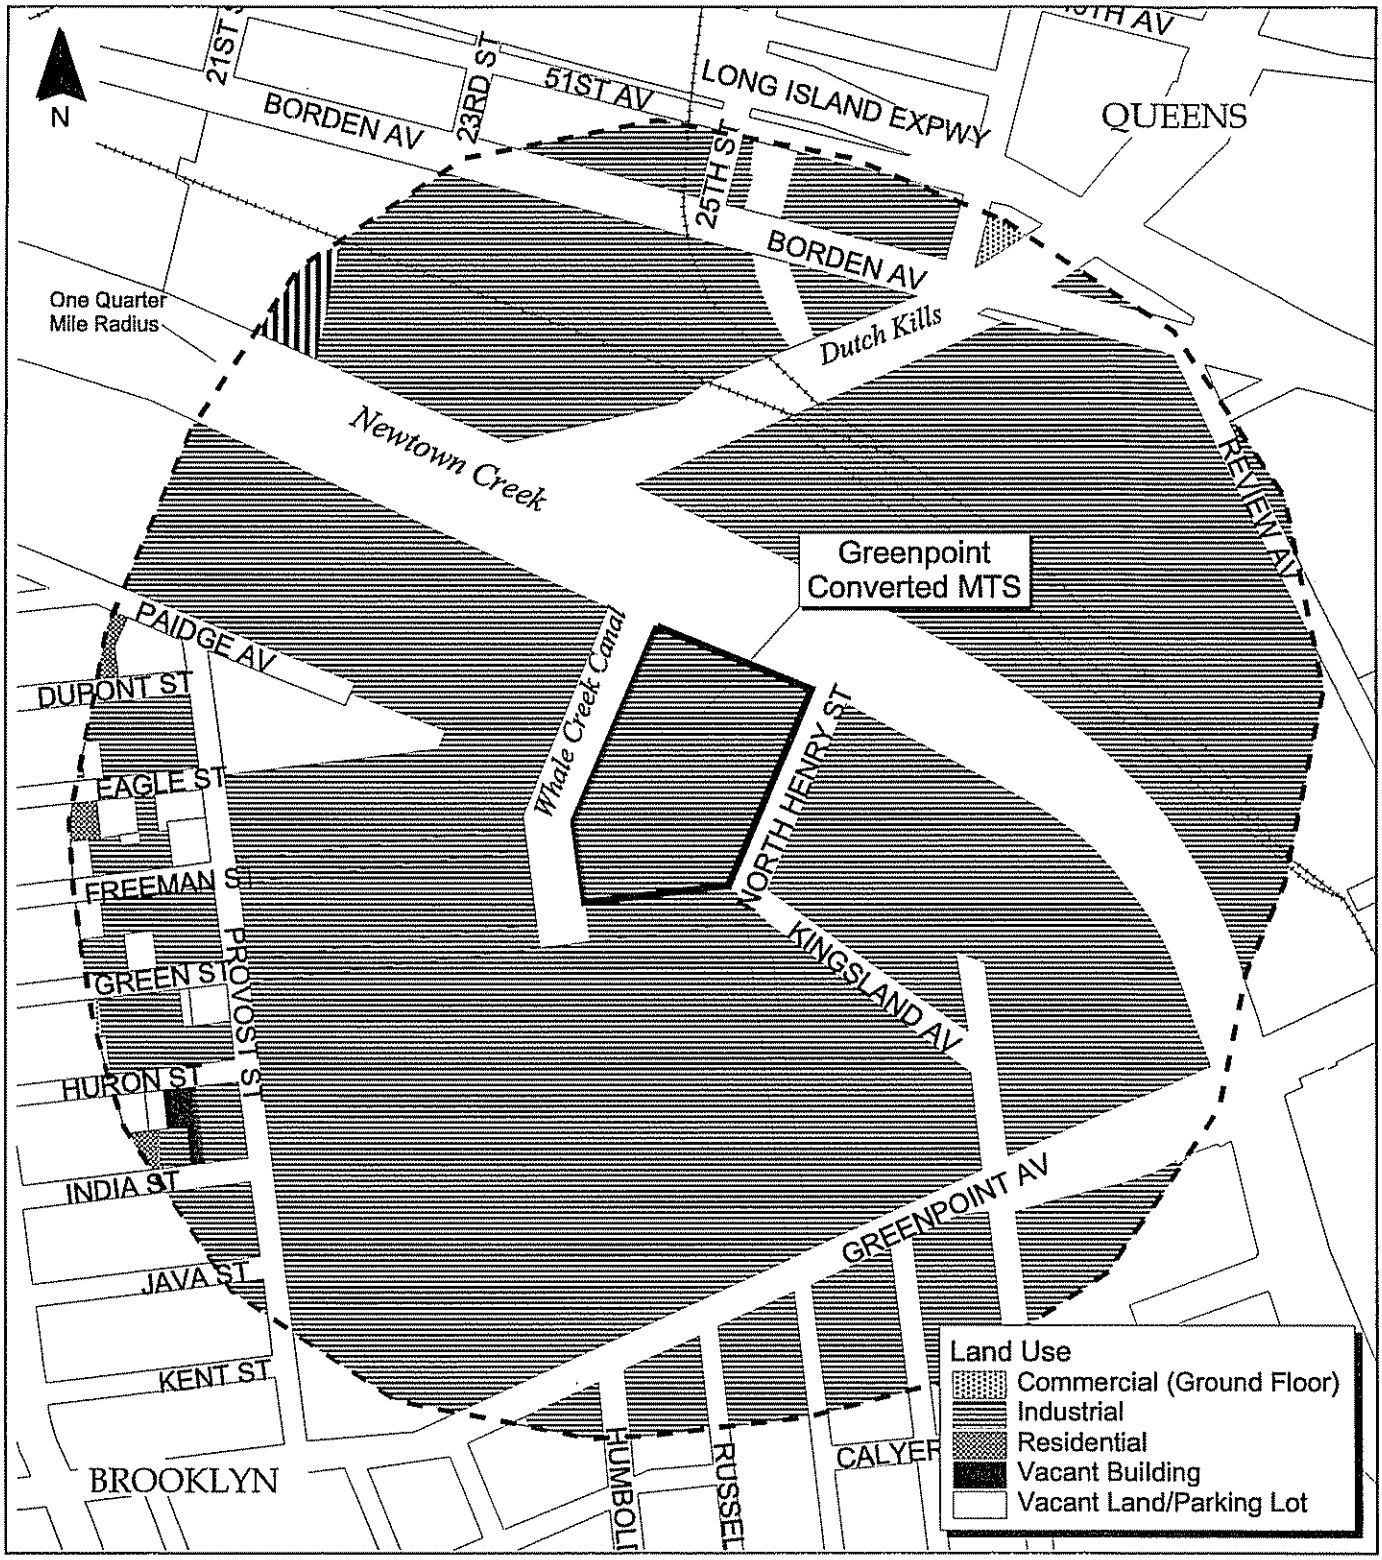
Section 2.4.2 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

20.2 Land Use, Zoning, and Public Policy

20.2.1 Existing Conditions

20.2.1.1 Definition of the Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 20.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 20.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.4.2 provides information on existing land uses and operations on the site.



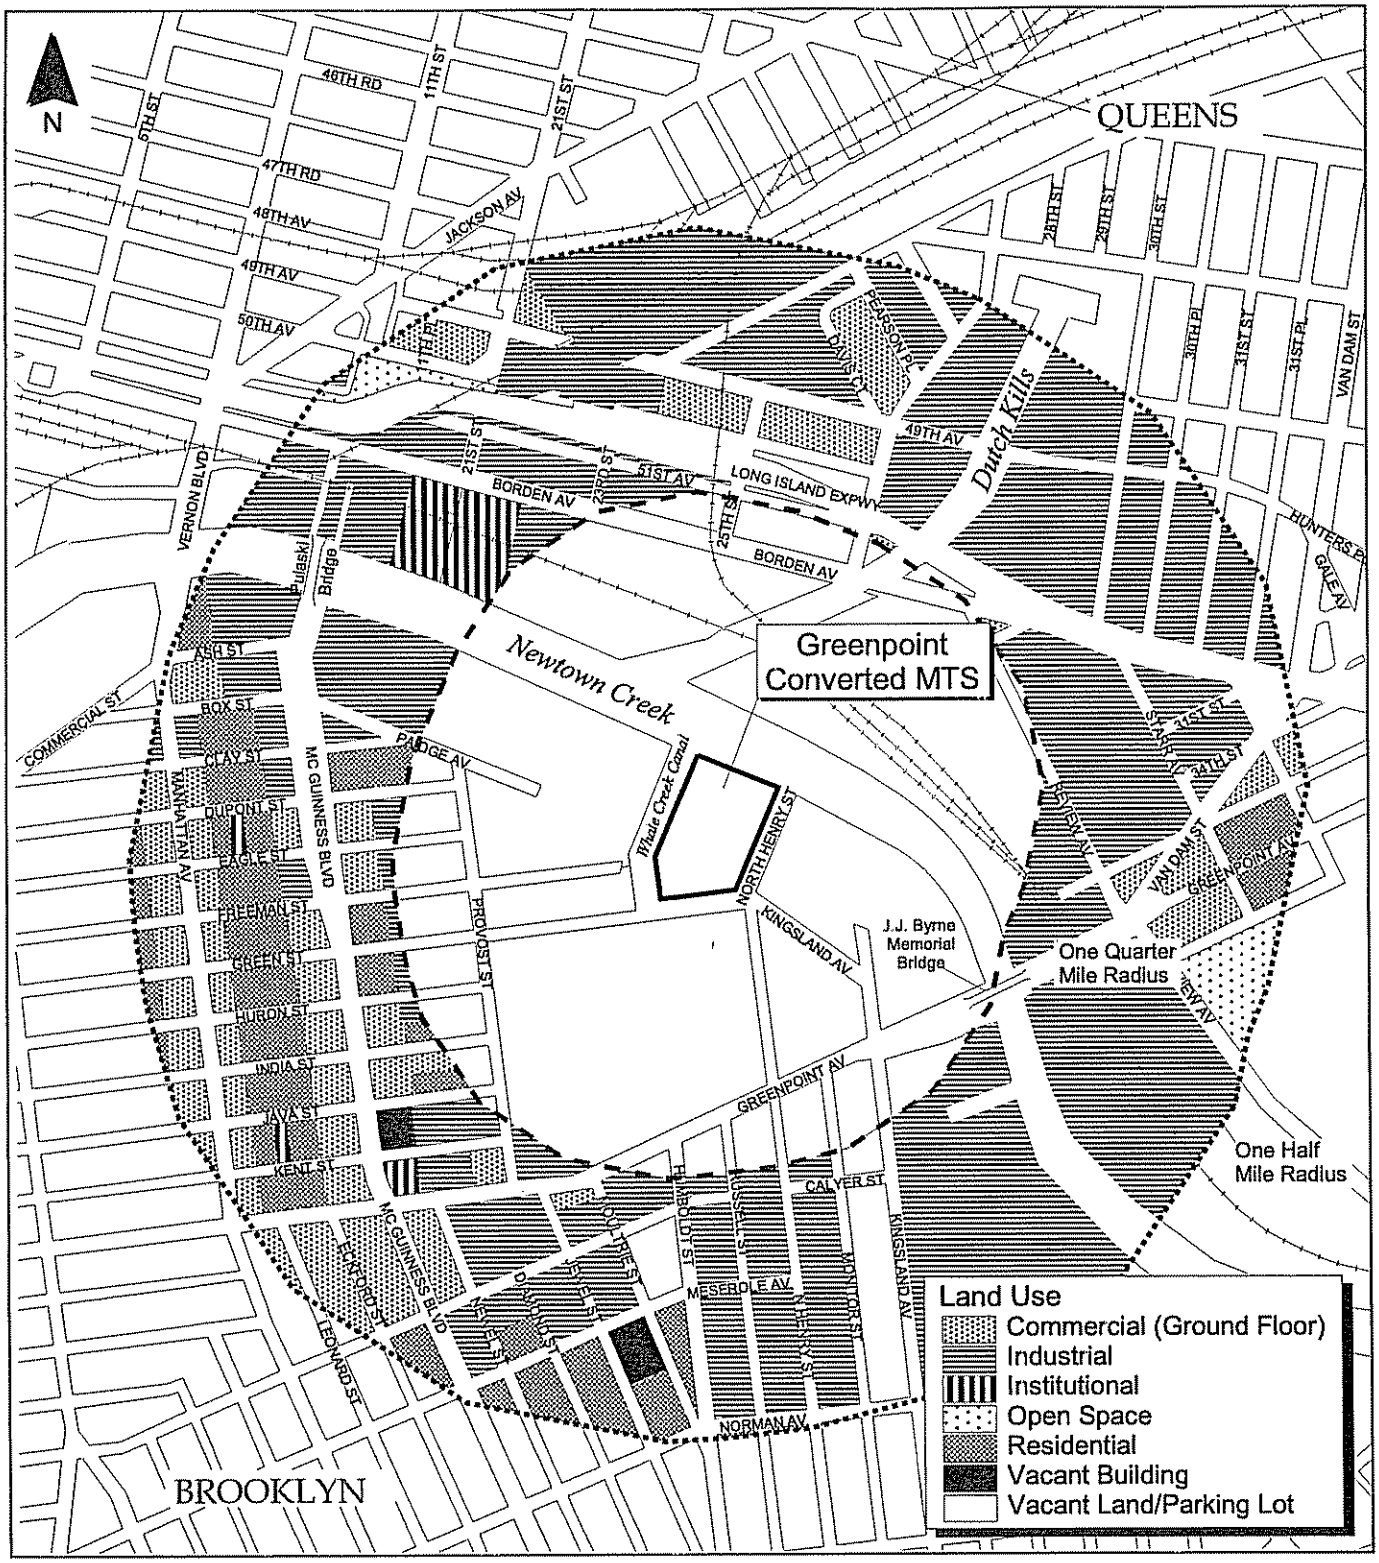
20.2.1.2 Land Use Patterns

20.2.1.2.1 General Context

The site is located on the heavily industrial Newtown Creek waterfront in Greenpoint, Brooklyn. It is surrounded by large-lot, primarily truck-dependent, heavy industrial uses on both the Queens and Brooklyn sides of the creek. These uses include various municipal facilities, petroleum (outdoor loading) facilities and warehousing.

20.2.1.2.2 Land Uses in the Primary Study Area

The primary study area is comprised almost exclusively of heavy industrial uses concentrated along Newtown Creek and dominated by the Newtown Creek WPCP. The WPCP, which occupies a large area immediately south of the site, is currently being expanded to the east and to the north (west of Whale Creek Canal), across from the site. A NYCDOT asphalt production facility and private recycling center for construction debris and fill are located east of the site on Kingsland Avenue. The Queens side of Newtown Creek is also characterized by industrial uses such as The Exhibit Company and numerous warehouses fronting on Borden and Review Avenues across from the site.



Site delineations and study area boundaries are approximate

Figure 20.2-2 Land Use in the Secondary Study Area

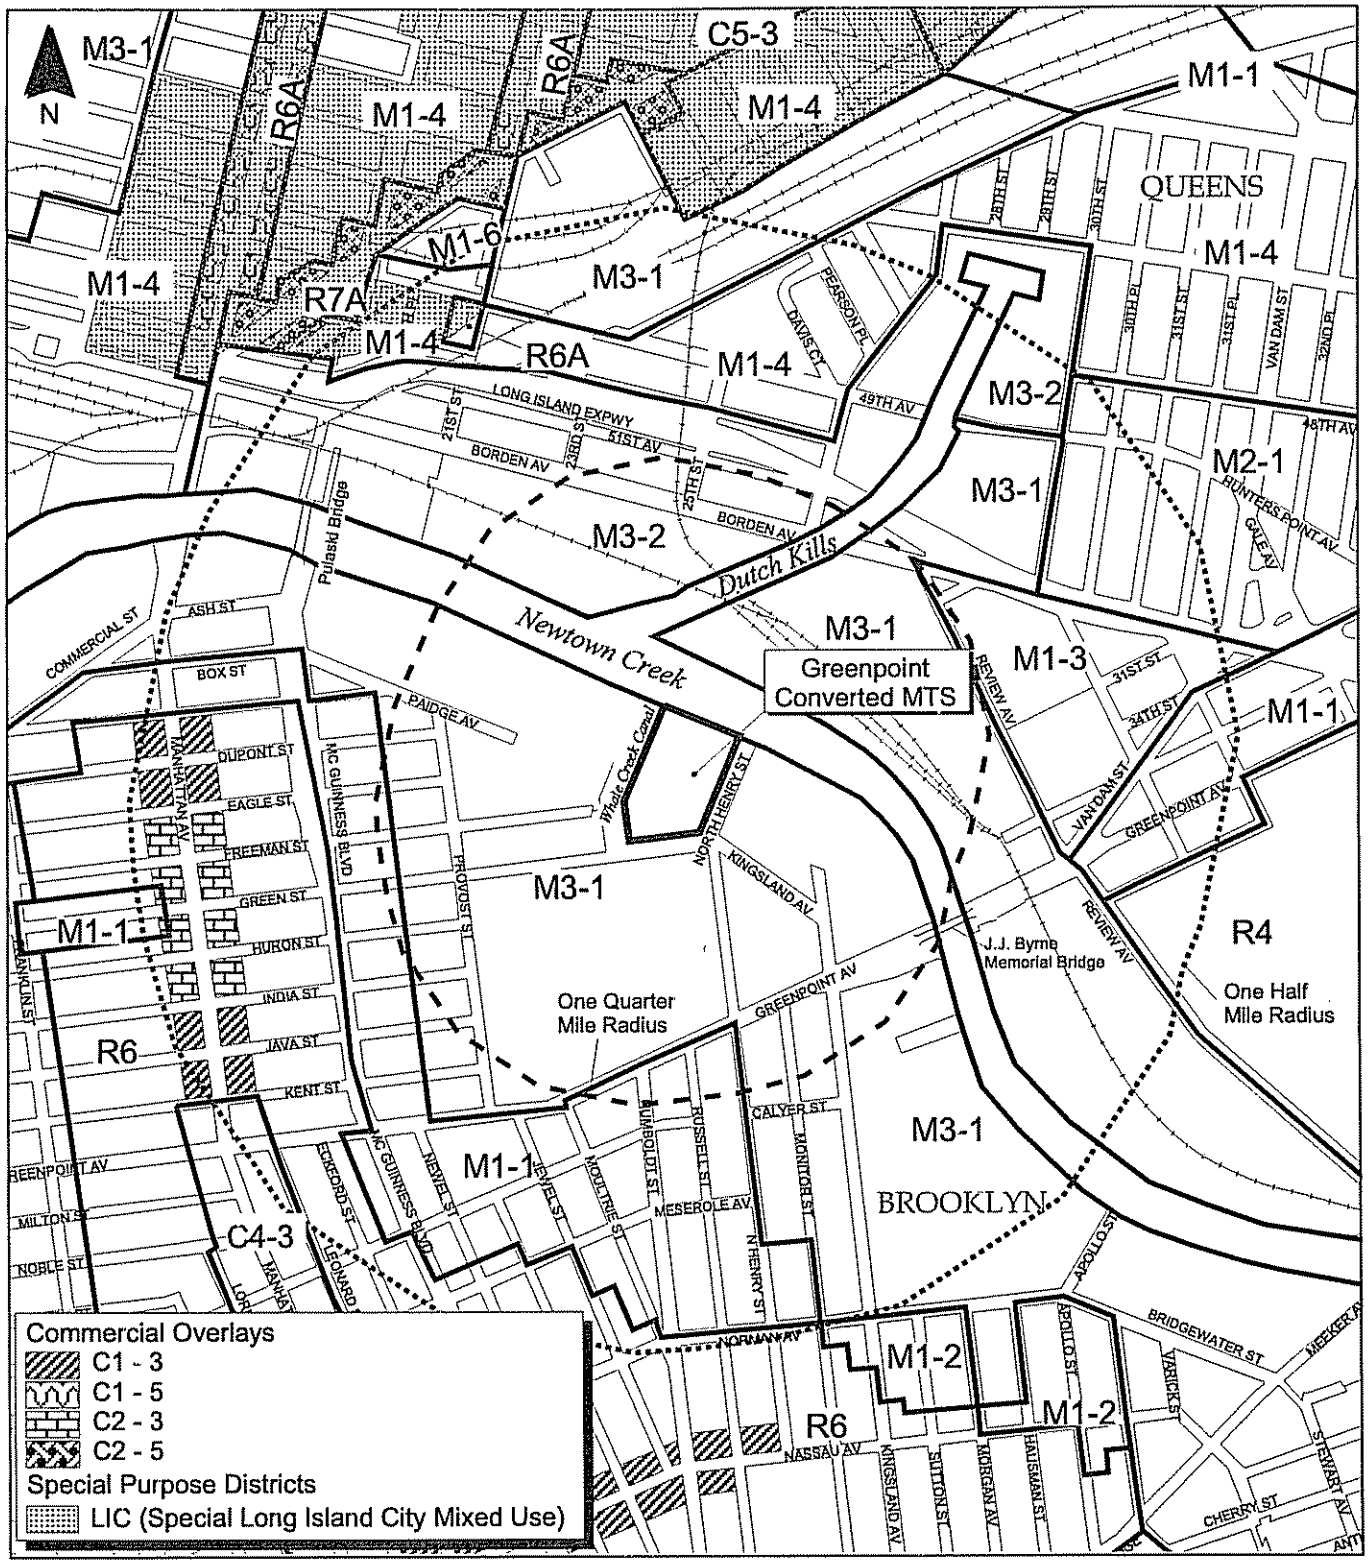
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

In addition to the uses bordering the site, the blocks south of the site along the west side of Provost Street are almost exclusively warehouses. Most of these are active, though there are some vacant warehouse buildings and vacant lots scattered throughout. Southeast of the site beyond a private recycling center and WPCP sites are Metro Fuel Oil Depot petroleum outdoor-loading facilities.

20.2.1.2.3 Land Uses in the Secondary Study Area



Within the secondary study area, heavy industrial uses are concentrated along both sides of Newtown Creek and Dutch Kills, and in about half of the study area in Brooklyn, particularly south of Greenpoint Avenue. West of the site in the secondary study area is a residential area comprised mostly of three- to four-story apartment buildings, whose ground-floor commercial uses line McGuinness Boulevard and Manhattan Avenue. In this area, an apartment building recently converted from industrial uses stands west of Provost Street on Dupont Street. South of Meserole Avenue in the southern portion of the study area, residential uses are interspersed with active warehouses.

The portion of the secondary study area that lies north of the site in Queens is comprised almost entirely of industrial uses and warehouses with the exceptions of the Salvation Army Veterans Residence northwest of the site at 21st Street and Borden Avenue, and some commercial uses north of the site along 49th Avenue and east of the site along Greenpoint Avenue.

20.2.1.3 Current Zoning On and Near the Site

20.2.1.3.1 Zoning Within the Primary Study Area

The site and the entire primary study area lie within manufacturing zoning districts. In Brooklyn, an M3-1 district extends along the southern side of Newtown Creek. In Queens, an M3-2 zoning district defines the area west of the Dutch Kills and an M3-1 defines the area to its east. (See Figure 20.2-3 and Table 3.4-1: Zoning District Characteristics.)

Site delineations and study area boundaries are approximate.

Figure 20.2-3 Zoning

Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

20.2.1.3.2 Zoning Within the Secondary Study Area

The secondary study area in Brooklyn is zoned M3-1 along the creek, and M1-1 inland, serving as a buffer between the heavier industrial district and residentially zoned (R6) district to the west and south. Nearly all of the secondary study area in Queens is zoned for manufacturing (M1-1, M1-3, M1-4, M2-1, M3-1 and M3-2), except for part of a block in the northwestern section, which is zoned R6A. The Long Island City Mixed Use District (overlay zone), intended to spur new mixed-use development, includes the R6A block and extends northward to cover a large area outside the secondary study area.

20.2.1.4 Plans and Policies

The FY 2004 CDNS for Brooklyn CD 1 contains only one recommendation that applies to the site and study area. It states explicitly that the community is opposed to any reopening of the Greenpoint Incinerator and recommends that it be demolished as soon as possible. Otherwise, the community expresses its concern over hosting new large-scale waterfront facilities, such as power plants, and its general dissatisfaction with hosting a large number of private waste transfer stations. Also, the Community District Board requests that DSNY garages for District 3 be relocated to District 3 and that the construction of new garages for Districts 1 and 4 proceed.

The CDNS for Queens CD 2 states the community's concerns over air quality and the effects of waste transfer stations on air quality, but does not make reference to recommended or anticipated physical development affecting the site or primary or secondary study areas.

The Greenpoint 197-a Plan has been prepared for an area in Brooklyn approximating the 11222 zip code district, which extends to Newtown Creek to the north, the East River to the west and far enough south to include McCarren Park and east to include the Keyspan site on Newtown Creek east of the Brooklyn-Queens Expressway (BQE). The plan overall supports redevelopment of the waterfront, but it notes a necessary balance between existing necessary uses, such as DSNY facilities, and the desire to have a waterfront that is accessible and enjoyable to the public. To this end, the plan notes those artistic and community open space elements that

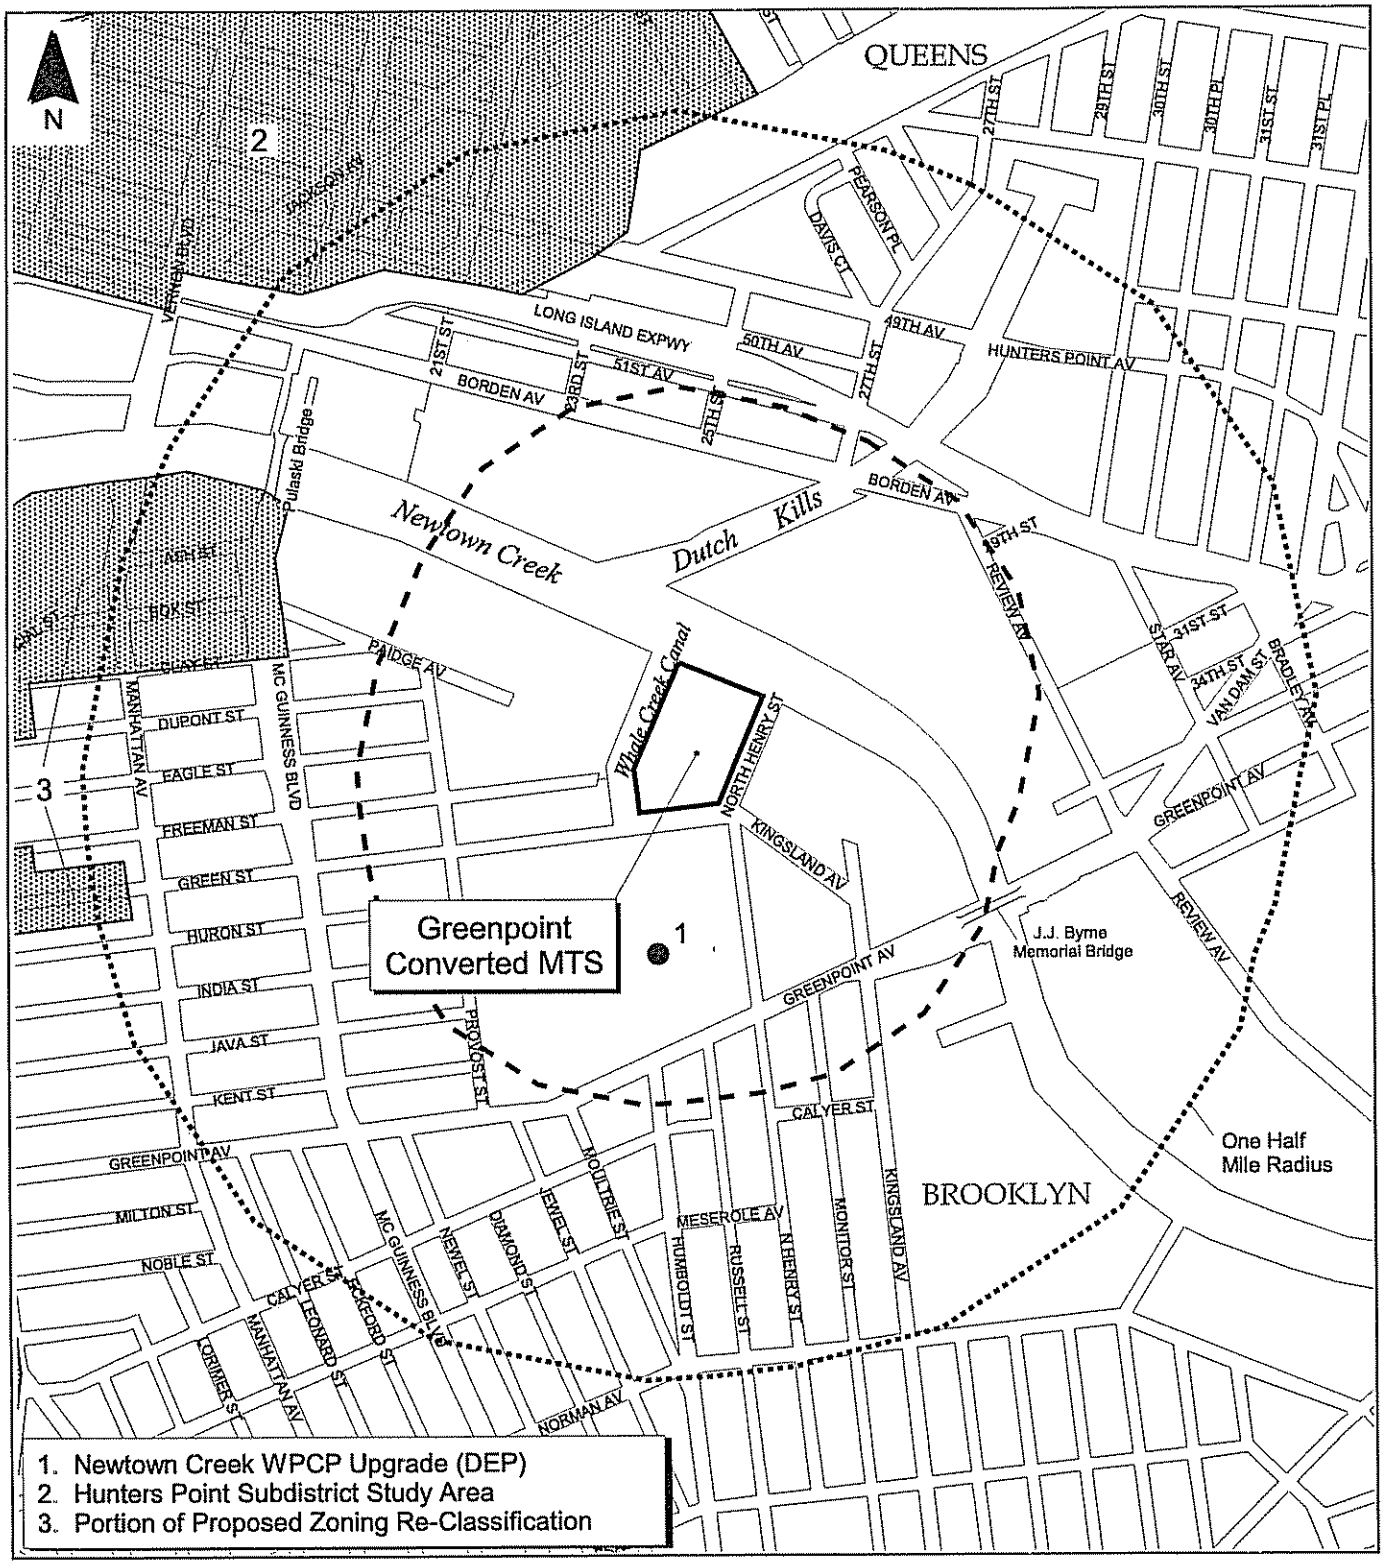
are planned to be incorporated in the Newtown Creek WPCP upgrade. (See Future No-Build Conditions, Section 20.2.2, for details regarding the WPCP design features likely to be complete by 2006.) Regarding the DSNY site, the plan refers to the community's concern with dismantling the incinerator in a way that is environmentally sensitive. Although several areas of rezoning are proposed, Newtown Creek is planned to remain M3, thus suitable for heavy industry and municipal uses.

Reach 13, Newtown Creek, is a tidal inlet of the East River, stretching eastward to include English Kills. The plan for Reach 13 states that there are many economic opportunities in this vicinity given its proximity to rail lines and deep water access. The area is identified as an SMIA and continues to be an important location for manufacturing, wholesale, distribution and municipal uses. The plan recommends maintenance of these activities and enhancements to accommodate water-dependent uses. It also calls for coordinated efforts to resolve existing environmental problems and to safeguard against new ones.

One recommendation of the plan is to develop environmentally sound designs and clear performance standards for municipal uses in Newtown Creek, including coordinating municipal agencies with the public and encouraging the consideration of such site development mitigation strategies as the use of landscape buffers, odor control measures and truck routing guidelines.

The plan for Reach 13 makes the point that the reach is not an appropriate location for the development of public access to the waterfront. Public access does not exist, and the best views of the creek are from sidewalks on the Pulaski Bridge and the J.J. Byrne Memorial Bridge, which are used by pedestrians and cyclists. The plan suggests that communities in neighboring reaches provide better opportunities for public access to the waterfront. (See Section 20.12 for a review of consistency with the WRP.)

20.2.2 Future No-Build Conditions



It is reasonable to anticipate that Future No-Build Conditions in the primary and secondary study areas generally will resemble the Existing Conditions. The site will remain DSNY property and the existing, inactive MTS will remain, as will the associated DSNY parking. The DSNY auxiliary field force will continue to use some interior spaces of the defunct incinerator until the incinerator is demolished prior to 2006.

Planned developments near the site generally will maintain existing development intensity and reinforce the existing land use pattern. Figure 20.2-4 shows the planned development sites. The Newtown Creek WPCP, southeast of the site, is in the midst of major expansion/rehabilitation on the adjacent block between Kingsland Avenue and Greenpoint Avenue. The WPCP support building, under construction west of the Whale Creek, and the adjacent landscaped nature walk along the water, are scheduled for completion in 2004. The redeveloped WPCP will also feature a pool and park for children and a series of 10 public art projects to be installed along the 10-block-long chain-link fence surrounding the facility.

20.2.3 Potential Impacts with the Greenpoint Converted MTS

20.2.3.1 Land Use and Zoning

The Greenpoint Converted MTS would entail replacement of the existing MTS with a similar, new facility that would include containerization functions. The new facility would be constructed further inland from the location of the incinerator, thus somewhat decreasing the density of the site and its waterfront. The Greenpoint Converted MTS, which would be situated in relative isolation amid an increasingly industrial context, would not affect the use of the site, nor would it likely affect the surrounding land uses or zoning patterns.

Site delineations and study area boundaries are approximate.
Base Map Source: New York City Department of City Planning

Figure 20.2-4 Planned Development Sites

Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

20.2.3.2 Consistency with Public Plans and Policies

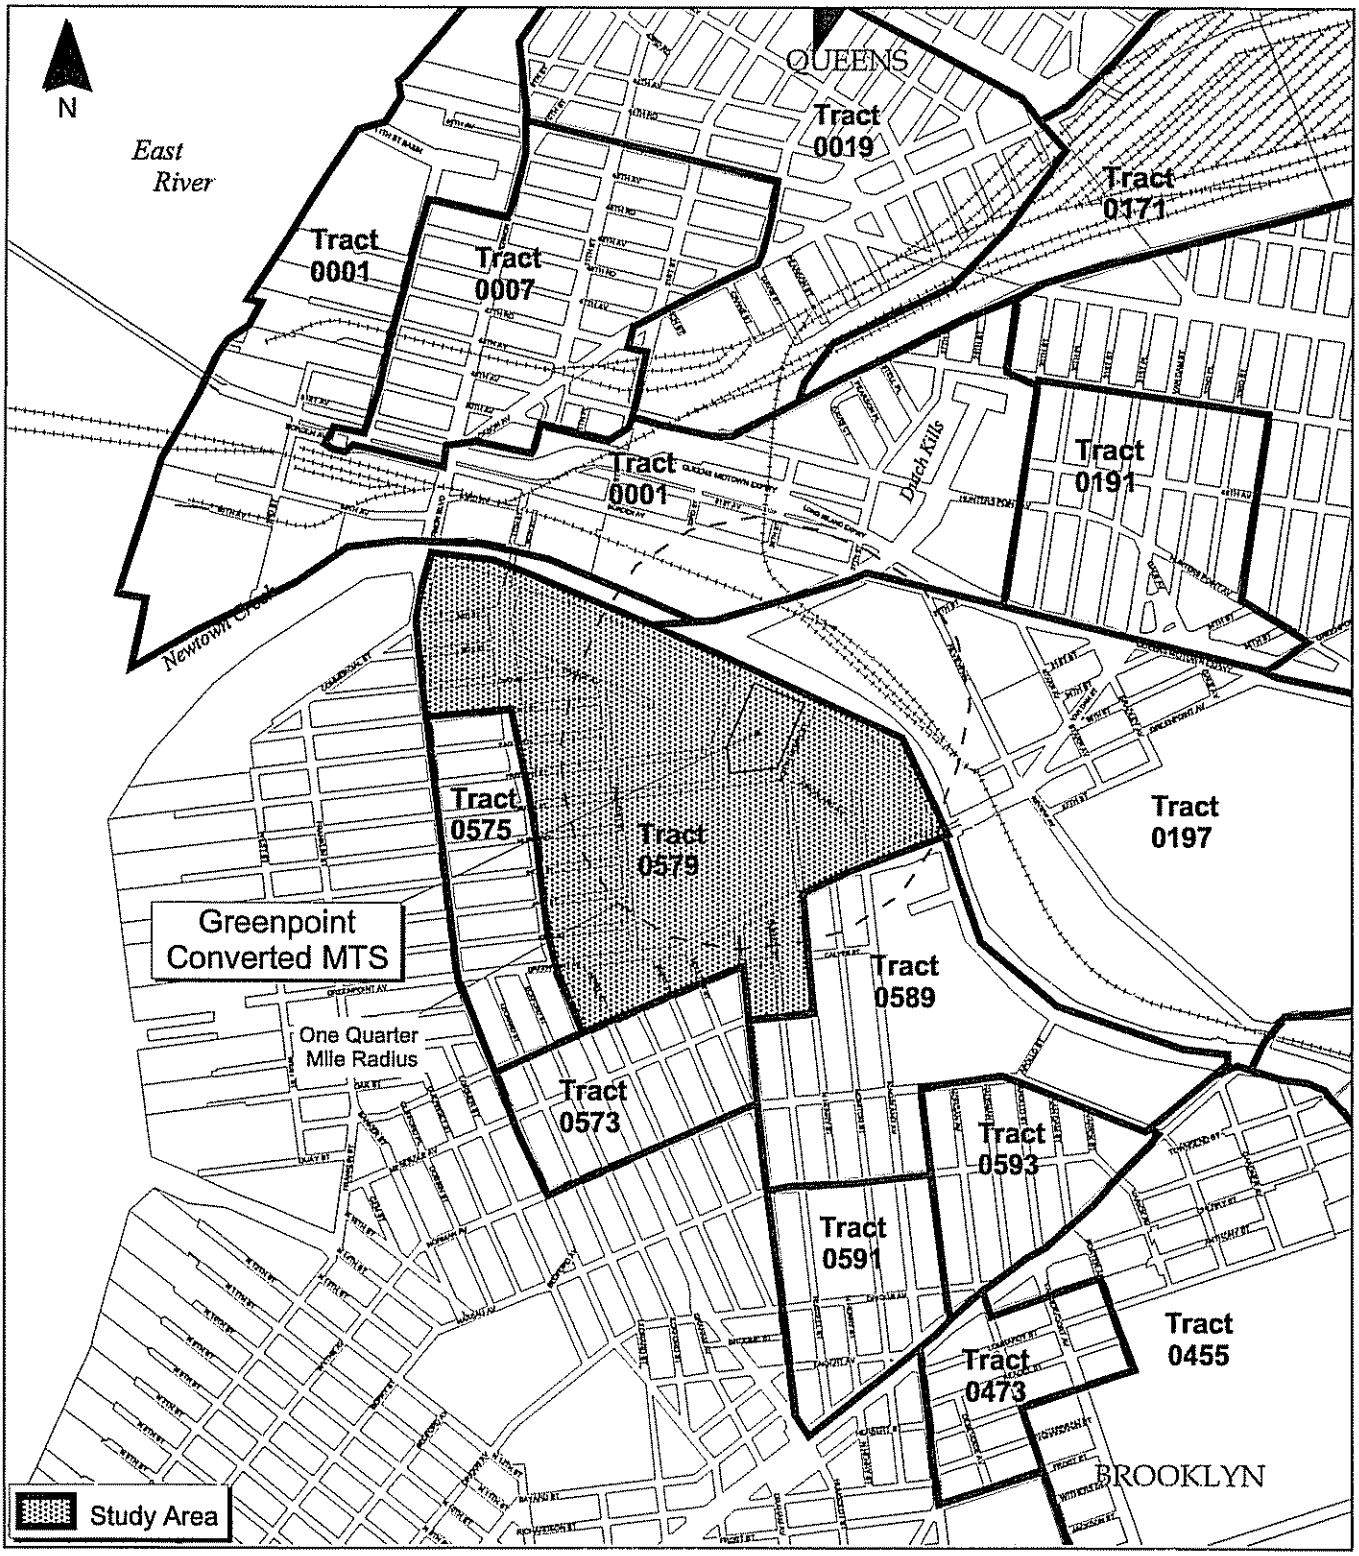
The Greenpoint Converted MTS would be consistent with the stated objectives of the pertinent plans and policies affecting the site and environs, primarily because development of the facility would maintain the waterfront industrial uses and zoning and incorporate environmentally sound design, as recommended in the Reach 13 plan. The Greenpoint Incinerator already will have already been demolished.

20.3 Socioeconomic Conditions

20.3.1 Existing Conditions

20.3.1.1 Definition of the Study Areas

Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (See Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area is comprised of Census Tract 579 in Brooklyn (see Figure 20.3-1), which has a northeastern boundary of Newtown Creek and is bounded on the west, south and east roughly by McGuiness Boulevard, Calyer Street and Greenpoint Avenue. For comparison purposes, census data were also gathered at the borough and City levels.



Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

20.3.1.2 Demographic Characteristics

20.3.1.2.1 Population

In 2000, the study area population consisted of 1,440 persons (see Table 20.3-1). In terms of total population growth from 1990 to 2000, the study area experienced a greater percentage increase (12%) than did the borough (7%) and the City (9%) during the same period.

The age-sex distribution for the area was slightly different from the population distribution of the borough and the City, with a slightly greater proportion of males to females. The study area contained relatively the same percentage of children and teenagers as the borough or City; approximately 28% of the study area population was under the age of 20, compared to 30% for the borough and 27% for the City.

Site delineations and study area boundaries are approximate

1990-2000 Population

	Study Area	Brooklyn	City
2000	1,440	2,465,326	8,008,278
1990	1,288	2,300,664	7,322,564
Percent Change	+11.8%	+7.2%	+9.4%

Source: U.S. Census, 1990, 2000

20.3.1.2.2 Racial and Ethnic Characteristics

The 2000 study area population had a far greater proportion (59%) of people of Hispanic origin (all races) than did Brooklyn (20%) or the City (27%). Of the 41% not of Hispanic origin, 6% were Black, 74% were White and 12% were Asian. In Brooklyn and the City, Blacks represented approximately 43% and 33% of the non-Hispanic populations, respectively, while Whites represented 43% and 48%, respectively, and Asians represented 9% and 13%, respectively.

From 1990 to 2000, the number of study area residents of Hispanic origin increased by a greater rate (18%) than in the borough (9%) but a smaller rate than in the City (24%) during the same period. Because the 2000 Census introduced the option for respondents to identify themselves as two or more races, racial categories are not directly comparable with 1990.

20.3.1.2.3 Families and Households

There were 325 families in the study area in 2000 and the percentage of these families that had children under the age of 18 (47%) was slightly smaller than those families in Brooklyn with children under 18 (51%) and in the City (49%). There was roughly the same percentage of married-couple families in the study area (61%) as in the borough (59%) or the City (62%), and 55% of these families in the study area had children, more than those of Brooklyn (50%) and the City (48%).

Twenty-nine percent of families in the study area were headed by a female householder, similar to the borough (33%) and the City (30%). Forty percent of the female householder families in the study area had children under the age of 18, a percentage noticeably lower than the percentage in the borough and the City, which were equal (55%).

There were 543 households in the study area in 2000. The average number of persons per household in 1990 was nearly the same for the study area (2.7 persons), Brooklyn (2.8 persons) and the City (2.6 persons).

From 1990 to 2000, the number of households in the study area increased by 21%, compared with a 6% increase in the borough and a 7% increase in the City.

20.3.1.2.4 Employment

In 2000, the labor force and employment rate for the three areas (study area, borough, City) was approximately the same. Within the study area, 59% of persons aged 16 and older participated in the labor force in 2000, compared to 55% in Brooklyn and 58% in the City. The majority of these people in all three areas were employed as private wage and salary workers.

In the study area, 13% of employed persons 16 years of age and older were government workers, slightly less than the proportion in Brooklyn (19%) and the City (16%). Four percent of the study area's working population was self-employed, about the same proportion as in Brooklyn (5%) and the City (6%).

From 1990 to 2000, the number of employed persons within the three areas remained steady. However, among employed persons, while the study area showed an increase in government workers, the borough and City decreased. Those engaged in government jobs increased by 6% in the study area, compared to a 14% decrease in the Borough and a 10% decrease in the City.

Current forecasts indicate that about 13,550 employees worked in Brooklyn CD 1 and Queens CD 2 in 2005.[1]

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03

20.3.1.2.5 Housing

Most housing units (80%) in the study area were constructed before 1960, which is more than in Brooklyn and the City (73% and 67%, respectively). As of 2000, there were 521 housing units in the study area with a vacancy rate of about 7%, slightly higher than the borough (5%) and the City (6%). Like the borough and the City, there were more renters than owners. Nearly all of the housing units were renter-occupied (88%), considerably greater than the borough (69%) and the City (66%).

Although the 2000 median value of housing units in the study area ($233,900) was similar to those of Brooklyn ($224,100) and the City ($211,900), the change in value from 1990 to 2000 was much different. The median housing unit in the study area increased in value by 450%, compared to a 15% increase in the borough and a 13% increase in the City. Additionally, while the value of the housing units in the study area was higher than those of Brooklyn and the City, the median gross rents ($585) were lower than those in the borough ($672) and the City ($705).

The turnover in the study area (42%) from 1995 until 2000 was roughly equal to that of the borough and the City (both 43%).

From 1990 to 2000, a total of 12 housing units were added in the study area, representing a 2% increase, lower than the borough and the City (both 7%).

20.3.1.2.6 Education

In 2000, the school enrollment for the three areas was roughly the same, with the study area at 30%, the borough at 31% and the City at 29%. Of those enrolled in school within the study area, 67% were enrolled in elementary school or high school and 19% were enrolled in college or beyond. In Brooklyn, 64% were enrolled in elementary or high school and 24% in college or beyond, while 62% of the City's enrolled population was in elementary or high school and 27% in college or beyond.

The study area witnessed a 12% increase in the number of persons enrolled in school from 1990 to 2000 (141 more people), with the largest increase in enrollments occurring at the pre-primary school level (1,325%, or from 4 people to 57). Brooklyn and the City also experienced tremendous growth in the pre-primary school age group (145% and 150%, respectively).

A markedly smaller proportion (29%) of the study area population aged 25 and over had a college degree or some college education compared to Brooklyn (42%) and the City (48%). Compared to the borough and the City, a larger portion of the study area population (aged 25 and older) did not graduate from high school. A higher percentage of people in the study area (21%) had some high school education but lacked a diploma versus 18% in the borough and 16% in the City. Additionally, the study area had twice the proportion of people over the age of 25 with less than a 9th-grade education (27%) as the borough (13%) and the City (12%).

Despite the lower educational levels, from 1990 to 2000 the study area witnessed slightly rising levels of educational attainment. The number of college graduates in the study area increased 8%, although the trend in the borough and the City was much greater (41% and 29%, respectively).

20.3.1.2.7 Income and Poverty

In 2000, both median household income ($23,445) and median family income ($25,594) were lower than in Brooklyn ($32,135 and $36,188, respectively) and the City ($38,293 and $41,887, respectively). Compared to the larger two areas, a greater percentage of study area households were concentrated at the lowest income levels, with the majority of annual household incomes (55%) below $25,000. About 30% of the area households had annual incomes less than $10,000, compared with 19% in Brooklyn and 16% in the City. Only 21% of households in the study area had incomes of $50,000 and above, compared with 33% in the borough and 40% in the City.

A similar percentage of persons under the age of 18 were living below the poverty level in the study area (32%), the borough (34%) and the City (30%) in 2000. The 2000 Census also reported that a greater percentage of the population aged 65 and older were living below the poverty level in the study area (44% percent) compared to Brooklyn (22% percent) and the City (18%).

From 1990 to 2000, the percentage of people living below the poverty level in the study area decreased by 8%, compared to an increase in Brooklyn of 19% and in the City of 20%.

20.3.1 3 Economic Conditions

The study area contains a range of industrial uses concentrated along Newtown Creek, from warehouse and distribution facilities to oil loading facilities and private waste transfer operations. In Brooklyn, DSNY-owned property used as a storage yard and the NYCDEP Newtown Creek WPCP occupy large areas adjacent to the site, with an NYCDOT asphalt production facility nearby. Further southeast, are the outdoor-loading facilities of the Metro Fuel Oil Depot. The Queens side of Newtown Creek has similar industries, with Case Paper Manufacturers, the Exhibit Company and other warehouses fronting on Borden Avenue and Review Avenue.

Further beyond the surrounding industrial uses are ground-floor stores on the north-south avenues west of the site, along McGuinness Boulevard and Manhattan Avenue. Small-scale commercial establishments line the south side of Greenpoint Avenue south of the site. Further to the south along Meserole Avenue is a mix of residential uses and warehouses.

20.3.2 Future No-Build Conditions

20.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Brooklyn CD 1 and Queens CD 2 will remain about the same as current conditions.[2]

[2] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

20.3.2.2 Economic Conditions

The study area contains stable industrial areas that are not expected to see significant new business development by the Future No-Build year. South of the site, the NYCDEP plans to expand and double the capacity of the WPCP, adding approximately 14 new government sector jobs as a result of the plant upgrade.

Regional projections indicate that employment in Brooklyn CD 1 and Queens CD 2 will remain about the same as current conditions.[3]

The near-term economic health of industrial areas such as Greenpoint may be supported by established City programs available through IDA. Programs such as the Industrial Incentive Program and the Small Industry Incentive Program provide business tax incentives for capital renovation and expansion projects. However, no significant changes are expected through 2006.

20.3.3 Potential Impacts with the Greenpoint Converted MTS

The Greenpoint Converted MTS represents the reactivation of solid waste transfer operations on the site with added containerization operations. Therefore, it would not result in socioeconomic changes in the study area. No significant direct or indirect impacts are anticipated related to socioeconomic conditions.

20.3.3.1 Residential Impacts

No direct displacement of residential uses would occur as a result of the Greenpoint Converted MTS, and land use and neighborhood character analyses predict no adverse impacts.

[3] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

20.3.3.2 Direct Business and Institutional Impacts

The Greenpoint Converted MTS would not result in direct displacement of businesses or institutional uses nearby.

20.3.3.3 Indirect Business and Institutional Impacts

The businesses adjacent to and near the Greenpoint Converted MTS are industrial uses that would not be affected by reactivating MTS operations and added containerization activities.

20.3.3.4 Employment Impacts

The Greenpoint Converted MTS is expected to generate approximately 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

20.4 Community Facilities and Services

20.4.1 Existing Conditions

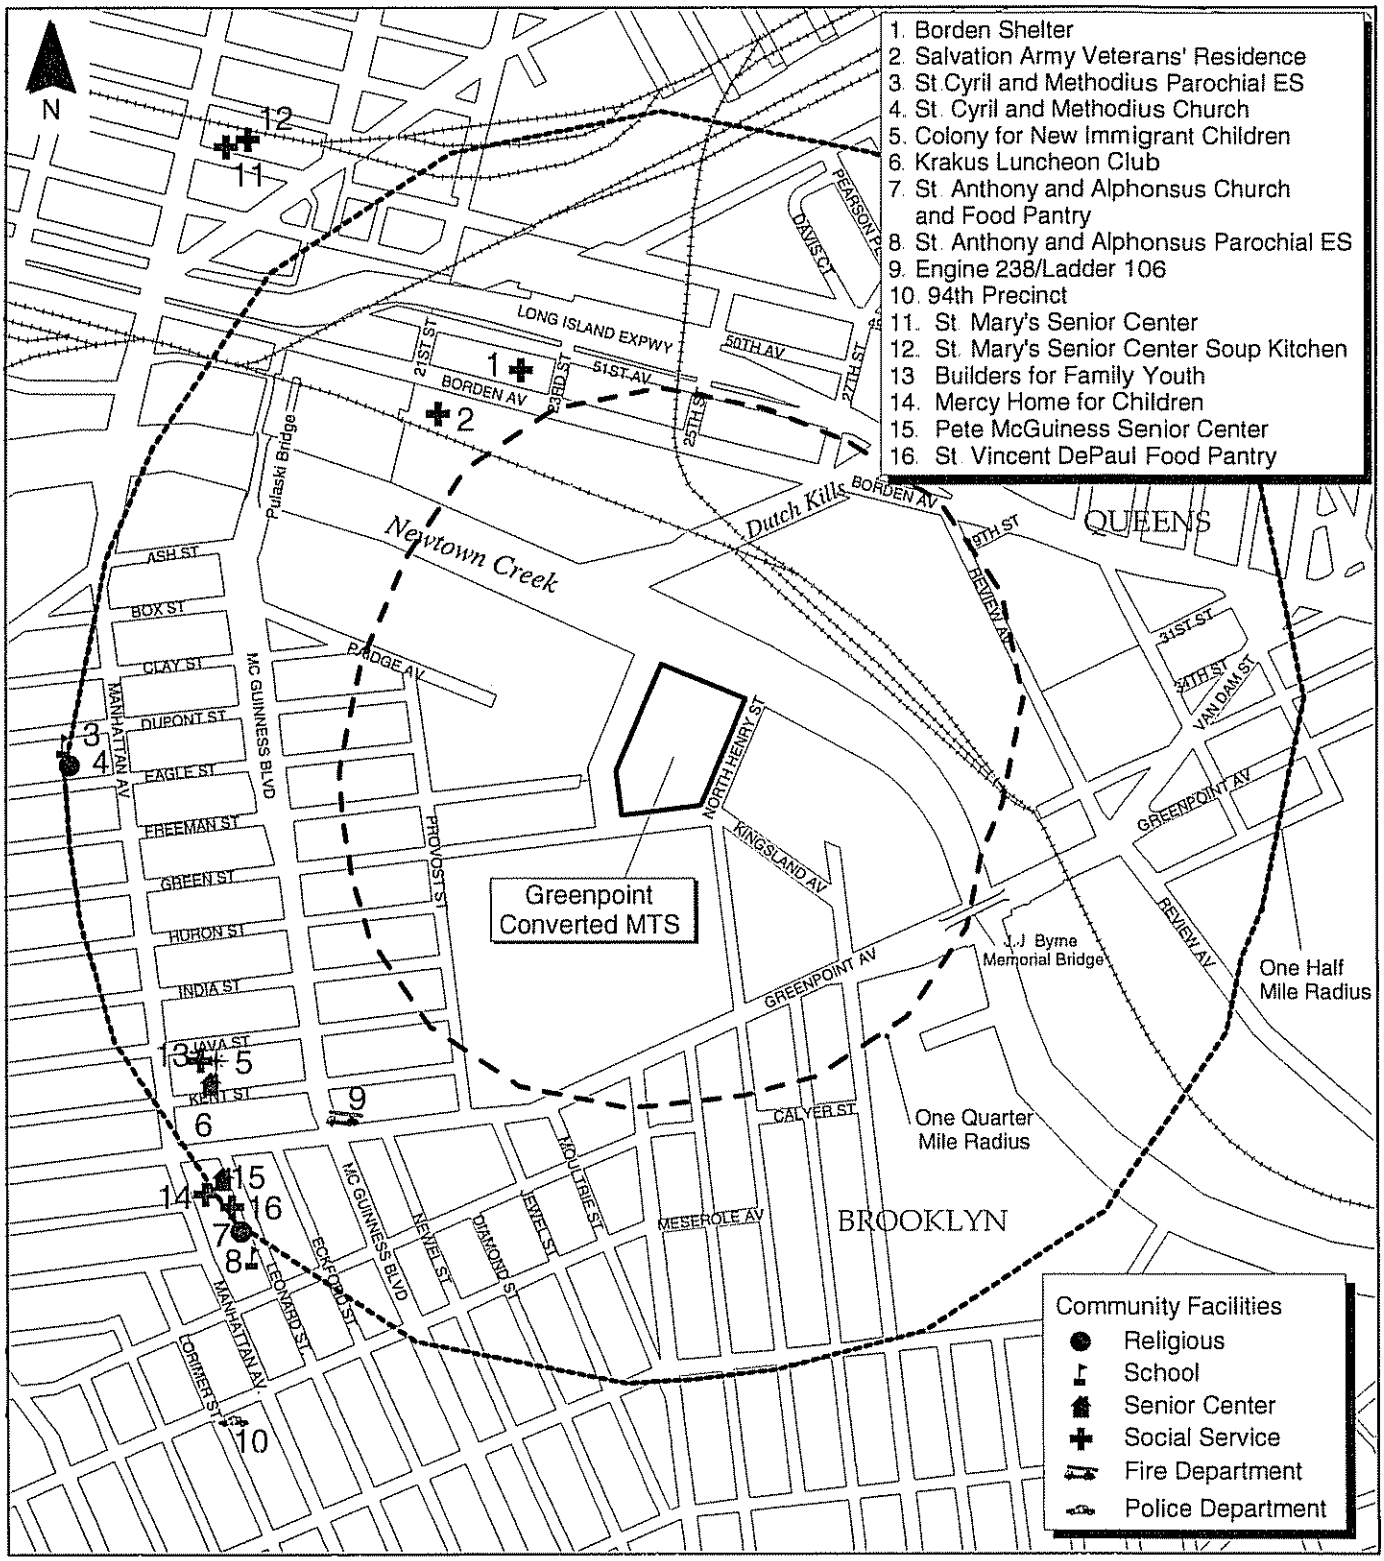
20.4.1.1 Definition of the Study Areas

The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼- and ½-mile from the site.

20.4.1.2 Summary of Community Facilities and Services

Consistent with its industrial character, the primary study area contains no community facilities. Nine community facilities are located within the secondary study area and nine are outside the secondary study area. Community facilities serving or located within or near the study area are listed in Table 20.4-1 and shown in Figure 20.4-1.

20.4.2 Future No-Build Conditions



There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

20.4.3 Potential Impacts with the Greenpoint Converted MTS

The Greenpoint Converted MTS would create no significant new demand on services and community facilities and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the Greenpoint Converted MTS (see Appendix A).

Table 20.4-1
Community Facilities and Services

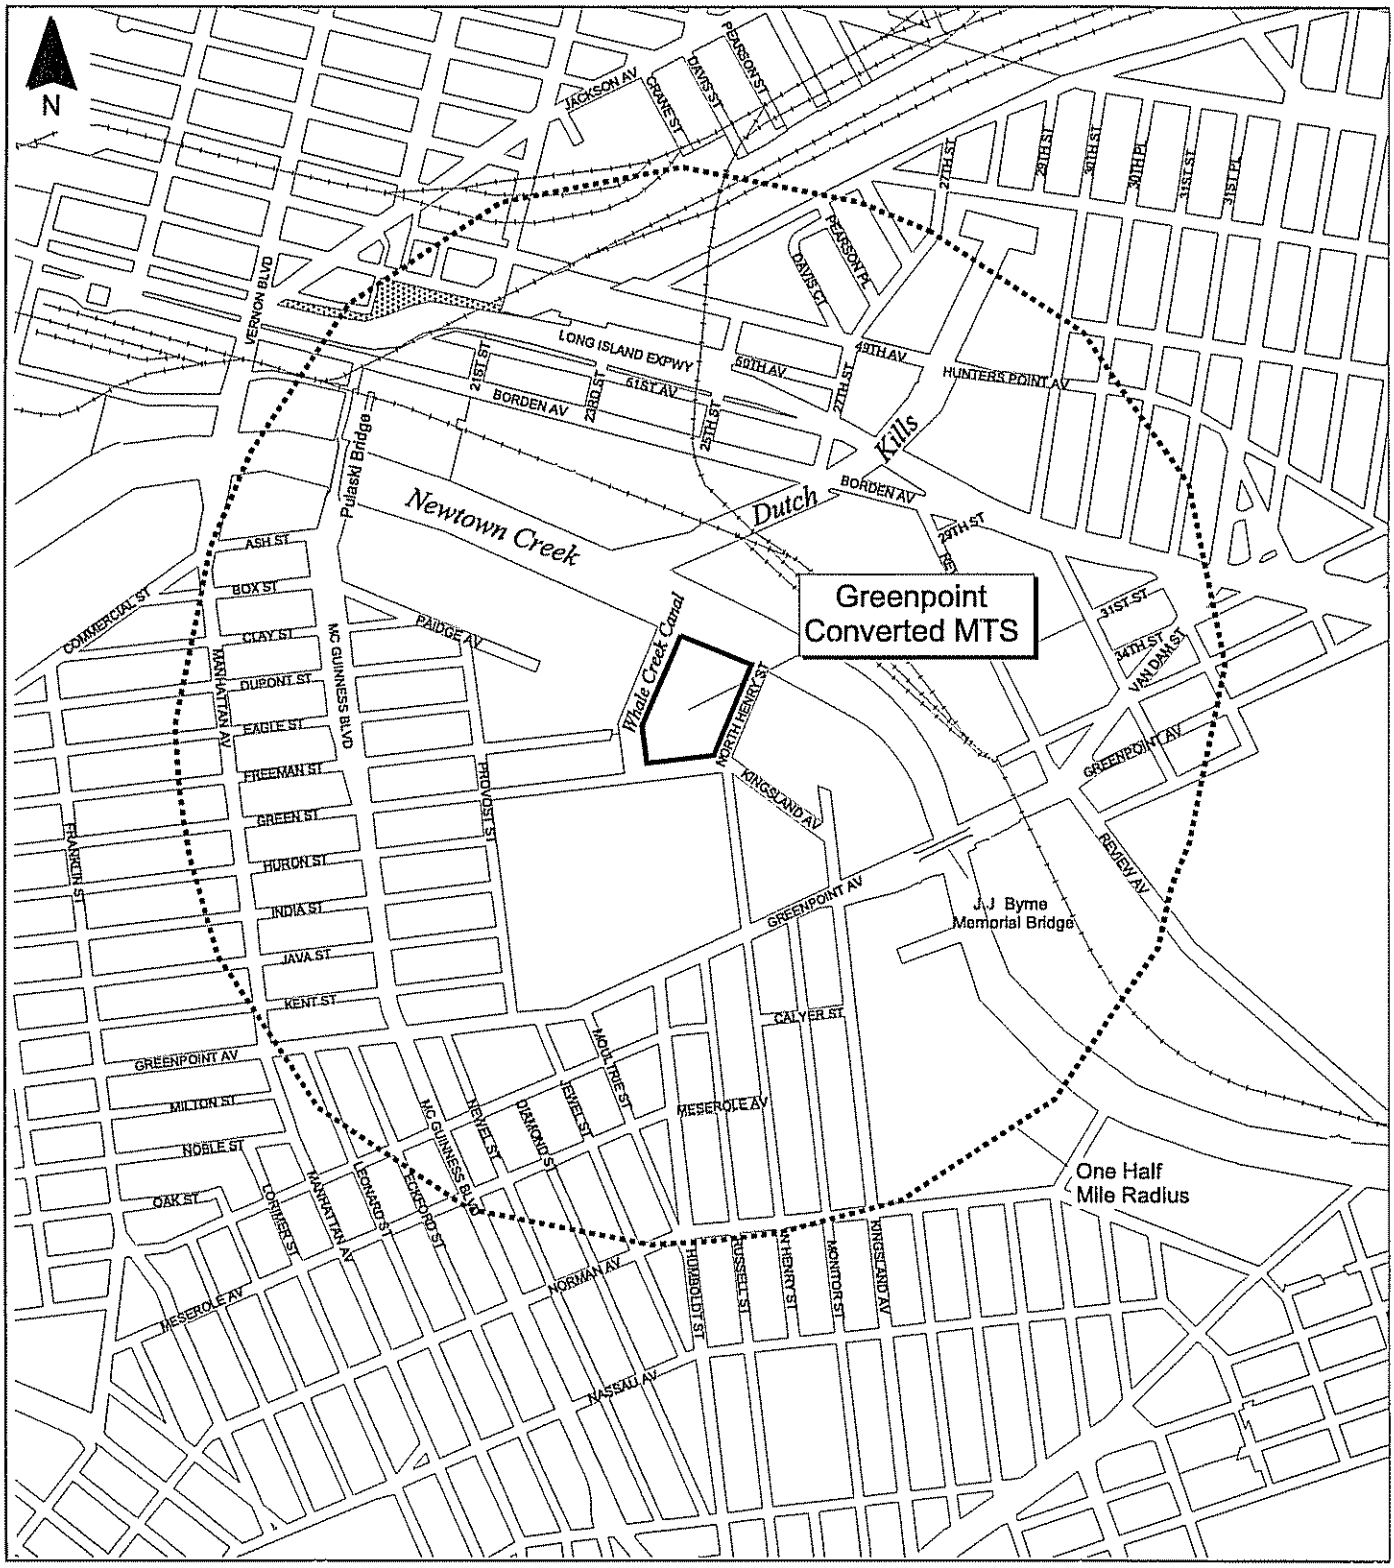
20.5 Open Space

20.5.1 Existing Conditions

20.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

20.5.1.2 Summary of Open Space in the Study Area



Currently the only designated open space in the study area is an undeveloped park area northwest of the site situated adjacent to the north side of the Long Island Expressway (LIE) (see Figure 20.5-1). Though mapped parkland, it is not suitable for use by visitors, nor is it landscaped to provide visual relief in this heavily trafficked area.

20.5.2 Future No-Build Conditions

The nature walk and children's pool and park that are planned as part of the Newtown Creek WPCP support building construction west of Whale Creek Canal would be completed during the final stages of WPCP construction in 2004. There are no DPR plans for new open space resources in the study area or improvements by the Future No-Build year.

20.5.3 Potential Impacts with the Greenpoint Converted MTS

No impacts to either the existing park area along the northern edge of the LIE or the planned open space features of the WPCP would result from the Greenpoint Converted MTS. Newtown Creek and the LIE buffer the existing park area from the site.

Site delineations and study area boundaries are approximate.

The landscaped walkway has been designed under the assumption that the existing Greenpoint MTS would remain in operation throughout the construction period. Because the Greenpoint Converted MTS would be a similar use to the former one and in the same approximate location, it would not present any notable new challenges to be assumed in the design and use of the publicly accessible area. However, views of the Greenpoint Converted MTS from the future nature walk west of Whale Creek Canal would include the barge loading area where gantry cranes would load containerized waste onto barges moored in the canal, not unlike other industrial views on both sides of the creek.

20.6 Cultural Resources

20.6.1 Existing Conditions

20.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site.

20.6.1.2 Development History of the Area

The 946-acre triangular parcel of land that is now known as Greenpoint was bought by Dutch settlers in 1638 from the Keshaechqueren Indians and named for a grassy expanse that extended into the East River. In the early 19th century, Greenpoint was sparsely populated by Dutch Huguenot descendents and by 1850 it had become an industrial center. Greenpoint was the site of "the five black arts: printing, pottery, petroleum and gas refining, glassmaking, and iron making."[4] Shipbuilding industries also developed along the East River, supporting the Brooklyn Navy Yard to the south. Consequently, area streets were named for people, places and items important to local industries. Major industrial firms of the time were located here, such as the Continental Iron Works, which built the ironclad ship the Monitor used in the Civil War, and the Astral Oil Works, which was opened by Charles Pratt and merged with the Standard Oil Company in 1874. The Astral Apartments on Franklin Street, built by Pratt in 1886 to provide workers with decent housing, are now landmarked by the City as significant examples of model tenements.

The history of Newtown Creek, which forms the boundary separating Brooklyn from Queens, is an important part of the study area's history. It was the route to Maspeth taken by European colonists in 1642. The British spent the winter near the creek during the Revolutionary War, and in the early 1800s it was a major channel for commercial vessels and small boats.

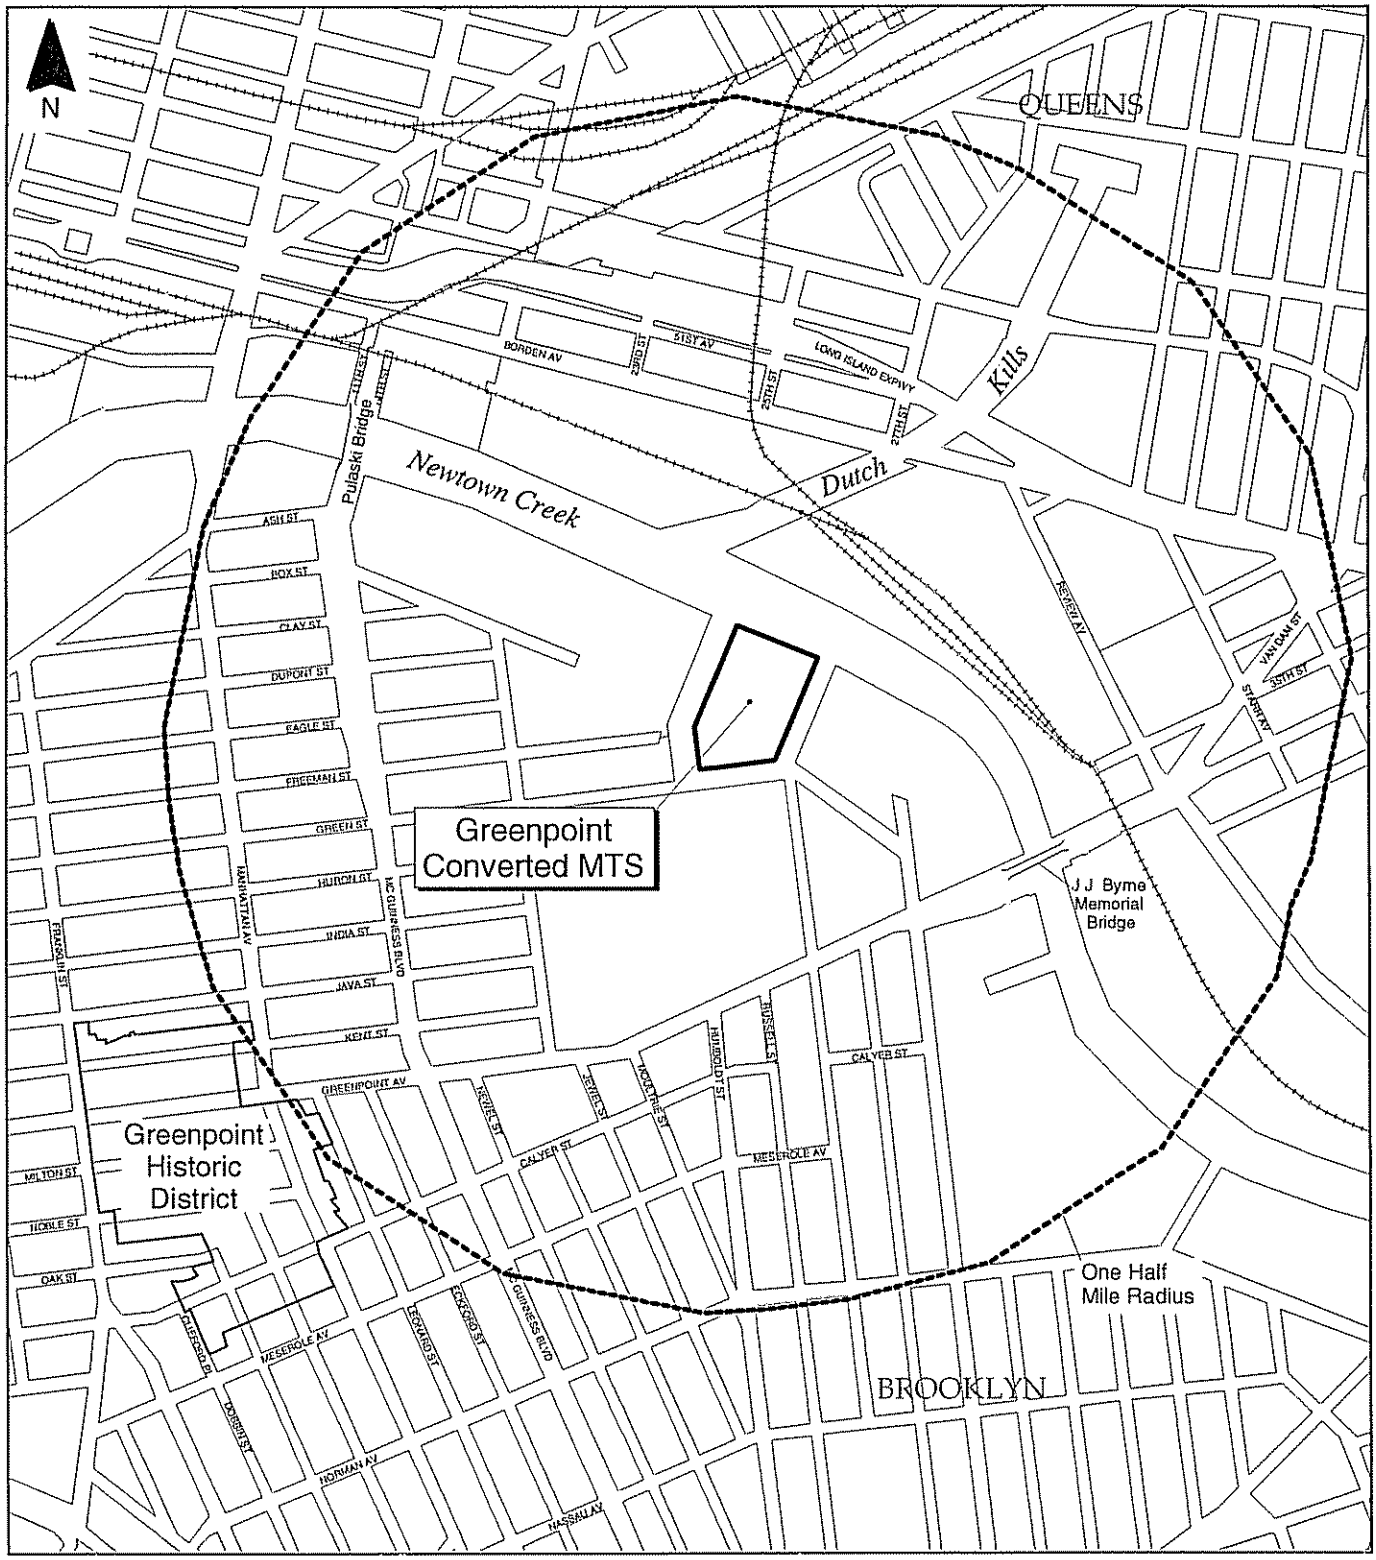
---

[4] Jackson, Kenneth T., Editor, Encyclopedia of New York City. Yale University Press, New Haven (The New York Historical Society, New York), 1995, p.506.

The first oil and coal oil refineries opened along its banks around 1860. Long Island City and Sunnyside were home to waterside industrial uses such as oil refineries and factories for varnish, ceramic pipe and barrel-making in the mid- to late-1800s. Due to the practice of dumping sludge and acids into the creek, the creek was, by 1900, already well known for its foul odors and pollution, with water corroding the paint on ships and leaving noxious deposits on the shore.

The state and City tried to improve Newtown Creek, and the channel was constantly dredged and widened by the federal government. Ship building, manufacturing and warehousing gradually diminished during the first half of the 20th century, with the active factory life of Greenpoint largely ending after World War II. After World War II, the creek was no longer important for marine traffic, with waterborne transport being replaced by trucks and airplanes, but many industries continued to be located along the creek.

20.6.1.3 Cultural Resources on the Site



There are no elements of architectural or archaeological significance within the site.

20.6.1.4 Historic Resources Within the Study Area

A small portion of the Greenpoint Historic District lies at the study area's southwestern edge (see Figure 20.6-1). This City-designated district is listed on the State and National Registers of Historic Places and it contains a wide variety of buildings and types dating to the 1860s and 1870s.

20.6.2 Future No-Build Conditions

There are no additional elements of potential architectural or archaeological significance slated for review. Therefore, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

Site delineations and study area boundaries are approximate

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

20.6.3 Potential Impacts with the Greenpoint Converted MTS

As there are no existing or anticipated architecturally or archaeologically significant resources on the site or the study area, the Greenpoint Converted MTS would have no effect on any cultural resources. SHPO has concluded that the project would have no impact upon cultural resources in, or eligible for inclusion on, the State and National Registers of Historic Places. The LPC has stated that the site contains no architectural or archaeological significance (see Appendix A).

20.7 Urban Design, Visual Resources, and Shadows

20.7.1 Existing Conditions

20.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (see Figure 20.8-1). The site has been developed in a manner consistent with adjacent properties and the overall study area. It is a non-sensitive industrial area, in terms of urban design and visual quality assessment. There are no sensitive-view corridors or publicly accessible open areas or points of waterfront access areas that would reasonably be expected to experience visual-quality impacts from the proposed development.

20.7.1.2 Description of the Site

The existing MTS and non-operational incinerator comprise most of the on-site development. The five-story main building of the incinerator blocks much of the existing MTS and Newtown Creek waterfront from inland views (see Figure 20.7-1). A fenced-in parking area is located south of the incinerator and the remainder of the site is paved. There is no formal landscaping on the site, although tall grass and a few small trees are present along the edges of Whale Creek Canal and the slip along North Henry Street, as described in Section 20.9.1.4.

20.7.1.3 Urban Design and Visual Resources of the Study Area

20.7.3.1 Visual Quality and Urban Design

The visual quality of the study area is characterized by the wide streets and industrial uses that surround the site, dominated by the Newtown Creek WPCP located to the south and west of the site and an auto scrap yard across Newtown Creek (in Queens) to the north (see Figure 20.7-1 and Figure 20.7-2).

This page intentionally left blank.

Figure 20.7-1 : View toward site from Green Street.

Figure 20.7-1 and 20.7-2
Urban Design and Visual Quality
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

The only publicly accessible views of the existing MTS are from North Henry Street and Kingsland Avenue, neither of which are through-streets used by the general public. Rather, these streets serve primarily as access roads to the site and the surrounding industrial uses. A portion of North Henry Street north of Greenpoint Avenue and a segment of Kingsland Avenue at Green Street and Greenpoint Avenue have been demapped as part of the WPCP expansion, thus further insulating the site from the community (see Figure 20.7-3).

The area around the site is almost entirely paved. In fact, because there are many truck-dependent uses in the area, the wide streets and sidewalks, where they exist, tend to be used for truck parking. There is little or no pedestrian activity.

20.7.2 Future No-Build Conditions

The only plans for the surrounding environs that would lead to changes in urban design or visual quality conditions by the Future No-Build year are those related to the expansion of the Newtown Creek WPCP and removal of the Greenpoint Incinerator. This multi-site WPCP development would intensify the industrial character of the area but not change the visual conditions significantly. It would, however, further isolate the site from view. The planned nature walk, children's pool and park and art installations along the WPCP site perimeter are to be completed around 2004, introducing a new recreational opportunity to the study area. Otherwise, the anticipated Future No-Build Conditions are fundamentally the same as Existing Conditions.

20.7.3 Potential Impacts with the Greenpoint Converted MTS

The Greenpoint Converted MTS would replace the existing MTS with a similar, new containerization facility on a widened platform. It would be located further inland, where the incinerator, which will have been demolished, stood, and an administration building and parking lot would be built south of it. The Greenpoint Converted MTS would be more visible from North Henry Street and Kingsland Avenue than the existing MTS because it would be larger and no incinerator would block it from view. The container storage area near the northern edge of the platform may be visible from North Henry Street as well. Views from the proposed walkway

This page intentionally left blank.

Urban Design and Visual Quality
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

across the canal would be of industrial operations, including containerization barge loading activities. The development, however, would be in keeping with the established industrial urban design and visual character of the area, and so no significant adverse impacts to urban design or visual quality would result.

20.7.3.2 Shadows

According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.)

With the expected completion of a public nature walk on the west side of Whale Creek Canal, across from the site (less than 200 feet away), a full shadow impact assessment was prepared. There are no expected physical changes to the project site or vicinity that might create new shadows on these resources in the Future No-Build Condition. Therefore, the shadow assessment considered only the consequences of the Greenpoint Converted MTS development.

The proposed 100-foot-tall Greenpoint Converted MTS facility would result in minimal shadows across the new nature walk (for 10 minutes each in March and June (7:30 to 7:40 a.m. and 7:00 to 7:10 a.m., respectively). Due to the short presence of the project shadow on resources during these times, significant impacts are not anticipated.

For the December 21st analysis period, project shadows are anticipated to fall over the new nature walk for 30 minutes, between 8:50 a.m. and 9:20 a.m. During this period, sunrise would occur at 7:16 a.m. and sunset would occur at 4:32 p.m. (see Figure 20.7-4.) At its time of greatest penetration, shadows are projected to cover approximately 150 feet of the greater than 500-foot long walkway. The affected features of the walk are anticipated to include benches for sitting and manmade landscape areas. While these features would be affected by the reduction in sunlight, 30 minutes per day along a short stretch of the walk is not considered a significant impact.

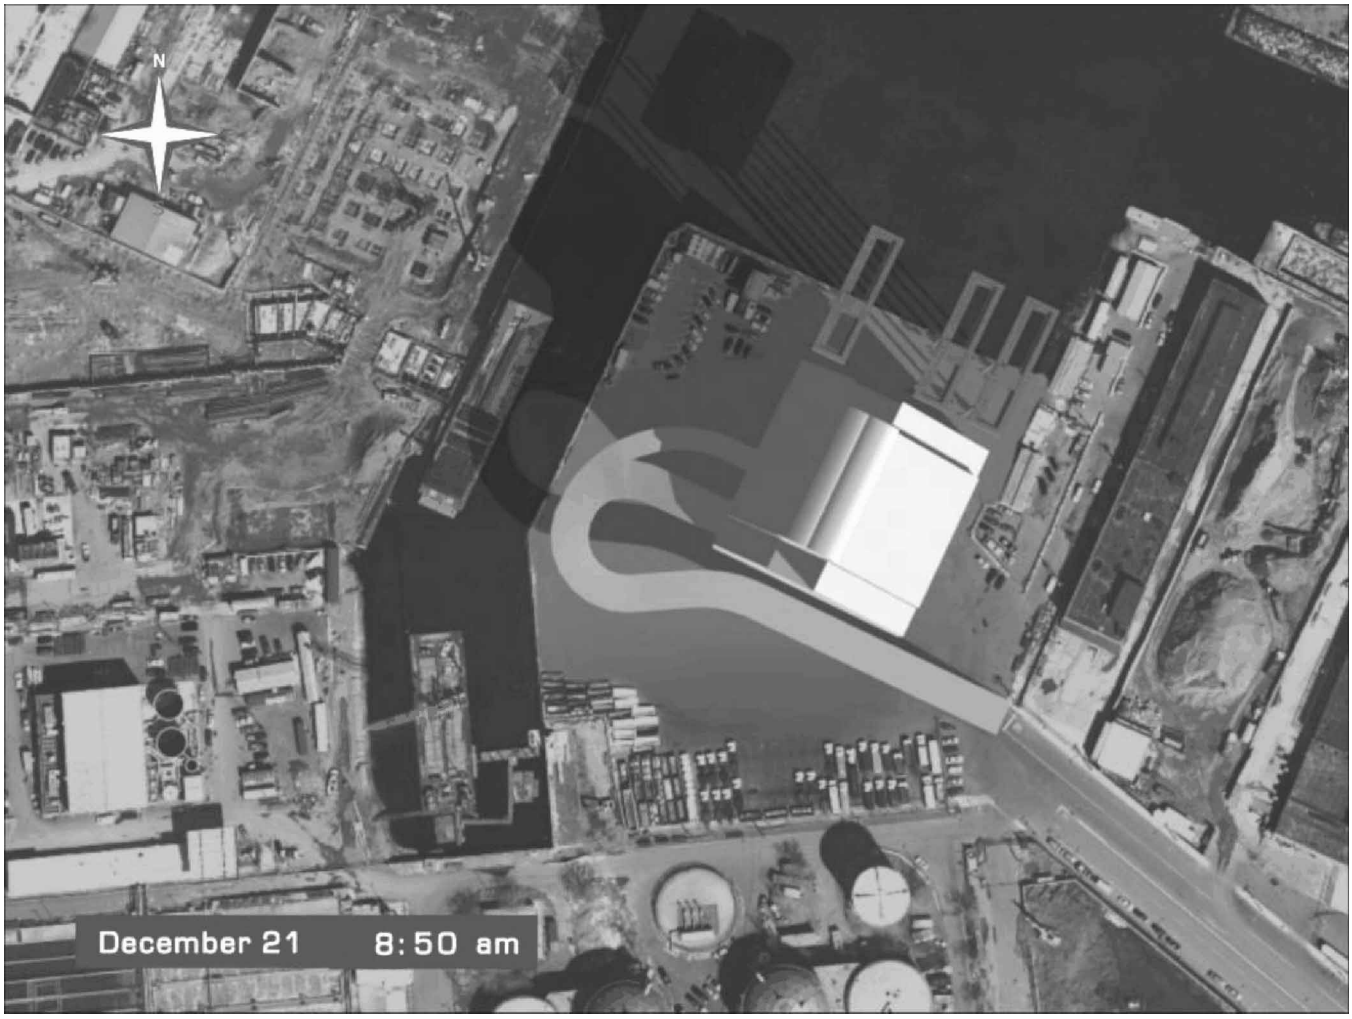

Figure 20.7-4 Shadow Diagram

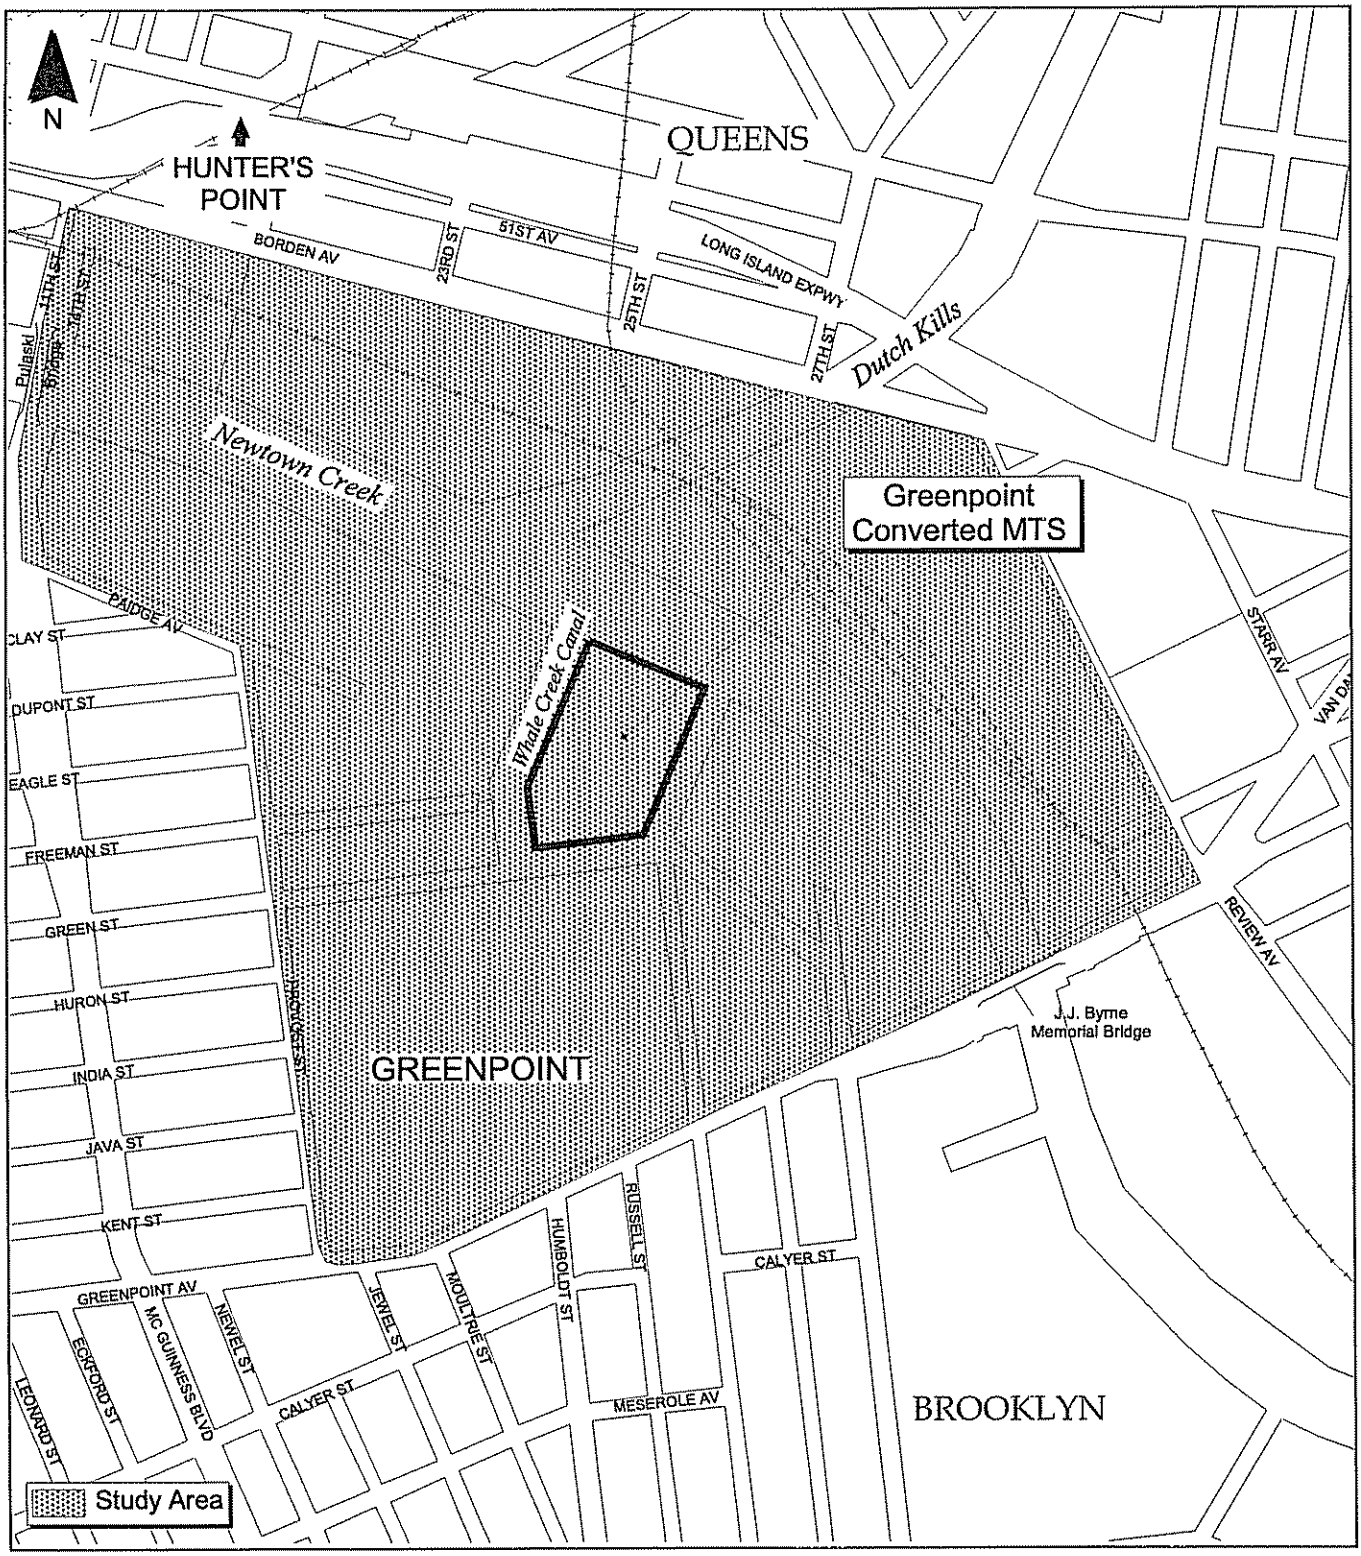
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

20.8 Neighborhood Character

20.8.1 Existing Conditions



20.8.1.1 Definition of the Study Area

The neighborhood character study area is defined by predominantly industrial land use and visual quality, which are the two major factors contributing to the neighborhood character of the site and surrounding properties. The study area is defined by physical landscape elements that distinctly mark the edge of a specific neighborhood character, visually insulate the site and study area or physically obstruct pedestrian and vehicular access to it from outlying areas.

With these criteria, the study area is bounded by McGuinness Boulevard and the Pulaski Bridge, Paidge Avenue and Provost Street to the west; Greenpoint Avenue and the J. J. Byrne Memorial Bridge to the south and east and Borden Avenue to the north (see Figure 20.8-1). It includes a portion of the industrial waterfront in Sunnyside, Queens, north of the site across Newtown Creek. Although the creek clearly is a physical barrier limiting access to the site from the north, this portion of the Queens waterfront is included in the study area because it mirrors the industrial character of the study area south of the creek and is visually connected with it. While the land uses and visual quality along most of the Newtown Creek waterfront beyond the study area are similar to that within the study area, Greenpoint Avenue and McGuinness Boulevard — the major arterial roadways that cross the creek — effectively define the eastern and western ends of the study area.

20.8.1.2 Description of Neighborhood Character

The study area, which encompasses a working waterfront, is characterized by large-scale, municipal facilities and water-dependent industrial uses on large lots. It contains no residential uses, although there are some mid-block residential uses just beyond, west of Provost Street on the Brooklyn side. Consistent with a heavily industrial area, there are no sensitive visual resources or unique features, and the streets are generally not well suited to pedestrian activity.

Site delineations are approximate

HDR | HydroQual | URBITRAN | PB | EEA Cambridge Environmental Inc

Figure 20.8-1 Neighborhood Location
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

The Newtown Creek WPCP to the south of the site comprises a large portion of the study area. In addition, there are fuel storage facilities along the waterfront and entire blocks under construction for the Newtown Creek WPCP expansion. Similarly, the northern portion of the study area in Queens is comprised of industrial activities and related unbuilt spaces.

20.8.2 Future No-Build Conditions

The expansion of the Newtown Creek WPCP would contribute to the industrial character of the area and will change the street pattern in the immediate area. Designs for the WPCP expansion include a nature walk, a pool and park for children adjacent to it and the incorporation of public art installations along the perimeter of the WPCP site. However, there are no other known plans for development on the site or in the study area that would potentially lead to changes in neighborhood character. This portion of industrial waterfront would be more isolated in 2006 than currently by the expansive WPCP facility. The incinerator will be demolished, but the site will remain DSNY property and Future No-Build Conditions are otherwise expected to be the same as Existing Conditions.

20.8.3 Potential Impacts with the Greenpoint Converted MTS

No change to the industrial neighborhood character would be expected because the Greenpoint Converted MTS would be a reactivation of waste-handling operations on a site that, except for the demolition of the incinerator, would remain otherwise unchanged. Technical analyses predict no unmitigatible impacts associated with traffic, air, odor or noise would result. Moreover, the area will be more industrial and isolated, making it less likely that the site would be observable from much of its surroundings in the neighborhood character study area. Therefore, no impacts to neighborhood character are predicted.

20.9 Natural Resources

20.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from the Greenpoint Converted MTS.

20.9.1.1 Definition of Study Area

The study area includes the site and the waterfront section that is bulkheaded and bounded by Newtown Creek to the north and Whale Creek Canal to the west (see Figure 2.4-1). The existing MTS, incinerator and associated parking areas occupy the entire upland portion of the site. This part of the study area and the surrounding neighborhood areas are completely developed and, therefore, have very limited terrestrial natural resources. Such resources that do exist are discussed in following sections. Because Future Build Conditions would include dredging of bottom sediments and construction of a new MTS, a description of aquatic communities is included.

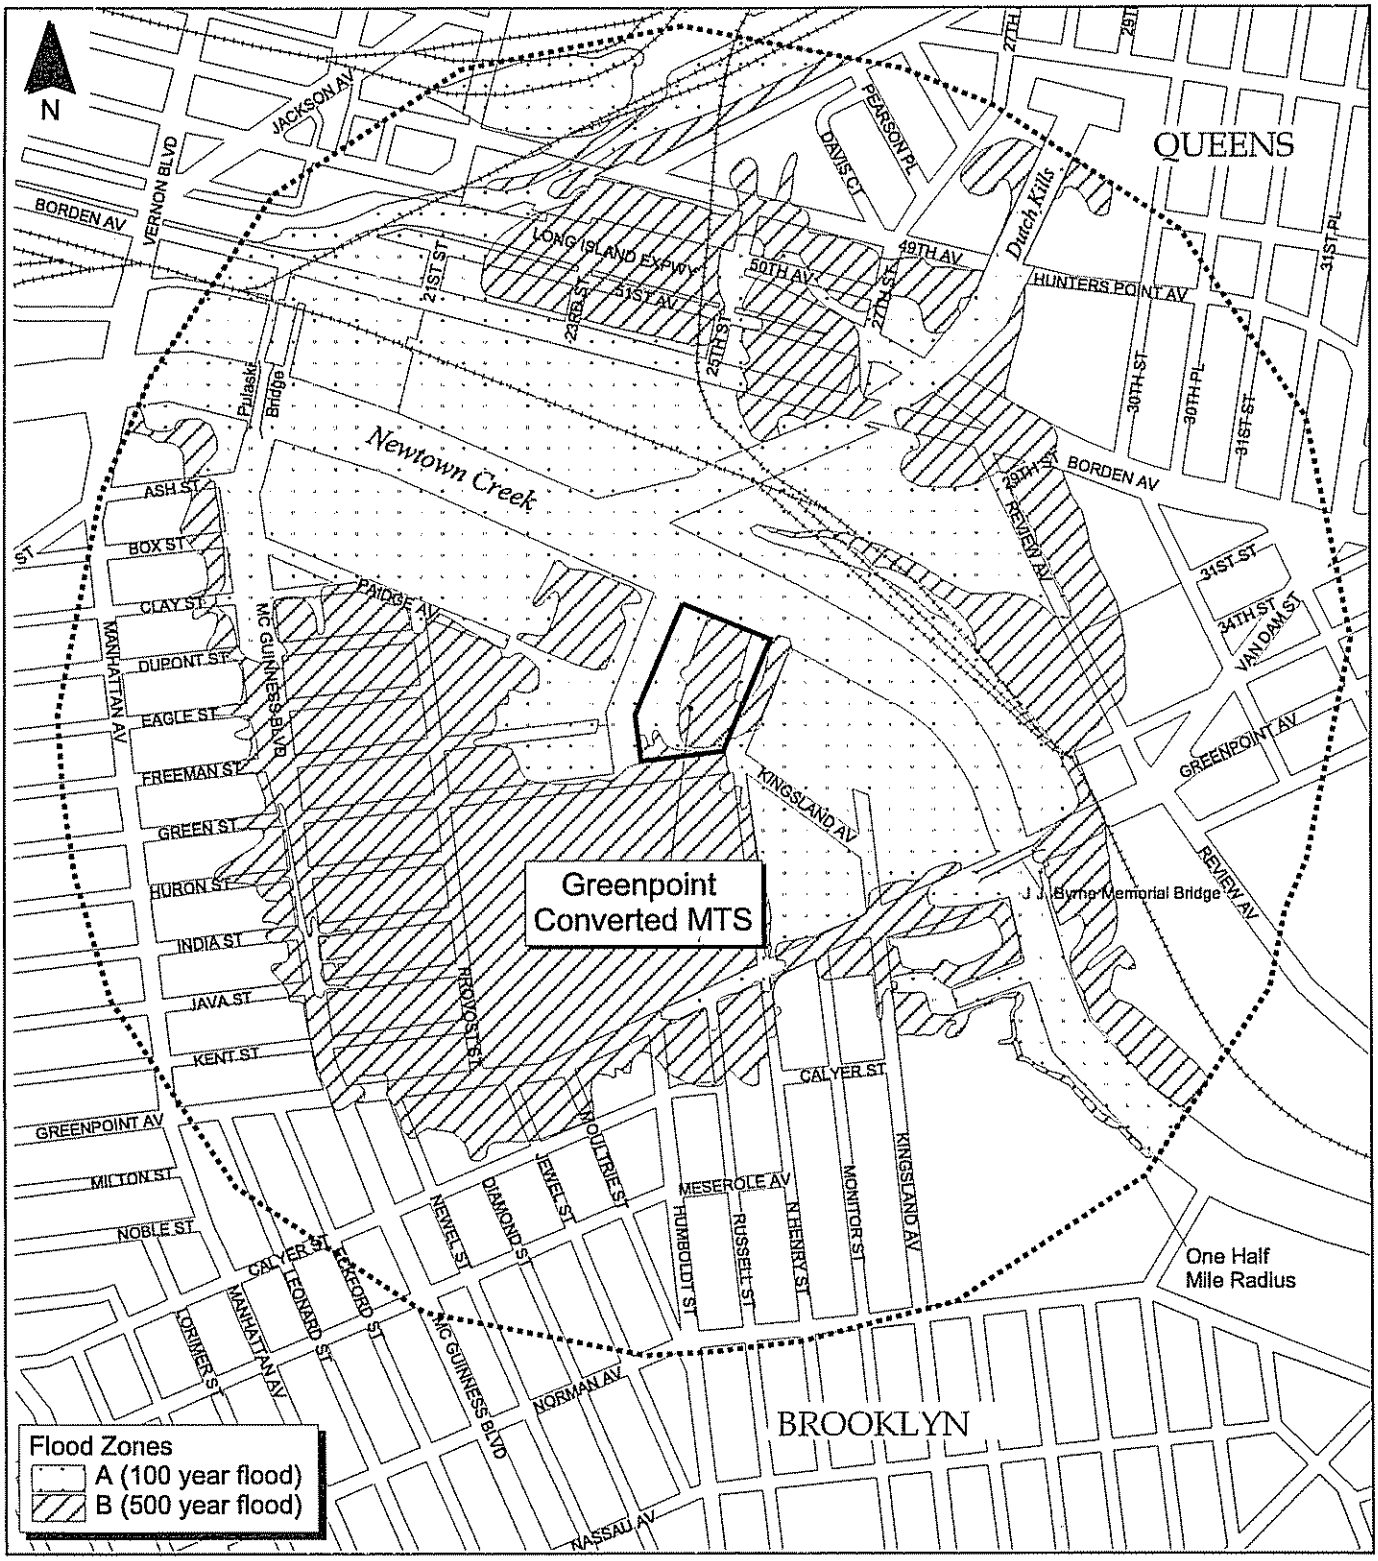
20.9.1.2 Geology

Based on borings conducted for the *MTS Conversion Conceptual Design Report* (2003), the geology of the site consists of bedrock, located at depths ranging from 59 to 79 feet below grade, overlain with multiple layers of sediment. The first layer, the surficial stratum, ranged in thickness from 25 to 36 feet and consisted of loosely packed, silty sand with miscellaneous aggregate including deleterious materials. A compressed organic silt layer, approximately 4 feet in thickness, was located beneath the surficial stratum, which was in turn underlain with an approximately 8-foot-thick layer of dense, silty sand. A stiff layer of varied clay and silt ranging in thickness from 18 to 30 feet was encountered beneath the fill, organic silt, and silty sand. Lastly, a 4- to 12-foot-thick layer of medium dense silty sand overlaid the bedrock, which consisted of a hard, slightly weathered, gray, fine-grained gneiss.

Surface sediment collected from the site in 2003 indicates the sediment make-up to be 95.2% silt and clay, 4.8% sand and 0.1% gravel.[5] There were approximately 155,916 mg/kg TOC in the sediment. The sediment was found to be somewhat degraded due to contaminants in the sample material. The metal with the highest concentration in the sediment was lead, with 288.33 mg/kg. Barium and chromium also had high concentrations at this location, with 128.83 mg/kg and 117.33 mg/kg, respectively.

20.9.1.3 Floodplains

The site is constructed within the 100-year coastal floodplain (see Figure 20.9-1). No intertidal wetlands exist in the study area. Newtown Creek and Whale Creek, which are NYSDEC-designated littoral zones, are part of the study area (see Figure 20.9-2).



20.9.1.4 Ecosystems

The site is essentially fully developed with the existing MTS and incinerator buildings. Parking areas and paved roadways comprise the remainder of the site, leaving little terrestrial natural resources to be impacted. A few opportunistic species of Japanese knotweed (*Polygonum cuspidatum*), eastern cottonwood (*Populus deltoides*) and tree-of-heaven (*Ailanthus altissima*) were observed on the far side of the barge basin bordering the adjacent property on the east side of the study area and to the south along the fence line between the incinerator and the adjacent oil storage facility. The vegetative cover was too sparse in these areas to be mapped.

A field program that took place in 2003 was designed to fully characterize the marine biological resources of the study area. The program included monthly sampling for adult finfish, finfish eggs and larvae, and water quality; and quarterly sampling for benthic organisms and sessile colonizing organisms. Results of the program are presented in the following paragraphs.

Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The sediment and water surrounding the Greenpoint Converted MTS are highly contaminated. Visible oil slicks and floating debris were seen in the water, water quality was poor and the sediment held the highest metal concentrations of the eight MTSs studied. There are two major stressors on the environment surrounding this facility. One, it is located directly across from a scrap metal facility that loads shredded metal pieces to barge for transport. Metal dust and pieces are constantly falling into the water, leading to increased metal concentrations in the sediment. And two, the facility is located along Newtown Creek, a narrow, organically enriched waterway that is not strongly influenced by currents. These two stressors surely influenced the marine communities described below.

Ninety-eight (98) adult finfish, representing 16 species, were collected at the Greenpoint Converted MTS in 2003.[6] The most abundant finfish collected was the striped bass (*Morone saxatilis*). Four species that have EFH listing were collected at the Greenpoint Converted MTS: Atlantic herring (*Clupea harengus*), bluefish (*Pomatomus saltatrix*), winter flounder (*Pleuronectes americanus*) and summer flounder (*Paralichthys dentatus*). Bay anchovy (*Anchoa mitchilli*) eggs and larvae were most abundant at this facility. There were winter flounder and windowpane (*Scophthalmus aquosus*) larvae, both of which are EFH-listed, but no EFH-listed eggs were recovered. A Jaccard's Index[7] also revealed that the Greenpoint Converted MTS had the fewest finfish larvae and egg species in common with the other MTSs studied in 2003.

The most abundant megainvertebrate collected at the Greenpoint Converted MTS was the sea grape (*Molgula manhattensis*). This organism attaches to hard substrate and was most often collected from debris that was removed from the seabed during trawling events. Sevenspine bay shrimp (*Crangon septemspinosa*) was also collected in high numbers. The highest total number and abundance of benthic invertebrates was collected from the Greenpoint Converted MTS. The most abundant species collected was *Streblospio benedicti*, a polychaete worm tolerant of degraded environmental conditions. Abundances of this species were 80,000 individuals per

[6] Ibid.

[7] A Jaccard's Index is a statistical test that shows the similarity of organisms present at compared MTSs. It shows the proportion of the number of species observed in either of two MTSs that occurred in both MTSs The index ranges from zero to one. An index of zero means that the MTSs are completely dissimilar and have no species in common. An index of one means the MTSs have all the same species.

square meter. The dominant epibenthic colonizers were *Corophium insidiosum* (amphipods), *Molgula manhattensis* (sea grape) and *Polydora* sp. (polychaete worms), and hydrozoans, mud and algal film, all organisms tolerant of degraded environments.

The highest number of adult finfish was collected in front of the MTS structure and the highest number of megainvertebrates was collected to the west, both locations closest to the scrap metal facility. Large pieces of debris were encountered monthly during trawling events, especially in front and to the west of the MTS. Several tires, pilings, bumpers, car parts, and an engine block were also encountered. Often within the garbage, finfish and megainvertebrates were encountered. A mini reef-effect was occurring where these animals were using the trash as protective environments and many of the items had encrusting organisms that would provide food for finfish and megainvertebrates. The structure was apparently attractive enough to some organisms that they endured the stressed environmental conditions.

NYSDEC Breeding Bird Atlas records list the common nighthawk (*Chordeiles minor*) as a species suspected of breeding in the area surrounding the study area. The state legal status of this wild bird is Protected-Special Concern, which includes those species that are not yet recognized as endangered or threatened, but for which documented concern exists for their continued welfare in New York, and that are federally-protected wild birds. The peregrine falcon (*Falco peregrinus*), a federally listed endangered species, was not listed as present for this site in the recent response from the USF&WS.

20.9.2 Future No-Build Conditions

If the Greenpoint Converted MTS were not to be constructed, the study area would remain as it is except for the demolition and removal of the incinerator. The limited aquatic and terrestrial natural resources would remain, and the study area would continue to be an ecologically unproductive and stressed urban area.

20.9.3 Potential Impacts with the Greenpoint Converted MTS

20.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

20.9.3.2 Floodplains

Potential development of the Greenpoint Converted MTS would have no effect on the elevation of the site. The facility would be constructed within the 100-year floodplain, and would not include any provisions for raising any portions of the site over this level.

20.9.3.3 Ecosystems

Construction of the Greenpoint Converted MTS would involve removal of the existing MTS and construction of a new, upland facility. The existing platform will be replaced by a smaller platform. This would result in 21,647 square feet of unshaded marine environment that was previously shaded by the existing MTS. Assuming normal operations, this procedure should not involve any measurable impacts to the aquatic or terrestrial natural resources. During the demolition of the existing MTS, the upper organic silts lying beneath the structure that was above water would be disturbed to some degree, resulting in re-suspension of the sediment. However, the amount of re-suspended sediment is expected to be low, and the impacts, if any, highly localized. Turbidity and short-term, lowered, dissolved oxygen are possible, but not measurable, against the normal background fluctuations. Any dredging activities in the area to accommodate barges would result in an immediate, short-term destruction of the benthic invertebrates in the area; however, recolonization of the area by benthic invertebrates could be expected within 6 to 12 months after cessation of dredging activities.[8] Given the relatively small

---

8 U.S. Army Corps of Engineers, 1999 The New York District's Biological monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

size of the project, the low benthic diversity, and the existing impacts to the natural resources of the study area, minimal impact is expected from the disturbance of the environment associated with the Greenpoint Converted MTS. The removal of the existing platform will also remove the existing epibenthic community; however, the new platform will give some surface area, though decreased, for epibenthic communities to colonize the site.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction; flatfish (flounders) are least sensitive. Herring catch was higher at the Greenpoint Converted MTS than flounder catch, so it can be assumed that this site will experience avoidance by this species. Finfish eggs and larvae are more sensitive to suspended sediment and those that settle to the harbor floor may be smothered by sediment. The number of finfish eggs and larvae were lower at the Greenpoint Converted MTS than at the other MTSs studied. The lower ichthyoplankton numbers, along with the lesser degree of marine construction (fabrication of a small pier), will minimize impacts to ichthyoplankton. Additionally, larvae exposed to degraded environmental conditions will be able to swim away from the impacted environments.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The proposed plan for the Greenpoint Converted MTS is for a decrease of 21,647 square feet of pier. This will result in decreased shading that will allow more sunlight for primary production in the area. The smaller platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[9] Epibenthic communities, however, will have a smaller surface area to colonize, but the decrease should not be significant, and finfish should return to the area with the return of food sources.

---

9 Hudson River Center Site Aquatic Environmental Study Final Report, 1988. Prepared for New York City Public Development Corp by EEA, Inc.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by EEA in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[10]

Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as they provide shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. However, because the decrease in shading over water is very small, there are not expected to be significant community changes. There is a possibility of a slight shift in the finfish community with the decrease in over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

Construction of the new upland facility would not have any significant impact on the few areas of vegetation present on the site. Existing on-site buildings and paved parking areas have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Vegetation observed on the site was opportunistic weeds and plants, none of which were rare, endangered or particularly important from an ecological perspective. No significant terrestrial impacts would result from the Greenpoint Converted MTS because the site is already fully developed and the creek is heavily contaminated. The construction of a smaller platform will eliminate some shading of the marine environment in this area, lending to more primary production capabilities in the water column.

According to the Atlas of Breeding Birds in New York State, the common nighthawk nests on flat-roofed structures in cities and towns and feeds upon insects during flight. The Greenpoint Converted MTS is not likely to directly impact any potential nesting habitat or prey species that the nighthawk depends upon.[11]

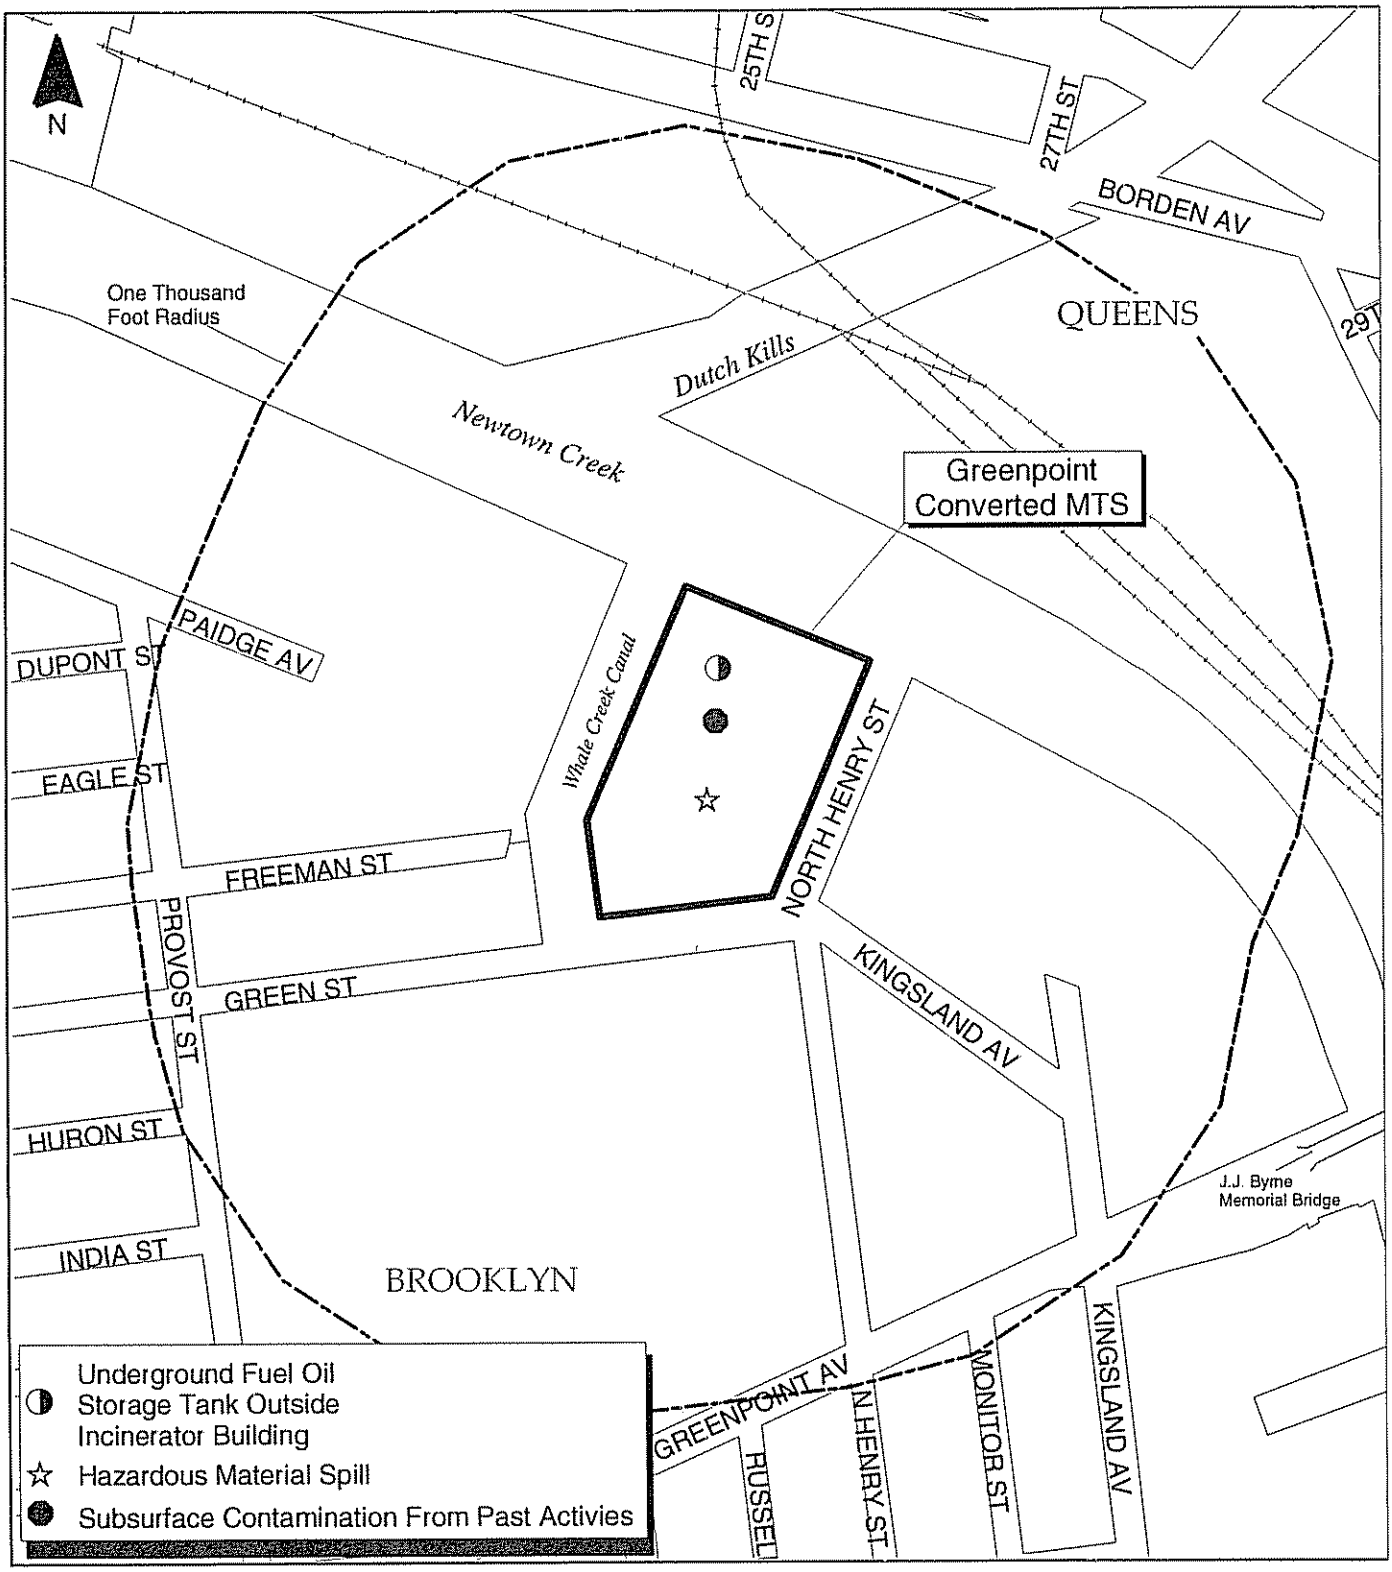
20.10 Hazardous Materials



20.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in April 1999 and updated in February 2003. It included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the FDNY for UST records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted, most recently in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors. Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

20.10.1.1 Definition of Study Area

The study area includes the site and neighboring properties within a 1,000-foot radius (see Figure 20.10-1).

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

20.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater and building components/equipment within the study area where the presence or likely presence of hazardous materials exists and implementation of the Greenpoint Converted MTS could lead to an increased exposure of people or the environment to those hazardous materials. The areas of concern within the study area include:

- Residual contamination of the subsurface soils and groundwater may exist. Portions of the site were occupied by manufacturing facilities and an oil storage terminal. In addition, the site was filled with soils and ash that may have contained hazardous materials.
- The site is adjacent to the former Mobil Oil Brooklyn Terminal, which is listed on the NPL for cleanup under Superfund. The site was assigned an NFRAP designation by the USEPA. An NFRAP designation means that USEPA has completed its preliminary assessment and determined that no further steps are to be taken to list this site on the NPL.
- The incinerator building may contain ACMs and lead-based paints.
- A 5,000 gallon underground oil tank is located adjacent to the incinerator building. On February 22, 2001, the underground tank failed tightness testing. NYSDEC information indicated there was a minimal potential for hazard; however, the spill report is still administratively "active."

A field program to investigate the potential impacts to the soil and groundwater from the historic use of the property as an incinerator and MTS was completed in November 2003 in accordance with a NYSDEC-approved work plan.[12] The field investigation included:

- Performing a ground-penetrating radar and magnetometer survey over accessible areas of the site.
- Collection of one subsurface soil sample for analysis from 11 boring locations.
- Collection of one surface soil sample from one of the boring locations.
- Collection and analysis of one groundwater sample from two boring locations.

[12] New York City Department of Sanitation, October 2003. Final Phase II Site Investigation Work Plan, Greenpoint Marine Transfer Station, Brooklyn, New York.

- Collection and analysis of one groundwater sample from three permanent monitoring wells.
- Laboratory analysis of the soil samples for asbestos, VOCs, SVOCs, pesticides/PCBs and RCRA metals.
- Laboratory analysis of the groundwater samples for VOCs, SVOCs, pesticides/PCBs and RCRA metals.
- Resampling and analysis of soils for total and TCLP lead in all locations where total lead concentrations exceeded NSYDEC TAGM guidelines.
- Determination of the direction of the groundwater gradient by land survey measurements and measurement to the top of the groundwater surface.
- Comparison of the analytical results obtained from the soil and groundwater sampling program with NYSDEC TAGM guidelines.
- Preparation and submittal of a detailed site investigation report.[13]

Low level soil and groundwater contamination was detected throughout many areas of the site. Additional soil sampling and analysis was required to determine if the soil samples that were above the TAGM guidance values exhibited characteristics to be classified as a hazardous waste. No soil samples exhibited hazardous waste characteristics. Soil and groundwater contamination discovered in this area is consistent with the current and former land uses as an incinerator and MTS, and surrounding land uses by petroleum bulk storage facilities and petroleum pipelines.

20.10.2 Future No-Build Conditions

The site would remain as is except for the demotion of the incinerator. Any asbestos-containing building materials and lead based paints found in the incinerator building would be removed prior to demolition in a manner that is consistent with City building codes and practices. Any subsurface contamination existing in the soils and groundwater would remain. An active groundwater recovery and treatment system is operational on adjacent parcels. Exposure to contaminated soils is minimal because most of the site is paved or built over

20.10.3 Potential Impacts with the Greenpoint Converted MTS

[13] New York City Department of Sanitation. July 2004. Phase II Site Investigation, Greenpoint Marine Transfer Station, Brooklyn, New York. Prepared by EEA, Inc.

Low level soil and groundwater contamination is present at the existing MTS; however, this contamination should not prevent development of the site. If the Greenpoint Converted MTS were implemented, any residual contaminated soil would require appropriate disposal in a manner that is consistent with the level of contamination found during the demolition/construction phase. The necessary and appropriate health and safety measures would be used during construction to mitigate and minimize any exposure risk to workers or the general public.

20.11 Water Quality

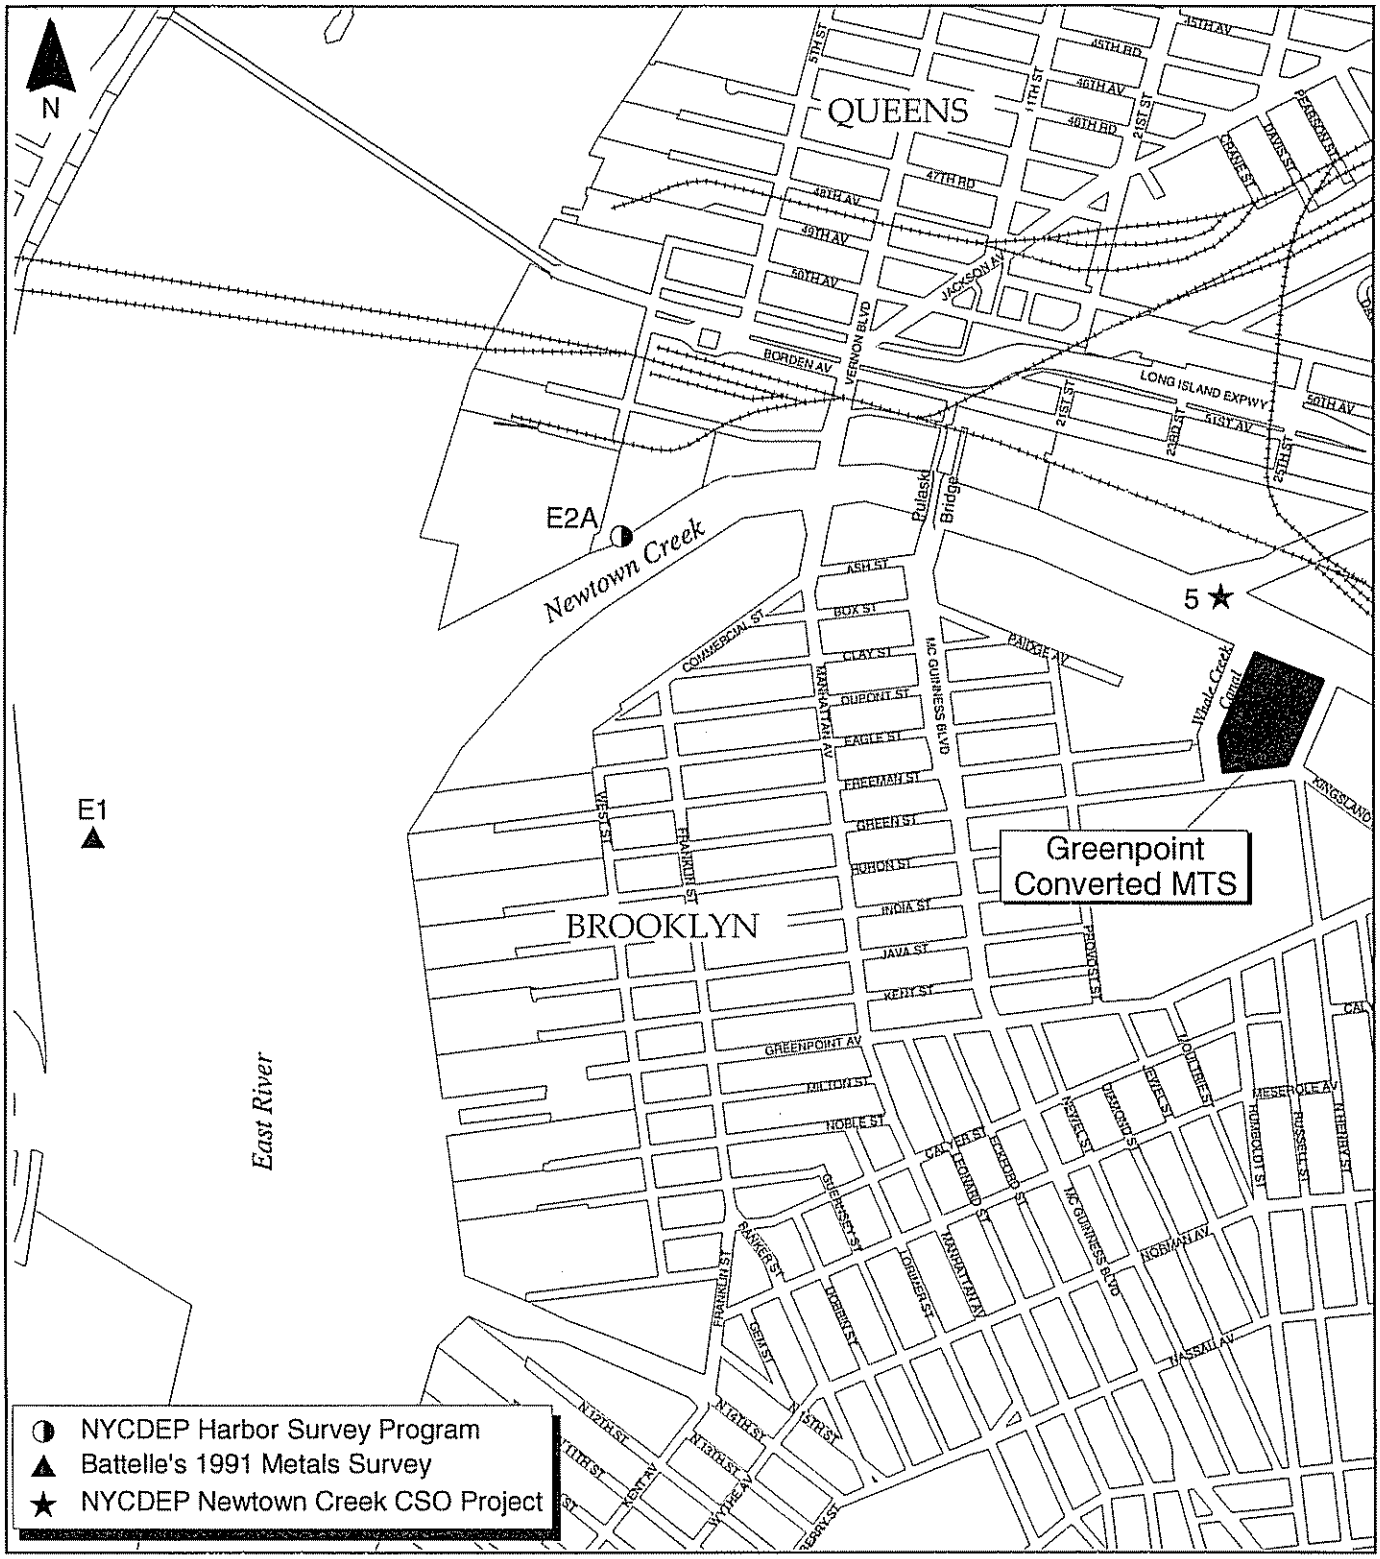
20.11.1 Existing Conditions

20.11.1.1 Definition of the Study Area

The water quality study area encompasses the East River, Newtown Creek and Whale Creek Canal, and also includes discharges from point sources and CSOs within ½-mile of the site.

20.11.1.2 Water Quality

The water quality data for the following monitoring stations, shown in Figure 20.11-1, are generally representative of water quality in the study area:



- NYCDEP Harbor Survey Program – Station E-2A at Newtown Creek; and
- Battelle's 1991 Metals Survey – Station E-1 in the lower East River.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 20.11-1. These standards and guidance values for the waters in the vicinity of the site correspond to "Class SD," which indicates fish survival only.

As shown in Table 20.11-1, the data indicate that, on average, NYSDEC standards and guidance values are met. The mercury concentration for Battelle Station E-1 did not conform to the water quality standard for mercury.

20.11.1.3 Permitted Discharges

A review of the most recently available NYSDEC and USEPA databases indicated that there are sixteen permitted discharges in the vicinity of the site. Those within a ½-mile radius are shown in Figure 20.11-2 and listed in Table 20.11-2. These discharges consist of 11 CSOs and five industrial sites, all of which are permitted by the NYSDEC.

Site delineations are approximate

20.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, estimates of stormwater pollutant loadings were calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and infiltration. A runoff flow of 0.341 cfs was calculated using the impervious site area (5.7 acres), an average rainfall intensity per storm of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 20.11-3, represent the existing loads at the site.

Table 20.11-3
Estimated Existing Pollutant Loads and Runoff Flows
Greenpoint Converted MTS Study Area

Pollutant	Concentration	Pollutant Loading (lbs/day)
Fecal Coliform MPN/100 ml	34,000	62,577[1]
BOD mg/L	11	20
Heavy Metals		
Copper µg/L	35	0.064
Lead µg/L	28	0.052
Zinc µg/L	154	0.283
Total Impervious Area (acre) = 5 69		Runoff Coefficient (C) = 1.00
Average Rainfall Intensity per Storm (inch/hour) = 0 06[2]		Runoff Flow (cfs) = 0.341

Notes:
(1) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
(2) Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

20.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to the ongoing NYCDEP CSO Abatement Program, which will reduce untreated discharges to receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from the City WPCPs; and as other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

20.11.3 Potential Impacts with the Greenpoint Converted MTS

With the development and operation of the Greenpoint Converted MTS, there would be a decrease in the impervious area and therefore the stormwater loadings at the site would decrease. Table 20.11-4 shows the existing impervious area, the change in the impervious area and pollutant loads. With the development of the Greenpoint Converted MTS, conditions would not be significantly different from Future No-Build Conditions.

All solid waste processing at the Greenpoint Converted MTS would occur within structures on the site. All process wastewater from waste handling operations in the facility, such as washdown water, would be routed to an on-site pretreatment system (e.g., oil/water separation). After treatment, the process wastewater would be discharged to the municipal sewer system and, ultimately, to the Newtown Creek WPCP, where it would be treated prior to discharge to the East River and, therefore, would not adversely affect water quality.

Stormwater loads and the impervious area for the Greenpoint Converted MTS, shown in Table 20.11-4, would be expected to decrease from Existing Conditions. According to the 208 Model, the decreased loads would have no significant impact on water quality in the adjacent surface waters.

Unimpeded operation of the Greenpoint Converted MTS may also require dredging activities to construct the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any proposed dredging activities. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant adverse long-term impacts.

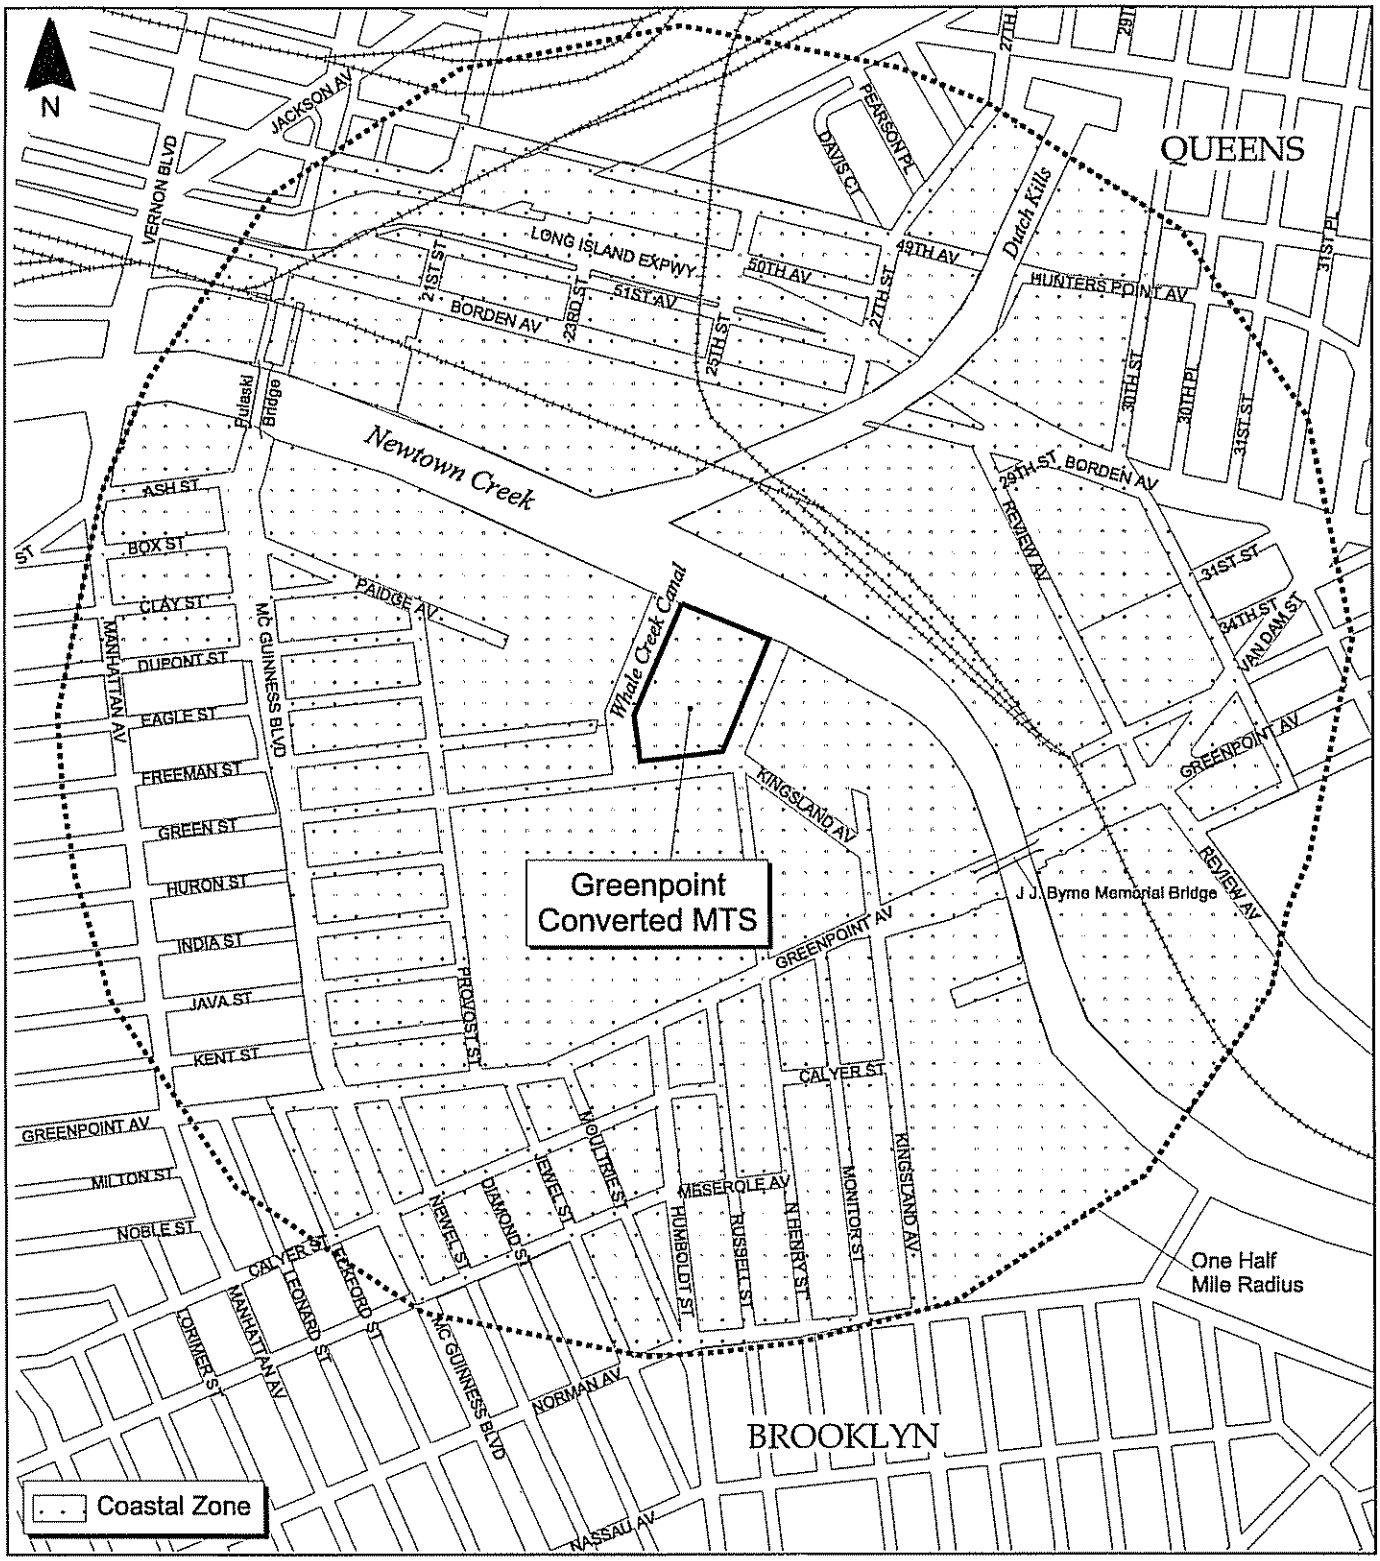
Table 20.11-4
Impervious Area and Estimated Pollutant Loads
Greenpoint Converted MTS

			Estimated Pollutant Loadings/Incremental Change [1]				
Condition	**Total Impervious Area (acres)**	**Change in Impervious Area (acres)**	**Fecal Coliform[2]**	**BOD (lbs/day)**	**Copper (lbs/day)**	**Lead (lbs/day)**	**Zinc (lbs/day)**
Existing Conditions	5.69	0.0	62,577/NA	20/NA	0.064/NA	0.052/NA	0.283/NA
Future Build Conditions	4.90	-0.79	53,908/-8,670	17/-3	0.055/-0.008	0.044/-0.007	0.244/-0.039

Notes:

[1] Incremental change refers to the difference in pollutant loading between the Existing Conditions and Future Build Conditions.

[2] Coliform loads are not shown in lbs/day Loading comparable to MPN/100 ml.



NA = Not Applicable

20.12 Waterfront Revitalization

20.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of Newtown Creek, the Greenpoint Converted MTS would be within the City's coastal zone boundary (see Figure 20.12-1). According to "The New Waterfront Revitalization Program," the Greenpoint Converted MTS would be classified as a water-dependent industrial use and would be located within Reach 13/Newtown Creek as indicated within the "New York City Comprehensive Waterfront Plan – Reclaiming the City's Edge" and the "Plan for the Brooklyn Waterfront." The site would also be located within the Newtown Creek SMIA. The Greenpoint Converted MTS is subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The Greenpoint Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These include subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3, and 8.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. Further discussion is provided below for those policies or subpolicies needing more clarification or found to be inconsistent with a component of the Greenpoint Converted MTS. A description of waste handling operations that would occur at the Greenpoint Converted MTS is provided in Section 2.4.2.

Site delineations and study area boundaries are approximate.

Figure 20.12-1 Coastal Zone Boundary

Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

20.12.2 Consistency Assessment

Policy 1. Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the Greenpoint Converted MTS. As part of the Greenpoint Converted MTS, connections from the new facility to existing utilities (e.g., sewer and electrical connections, etc) in the vicinity would be established.

Policy 2. Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The Greenpoint Converted MTS would be located within the Newtown Creek SMIA and would be located within an existing M3-1 zoning designation at the site of the existing MTS. It would involve the conversion of the existing over-water, truck-to-barge waste MTS into an upland TCB transfer station that would transport DSNY-managed Waste to remote out-of-City disposal facilities via marine transport. A large portion of the Greenpoint Converted MTS would be located on the site of the existing Greenpoint incinerator building, which will be demolished under the Future No-Build Conditions.

The Greenpoint Converted MTS site, as described in Section 2.4.2, would largely represent the reactivation of an existing industrial and water-dependent use. It would serve to maintain this use while restoring and revitalizing existing

industrial waterfront property, and it would be compatible with existing neighboring industrial uses. Upland development would involve construction of four primary components: (1) an elevated access ramp; (2) an enclosed processing building, including the tipping floor, loading floor and pier level; (3) an outside gantry crane system; and (4) a bulkhead/fendering system. The Greenpoint Converted MTS would be consistent with existing land uses in the immediate vicinity of the site and the "Plan for the Brooklyn Waterfront," which recommends the continued industrial use of the site. Although the Greenpoint Converted MTS would not encourage or facilitate the siting of any additional water-dependent uses, it would represent an upland expansion and reactivation of an existing water-dependent use and would be compatible with surrounding uses.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses*

The Greenpoint Converted MTS would involve the demolition of the existing MTS and the construction of a new MTS within the upland portions of the site. It would allow for marine transport of solid waste to licensed out-of-City disposal facilities. Upland development would involve four primary components: (1) an elevated access ramp; (2) an enclosed processing building, which includes the tipping floor, loading floor and pier level; (3) an outside gantry crane system; and (4) a rehabilitated bulkhead and fendering system. The entire pier deck floor area serviced by the gantry cranes would be located outside the confines of the enclosed facility. The Greenpoint Converted MTS would be consistent with existing waterfront uses in the vicinity of the site.

The Greenpoint Converted MTS would require dredging to improve existing water depths at and in the immediate vicinity of the site and allow for the unimpeded operation of barges and tugboats once it became operational. All dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be acquired prior to any proposed dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The Greenpoint Converted MTS would be located within an existing, heavily industrialized area, and would not interfere with any maritime industrial, commercial or recreational vessel activities in the area. Activities within Newtown Creek resulting from the Greenpoint Converted MTS would be limited to barge loading along the pier level and the periodic swapping of loaded barges at the slips. Four of five barges would be filled on a daily basis. These swapping activities would be similar to previous barge activities at the site. Therefore, no adverse impact to other uses within the water body would be anticipated. The Greenpoint Converted MTS would be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The Greenpoint Converted MTS would involve the conversion of the existing over-water MTS where loose waste was placed in open barges, into an upland TCB transfer station where DSNY-managed Waste would be transferred into containers that would be sealed and placed into flat deck barges, then transported to an out-of-City disposal site. All solid waste handling would be done within an

enclosed processing building and, therefore, would be protective of the aquatic environment and surrounding land and water uses. Building ventilation would be maintained under negative pressure, which would maintain dust inside the building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environment. Litter control methods, such as routine sweeping and washing of the tipping floor, would also be implemented at the facility to minimize or eliminate the potential for litter entering surface waters. All process wastewaters would be treated on site prior to being discharged to the municipal sewer system. In addition, any on-site storage of petroleum and handling of unauthorized wastes would be managed in accordance with applicable federal, state and local regulations.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs, Recognized Ecological Complexes, and SCFWHs, the Greenpoint Converted MTS would not be located within any designated areas. It would represent an upland expansion in size of a previous over-water use and would not be anticipated to result in any long-term impacts to natural resources in the vicinity of the site. The Greenpoint Converted MTS would be consistent with this subpolicy.

4.2 Protect and restore tidal and freshwater wetlands.

A review of NYSDEC tidal and freshwater wetland and NWI maps was conducted to determine the presence of wetlands. As noted in Section 20.9.1, the site contains no freshwater wetlands. The Greenpoint Converted MTS would be

within Newtown Creek, which is identified as a littoral zone, a state-designated wetland. The demolition of the existing MTS and subsequent development of the Greenpoint Converted MTS would result in limited, short-term impacts to these tidal wetlands.

Impacts to littoral zones would be minimized due to the impacted nature of the existing waterway, previous and ongoing industrial activities at and in the vicinity of the site, and permitted dredging activities that have historically occurred at the site. The Greenpoint Converted MTS would be largely land-based and would require the demolition of the existing MTS. It will be sited at the approximate location of the Greenpoint incinerator, which will be demolished as part of the Future No-Build Conditions. Dredging would be required to improve existing water depths at and in the immediate vicinity of the site and allow for the unimpeded operation of barges and tugboats once the Greenpoint Converted MTS is operational. Potential impacts due to dredging would be short-term and localized. All dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be acquired prior to any dredging activities. Mitigation, if required, would be proposed during the environmental review and permitting of the Greenpoint Converted MTS to address any potential impacts to wetlands that may occur due to its development. The Greenpoint Converted MTS would, therefore, be consistent with this policy.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

There are no known vulnerable fish or plant species found within the vicinity of the Greenpoint Converted MTS. A review of the "Atlas of Breeding Birds in New York," indicates the Common Nighthawk (*Chordeiles minor*) as a species suspected to be breeding in the area. The Common Nighthawk is classified by the state as a Protected-Special Concern species. As noted in Section 20.9.3, the Greenpoint Converted MTS would not impact these species and their habitats.

The Greenpoint Converted MTS would involve the demolition of the existing MTS and construction of the new facility, which will be located upland to minimize potential impacts to natural resources. Upland development would include an elevated access ramp; an enclosed processing building, which includes the tipping floor, loading floor and pier level; an outside gantry crane system; and a rehabilitated bulkhead and fendering system. Development of the Greenpoint Converted MTS would involve dredging, but potential impacts to plant, fish and wildlife species would be minimized and all dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be obtained prior to any dredging activities.

In addition, all handling and containerization of solid waste would be performed inside the processing building, thereby limiting the risk of an introduction of hazardous wastes or other pollutants into the environment that could impact surrounding fish and wildlife resources. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer systems. Stormwater runoff from the Greenpoint Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The Greenpoint Converted MTS would, therefore, be consistent with this subpolicy.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The Greenpoint Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, the processing areas would be cleaned on a regular basis. All sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site disposal treatment system that would include an oil-water separator, and then discharged to the municipal sewer system. In addition, the slope of the tipping

floor would prevent the build-up of free liquids by directing all liquids to drains. Stormwater runoff from the Greenpoint Converted MTS would be managed in accordance with applicable regulations.

5.2 *Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.*

During the development and operation of the Greenpoint Converted MTS, BMPs would be used to the extent possible to minimize any nonpoint discharges. The Greenpoint Converted MTS would comply with applicable federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be performed inside the enclosed processing building, limiting the risk for the introduction of hazardous wastes or other pollutants into the environment. During construction, non-structural (such as silt curtains) or structural measures would be used to manage erosion and stormwater runoff. In addition, litter control methods would be implemented at the facility to minimize or eliminate the potential for litter to enter surface waters.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

Development of the Greenpoint Converted MTS would include demolition of the existing MTS. Barges would be staged along a refurbished or reconstructed bulkhead wall for loading and unloading of containers. Dredging would be needed to remove accumulated sediments in the barge berthing areas to provide adequate draft for barges and tugboats. Potential impacts due to dredging would be short-term and localized. All dredging would be conducted in compliance with applicable federal, state and local regulations and removed materials would be disposed of at a permitted upland facility.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The Greenpoint Converted MTS would result in no adverse impact to the quality or quantity of groundwaters or surface waters at or in the immediate vicinity of the site. Applicable and appropriate measures would be implemented at the Greenpoint Converted MTS in accordance with federal, state and local regulations. The Greenpoint Converted MTS would be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 *Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.*

According to a review of the FEMA National Flood Insurance Program maps, the site is located within the 100-year flood plain (Zone A) and the 500-year flood plain boundary (Zone B). Development of the Greenpoint Converted MTS would not affect the potential for flooding or erosion. All demolition and redevelopment activities would comply with applicable building code requirements and, to the extent practicable and necessary, non-structural (such as silt curtains) or structural measures would be implemented to minimize damage from flooding or erosion.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 *Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.*

The Greenpoint Converted MTS would involve the management and processing of solid waste through a TCB system. Waste would be transported in waterproof, airtight, sealed containers. All waste handling operations would occur inside an enclosed processing building, which would minimize the escape of litter into the surrounding water body. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours of tipping. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations (6NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the Greenpoint Converted MTS. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility. Litter control methods would be implemented at the facility to minimize or eliminate the potential for litter entering surface waters. The Greenpoint Converted MTS would not result in adverse impacts and would operate in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

On-site storage of petroleum or hazardous materials related to the operation of the Greenpoint Converted MTS would be minimal and all storage would be in accordance with applicable federal, state and local regulations. Spill prevention and control plans would be used to prevent any hazardous materials from entering the environment.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.

Due to the existing, heavy industrial uses at and in the immediate vicinity of the Greenpoint Converted MTS, public access would generally not be compatible with the principal use of the site. Therefore, this subpolicy is not applicable.

8.2 Incorporate public access into new public and private development where compatible with proposed land use and coastal location.

The Greenpoint Converted MTS would be a stand-alone, water-dependent facility fronting Newtown Creek. Public access would not be compatible with the Greenpoint Converted MTS; however, its development would not preclude any future development of public access along Newtown Creek.

8.3 Provide visual access to coastal lands, waters and open space where physically practical.

The Greenpoint Converted MTS would be compatible and consistent with adjacent properties along the waterfront and would not obstruct or impair visual access to coastal lands, waters or open space. It would involve construction of a new TCB MTS at the location of the incinerator, which will have been demolished, but it would have little effect on the visual quality of its industrial setting. The barge slip gantry cranes were designed as slender structures to minimize their visual impact. As discussed in Section 20.7.3, visual access to the coastal lands is minimal and, therefore, no impacts to visual access would be anticipated. See also response to Subpolicy 9.1.

8.4 Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

No mapped parklands or open space areas have been identified at or within the immediate vicinity of the site. Therefore, this subpolicy is not applicable.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The Greenpoint Converted MTS would not result in a significant impact on views, as noted in Section 20.7.3. Based on the information discussed in that section, the Greenpoint Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The Greenpoint Converted MTS would be an upland expansion of an existing over-water use and would pose no new impacts to scenic values associated with natural resources. It would be compatible with surrounding buildings and would be consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

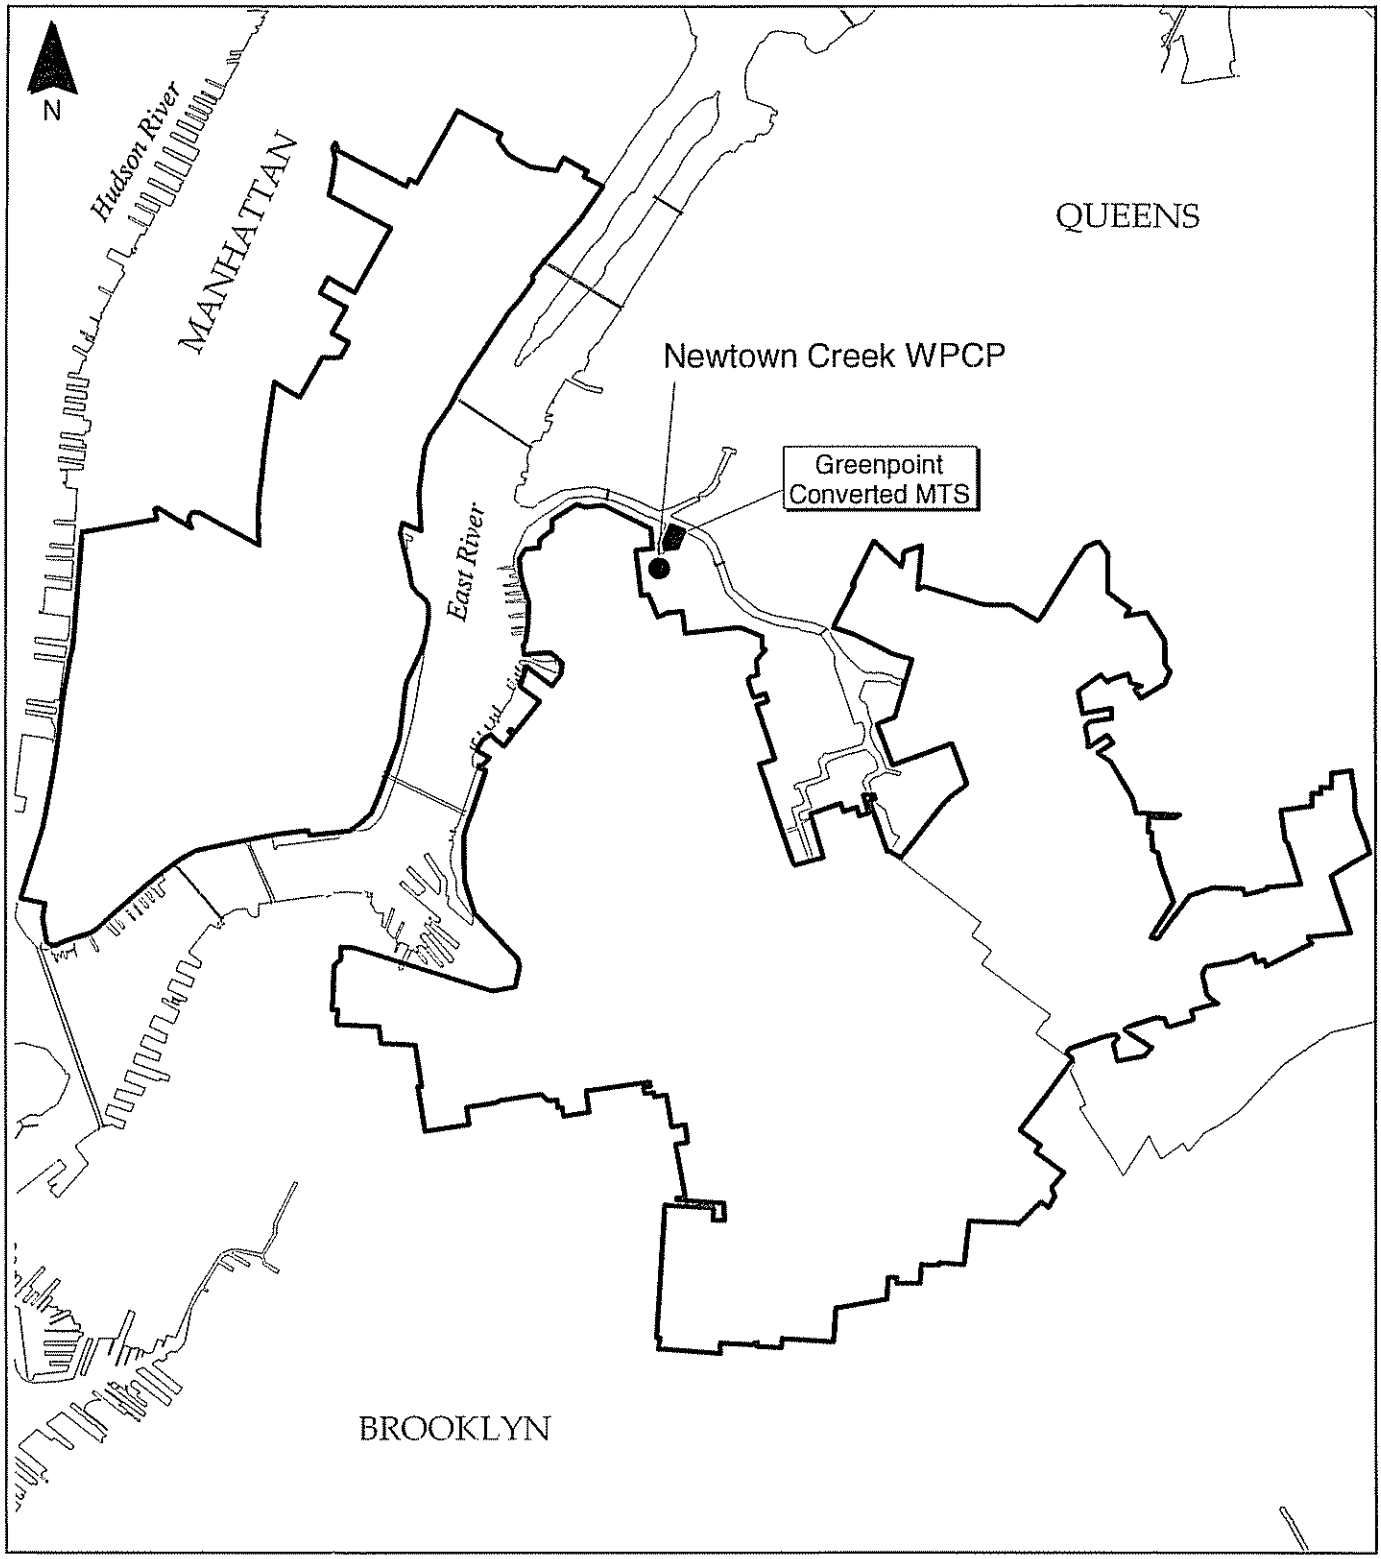
No effects on cultural resources would result from the Greenpoint Converted MTS, as stated in Section 20.6.3. Based on the information presented in that section, the Greenpoint Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site or in the immediate vicinity of the site. This subpolicy is, therefore, not applicable.

20.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

20.13.1 Existing Conditions



20.13.1.1 Water Supply

Water is supplied to the existing Greenpoint MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. A 6-inch-diameter water line provides potable water for both process and sanitary requirements. Adjacent to the existing site is a pump house connected to an incoming 6-inch water line, which ensures adequate pressure for the fresh water fire system. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

20.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Newtown Creek WPCP, which serves portions of Manhattan, Queens and Brooklyn. The WPCP drainage area is illustrated in Figure 20.13-1. From July 2002 through June 2003, the WPCP treated an average of 216 mgd of wastewater under dry weather flow conditions and an average flow of 238 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 20.13-1). The maximum dry weather flow during this period was 239 mgd in August 2002 and the maximum average flow was 259 during June 2003. Effluent from the plant is discharged to the East River and is regulated by NYSDEC under the SPDES program. The current SPDES permit limit for flow to the Newtown Creek WPCP is 310 mgd. It is estimated that current on-site employee water usage is about 75 gpd. This estimate is based on three employees (one guard per shift, three shifts per day) using 25 gallons per person per day (2001 CEQR Technical Manual). As the facility does not currently accept waste, no significant process water is used and no operations personnel are currently assigned to the site.

Duplex sewage ejection pumps within the existing Greenpoint MTS convey wastewaters to the municipal sewer system through a 6-inch-diameter pipe that discharges to a 15-inch sewer (combined sanitary and stormwater system) running south along North Henry Street. The sewer connects to an interceptor that eventually conveys the wastewater to the Newtown Creek WPCP for treatment.

March	218	240
April	207	228
May	201	219
June	218	259
Average Effluent	**216**	**238**

Note:
[1] Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

20.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each of the three employees at the existing MTS produces approximately 9 pounds of solid waste per week for a facility total of 27 pounds per week (approximately 4 pounds per day). The solid waste is collected by DSNY personnel and transported by truck to an appropriately licensed solid waste management facility.

20.13.1.4 Energy

Consolidated Edison of New York supplies electrical service to the facility. A review of applicable service plans shows electric lines along North Henry Street. Utility maps from KeySpan show that there is a 2-inch gas main running up North Henry Street that serves the facility. Current electricity and gas utilization is negligible due to the low staffing levels for security.

20.13.2 Future No-Build Conditions

The existing Greenpoint MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near the Existing Conditions levels for security employees. Wastewater flows to the Newtown Creek WPCP would continue to increase and would be projected to be 240.4 mgd by 2006.

20.13.3 Potential Impacts with the Greenpoint Converted MTS

20.13.3.1 Water Supply

The Greenpoint Converted MTS would have up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The Greenpoint Converted MTS would have no impact on the existing system's ability to supply water reliably. According to NYCDEP, the water pressure in the area is about 45 psi. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

20.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,330 gpd for the Greenpoint Converted MTS, the small quantities of wastewater sent to the Newtown Creek WPCP would not significantly impact the sewage flow rate or the ability of the Newtown Creek WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 240.4 mgd in 2006, which would be well below the permitted capacity of 310 mgd. In addition, the new wastewater flows from the proposed action would not result in a significant increase in combined sewer overflows (CSO).

20.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees per day, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the Greenpoint Converted MTS and would not significantly impact the system.

20.13.3.4 Energy

The Greenpoint Converted MTS would require approximately 5.51E+10 BTU/year of electricity to operate the facility. Natural gas facility heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the Greenpoint Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

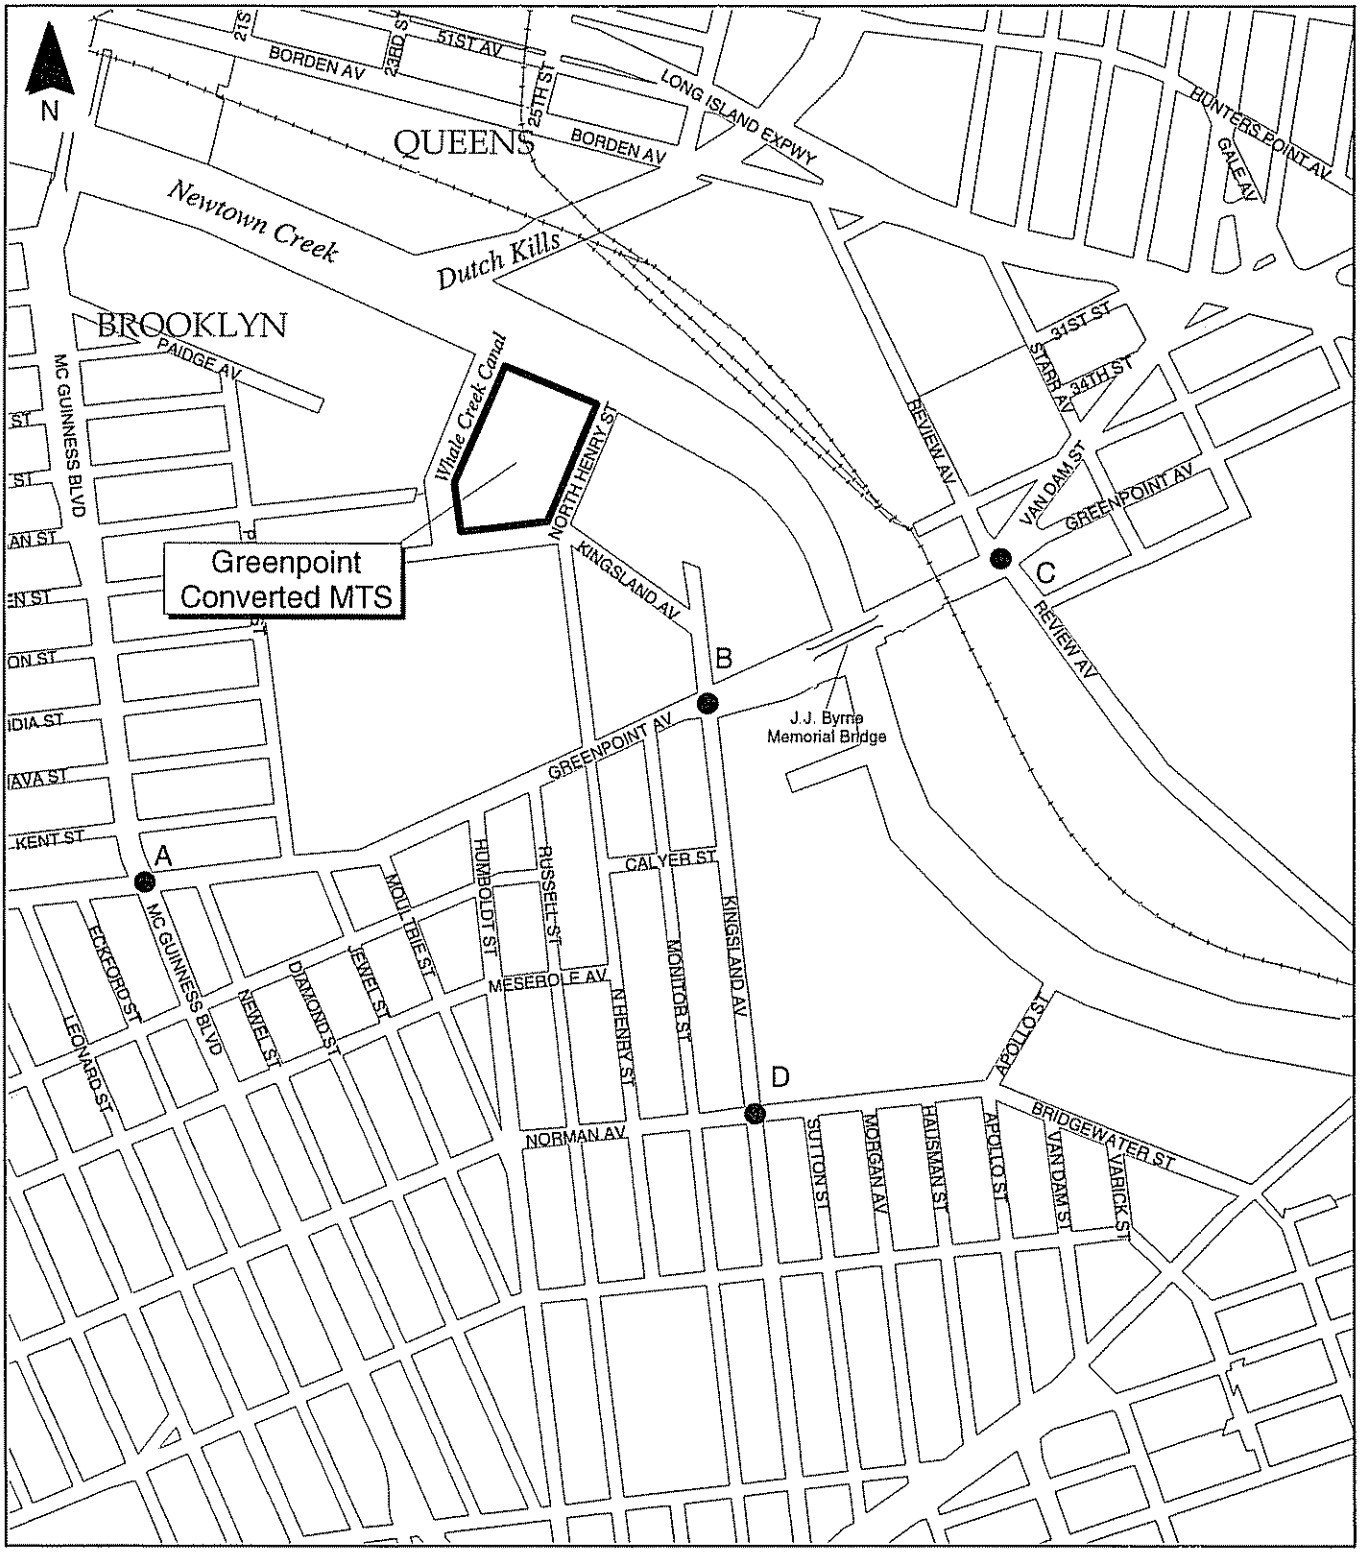
Consolidated Edison was also notified of the natural gas requirements of the Greenpoint Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts on the utility.

20.14 Traffic, Parking, Transit, and Pedestrians

20.14.1 Introduction

The Greenpoint Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

20.14.2 Existing Conditions



20.14.2.1 Definition of Study Area

The traffic analysis study area is broad and includes the Greenpoint and Long Island City neighborhoods of Brooklyn and Queens, respectively. It includes the corridor along Greenpoint Avenue that is bounded by McGuiness Boulevard on the west and the LIE on the east. The traffic study area is predominantly light industrial in nature. There are no CEQR-defined areas of concern located within the study area. Figure 20.14-1 shows the locations of the intersections selected for analysis (locations A through D). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points more than ½-mile away in conjunction with local truck routes. Eastbound and westbound collection vehicles would approach the site along Greenpoint Avenue and turn northbound onto Kingsland Avenue. Northbound collection vehicles would approach from the south via Kingsland Avenue.

20.14.2.2 Surface Network

Two major highways, the predominantly east-west LIE and the predominantly north-south BQE, service the traffic analysis study area. Greenpoint Avenue is a local truck route that provides access from the east and west of the site. McGuiness Boulevard and Kingsland Avenue are local truck routes that provide access from south of the site. Maps showing all major truck routes and local truck routes in Brooklyn and Queens are provided in Section 3.16 (see Figures 3.16-3 and 3.16-5).

Site delineations are approximate.

HDR | HydroQual | URBITRAN | PB | EEA Cambridge Environmental Inc

Figure 20.14-1 Traffic Analysis Study Area

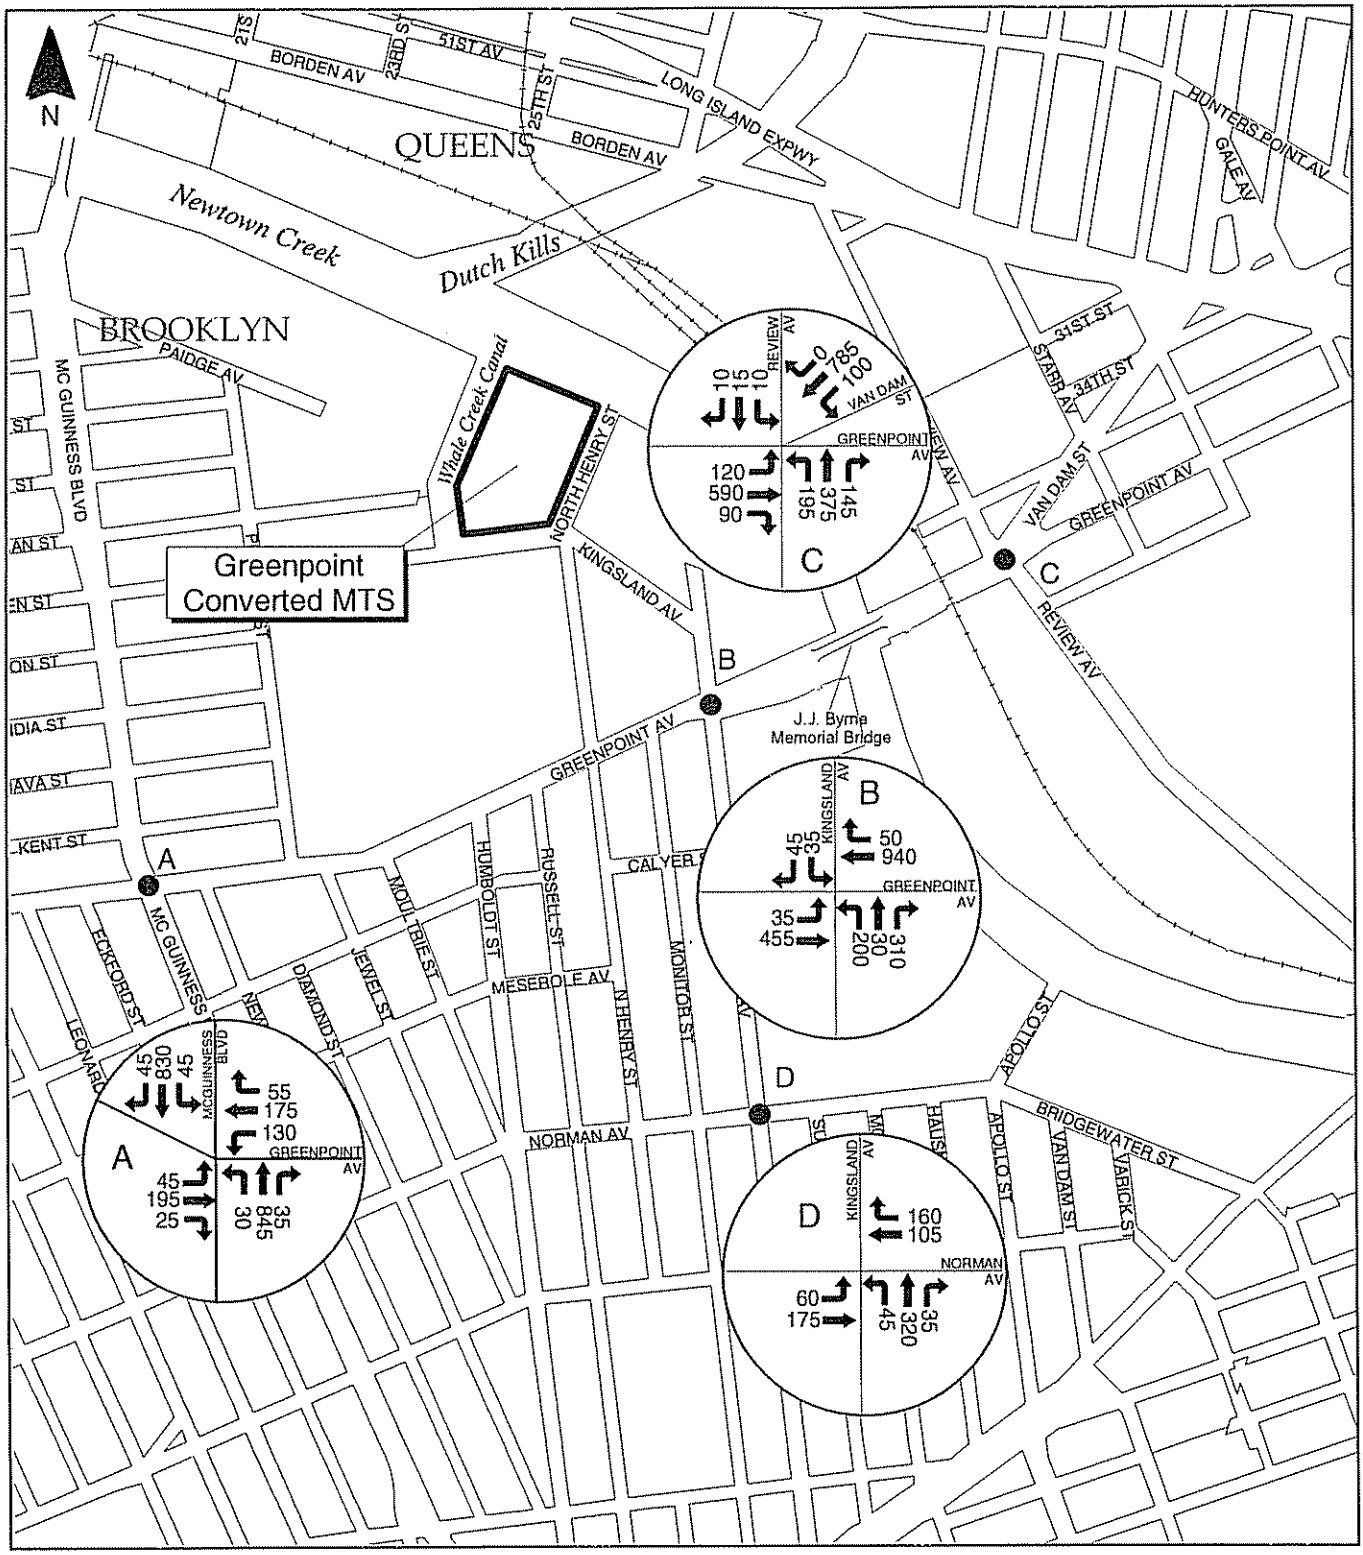
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Greenpoint Avenue (and Van Dam Street in Queens) and McGuiness Boulevard are principal arterials that provide access to the LIE and BQE, respectively. Norman Avenue is a minor arterial that provides local east-west truck access through the industrial areas of Greenpoint. Kingsland Avenue is a northbound collector road for local traffic and provides access for local and industrial traffic between the BQE (and points south) and Greenpoint Avenue. Review Avenue is a minor arterial and a designated truck route that services the industrial areas north and adjacent to Newtown Creek in Queens.

DSNY and other agency collection vehicles approaching the Greenpoint Converted MTS from the LIE would exit at Greenpoint Avenue and travel west towards the Converted MTS. Other vehicles approaching the Converted MTS from Queens would follow Van Dam Street or Review Avenue to Greenpoint Avenue. DSNY and other agency collection vehicles traveling to the facility from the south would approach the area using the BQE and exit onto Meeker Street. Other vehicles would travel north along Vandervoort Avenue to Meeker Street. From Meeker Street, the vehicles would proceed north along McGuiness Avenue or along various local roads to Norman Avenue and then to Kingsland Avenue. All inbound DSNY and other agency collection vehicles converge at the intersection of Greenpoint Avenue and Kingsland Avenue. At this intersection, all vehicles would proceed north along Kingsland Avenue to the Converted MTS. Exiting vehicles would follow the same truck routes back to their respective CDs, except for vehicles that traveled north on Kingsland Avenue. These vehicles would turn west on Greenpoint Avenue, then travel south on Monitor Street to Norman Avenue, and then follow truck routes back to their CDs.



20.14.2.3 Existing Traffic Operations

The four intersections listed below were identified for analysis because they are the most likely to be impacted by the Greenpoint Converted MTS. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Greenpoint Avenue and McGuiness Boulevard – Signalized Intersection (see Figure 20.14-1 – location A)
- Greenpoint Avenue and Kingsland Avenue – Signalized Intersection (see Figure 20.14-1 – location B)
- Greenpoint Avenue and Review Avenue and Van Dam Street – Signalized Intersection (see Figure 20.14-1 – location C)
- Norman Avenue and Kingsland Avenue – Signalized Intersection (see Figure 20.14-1 – location D)

Greenpoint Avenue (and Van Dam Street in Queens) and McGuiness Boulevard are principal arterials that provide access to the LIE and BQE, respectively. Norman Avenue is a minor arterial that provides east-west access through the industrial areas of Greenpoint. Kingsland Avenue is a northbound collector road for local traffic and provides access for local and industrial traffic between the BQE (and points south) and Greenpoint Avenue. Review Avenue is a minor arterial that services the industrial areas north and adjacent to Newtown Creek in Queens.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between February 4 and February 6, 2003, while ATR counts were conducted between February 3 and February 7, 2003. Figures 20.14-2, 20.14-3 and 20.14-4 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:30 a.m. and 8:30 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 4:45 p.m. and 5:45 p.m. Table 20.14-1 presents the v/c ratio, delay and LOS for the four intersections during the AM, Facility, and PM peaks.

Existing truck traffic through most of the intersections was relatively high. The percentages of trucks increases steadily during the morning hours, remaining at between 20% and 25% during mid-day hours, then decreases to 12% or lower during the PM peak hours.

20.14.2.3.1 LOS at Signalized Intersections

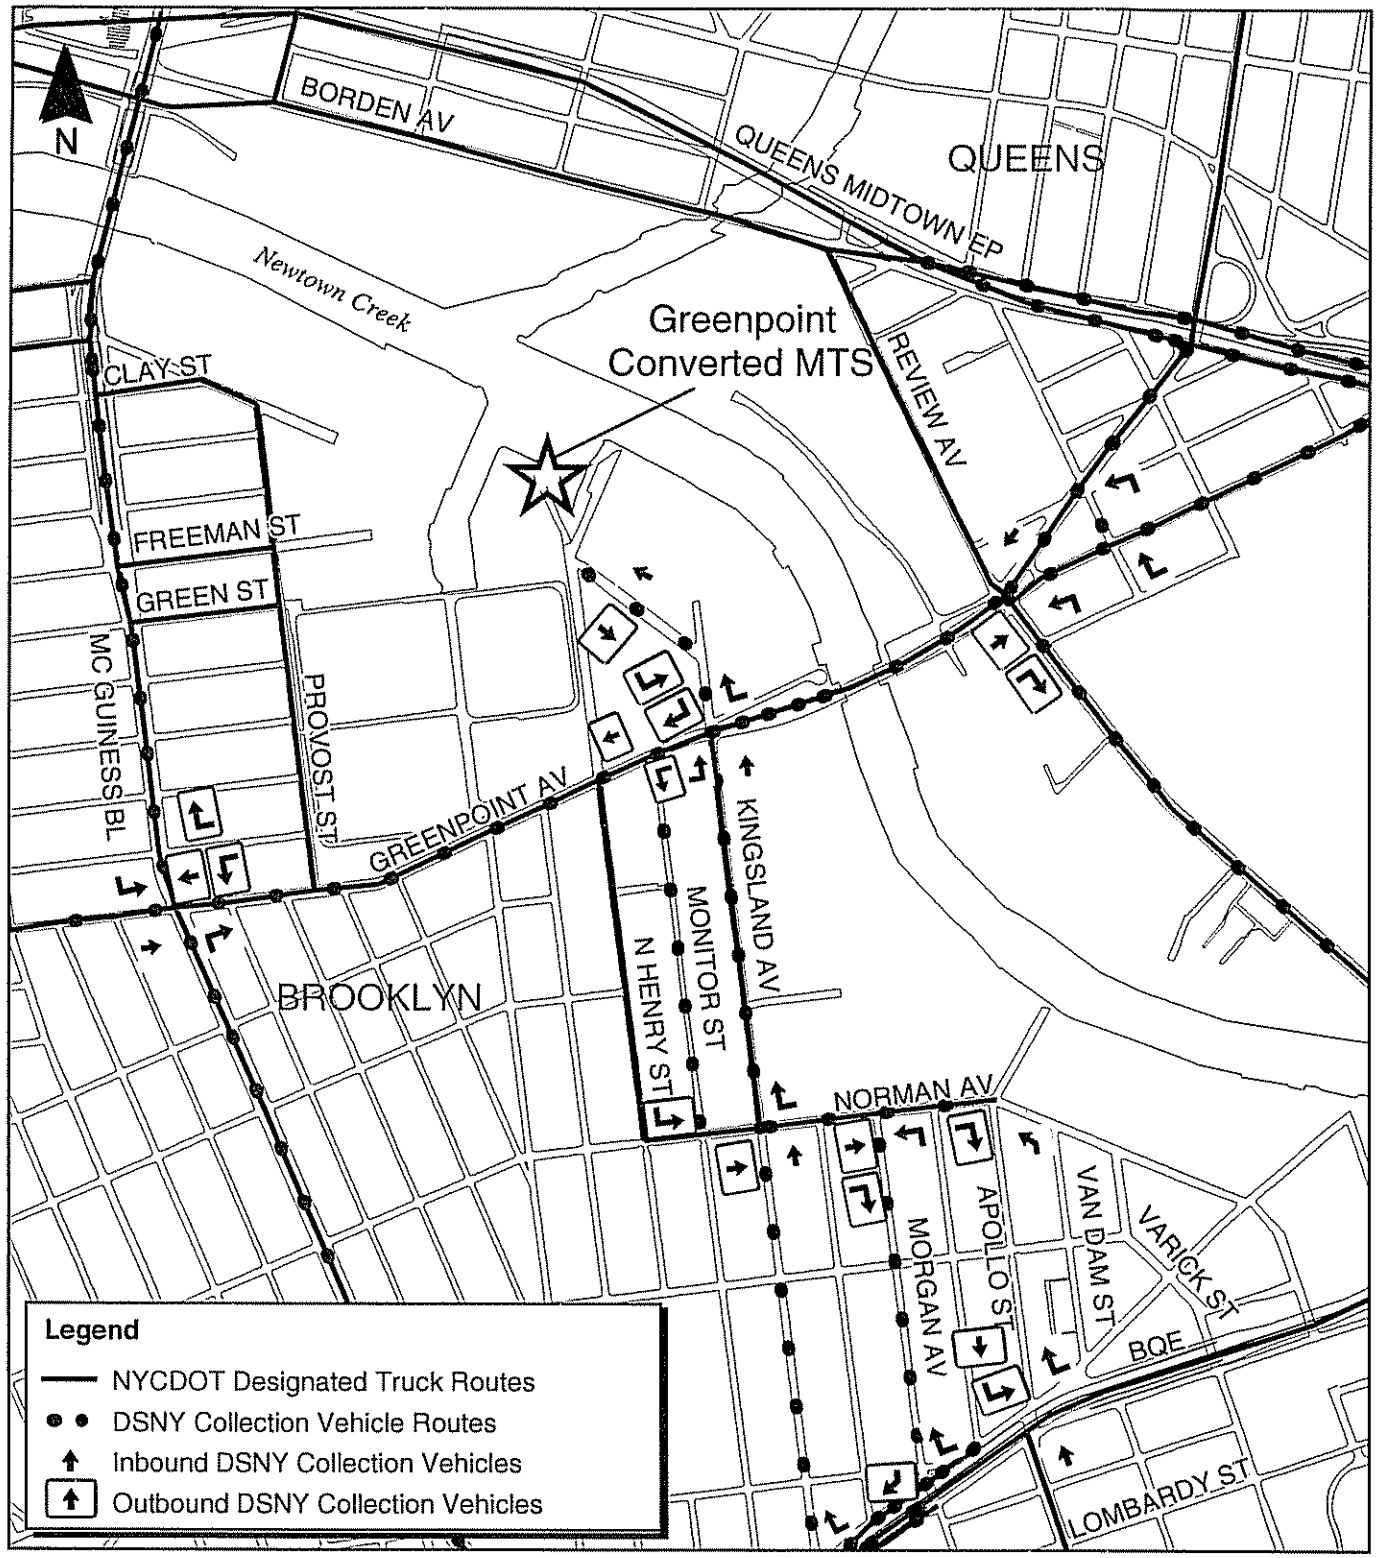

Table 20.14-1 shows that the signalized intersections generally operated at an overall LOS of B or C with the following exceptions. The lane group with the least favorable LOS was the westbound approach at the intersection of Greenpoint Avenue and McGuiness Boulevard. During both the Facility and PM peak hours, this approach operated at LOS F with delays of 86.9 and 87.4 seconds, respectively. During the PM peak hour, the westbound approach at the intersection of Greenpoint Avenue and Review Avenue and Van Dam Street operated at LOS E with 57.5 seconds of delay. Several other lane groups at various intersections operated at LOS D during various peak hours.

20.14.2.3.2 LOS at Unsignalized Intersections

No unsignalized intersections were analyzed.

20.14.2.4 Existing DSNY-Related Traffic

The privately owned Waste Management Review transfer facility, located on Review Avenue between Greenpoint Avenue and Laurel Hill Boulevard in the nearby West Maspeth section of Queens, accepts waste from Queens CDs 2, 3, 4, 5, 6 and 14. The existing DSNY-related traffic in the vicinity of the Greenpoint Converted MTS is generated by the Review Avenue facility. Within the study area, DSNY-related traffic is primarily routed along Greenpoint Avenue, Review Avenue and Van Dam Street. The existing routes to the commercial vendors are presented in Figure 20.14-5.

Site delineations are approximate

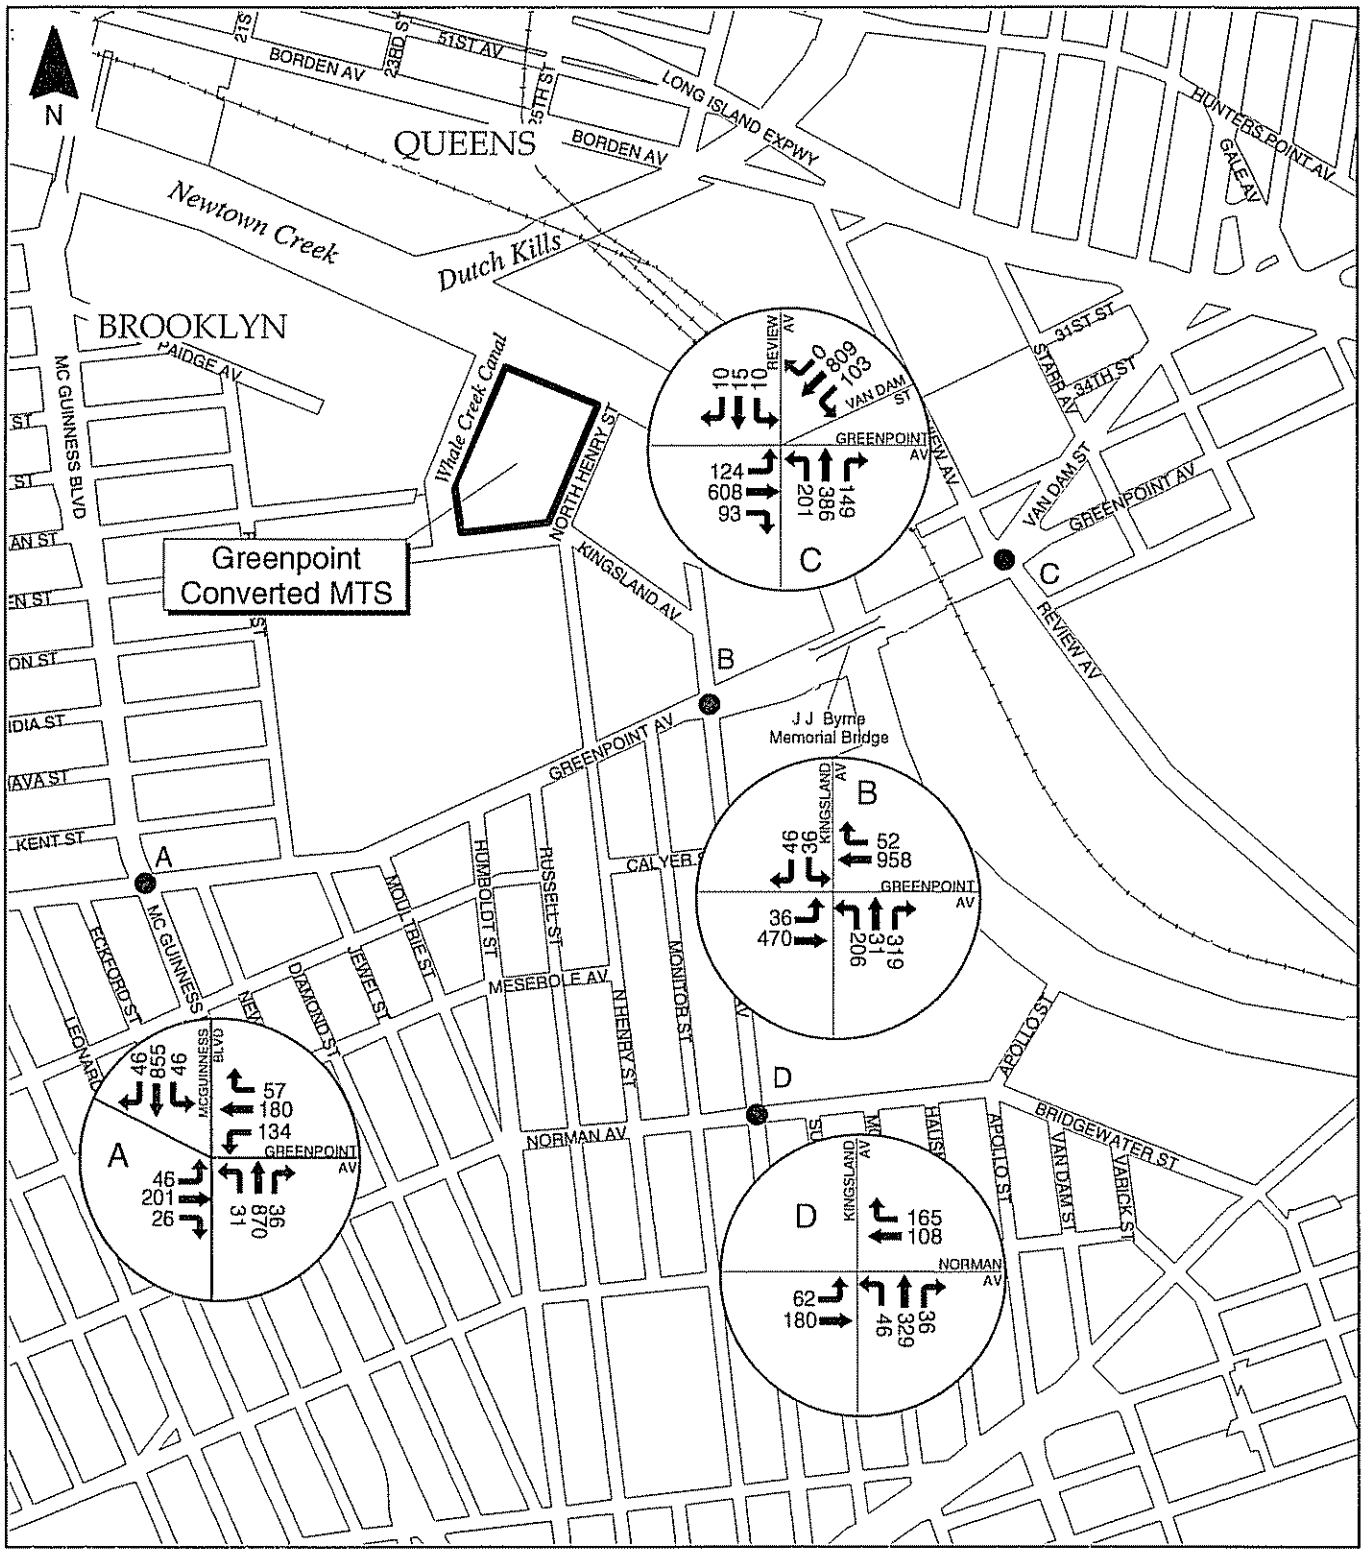
Figure 20.14-5 DSNY Collection Vehicle Routes
Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

20.14.2.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The "Greenpoint Avenue" stop on the MTA's "G" subway line is located approximately one mile southwest of the site at the Greenpoint Avenue/Manhattan Avenue intersection. The MTA operates one bus line, B24, along Greenpoint Avenue. Bus stops are located at the Greenpoint Avenue/McGuiness Boulevard and Greenpoint Avenue/Review Avenue/Van Dam Street intersections and scheduled stops occur at various times during the day.

20.14.2.6 Pedestrian Activity

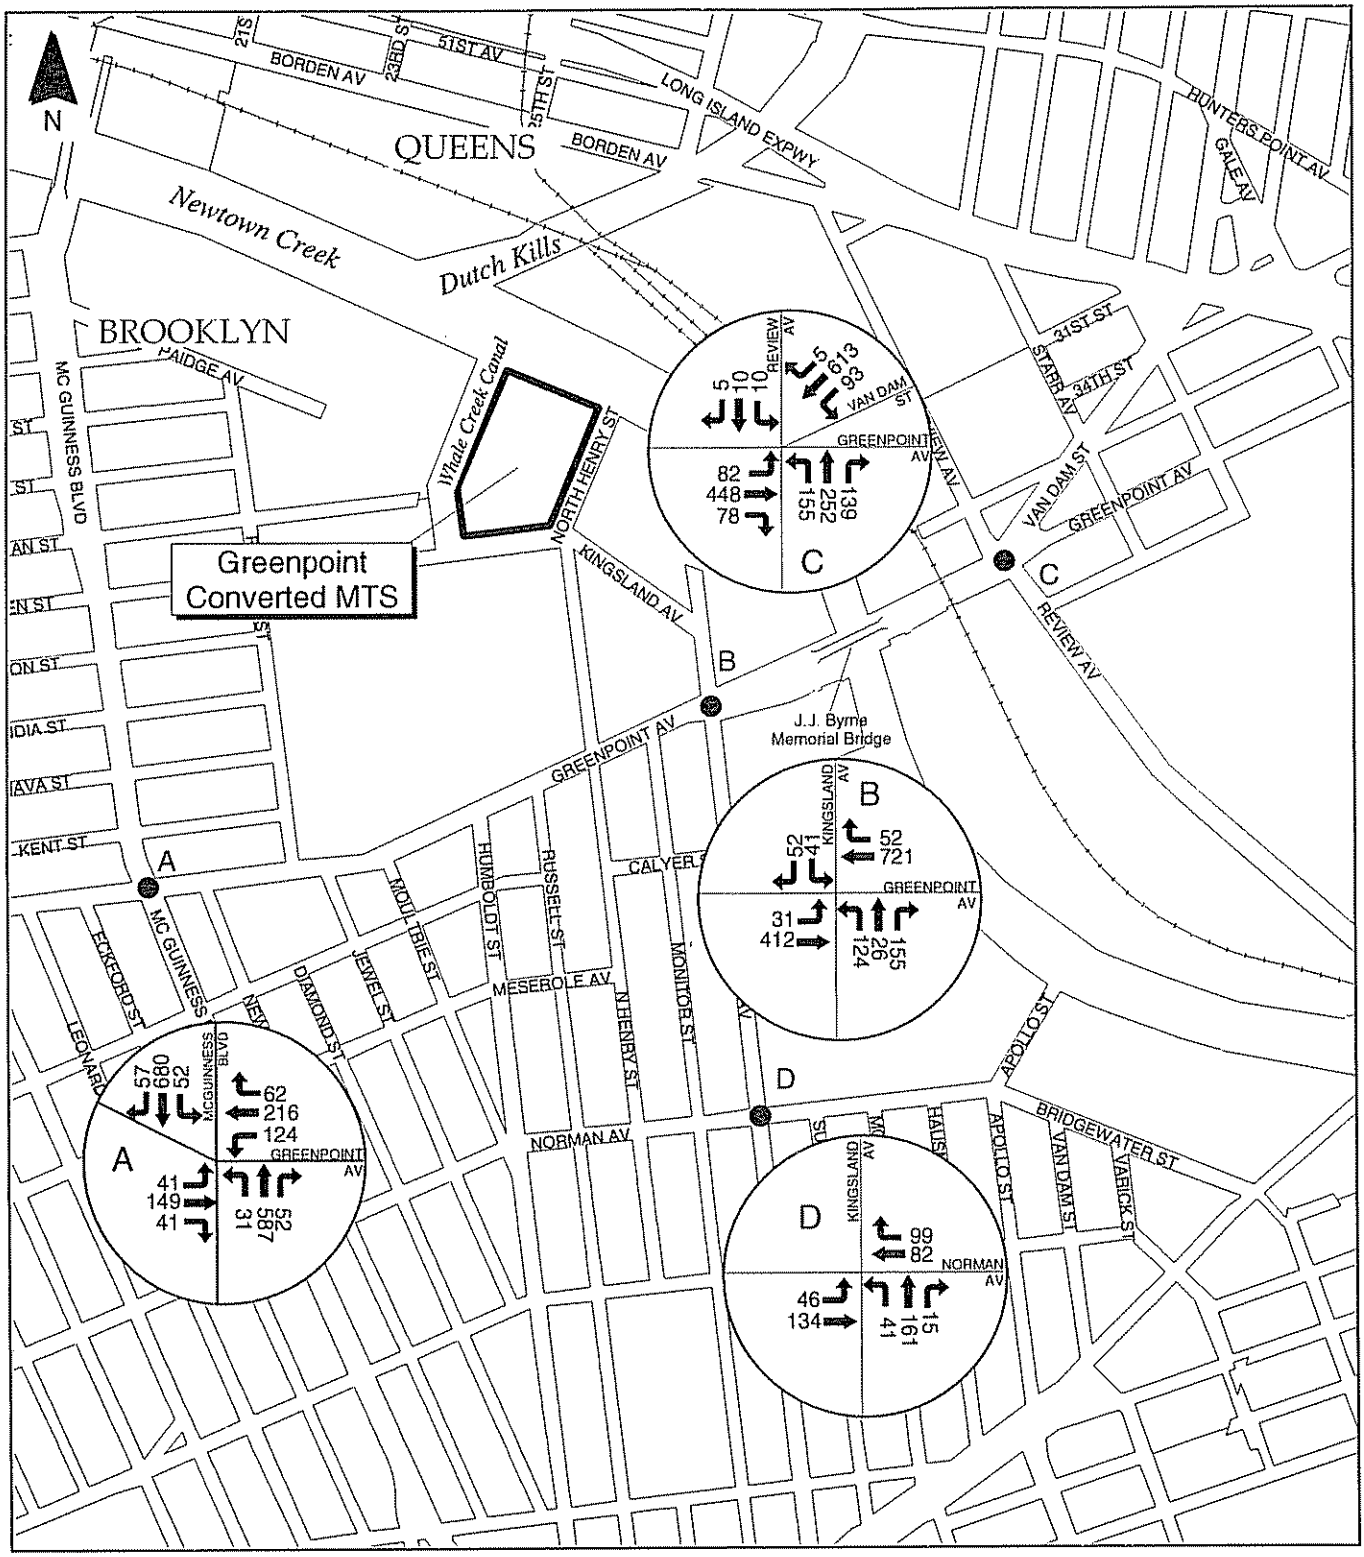


Pedestrian activity is generally low within the study area. Striped crosswalks and pedestrian signals are provided at all signalized study intersections. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.

20.14.3 Future No-Build Conditions

20.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 100 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes in the study area.



Figures 20.14-6, 20.14-7 and 20.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 20.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, signalized intersections experienced relatively small increases in delay (less than 5 seconds) and are projected to remain at their Existing Condition LOS, with the following exceptions:

- During the AM peak hour, the delay of the eastbound approach at the intersection of Greenpoint Avenue and Review Avenue and Van Dam Street increased from 36.9 to 51.2 seconds (LOS D in both cases).

- During the Facility peak hour, the delay of the westbound approach at the intersection of Greenpoint Avenue and McGuiness Boulevard increased from 86.9 to 99.8 seconds (LOS F in both cases).

- During the PM peak hour, the delay of the westbound approach at the intersection of Greenpoint Avenue and McGuiness Boulevard increased from 87.4 to 100.0 seconds (LOS F in both cases). Also during this period, both the eastbound (29.7 to 37.4 seconds) and westbound (57.5 to 75.6 seconds) approaches at the Greenpoint Avenue and Review Avenue and Van Dam Street intersection experienced an increase in delay.

20.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

20.14.3.3 Pedestrian Activity

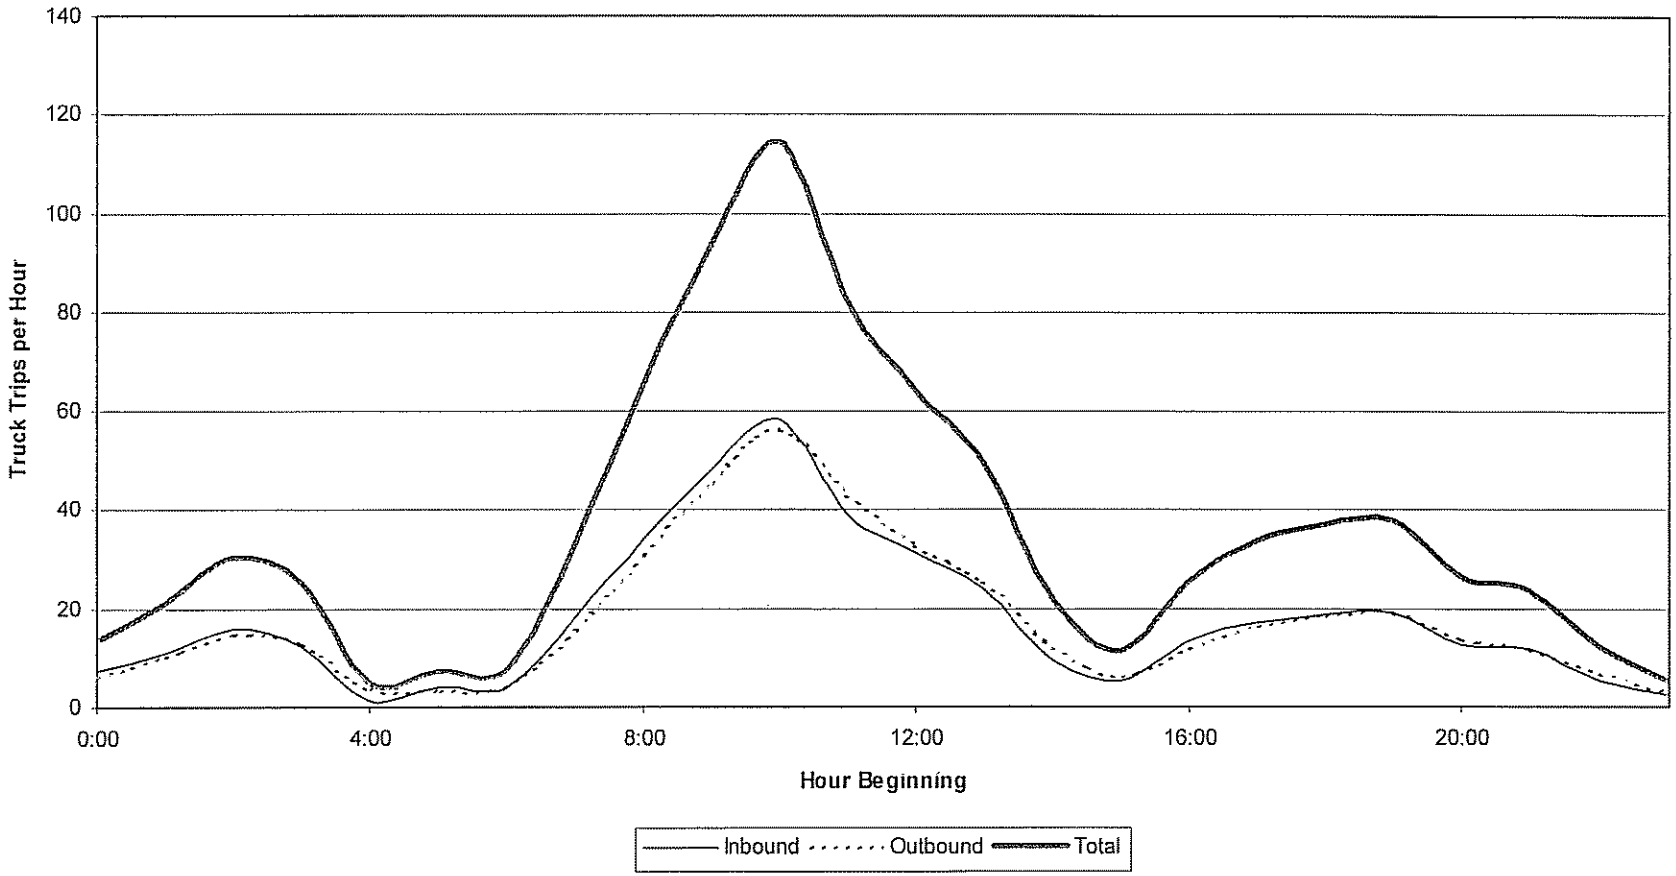
Future No-Build Conditions are expected to remain the same as Existing Conditions.

20.14.4 Potential Impacts with the Greenpoint Converted MTS

The Greenpoint Converted MTS would receive waste from Brooklyn (CDs 1, 3, 4 and 5 and the Auxiliary Field Force [AFF]), Queens (CDs 1, 2, 3, 4, 5 and 6) and Manhattan (AFF). Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Additionally, employee trips to and from the site may result in traffic impacts during the AM peak hour.

20.14.4.1 2006 Future Build Traffic Conditions

2006 Future Build Conditions assume that the Greenpoint Converted MTS would generate 423 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site or the intersection closest to the site if the streets adjacent to the site are not designated truck routes.



The proposed collection vehicle truck routes for the Greenpoint Converted MTS are shown in Figure 20.14-5.

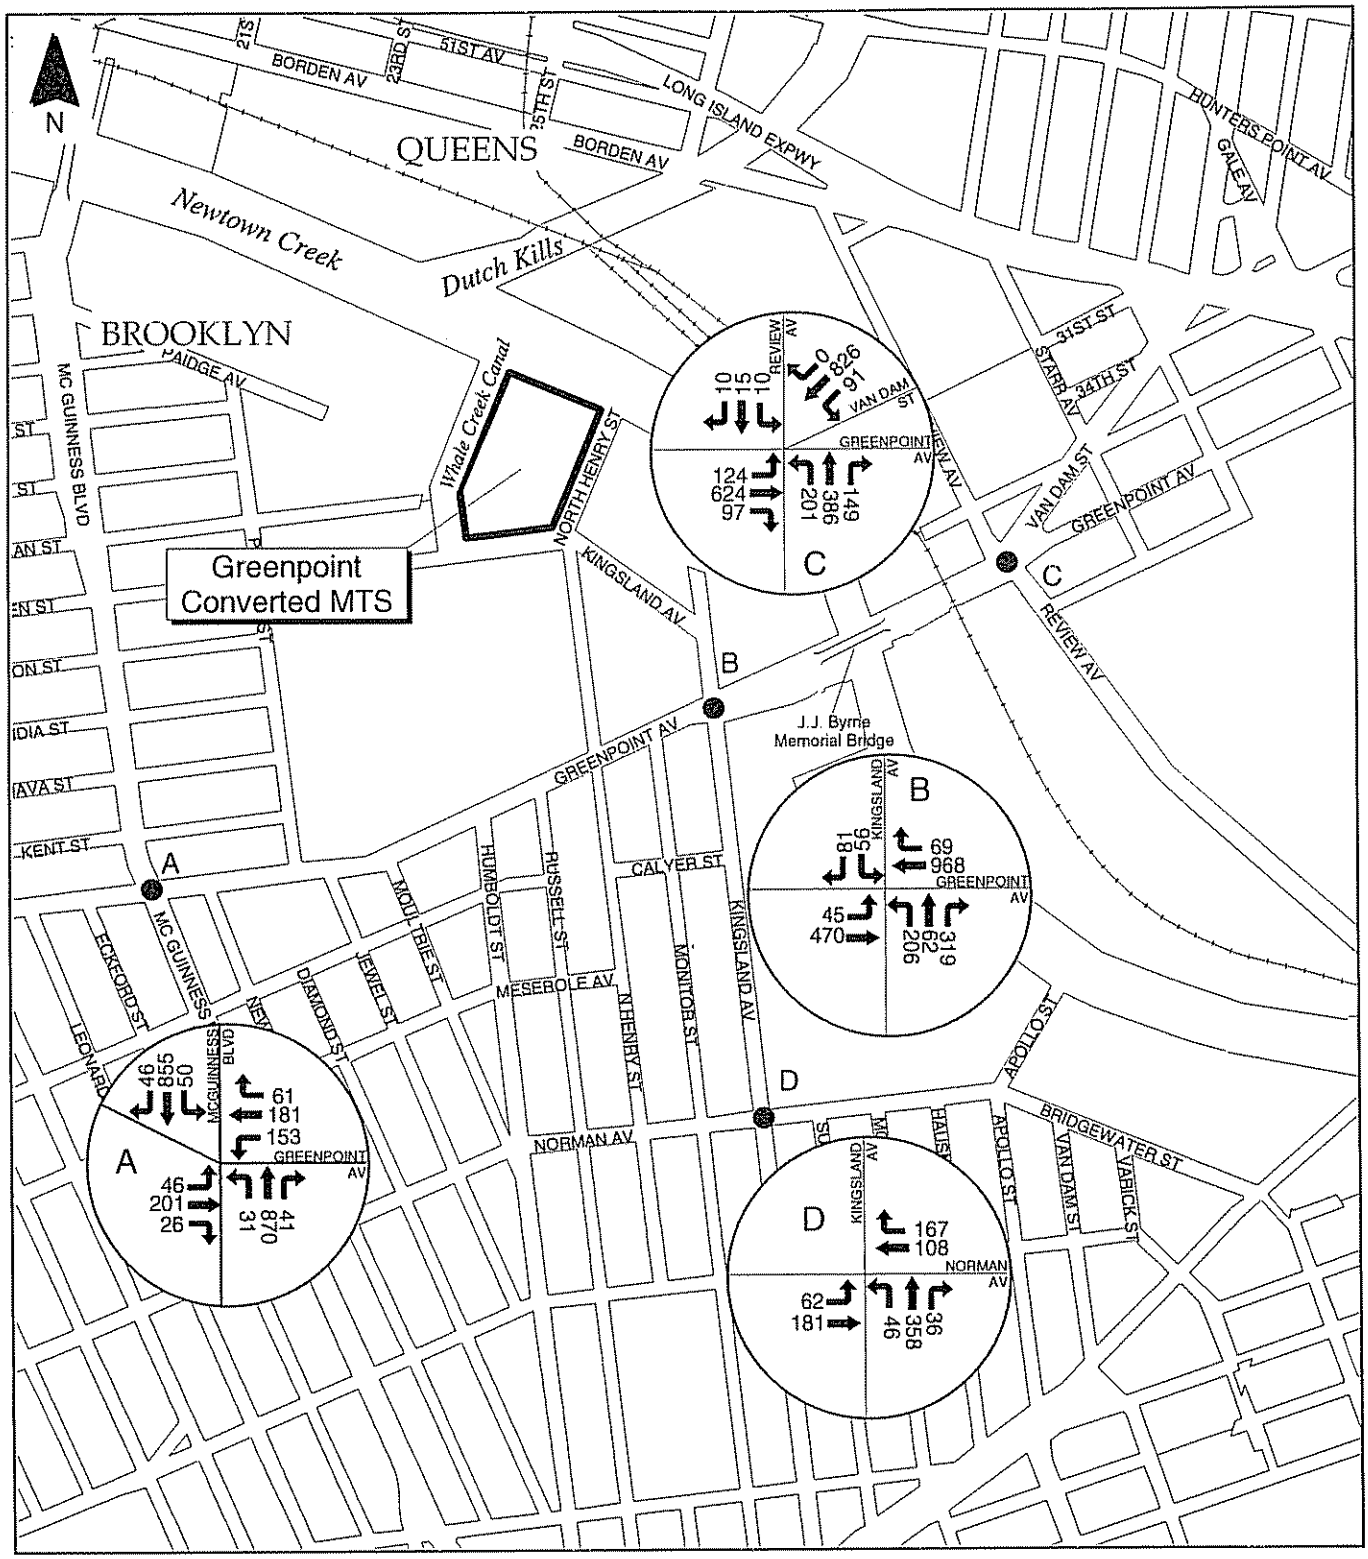


Figure 20.14-9 presents the average peak day temporal distribution of collection vehicles for the Greenpoint Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the Greenpoint Converted MTS is expected to vary between approximately 5 to 30 truck trips per hour in the late evening/early morning, 10 to 118 truck trips per hour in the mid-morning/early afternoon, and 10 to 40 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (118) occurs at approximately 10:00 a.m.

Employee trips generated as a result of the Greenpoint Converted MTS are expected to be about 44 per shift (22 entering and 22 departing). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Therefore, during shift changes, employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m.

Because only the AM peak (7:30 a.m. to 8:30 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the Greenpoint Converted MTS during the shift change (44) were considered as part of the net increase in site-generated traffic. Figures 20.14-10, 20.14-11 and 20.14-12 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 20.14-13, 20.14-14 and 20.14-15 show the intersections analyzed with only the net increase in site generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the Greenpoint Converted MTS. These projected net increases were routed through the intersections for each of the three peak hours. The highest net increase in trucks in the ingress or egress direction was 60. The highest net increase at any one intersection was 118 trucks. Both of these net increases occurred at the intersection of Greenpoint and Kingsland Avenues.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 75% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 55% of weekday traffic volumes. Table 20.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Greenpoint Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 20.14-3
Weekday and Weekend Traffic

DSNY and Other Agency Collection Vehicle Traffic		**Background Traffic EB and WB on Greenpoint Avenue [1]**	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday average vehicles/Day	Weekend average vehicles/Day
423	318	29,296	16,171

Note:
[1] EB and WB traffic data collected from ATR counts taken on Greenpoint Avenue between Kingsland Avenue and Monitor Street from September 11 to 17, 2003.

Table 20.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Greenpoint Converted MTS. Over an average peak day, the intersections should not experience an extended increase in delay. The three intersections that may experience potentially significant impacts are discussed in Section 20.14.4.2 and summarized in Table 20.14-5.

20.14.4.2 Impacts and Mitigation

Three of the four intersections may experience impacts great enough to be considered significant during one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines requires mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below; their effectiveness is summarized in Table 20.14-5.

DFL = defacto left
LTR = left, through and right movements
NB = northbound L = left movement
SB = southbound TR = through right movement
EB = eastbound TR = through right movement
WB = westbound R = right movement

Greenpoint Avenue/McGuiness Boulevard – During the AM peak hour, a potential impact was identified on the westbound approach when the increase in delay created a defacto left movement operating at LOS E with a delay of 67.6 seconds. During the Facility peak hour, the same (westbound) approach is expected to experience an increase in delay from 99.8 seconds to 185.3 seconds (LOS F in both cases). During the PM peak hour, the delay of the westbound approach is expected to increase from 100.0 seconds to 126.0 seconds (LOS F in both cases). During both the AM and Facility peak hours, an increase in green time of five seconds for the eastbound and westbound approaches should eliminate this unacceptable increase in delay.

This mitigation measure would subtract five seconds from the northbound and southbound approach green time, but would improve the LOS for the westbound approach to below Future No-Build Condition levels with minimal increases to the delay of the northbound and southbound approaches. During the PM peak hour, an increase in green time of two seconds for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract two seconds from the northbound and southbound approach green time, but would improve the LOS for the westbound approach (again) to below Future No-Build Condition levels with minimal increases to the delay of the northbound and southbound approaches.

Greenpoint Avenue/Kingsland Avenue – During the PM peak hour, a potential impact was identified on the southbound left movement when the delay increased from 30.5 seconds to 40.5 seconds (LOS C to LOS D).

An increase in green time of one second for the northbound and southbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract one second of green time from the eastbound and westbound approaches, but would reduce the delay for the southbound left movement from 40.5 seconds to 35.2 seconds. The delay of both the northbound and southbound (right) approaches would decrease by approximately one second. The eastbound and westbound approach delays would increase by approximately one second. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

Greenpoint Avenue/Review Avenue/Van Dam Street – During the AM peak hour, a potential impact was identified on the eastbound approach when the delay increased from 51.2 seconds to 60.3 seconds (LOS D to LOS E).

An increase in green time of one second for the eastbound and westbound approaches should eliminate this unacceptable increase in delay. This mitigation measure would subtract one second of green time from the northbound and southbound approaches, but would reduce the delay for the eastbound approach from 60.3 seconds to 43.4 seconds. The delay of the westbound approach would decrease by 3.5 seconds. The eastbound and westbound approach delays would increase by 2.5 seconds and 0.7 seconds, respectively. This mitigation should not generate any adverse impacts on other lane groups during other time periods.

Overall, the mitigation measures suggested would greatly enhance the intersection performance by reducing the delays to LOSs similar to those under the Future No-Build Condition.

20.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

20.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

20.15 Air Quality

20.15.1 Definition of the Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Greenpoint Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersection listed in Section 20.15.4.2.

20.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 20.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 20.15-1
Representative Ambient Air Quality Data
Greenpoint Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	MTA, Flatbush Avenue between Tillary Street and Johnson Avenue	8-Hour	3,436 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	4,695 $\mu g/m^3$	40,000 $\mu g/m^3$

		24-Hour	84 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	18 $\mu g/m^3$	80 $\mu g/m^3$

Notes:
Source: NYCDEP, April 2003 & USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.
(2) Values are the highest pollutant levels recorded during the 1999 calendar year.

20.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build Conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

20.15.4 Potential Impacts with the Greenpoint Converted MTS

20.15.4.1 On-Site Analysis

20.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 20.15-2. Figure 20.15-1 shows the locations of these sources within the site.

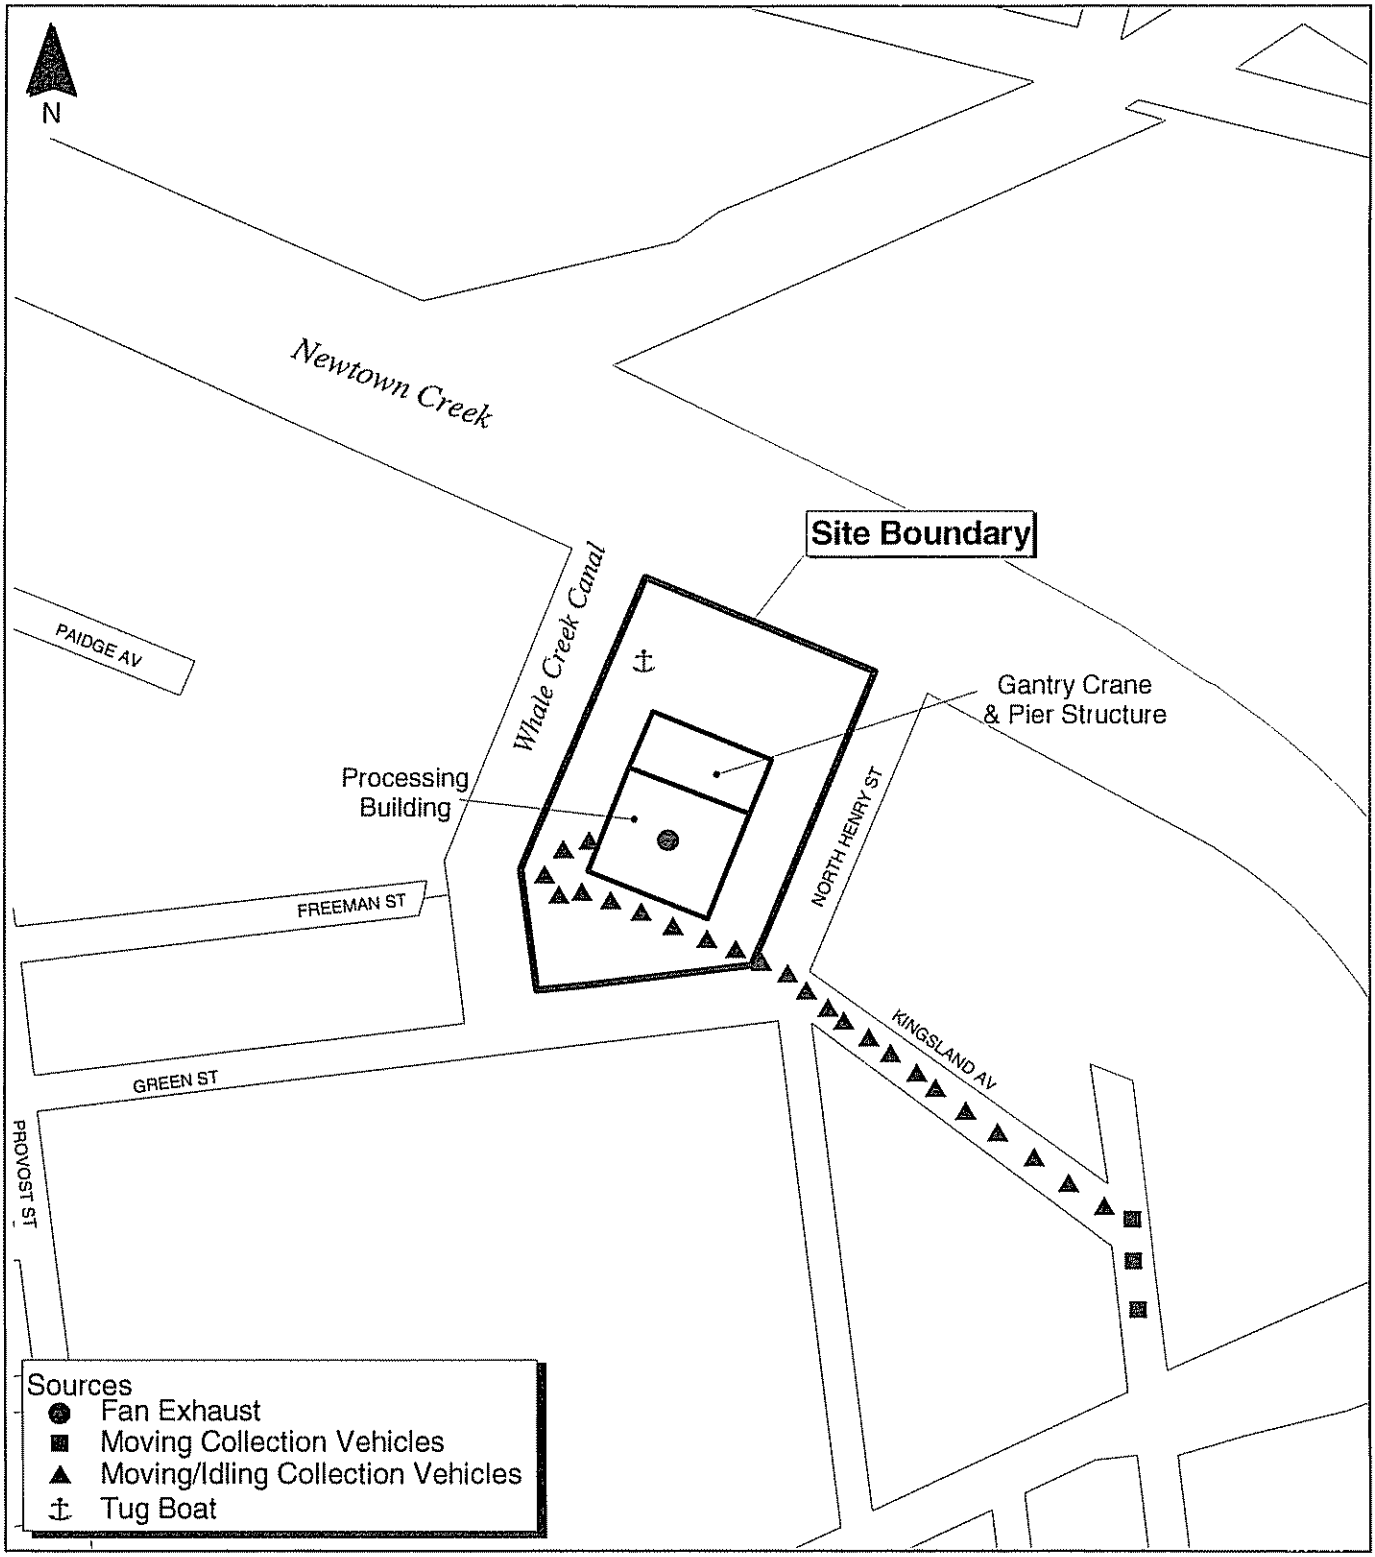
20.15.2.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 20.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from Greenpoint Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 20.15-3, are below the STVs. Based on the results presented in Table 20.15-3, operations at the Greenpoint Converted MTS would not significantly impact air quality in the area.

20.15.2.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 20.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest

Table 20.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
Greenpoint Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	46	18
Space Heaters	10	10
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3]	37 in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (37), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

Site delineations are approximate.
Base Map Source: New York City Department of City Planning
Note: These are modeled source locations used in the on-site air quality analysis and do not represent individual collection vehicles

Notes:

[1] The highest estimated pollutant concentrations found at any of the off-site receptor locations.

[2] Background concentrations were obtained from the NYCDEP in ~~April 2003~~memorandum dated February 18, 2005.

[3] NAAQS = National Ambient Air Quality Standard.

[4] Screening threshold value (STV) established by the NYCDEP and NYSDEC.

[5] Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

[6] The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

[7] The 24-hour PM_{10} NAAQS is based on a 99^{th} percentile concentration, which means that the high, 4^{th} high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

Notes to Table 20.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC.

(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.

(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

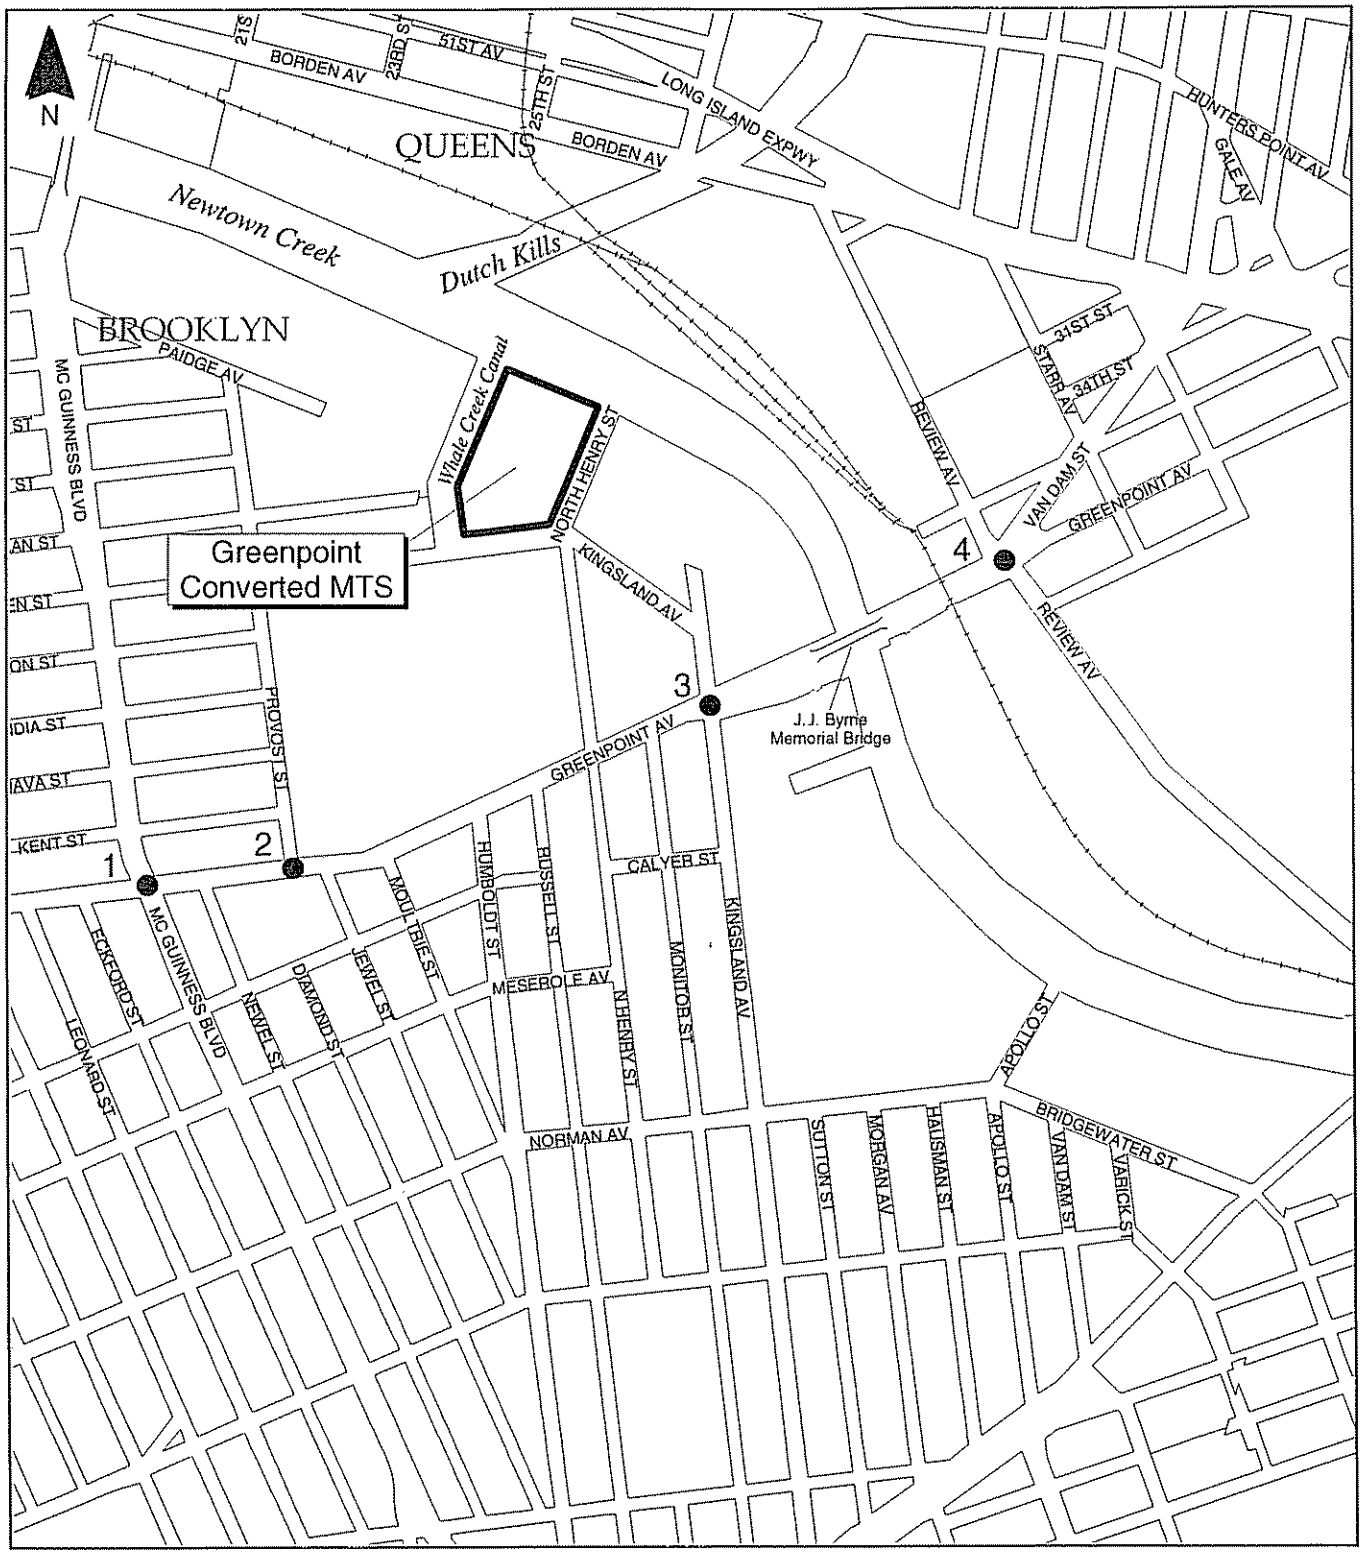
NA = Not Applicable

estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Greenpoint Converted MTS are not considered to be significant.

20.15.4.2 Off-Site Analysis

20.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other collection agency's collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, mobile source analyses were conducted at the following locations for the applicable (i.e., worst-case) time periods:



- The intersections of Kingsland Avenue at Greenpoint Avenue and Kingsland Avenue at Norman Avenue to determine whether Greenpoint Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 8-hour CO "de minimus" value or a violation of the 8-hour NAAQS;
- The intersections of Kingsland Avenue at Greenpoint Avenue, Kingsland Avenue at Norman Avenue, Greenpoint Avenue at Review Avenue and Van Dam Street, and Greenpoint Avenue at McGuiness Boulevard and Provost Street to determine whether Greenpoint Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and
- The intersections of Kingsland Avenue at Greenpoint Avenue, Kingsland Avenue at Norman Avenue, Greenpoint Avenue at Review Avenue and Van Dam Street, and Greenpoint Avenue at McGuiness Boulevard and Provost Street to determine whether Greenpoint Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 20.15-2.

20.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 20.15-5, are all within (less than) the applicable state and federal ambient air quality standards, STVs (for $PM_{2.5}$) and/or "de minimus" impact values (for CO) with the exception of the annual $PM_{2.5}$ neighborhood STV at the intersection of Kingsland Avenue at Greenpoint

Avenue. However, it should be noted that the off-site air analysis at this intersections as performed using a conservative Tier I approach which assumes peak hour conditions for every hour of the day. If a Tier II approach was performed for the annual $PM_{2.5}$ neighborhood analyses, the concentrations reported in Table 20.15-5 would decrease by as much as 40%, thereby bringing the results below the STV. In addition, a precipitation factor adjustment could be applied to Equation 1 in Section 13.2.1.3 of AP-42 used to determine the $PM_{2.5}$ emission factors. This factor assumes that annual average emissions are inversely proportional to the frequency of measurable (>0.01 inch) precipitation. Applying the precipitation factor to the off-site annual $PM_{2.5}$ neighborhood analysis would further decrease the concentrations reported in Table 20.15-5. —Therefore, the off-site operations of the Greenpoint Converted MTS, ~~therefore,~~ are not considered to be significant.

Notes for Table 20.15-5:

(1) CO and PM_{10} concentrations are the maximum concentrations estimated using the AM, Facility, and PM peak traffic information plus background concentration (8 hr CO = 2.3 ppm; 24-hr PM_{10} = ~~57~~ 90 $\mu g/m^3$; Annual PM_{10} = ~~23~~ 20 $\mu g/m^3$).

(2) The maximum incremental concentrations of the on-site emissions at the intersection considered.

(3) The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced [or Future Build] traffic only) estimated by taking the difference between the maximum $PM_{2.5}$ concentrations for the Future No-Build and Future Build scenarios at any receptor three meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.

(4) The $PM_{2.5}$ concentrations are the maximum modeled incremental $PM_{2.5}$ impacts (due to project-induced [or Future Build] traffic only) estimated by taking the difference between the maximum $PM_{2.5}$ concentrations for the Future No-Build and Future Build scenarios at any receptor 15 meters from the edge of the roadways using AM, Facility, or PM peak traffic conditions.

(5) Incremental 1-hour vehicular trips were below CEQR CO air quality screening thresholds.

(6) The result of a Tier I analysis for this intersection (0.13$\mu g/m^3$) which assumed that peak period project traffic occur every hour of a 24-hour analysis period, was multiplied by a conservative ratio (0.40) of peak period project-induced traffic to average project-induced traffic to approximate the Tier II result (0.05$\mu g/m^3$).

ppm: parts per million

$\mu g/m^3$: microgram per cubic meter

NA = Not Applicable

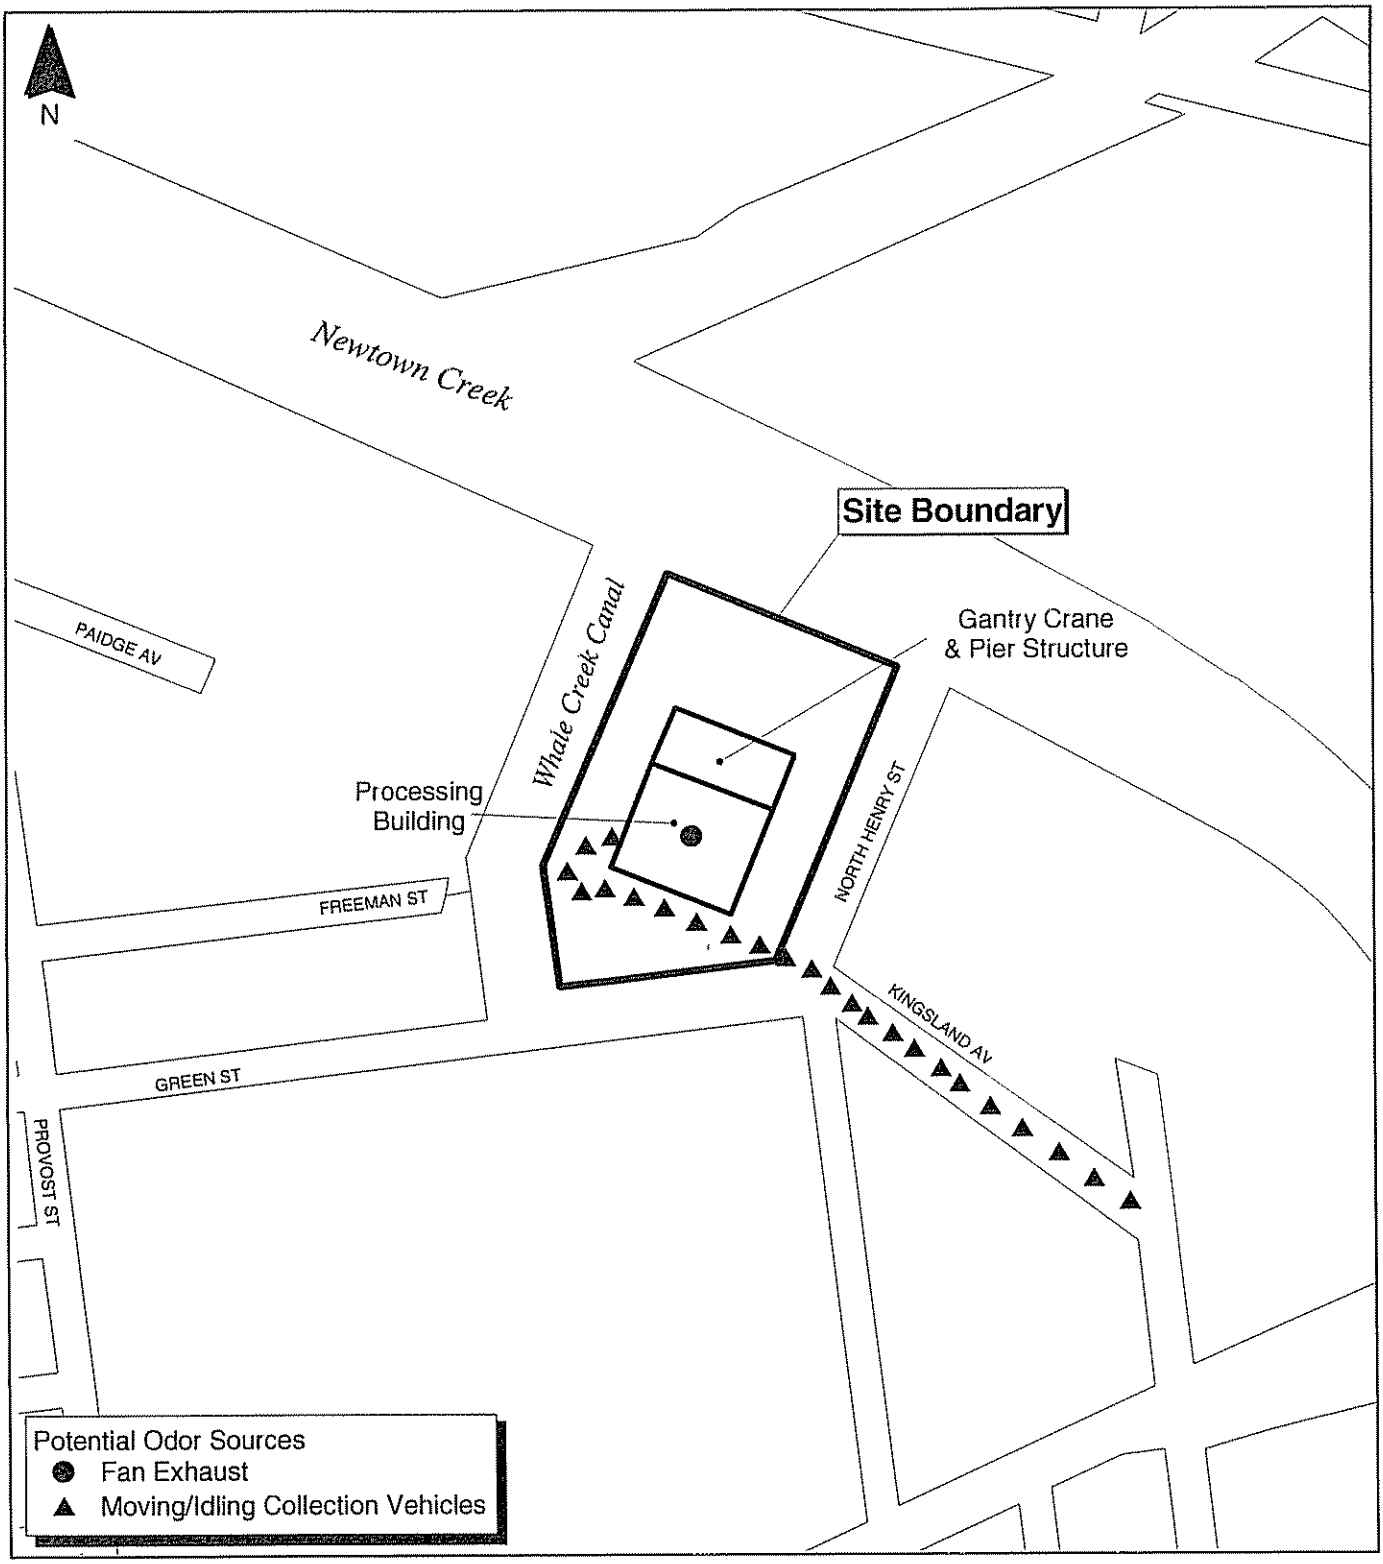
20.16 Odor

20.16.1 Existing Conditions

The existing MTS is not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is the apartment building located on Van Dam Street southwest of the LIE, approximately 1,188 feet away from the site boundary.

20.16.2 Future No-Build Conditions

No additional odor-producing sources are anticipated in the vicinity of the Greenpoint Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



20.16.3 Potential Impacts with the Greenpoint Converted MTS

20.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Greenpoint Converted MTS are provided in Table 20.16-1. Figure 20.16-1 shows the locations of these sources within the site.

Table 20.16-1
Odor Sources Included in Odor Analysis

Figure 20.16-1 Potential Odor Sources

Greenpoint Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Greenpoint Converted MTS.

20.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 20.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Greenpoint Converted MTS at any nearby sensitive receptor is less than 1, so odors from the Greenpoint Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 20.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Greenpoint Converted MTS

Parameter	Resulting Odor Unit [1]
Estimated Detectable Concentration	5.0
Highest Result	0.35
Type of Receptor	Fence Line Receptor
Location of Receptor	Site Boundary
Closest Sensitive Receptor Result [2]	0.03
Type of Receptor	Apartment Building
Distance to Receptor	2,498 Feet

Notes:
[1] Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.
[2] Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.

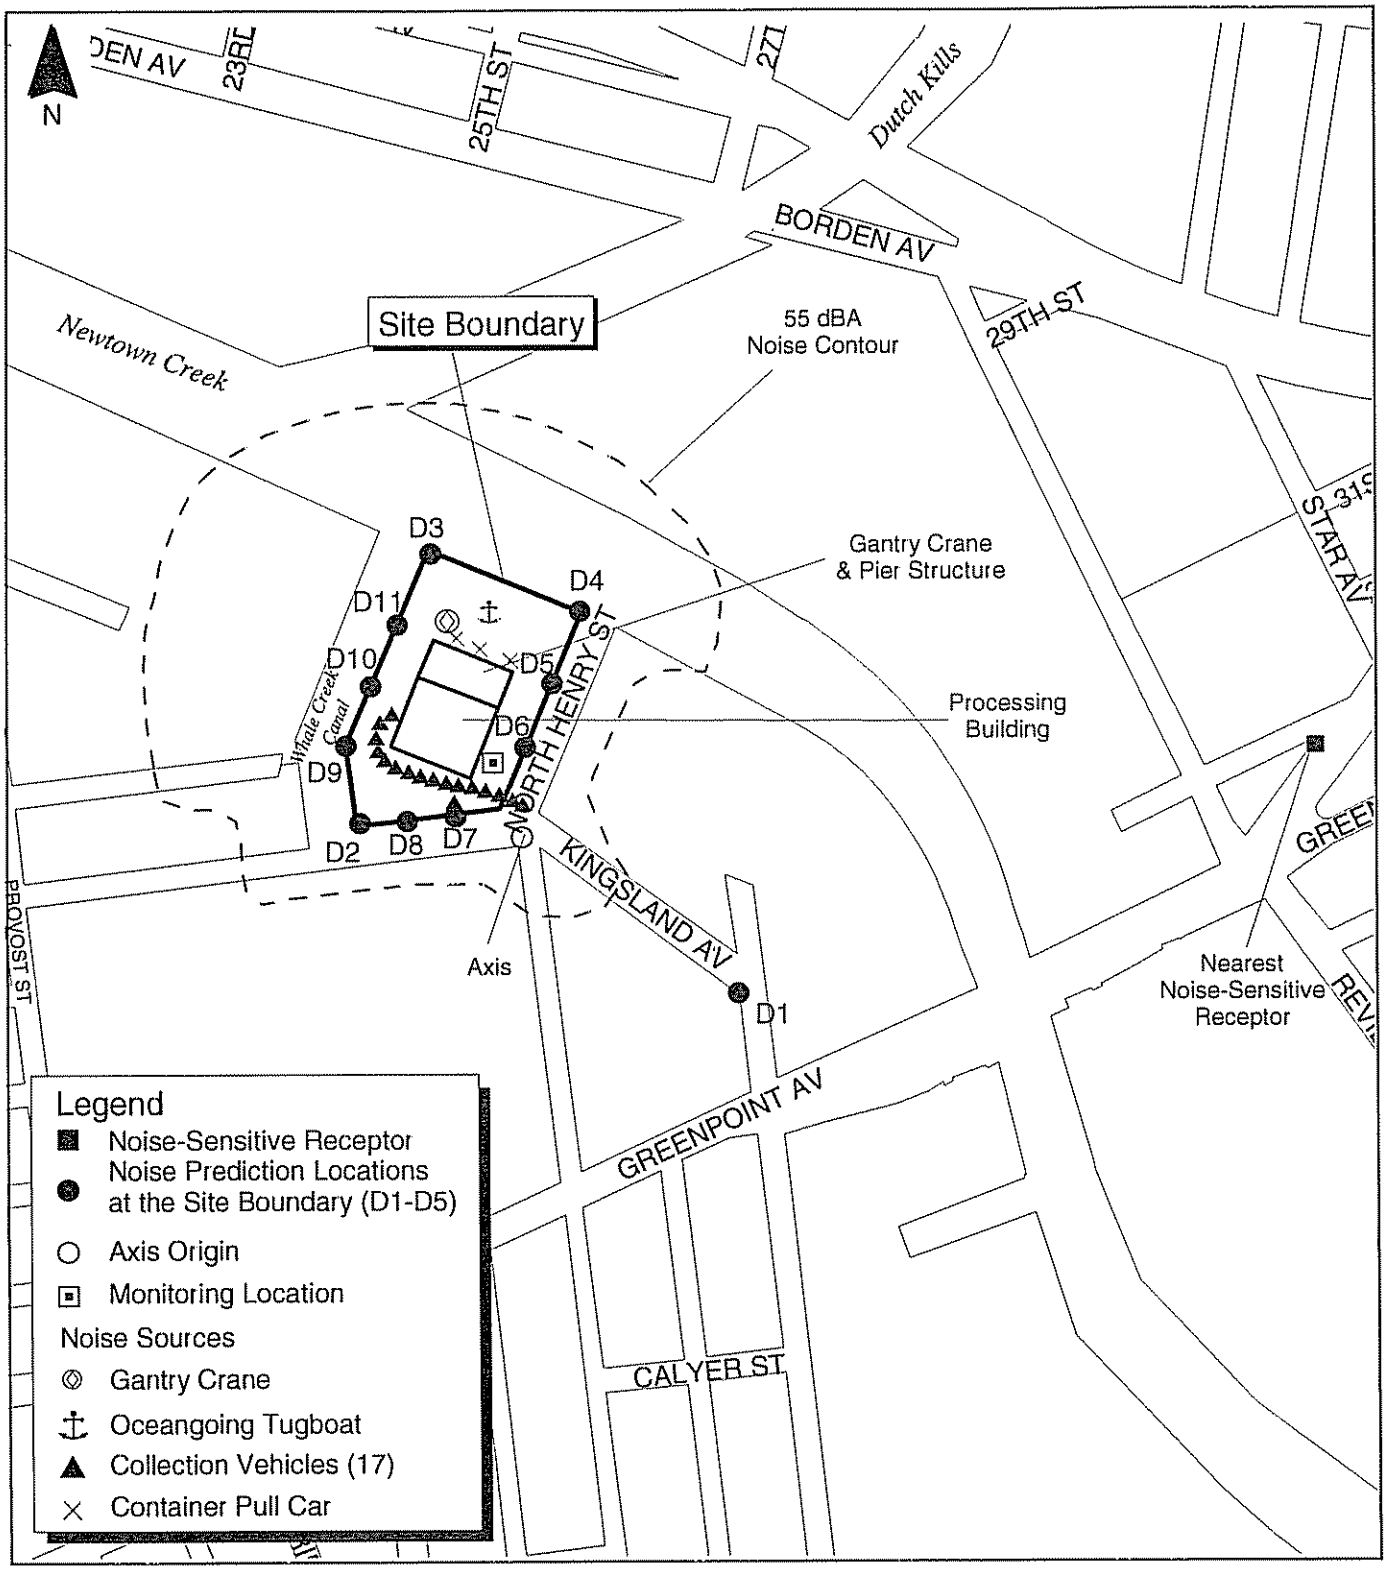
20.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Greenpoint Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

20.17.1 Existing Conditions

20.17.1.1 Introduction

Figure 20.17-1 shows the location of the Greenpoint Converted MTS, the surrounding area and points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is an apartment building on Van Dam Street southwest of the LIE, approximately 761 meters (2,498 feet) from the Greenpoint Converted MTS property line.



20.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptor. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[14] and the statistical metrics of L_{10}, L_{50} and L_{90}.[15] Table 20.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 2:00 a.m. and 3:00 a.m. and had an $L_{eq(1)}$ of 65.9 dBA on January 10, 2003. Activities and events that contribute to the on-site noise levels are as follows:

- Heavy truck traffic in the area;
- Boat traffic on Newtown Creek;
- Construction at the Newtown Creek WPCP; and
- Train traffic on LIRR tracks.

---

[14] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[15] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

2:00-3:00 p.m.	76.3	69.9	73.1	79.4	67.5	90.8

Note:
[1] The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

20.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of noise from the existing traffic and other background noise. A screening analysis was conducted to determine if noise monitoring would be required along the facility-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required. Therefore, off-site noise monitoring was not conducted.

20.17.2 Future No-Build Conditions

20.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

20.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 20.17-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 20.17-2
Off-Site Noise Traffic Volume
Greenpoint Converted MTS

Location	Hour	Existing Traffic Volume [1] (Vehicles / Hour)	Future No-Build Traffic Volume [2] (Vehicles / Hour)
Greenpoint Avenue east of McGuiness Boulevard	2:00 a.m.	88	92
Greenpoint Avenue east of McGuiness Boulevard	10:00 a.m.	766	797
Greenpoint Avenue east of Kingsland Avenue	2:00 a.m.	152	159
McGuiness Boulevard north of India Street	2:00 a.m.	39	40

Notes:
[1] Existing Traffic Volumes are based on ATR data.
[2] Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

20.17.3 Potential Impacts with the Greenpoint Converted MTS

20 17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Greenpoint Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analyses are shown in Table 20.17-3. Spectral noise levels used in the Performance Standards analysis are shown in Table 20.17-4. The number and types of equipment assumed for this analysis were based on the Greenpoint Converted MTS's peak design capacity. Shown earlier, Figure 20.17-1 indicates the Greenpoint Converted MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 20.17-3

[2] Trucks and tugboats are not included in the Performance Standard analysis because they are transportation facilities.

[3] Noise level representative of each piece of equipment.

[4] Noise level will be specified for the gantry crane in DSNY's plans and specification for construction of the Converted MTS's.

Hz = Hertz

K = Thousand

20.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Greenpoint Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 62 meters (203 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is 761 meters (2,498 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (see Figure 20.17-1); therefore, an on-site noise analysis, including noise monitoring, was not required.

20.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points representative of the Greenpoint Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (assuming tugboats are transportation facilities) (see Table 20.17-5). Based on this analysis, ~~no~~ exceedances to the Performance Standards are predicted.

Table 20.17-5
Zoning Code Analysis
Predicted Spectral Noise Levels (L_{max}) at the Property Boundary

20.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Greenpoint Converted MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 20.17-6. Based on this analysis, the total L_{eq} does ~~not~~ exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 20.17-6
Current Noise Code Analysis
Greenpoint Converted MTS

Location at Plant Boundary[1]	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	~~59.0~~ 71.6
D2	~~66.8~~ 66.2
D3	~~64.4~~ 62.8
D4	~~63.6~~ 60.0

Bold=Exceedence

20.17.3.5 Mitigation Measures

Mitigation measures available were limited to those that affect the source, the propagation path or the receiver. The typical mitigation measure for the path of noise between source and receiver is a noise wall. Noise walls can be designed to provide noise attenuation for noise-sensitive areas located relatively close to the wall. Noise attenuation provided by the wall decreases as distance from the wall increases. Receiver treatments may include the construction of noise walls at residential property lines or the installation of replacement windows and air conditioning. The latter two mitigation measures are suggested in the 2001 CEQR Technical Manual. Typical mitigation measures at the source include: (1) changes in operations schedules to reduce noise emissions; (2) reduction in DSNY collection vehicles; (3) using noise mufflers for the exhaust pipes of material handling equipment (e.g., side loaders, yard tractors, etc.) or other source noise reduction methods; and (4) maintaining the equipment through regularly scheduled maintenance and repairs.

The data presented in this section is for the analysis to date. If the Greenpoint Converted MTS is included in the New SWMP, a supplemental analysis will be performed.

20.17.3.~~5~~6 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the Greenpoint Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 20.17-7.

Because the screening results presented below showed that the PCEs would not double on a roadway due to DSNY and other agency collection vehicles coming to or going from the Greenpoint Converted MTS, a detailed off-site noise analysis was not required.

20.17.3.~~6~~7 Combined On-Site and Off-Site Noise Levels

As a result of both the on- and off-site screening analyses performed for the Greenpoint Converted MTS, neither the on- or the off-site noise analyses were required; therefore, a combined noise analysis was not performed.

Table 20.17-7
Off-Site Noise Screening Results
Greenpoint Converted MTS

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
Greenpoint Avenue east of McGuiness Boulevard	2:00 a.m.	1,132	13	0	611	1,743	No
Greenpoint Avenue east of McGuiness Boulevard	10:00 a.m.	5,644	46	0	2,162	7,806	No
Greenpoint Avenue east of Kingsland Avenue	2:00 a.m.	1,891	11	0	517	2,408	No
McGuiness Boulevard north of India Street	2:00 a.m.	161	3	0	141	302	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include Greenpoint Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted to PCEs using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

20.18 Commercial Waste to the Greenpoint Converted MTS

20.18.1 Existing Conditions

No commercial waste is delivered to the Greenpoint MTS site under Existing Conditions. Commercial waste generated in Brooklyn is delivered to privately owned and operated transfer stations in the City, or taken directly out of the City to remote disposal locations.

20.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the Greenpoint Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

20.18.3 Potential Impacts of Sending Commercial Waste to the Greenpoint Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

20.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the Greenpoint Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 20.15, 20.16 and 20.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

20.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the Greenpoint Converted MTS were evaluated in Sections 20.14, 20.15 and 20.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 20.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 61 (inbound trip ends) per hour, which occurred during the AM peak. These 61 DSNY and other agency collection vehicles are also more than the 24 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the Greenpoint Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 61 DSNY and other collection agency vehicle trip ends at the Greenpoint Converted. Therefore, the addition of the 24 DSNY and other agency collection vehicles and commercial waste hauling vehicles at the Greenpoint Converted MTS during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 61 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 61 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24 hour period. Results showed there would be no unmitigatible significant adverse environmental impacts. Consequently, because the 24 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can be processed at the Greenpoint Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the Greenpoint Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 1,145 tons (or 109 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

CHAPTER 21 ENVIRONMENTAL REVIEW: WEST 135TH STREET CONVERTED MTS

21.1 Introduction

The results of the environmental analyses of the West 135th Street Converted MTS are presented in the following sections:

21.2 Land Use, Zoning, and Public Policy
21.3 Socioeconomic Conditions
21.4 Community Facilities and Services
21.5 Open Space
21.6 Cultural Resources
21.7 Urban Design, Visual Resources, and Shadows
21.8 Neighborhood Character
21.9 Natural Resources
21.10 Hazardous Materials
21.11 Water Quality
21.12 Waterfront Revitalization Program
21.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
21.14 Traffic, Parking, Transit, and Pedestrians
21.15 Air Quality
21.16 Odor
21.17 Noise
21.18 Commercial Waste to the West 135th Street Converted MTS

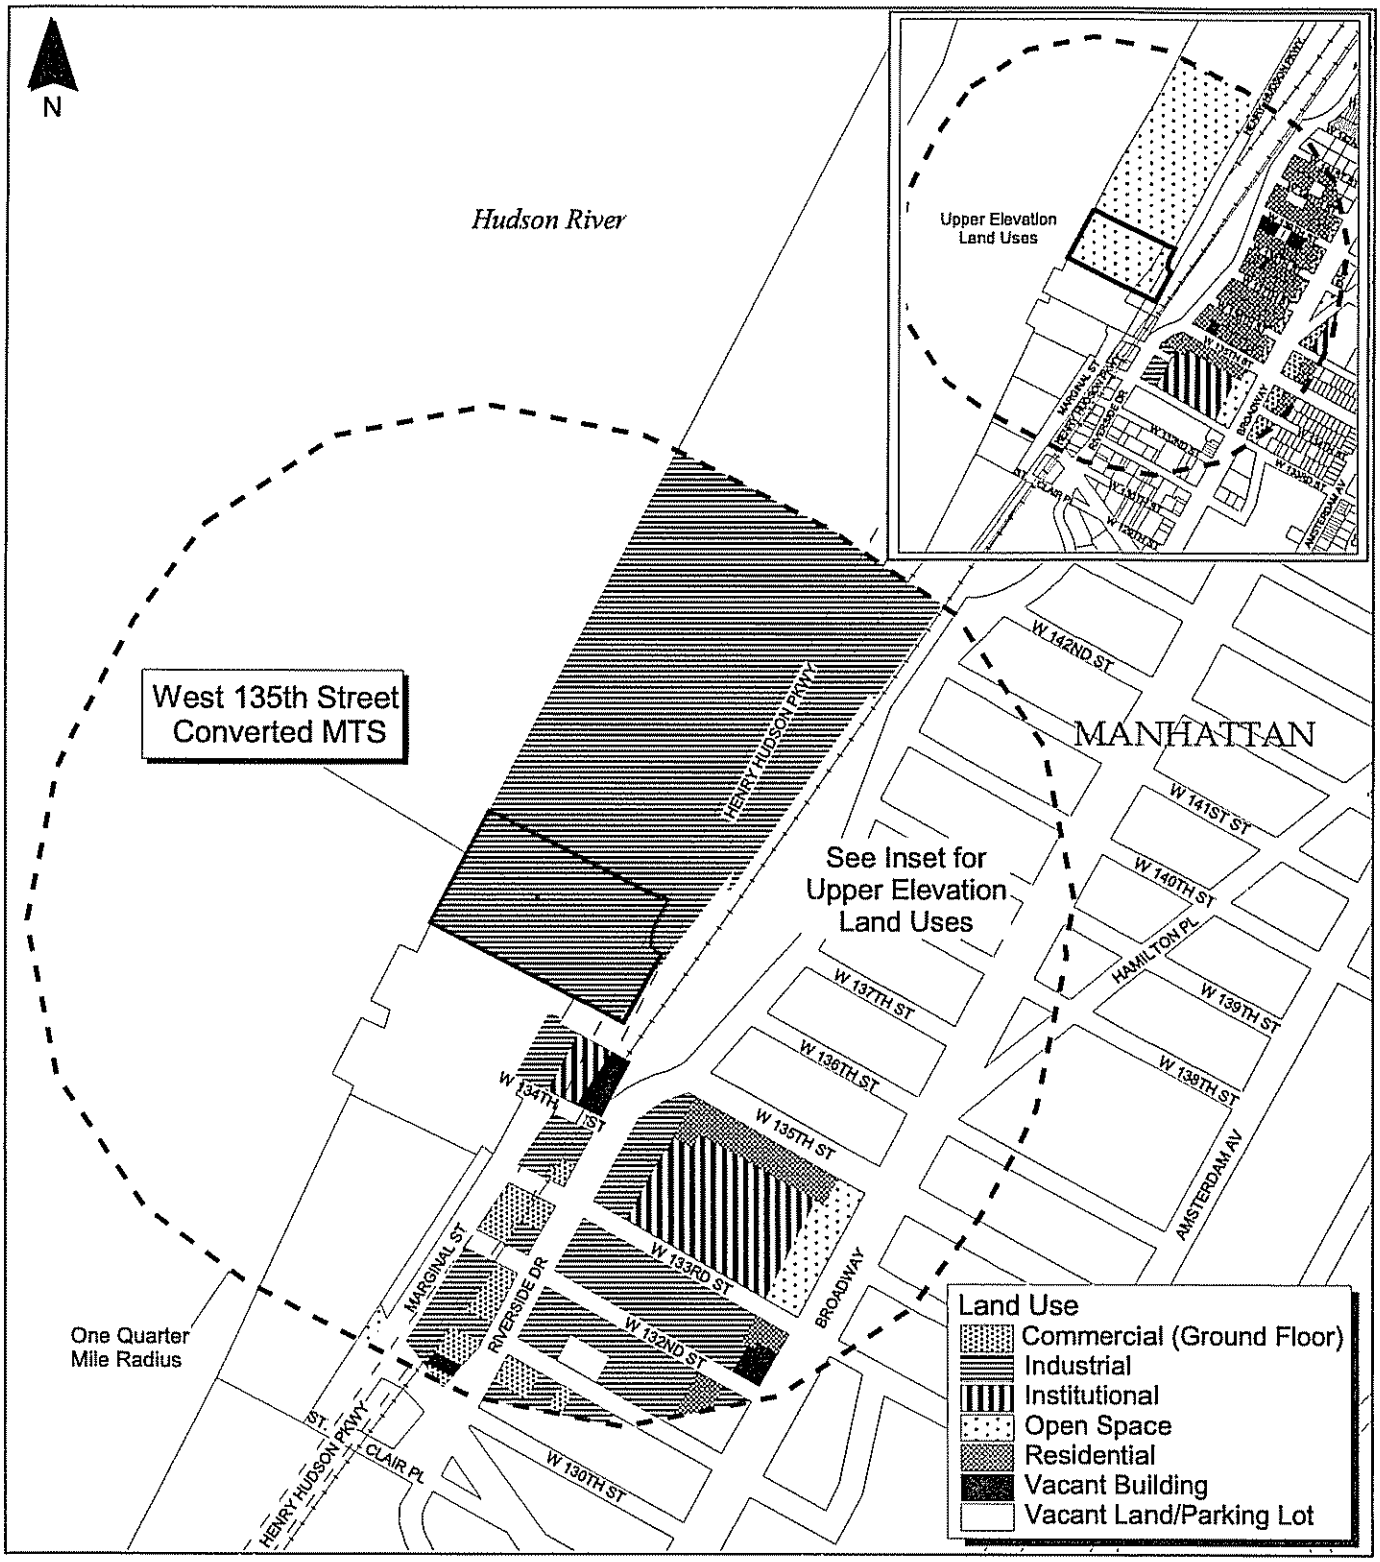
Section 2.4.3 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

21.2 Land Use, Zoning, and Public Policy

21.2.1 Existing Conditions

21.2.1.1 Definition of the Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 21.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 21.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.4.3 provides information on existing land uses and operations on the site.

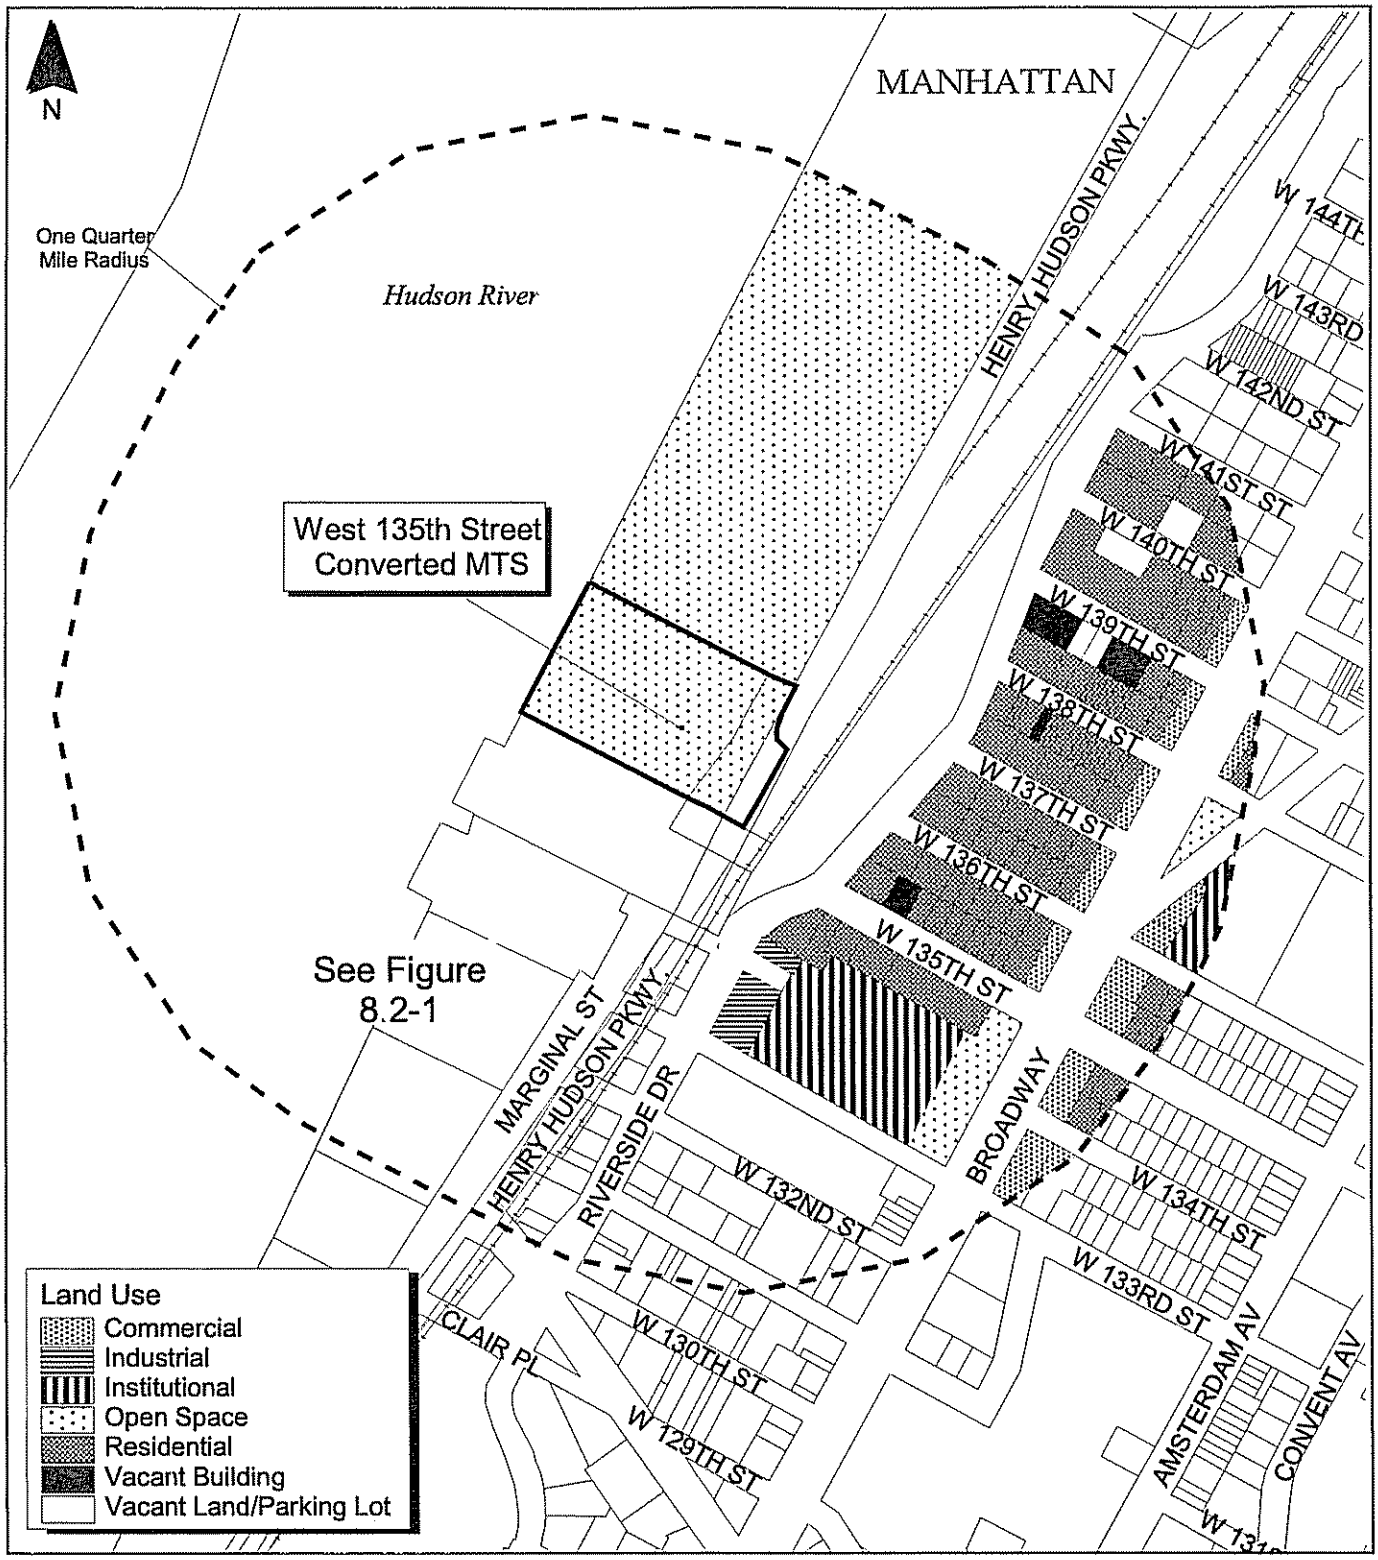


21.2.1.2 Land Use Patterns

21.2.1.2.1 General Context

Set in the larger context of Manhattan's Upper West Side and Hudson River waterfront, the site is surrounded by a variety of land uses in the immediate area, including primarily water-dependent municipal uses, parks and recreational areas and transportation infrastructure.

21.2.1.2.2 Land Uses in the Primary Study Area



Two major roadways, the Henry Hudson Parkway and Riverside Drive, separate the site from upland elevated areas to the east by providing a buffer of about 450 feet between the site and residential uses. In addition, these residential upland areas sit at a higher elevation than the site and do not have direct access to it via the cross streets. Most streets around the site are dead-end or one-way and directed away from the site. Essentially, the only way to access the site is to approach West 135th Street from the south via Twelfth Avenue, which runs between St. Clair Place and 137th Street under Riverside Drive.

Site delineations and study area boundaries are approximate.

Figure 21.2-2 Land Use in the Primary Study Area
Upper Elevation
West 135th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Immediately north of and adjacent to the site is the City's North River WPCP between West 135th and West 145th Streets, upon which Riverbank State Park is located. The park is an active recreation facility encompassing 28 acres of playing fields and courts, a café, cultural center and amphitheater. (See Section 21.5 for more detail on the park.) Adjacent to the WPCP, at grade level below the Henry Hudson Parkway, is a staging area used by the NYCDEP for ongoing construction at the plant. A variety of other uses are also below the parkway, including the 26th Precinct Police Station at West 135th Street, various warehouses, vacant buildings and commercial establishments. Immediately to the south of the site is a Consolidated Edison natural gas pumping facility.

A narrow portion of Riverside Park runs just to the east of the site, along the western edge of Riverside Drive and at the same elevation as Riverside Drive and the residential area adjacent to it.

The undeveloped piers and shore area south of the site located between West 125th and West 133rd Streets, known as "Harlem Piers," are publicly owned property currently used as informal public waterfront access and the subject of a current NYCEDC redevelopment plan.

East of Riverside Drive, the primary study area is almost entirely residential. These upland areas are comprised of apartment buildings generally six to seven stories tall, except for River View Towers on Riverside Drive north of West 139th Street, which is 24 stories tall. Toward the southern portion of the primary study area, particularly around Broadway, there are ground-level commercial uses and various automotive repair, garage and warehouse storage spaces on the cross streets, including NYCT's Manhattanville Bus Depot (between West 132nd and West 133rd Streets).

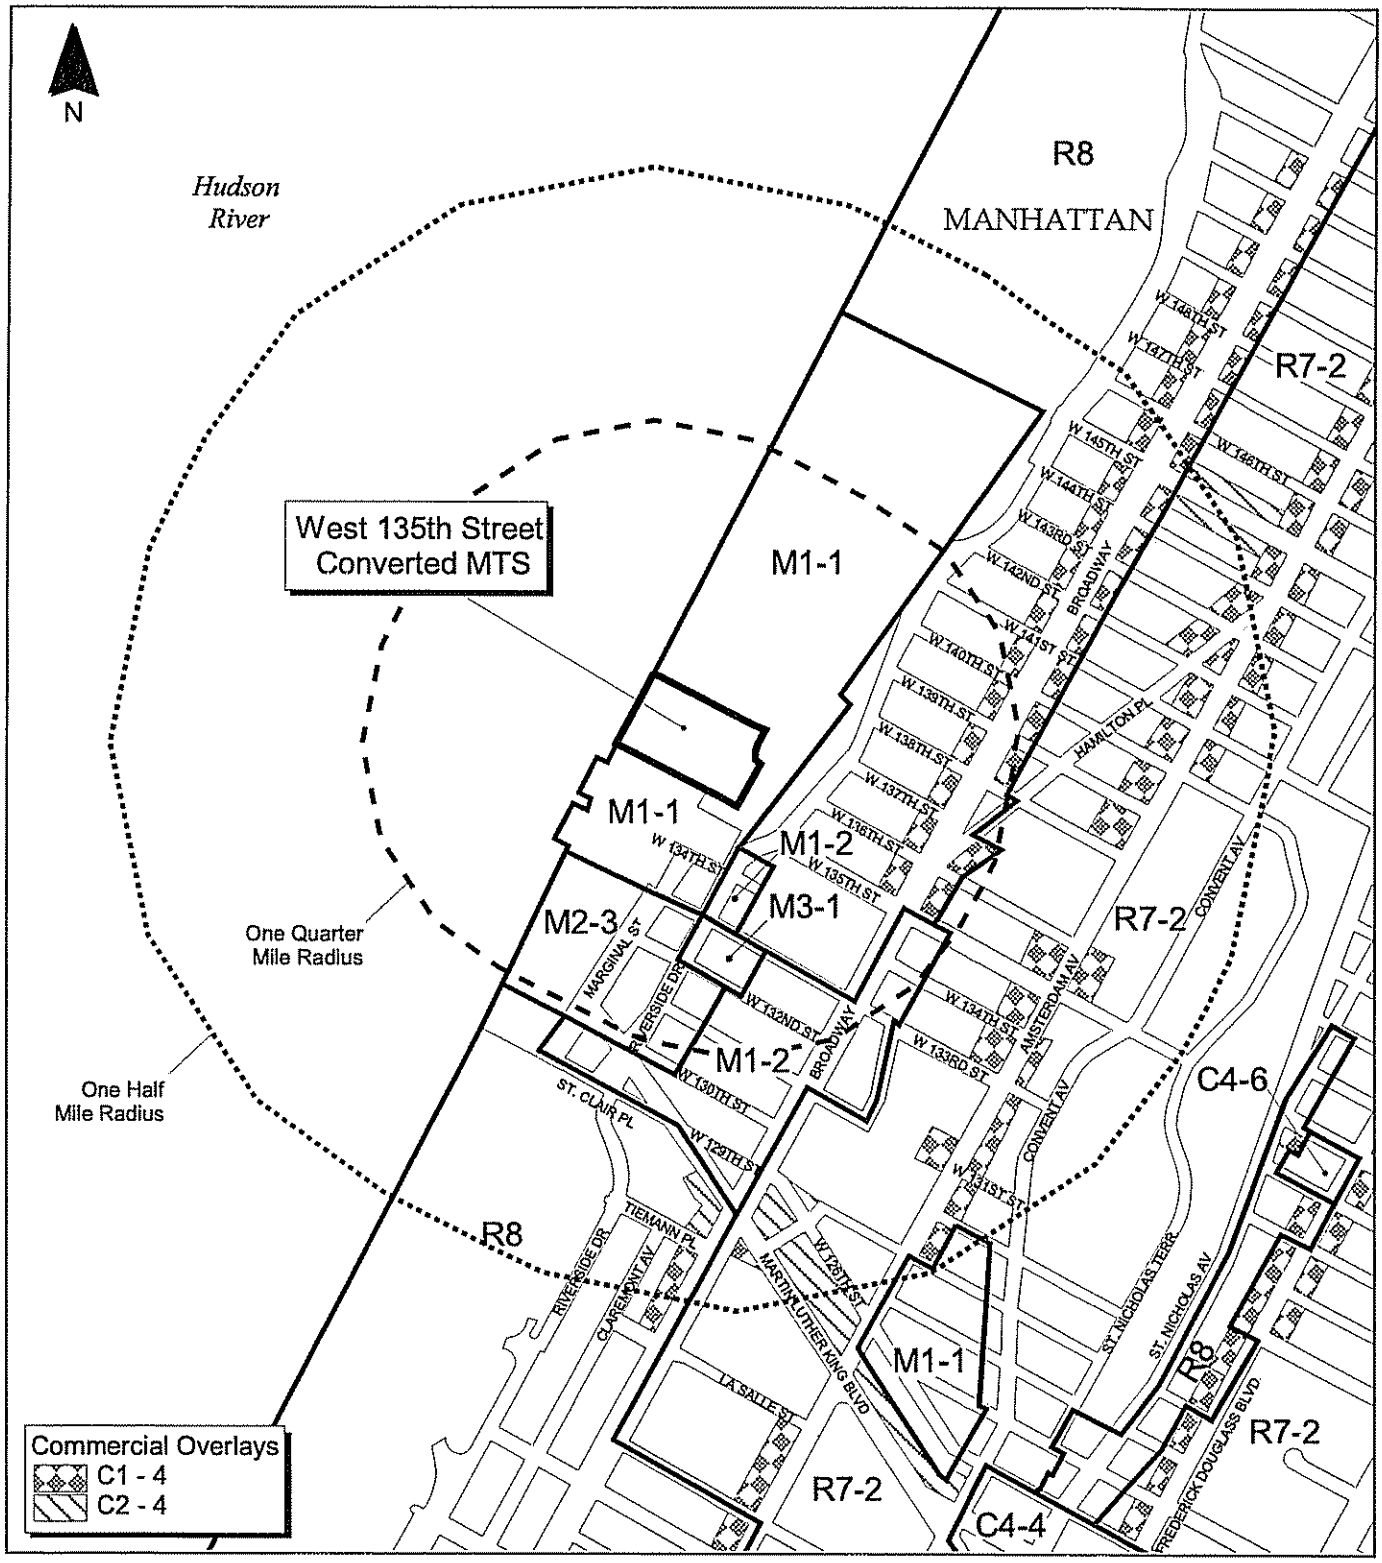
21.2.1.2.3 Land Uses in the Secondary Study Area

Land use in the secondary study area is generally characterized as residential, with related uses such as schools, churches and libraries, and commercial uses along Broadway and Amsterdam Avenue, the north-to-south arteries. City College, located east of the site on Amsterdam Avenue,

covers the area along the eastern perimeter of the secondary study area from about West 130th to West 140th Streets. Grant's Tomb, a national landmark and tourist attraction, is located south of the secondary study area at West 122nd Street and Riverside Drive.

21.2.1.3 Zoning On and Near the Site

21.2.1.3.1 Zoning Within the Primary Study Area



The site is located within an M1-1 zoning district, which extends along the waterfront from West 133rd to West 145th Streets and includes the North River WPCP and Riverbank State Park atop it. The remainder of the primary study area to the east of the Henry Hudson Parkway is zoned for high-density residential development (R8), with a commercial overlay along Broadway. The nearest residentially zoned area is approximately 220 feet from the site. Manufacturing zones cover the waterfront north and south of the site. (See Figure 21.2-3 and Table 3.4-1: Zoning District Characteristics.).

21.2.1.3.2 Zoning Within the Secondary Study Area

The shoreline areas north of the site within the secondary study area are zoned for industrial uses as far north as 145th Street. The manufacturing zoning continues into the secondary study area south of the site to about St. Clair Place and inland to include the area around the intersection of Broadway and West 132nd Street. The remainder of the secondary study area is zoned for residential use with commercial overlay zoning along Broadway and Amsterdam Avenue.

21.2.1.4 Plans and Policies

As described in NYCDPR's Comprehensive Manhattan Waterfront Plan (CMWP) (197-a Plan), Harlem Piers is the site of potential future mixed-use development, where interim improvements to bulkhead and areas along Marginal Street should be coordinated with DSNY to minimize pedestrian-vehicular conflicts. (See Section 21.5 for details on NYCDPR park plans and Section 21.12 for a review of consistency with the WRP.)

Site delineations and study area boundaries are approximate.

Figure 21.2-3 Zoning

West 135th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The CMWP recommends that NYCDEP's construction staging area be used "at least in part" to provide access between Riverside Park North and the proposed Harlem Piers. The plan also recommends extending public bus service to Riverbank State Park. Additionally, the CMWP recommends designating the northern portion of the park as a scenic landmark.

The NYCEDC prepared the West Harlem Master Plan, a master plan for the area extending from about St. Clair Place/West 125th Street to West 133rd Street and from the east side of Broadway west to the Hudson River, including the site of the West 135th Street Converted MTS (published in August 2002). The plan suggests three redevelopment components: the transportation system serving the waterfront, transportation, and upland development. Potential transportation improvements include an intermodal center, off-street parking improvements, reconfiguration of the Henry Hudson Parkway ramps and streetscape improvements. The intermodal center would be located between St. Clair Place and West 125th Street, west of Twelfth Avenue, and could include a new Metro-North station (currently being considered by MTA as part of the Penn Station Access Study), as well as provide for bus and ferry connections. The intermodal center is portrayed as the key to making West Harlem a regional attraction.

In the waterfront parcel just west and north of the proposed intermodal center, multi-use recreational activities are envisioned, while upland development largely through infill is expected to occur as a result of proposed infrastructure improvements and potential zoning changes.

Development of the Harlem Piers area is recommended as part of the CMWP and the New WRP. As specified by the Plan for the Manhattan Waterfront, a focus of this development is pedestrian planning and ensuring pedestrian and bikeway connectivity along the Hudson River near the proposed intermodal center; however, while the Harlem Piers development project is planned for completion by 2006, the timeframe for development of the intermodal center and other recreational facilities is not yet known.

CD 9, in its CDNS (FY 2004), is organized to emphasize the primary concerns for promoting an improved quality of life and advancing the economic development of the community. To this end, the CDNS refers to the Harlem Piers area as the last remaining opportunity for community

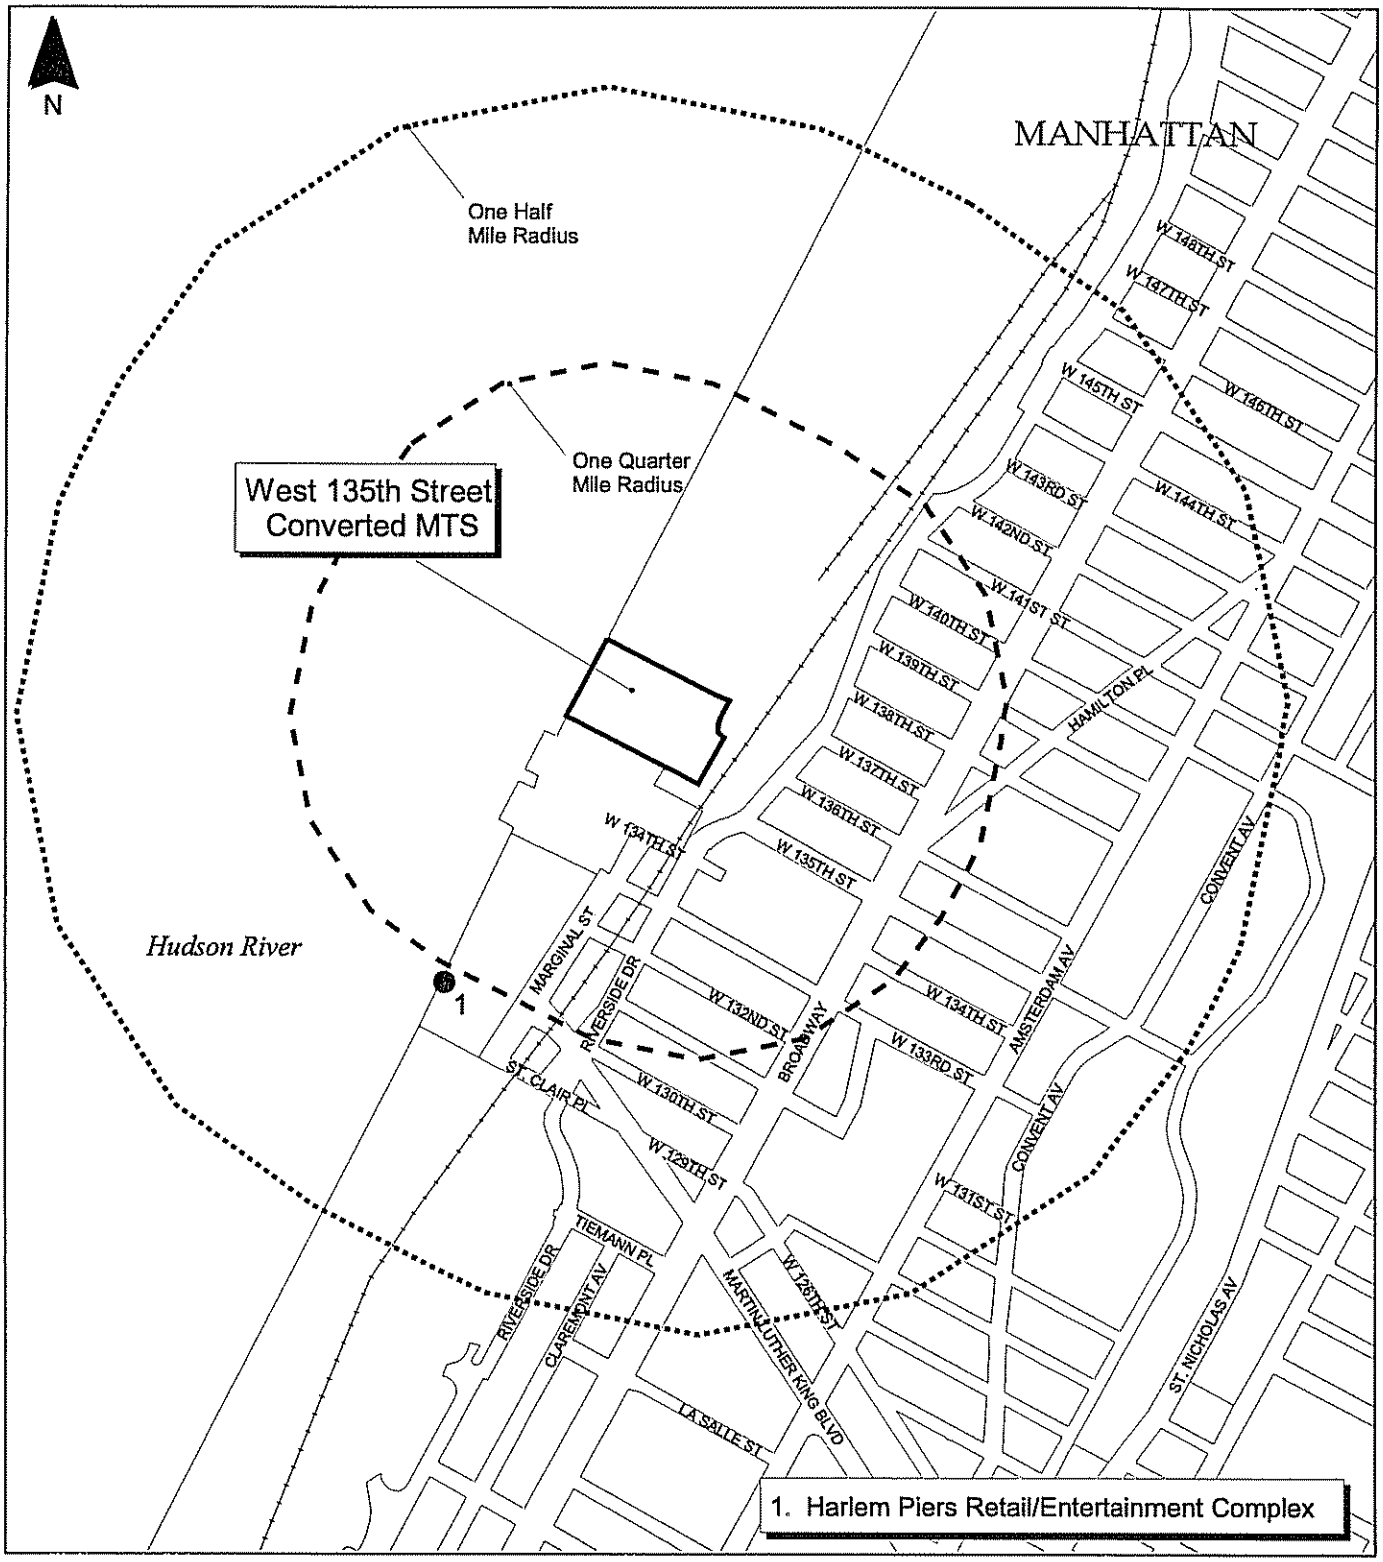
development and supports the notion of developing the area as a means of providing jobs and open space/waterfront access. Otherwise, the CDNS makes no reference to the site or its immediate environs. The Community Board's goals for the district are to see their prepared 197-a plan through approval and implementation, and to work to improve the quality of housing in the area.

The Frederick Douglass Boulevard Rezoning Study, also conducted by NYCDCP, makes recommendations in four categories: housing stock, quality of urban fabric, Frederick Douglass Boulevard image, and the development of public space. This proposed zoning map amendment would affect 44 blocks in south-central Harlem, and aims to balance growth and preservation in the residential core. The area to be rezoned is generally bounded by Central Park North, West 124th Street, Morningside Avenue and Adam Clayton Powell Boulevard, about one mile from the site.

Of particular interest is the proposed Hudson River Valley Greenway to be developed under the act of the same name. The goal of this act is to provide a continuous waterfront pathway from Albany to Battery Park in lower Manhattan. Currently, there is a "gap" between West 125th Street and West 135th Street. An interim pedestrian and bicycle route connection is currently provided on street until a formal connection can be developed. The driveway to the existing MTS at West 135th Street presents a cross-traffic obstacle to pedestrians and bicyclists traveling on the interim route. According to the Greenway Plan for New York City: Greenway Map, NYCDCP, 1996, this route includes an on-street path following St. Nicholas Avenue along St. Nicholas Park. The more recent New York City Cycling Map (2002) shows proposed on-street routes near the site along Convent Avenue, West 125th Street, West 120th Street and Twelfth Avenue where an off-street path is also proposed (to be part of a Hudson River Greenway route).

21.2.2 Future No-Build Conditions

According to NYCEDC, the Harlem Piers redevelopment (the waterfront component of the West Harlem Master Plan) will be completed by 2006. Current designs show that the Harlem Piers will include a park and wharf along the water's edge, a covered market square and a 10,000-square-foot multi-use structure at the western end of the piers site that could include retail and restaurant uses, as well as cultural and visitor's centers. Certain streetscape improvements are also planned, such as wider sidewalks, new street plantings and street art.



NYCDPR is working with NYCEDC to incorporate elements of its Hudson River Valley Greenway bicycle and pedestrian plan into work implemented as part of the Harlem Piers Redevelopment. Specific solutions to the problematic crossing of West 135th Street — a historically notable disjuncture in the bikeway — are still being discussed. Solutions may include the construction of a cantilever to carry the route from West 133rd Street to the north side of West 135th Street. (See Section 21.5 for a discussion of parks improvement in the area.)

The site will remain DSNY property, and the existing MTS will remain standing.

21.2.3 Potential Impacts with the West 135th Street Converted MTS

21.2.3.1 Land Use and Zoning

Reactivating waste transfer activities on the site and replacing the existing MTS with the West 135th Street Converted MTS would be consistent with zoning on or near the site and existing and proposed land uses, including the planned Harlem Piers development (see Figure 21.2-4). Notably, the location for waterborne waste transfer here is congruent with the North River WPCP immediately north. There are no sensitive uses beneath the viaduct or at the same elevation as the West 135th Street Converted MTS north of West 133rd Street.

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

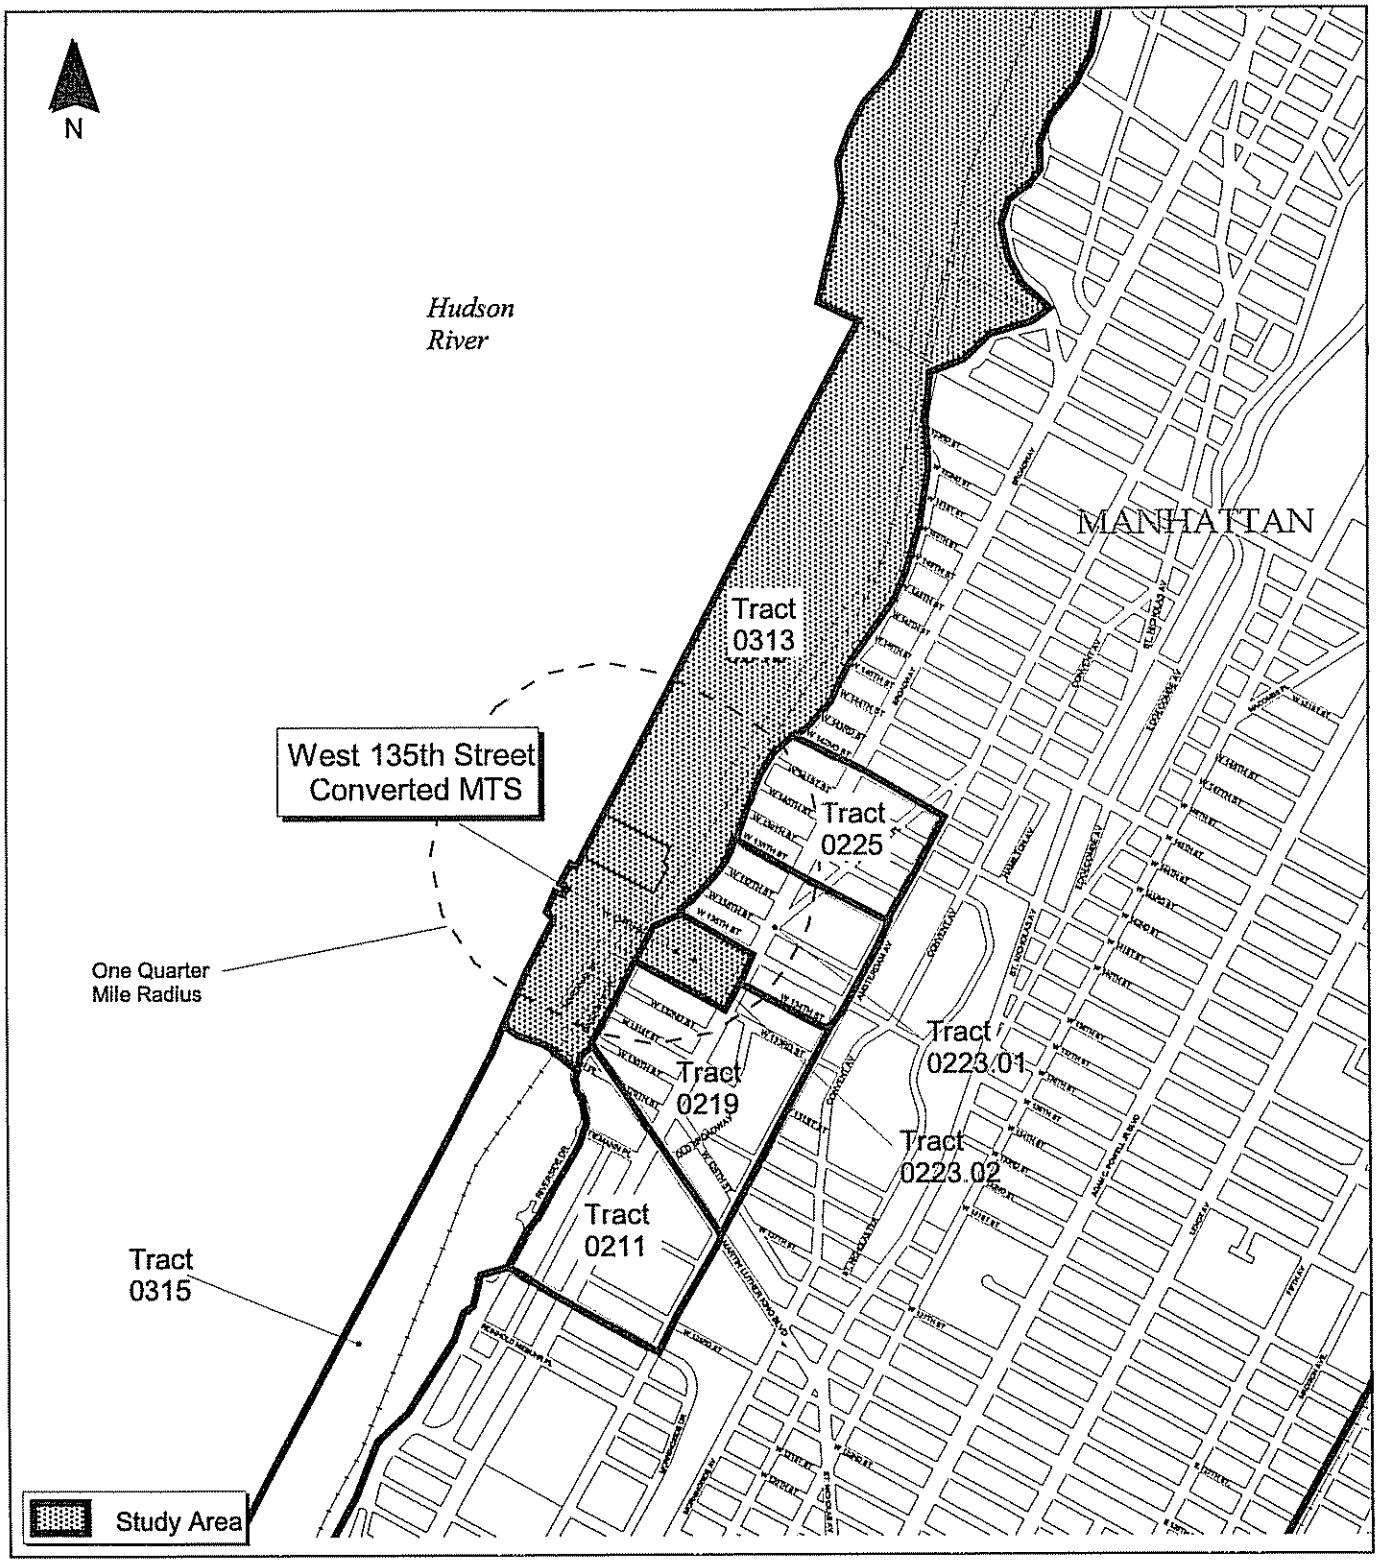
21.2.3.2 Consistency with Public Plans and Policies

There are no recommendations or objectives stated in relevant plans and policies that specifically relate to the site, study area or the West 135th Street Converted MTS, which would be consistent with the applicable 197-a Plan (the CMWP) insofar as it would not preclude the developments recommended in the plan for nearby areas.

21.3 Socioeconomic Conditions

21.3.1 Existing Conditions

21.3.1.1 Definition of the Study Areas



Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site, and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) The demographic study area is comprised of Census Tracts 223.02 and 313 (see Figure 21.3-1). Census Tract 223.03 covers an area bounded by Twelfth Avenue to the west, 133rd Street to the south, 135th Street to the north and Broadway to the east. Census Tract 313 covers the Hudson River south until St. Clair Place, east along Henry Hudson Parkway and Riverside Drive and north until I-95. For comparison purposes, census data were also gathered at the borough and City levels. The study area for the assessment of potential impacts on economic conditions extends as far north as West 145th Street, south to Tiemann Place and east to Convent Avenue.

Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

21.3.1.2 Demographic Characteristics

21.3.1.2.1 Population

The total 2000 study area population was 4,102 persons (see Table 21.3-1). In terms of total population growth from 1990 to 2000, the study area experienced a greater percentage increase (7%) than did the borough during the same period (3%), but its population did not grow as rapidly as the City's as a whole (9%).

Site delineations and study area boundaries are approximate.

Table 21.3-1
1990-2000 Population

	Study Area	Manhattan	City
2000	4,102	1,537,195	8,008,278
1990	3,836	1,487,536	7,322,564
Percent Change	+6.9%	+3.3%	+9.4%

Source: U.S. Census 1990, 2000

The age-sex distribution was slightly different from the population distribution of the borough and the City with an even greater proportion of females to males. The study area contained a considerably greater percentage of children and teenagers than did the borough or City; approximately 33% of the study area population was under the age of 20 compared to 19% for the borough and 27% for the City.

21.3.1.2.2 Racial and Ethnic Characteristics

The 2000 study area population had a far greater proportion (66%) of people of Hispanic origin (all races) than did Manhattan or the City (27%). Of the 34% not of Hispanic origin, 92% were Black and 3% were White. In Manhattan and the City, Blacks represented approximately 21% and 33% of the non-Hispanic populations, respectively, while Whites represented 63% and 48%, respectively.

From 1990 to 2000, the number of study area residents of Hispanic origin increased by a greater rate (45%) than in the borough (10%) and in the City (24%) during the same period. Because the 2000 Census introduced the option for respondents to identify themselves as two or more races, racial categories are not directly comparable with 1990.

21.3.1.2.3 Families and Households

There were 987 families in the study area in 2000 and the percentage of these families that had children under the age of 18 (about 55%) was considerably larger than those families in Manhattan with children under 18 (43%) and in New York City (49%). There was a

considerably smaller percentage of married-couple families in the study area than in the borough or the City, and 49% of these families had children, greater than Manhattan (39%) but about the same as the City (48%).

Fifty-one percent of the families in the study area were headed by a female householder, which is a higher percentage than in the borough or the City (both 30%). Sixty-four percent of the female householder families in the study area had children under the age of 18, slightly greater than the percentages in the borough (53%) and the City (55%).

There were 1,582 households in the study area in 2000, with an average household size of 2.6 persons, greater than Manhattan (2 persons) but equal to the City.

From 1990 to 2000, the number of households in the study area increased by 8%, compared with a 3% increase in the borough and a 7% increase in the City.

21.3.1.2.4 Employment

Within the study area, 45% of persons aged 16 and older participated in the labor force in 2000, compared to 64% in Manhattan and 58% in the City. The majority of these people in all three areas were employed as private wage and salary workers.

Twenty-two percent of employed persons 16 and over were government workers, compared to Manhattan (10%) and the City (16%). Moreover, 10% of the study area's working population was self-employed, about the same proportion as in Manhattan (9%) and somewhat higher than in the City (6%).

From 1990 to 2000, the number of employed persons within the study area decreased by 12%, while the number of employed persons in the borough and the City remained approximately the same. Among employed persons, those engaged in government jobs decreased by 47%, compared to a 15% decrease in the borough and a 10% decrease in the City.

Current forecasts indicate that about 36,397 employees worked in Manhattan CD 9 in 2005, which was about 1.6% of the borough's total employment.[1]

21.3.1.2.5 Housing

Most housing units in the two census tracts in the study area were constructed between 1970 and 1979, while the majority of housing units in both Manhattan and the City were built at least before 1959. As of 2000, there were 1,600 housing units in the study area, with a vacancy rate of about 1.2%, lower than either the borough (8%) or the City (6%). Nearly all the housing units were renter-occupied (94%), considerably greater than the borough (74%) and the City (66%). Median monthly rent ($496) was far lower than in the borough ($796), and in the City ($705).

The turnover in the study area (30%) from 1995 until 2000 was lower than that of the borough (45%) and the City (43%).

From 1990 to 2000, a total of 136 housing units were added in the study area, representing a 9% increase, markedly greater than the borough (2%) and slightly higher than the City (7%).

21.3.1.2.6 Education

Consistent with the higher percentage of children in the study area than in the borough or the City, there was a slightly higher rate of school enrollment (34%) than in either the borough (24%) or the City (29%). Of those enrolled in school within the study area in 2000, 73% were enrolled in elementary school or high school and 18% were enrolled in college or beyond. In Manhattan, 51% were enrolled in elementary school or high school and 39% in college or beyond, while 62% of the City's enrolled population was in elementary or high school and 27% in college or beyond.

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

The study area witnessed an 18% increase in the number of persons enrolled in school from 1990 to 2000, with the largest increase in enrollments occurring at the pre-primary school level (190%), comparable to City-wide trends.

The study area had a far lower educational attainment level than either the borough or the City. A markedly smaller proportion (37%) of the study area population aged 25 and over had a college degree or some college education compared to Manhattan (66%) and the City (48%). The study area had a similar percentage of people with only high school diplomas (23%) compared to the City (24%), and a far greater percentage than those in the borough (14%).

Despite the lower educational levels, from 1990 to 2000 the study area witnessed rising levels of educational attainment. The number of college graduates increased 34%, and the same trend was evident in the borough and the City, which experienced increases of 20% and 29%, respectively. Correspondingly, the number of people with less than a college education (between 8% and 14%) declined in the study area overall.

21.3.1.2.7 Income and Poverty

In 2000, both median household income ($17,400) and median family income ($25,196) were far lower than in Manhattan ($47,030 and $50,229, respectively) and the City ($38,293 and $41,887, respectively). Compared to the two larger areas, a greater percentage of study area households were concentrated at the lowest income levels, with the majority of annual household incomes below $25,000. Only 22% of households in the study area had incomes of $50,000 and above, compared with 48% in the borough and 40% in the City.

A greater percentage of persons in the study area under the age of 18 were living below the poverty level in 2000 (47%) than in Manhattan (32%) or the City (30%). The 2000 Census also reported that 38% of the persons 65 and older were living below the poverty level in the study area, compared to 19% in Manhattan and 18% in the City.

Within the study area, the percentage of families living below the poverty level (34%) was nearly twice that of Manhattan (18%) or the City (19%). The percentage of families living below the poverty level with children under the age of 18 (62%) was greater than the percentages in Manhattan (48%) or the City (55%).

From 1990 to 2000, the percentage of people living below the poverty level in the study area increased by 16%, as compared to a minimal change in Manhattan and 20% increase in the City.

21.3.1.3 Economic Conditions

The part of Harlem within approximately ½-mile of the site contains a mix of commercial, automotive repair, distribution and storage-related businesses. This area has experienced a strengthening of its retail sector in the last several years through the establishment of a major food retailer in the area (Fairway). The introduction of this use and the Harlem USA further east on West 125th Street outside of the study area is indicative of the increased momentum of economic activity in Harlem.

21.3.2 Future No-Build Conditions

21.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Manhattan CD 9 will remain about the same as current conditions.[2]

21.3.2.2 Economic Conditions

Ground-level commercial uses and various automotive repair, garage and warehouse storage spaces on and near Broadway will likely continue to comprise the mix of business uses near the site for the near term. Major commercial and public uses are planned south of the project site on

[2] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

undeveloped piers between West 125th and West 133rd Streets,[3] known as the Harlem Piers. The initial phases of this project involve the creation of waterfront open space as well as yet undetermined retail services. They are expected to be completed by 2006.

The near-term economic health of industrial areas, such as the industrial area in this section of Harlem, may also be supported by established City programs available through the IDA. These programs, such as the Industrial Incentive Program and the Small Industry Incentive Program, provide business tax incentives for capital renovation and expansion projects.

The designation of a portion of the study area as part of the Harlem/South Bronx EZ will likely have a positive economic effect on the larger Harlem community in the long-term. The EZ is expected to expand the range of economic opportunities in the portions of Harlem and Upper Manhattan that it covers.

Regional projections indicate that employment in Manhattan CD 9 will remain about 1.6% of the borough total.[4]

21.3.3 Potential Impacts with the West 135th Street Converted MTS

The West 135th Street Converted MTS represents the reactivation of solid waste transfer operations at the site with added containerization operations, which is a compatible activity given the site's industrial surroundings.

21.3.3.1 Residential Impacts

No direct residential displacement would occur as a result of the West 135th Street Converted MTS, and land use and neighborhood character analyses predict no adverse impacts.

---

[3] *Comprehensive Manhattan Waterfront Plan: A 197-a Plan as Modified and Adopted by the City Planning Commission and the City Council*; Rudolph W. Giuliani, Mayor; Joseph B. Rose, Director of Department of City Planning; Summer 1997, NYCDCP #98-07.

21.3.3.2 Direct Business and Institutional Impacts

The West 135th Street Converted MTS would not result in the direct displacement of businesses or institutional uses.

21.3.3.3 Indirect Business and Institutional Impacts

The West 135th Street Converted MTS would not result in indirect impacts to study area businesses or institutions.

21.3.3.4 Employment Impacts

The West 135th Street Converted MTS is expected to generate a total of approximately 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

[4] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

21.4 Community Facilities and Services

21.4.1 Existing Conditions

21.4.1.1 Definition of the Study Areas

The primary study area is defined as that area within ¼-mile of the site. The secondary study area is defined as the area between ¼- and ½-mile of the site.

21.4.1.2 Summary of Community Facilities and Services

There are three community facilities in the primary study area and 30 in the secondary study area. These facilities and others serving the site but located outside of the secondary study area are listed below in Table 21.4-1 and shown on Figure 21.4-1.

21.4.2 Future No-Build Conditions

There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. CD 7 has expressed an interest in having a high school within its district, but no plans have been made. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

21.4.3 Potential Impacts with the West 135th Street Converted MTS

The West 135th Street Converted MTS would not create any significant new demand on services and community facilities and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the West 135th Street Converted MTS.

21.5 Open Space

21.5.1 Existing Conditions

21.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

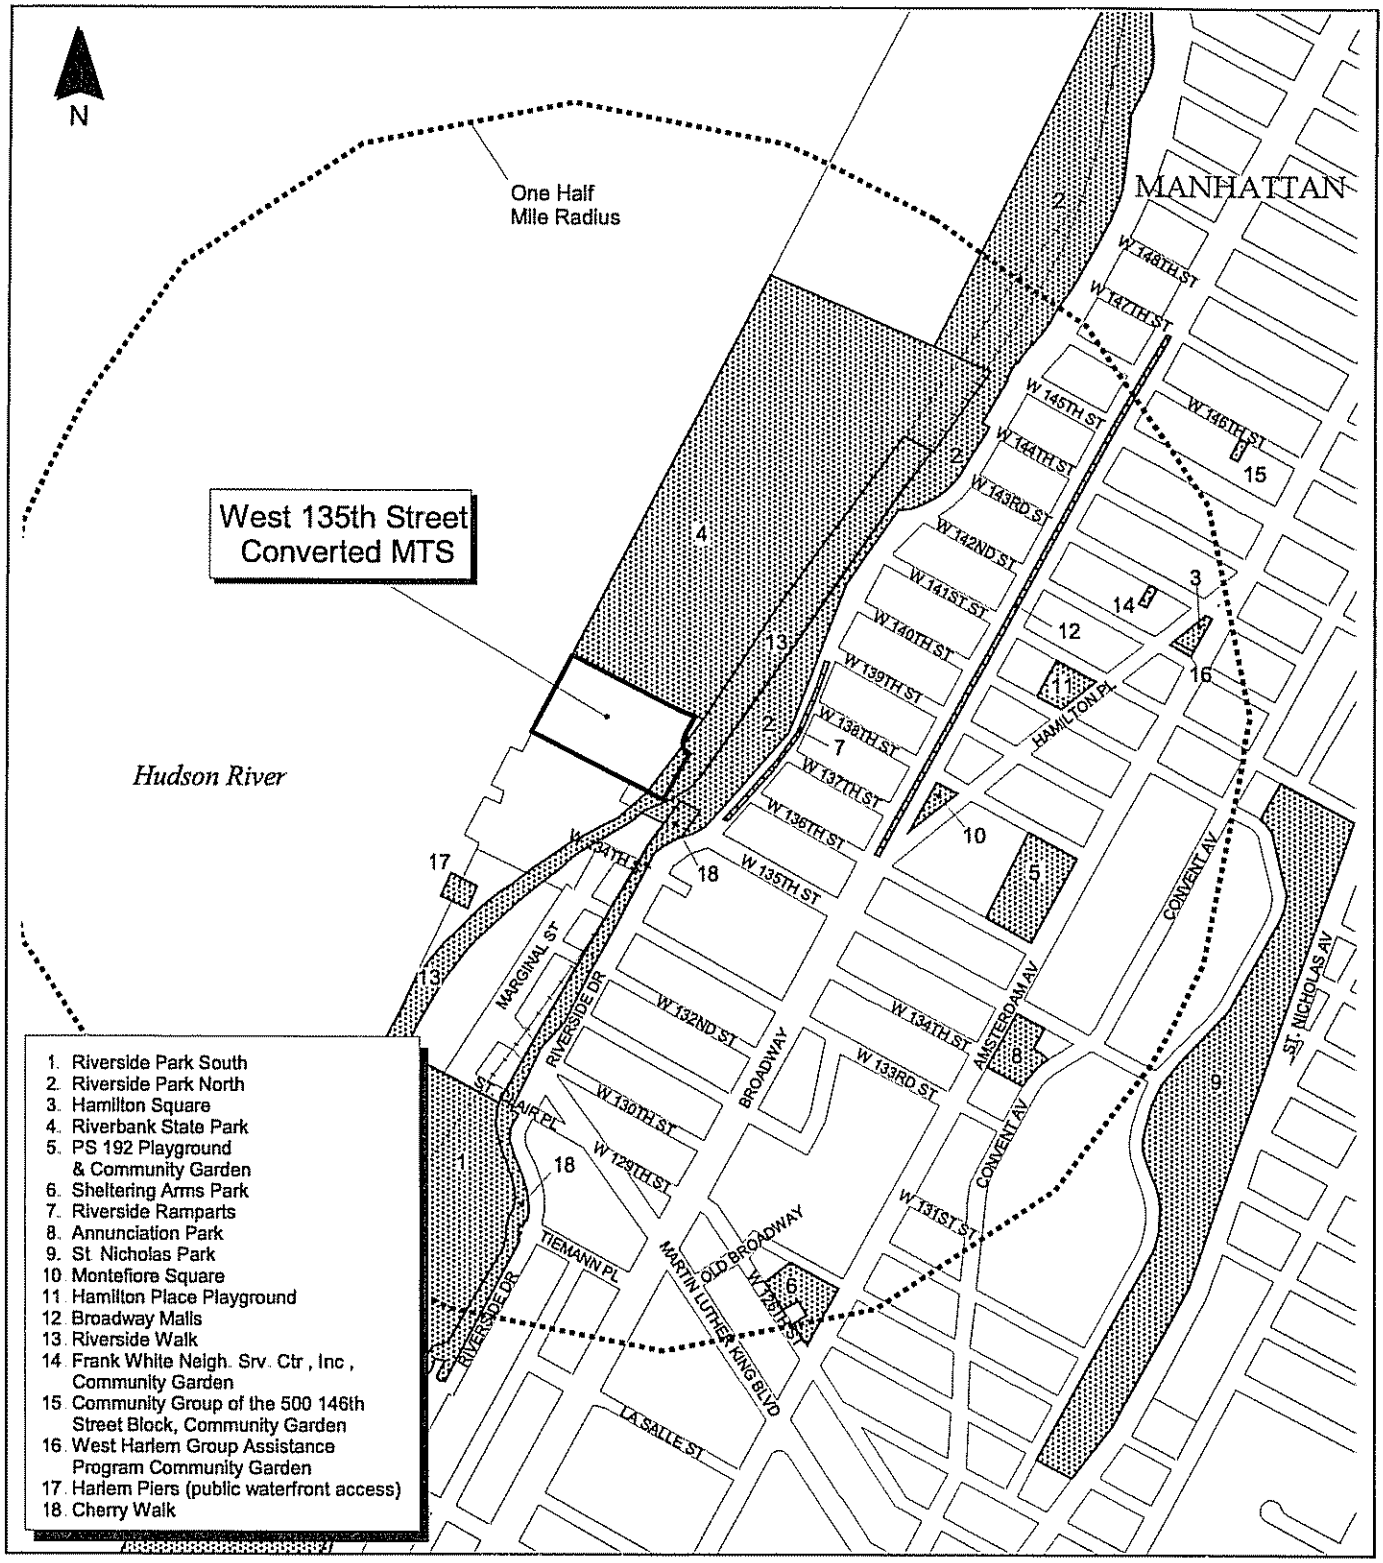
21.5.1.2 Summary of Open Space in the Study Area

There are 16 public parks and open spaces within the study area and five just beyond. They are listed in Table 21.5-1 and shown on Figure 21.5-1.

Of particular interest is the proposed Hudson River Valley Greenway under development to provide a continuous waterfront pathway from Albany to Battery Park in lower Manhattan. Currently, there is a "gap" between West 125th Street and West 135th Street and an interim pedestrian and bicycle route connection is provided on street until a formal connection can be developed.

21.5.2 Future No-Build Conditions

The NYCDPR has several projects programmed for Riverside Park and assumed to be completed by the 2006 Build year. These include:



- "Riverside Walk" Bicycle and Pedestrian Path (West 83rd – West 153rd Street) construction;
- West 143rd – West 148th Street path restoration;
- Broadway Malls Reconstruction (West 135th – West 168th Street);
- Application of artificial turf to P.S. 192 Playground (Jacob Schiff Playground); and
- Riverside Park Drive (Ralph Ellison Island West 149th – West 153rd Street).

Figure 21.5-1 Open Space/Parkland
West 135th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

NYCEDC has begun the site planning for "Harlem Piers," the waterfront component of the West Harlem Master Plan. A fundamental component of this is the creation of new strip of waterfront parkland extending along the Hudson River between West 129th Street and West 133rd Street.

NYCDPR currently has funding to design and construct a cantilever between 133rd Street and 135th Street, along the western side of the Henry Hudson Parkway and then continuing north of 135th Street along the North River WPCP haul road temporary path.

21.5.3 Potential Impacts with the West 135th Street Converted MTS

The West 135th Street Converted MTS would have no effect on any open space resources within the study area. It would not physically change, diminish or eliminate any open space or reduce its use or aesthetic value, or introduce a substantial new user population that would create or exacerbate over-utilization of open space resources.

21.6 Cultural Resources

21.6.1 Existing Conditions

21.6.1.1 Definition of the Study Area

The cultural resources study area is defined as that area within ½-mile of the site.

21.6.1.2 Development History of the Area

Portions of three distinct Upper Manhattan neighborhoods with their own development histories are part of the study area: Manhattanville, Hamilton Heights and Morningside Heights.

The Manhattanville area on the Upper West Side was a village with a population of about 500 people in the mid-19th century. The village contained churches, a grade school and Manhattan College (1853). It was set in the valley near the present intersection of West 125th Street and Broadway and was surrounded by country residences and open land. There was a ferry terminus on the Hudson River, a mill and a brewery.

The Hamilton Heights area to the northeast includes the neighborhood of Sugar Hill, which is often considered part of Harlem. The area was named for Alexander Hamilton, who spent the last two years of his life in what is now the Hamilton Grange National Monument at 287 Convent Avenue. Elevated subway lines were extended to the neighborhood around the turn of the century, and most of the housing dates to that time. City College of New York (now the north campus) is located on Convent Avenue between West 132nd and West 140th Streets. The Trinity Church cemetery is located at West 155th Street on one of the highest hills of Hamilton Heights.

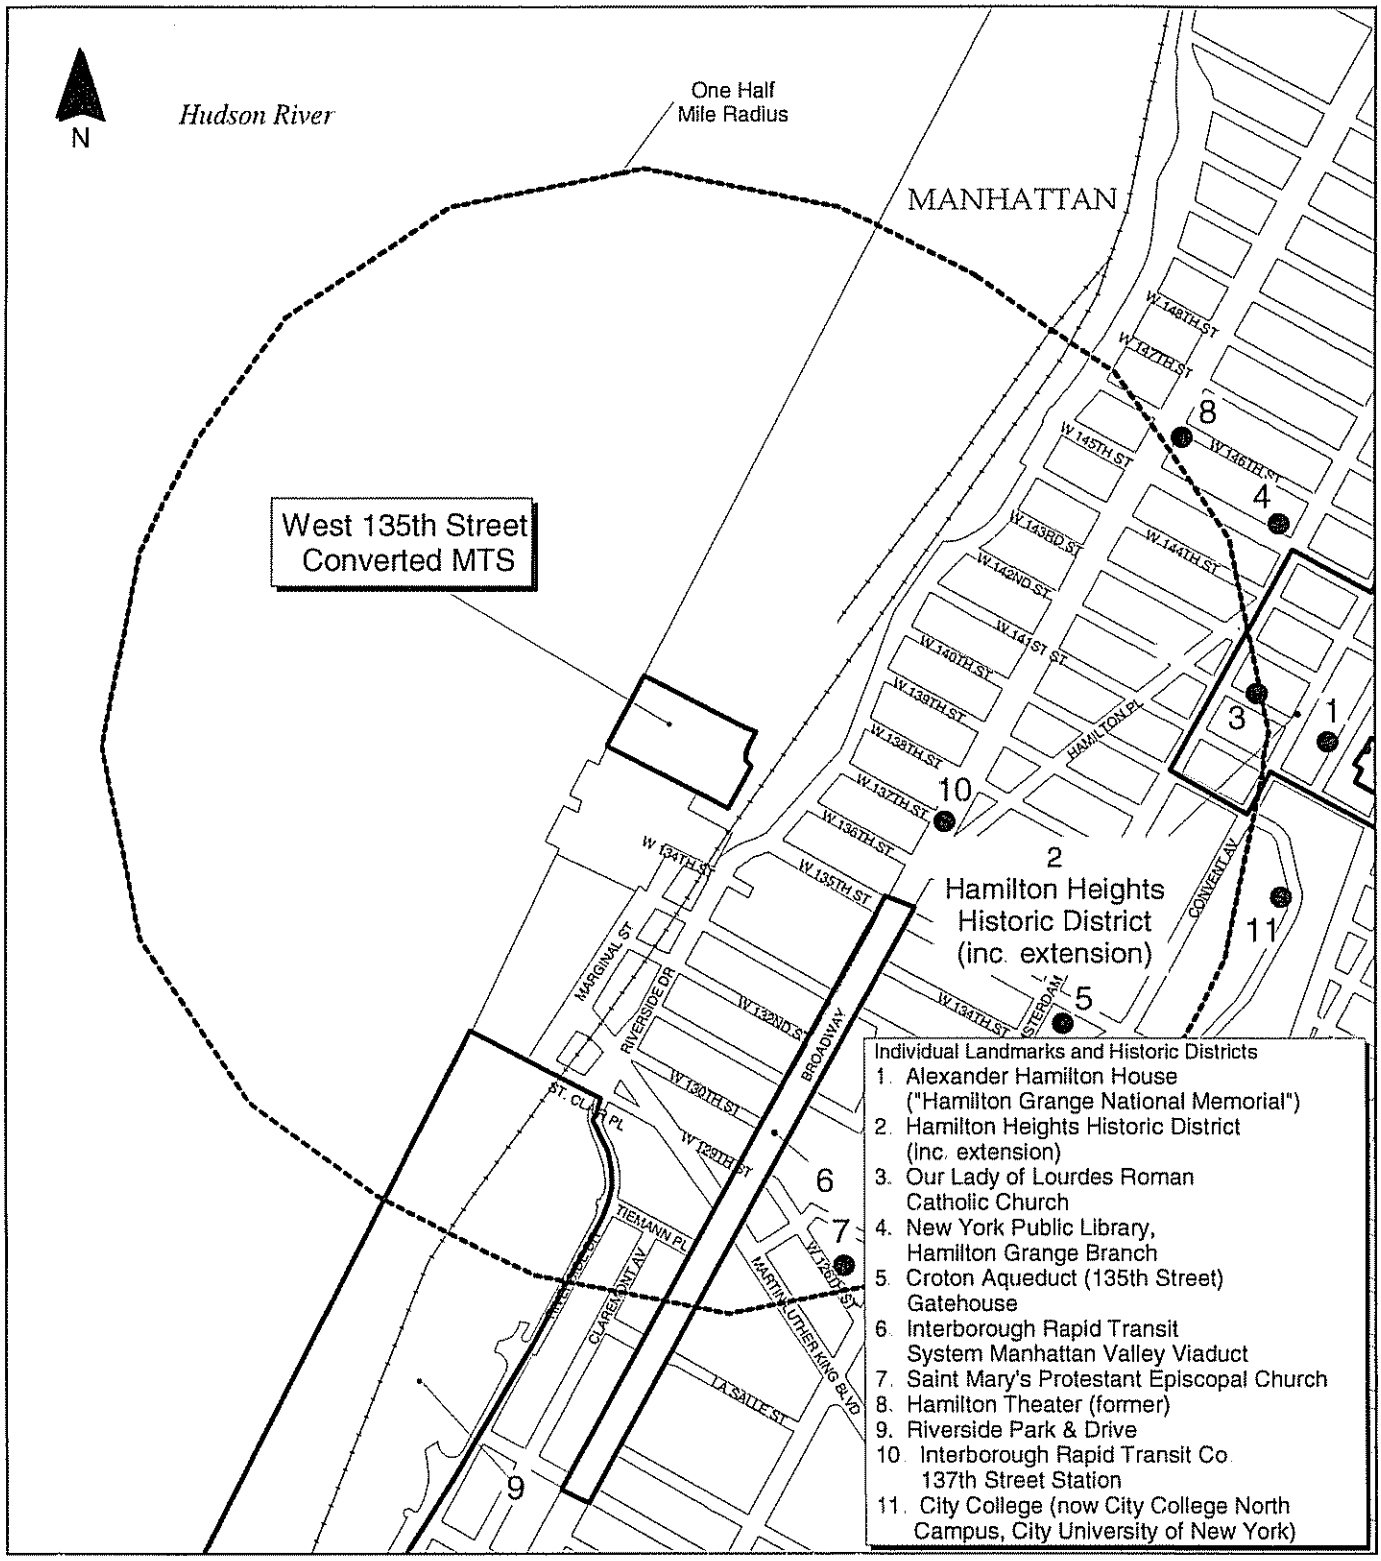
Morningside Heights is located south of the site and is bounded by West 125th Street to the north, Morningside Park to the east, West 110th Street to the south and the Hudson River to the west. The area was known as Vandewater's Heights in the 17th century, named after a local landowner when farms covered much of the area. Farmland gave way to other uses in the 18th century,

including the Bloomingdale Insane Asylum and an orphan asylum. Since the late 19th century, the area has been home to Riverside Church, Riverside Park, Columbia University, Barnard College and other prominent educational institutions.

21.6.1.3 Cultural Resources on the Site

There are no elements of architectural or archaeological significance within the site.

21.6.1.4 Historic Resources Within the Study Area



A historic district and ten historic properties are located within or near the study area (see Figure 21.6-1). These properties are listed in Table 21.6-1.

21.6.2 Future No-Build Conditions

There are no additional elements of potential historic significance slated for review. Because of the nature of architectural and archaeological resources and the fact that there is no reason to anticipate the designation of such resources in this area in the near future, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

21.6.3 Potential Impacts with the West 135th Converted MTS

Development of the West 135th Street Converted MTS would have no effect on the cultural resources named above. Based upon its review, SHPO has stated that the West 135th Converted MTS would have no impact upon cultural resources in, or be eligible for inclusion in, the State and National Registers of Historic Places (see Appendix A). The LPC has stated that the site does not have architectural or archeological significance (see Appendix A).

21.7 Urban Design, Visual Resources, and Shadows

21.7.1 Existing Conditions

21.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (see Figure 21.8-1), although it also includes upland areas east of the Henry Hudson Parkway. The site has been developed in a manner consistent with adjacent properties along the waterfront but not the upland areas. The adjacent Riverbank State Park and upland areas, including warehouses and residential buildings, are visible from the site and have views of the site, so are included as part of the study area.

21.7.1.2 Description of the Site

The site extends over water beyond the existing MTS platform (see Figure 21.7-1). The land portion of the site is paved and has no landscaping or decorative features. The remainder of the built site consists of paved road surfaces, the existing MTS facility (which is built entirely over the water) and the curved ramp that leads to its entrance.

21.7.1.3 Urban Design and Visual Resources of the Study Area

The shoreline surrounding the site has some grass cover and several scrub trees and appears to be managed as necessary to protect the soundness of Marginal Street where it runs along the shore. The 26th Precinct Police Station, located beneath the elevated Henry Hudson Parkway, resembles surrounding warehouses and vacant buildings found beneath the elevated highway (see Figure 21.7-2), which are generally nondescript, with no façade treatment. The design context of the shoreline, however, is defined by the functionalistic style of the existing MTS and the North River WPCP.

Figure 21.7-1 : View of MTS, looking west along 135th Street. (Photo 2000)

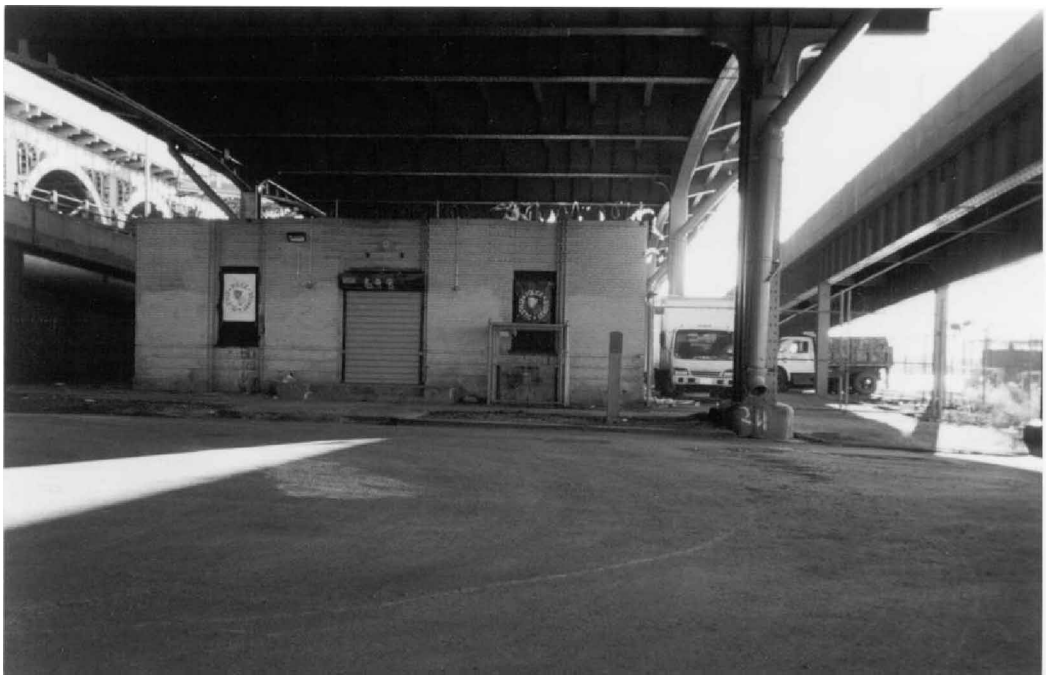

Figure 21.7-2 : Police precinct building located beneath Henry Hudson Parkway, on 135th Street.

This page intentionally left blank.

Although not excessively ornamented, the North River WPCP exhibits a designed finish uncharacteristic of many such municipal facilities, with such details as decorative arches, textured concrete and marine blue-glazed brick (see Figure 21.7-3). The low-density appearance of the area south of the North River WPCP is typical of shoreline industrial areas in the City, although the contemporary design of the existing MTS and the adjacent North River WPCP establish a more finished look to the area than may be found on other working waterfront areas.

The railroad tracks, elevated Henry Hudson Parkway and elevated Riverside Drive separate the site from the residential Manhattanville neighborhood visible to the east. This upland area east of Riverside Drive is characterized by massive residential blocks with pre-war apartment buildings stretching from about West 135th Street to West 139th Street. They typically stand approximately six to seven stories tall and feature combinations of brick veneer and stone lintels and sills. The lower floors of the buildings are visually buffered from views of the site and shoreline by distance and a change in elevation as well as mature deciduous trees in Riverside Park, while some upper-floor apartments may have views of the site.

Within the vicinity of P.S. 195, east of Twelfth Avenue and south of West 135th Street (approximately 700 feet east of the site), is a conglomeration of buildings that rises above the Twelfth Avenue viaduct. At the corner of Twelfth Avenue and West 135th Street is a light-brick Italianate building about seven stories high. Adjacent to and south of that building is the Lee Brother's, Inc. building (now used by Manhattan Mini-Storage) that stands about seven stories high, the upper five stories of which contain a vertical portico set into the white west-facing façade (see Figure 21.7-4). This building retains a commanding position over the viaduct and is topped with a large billboard that faces northbound and southbound traffic on Riverside Drive. The shorter building (about three stories tall) just to the south of it is also topped with a billboard. Behind these buildings are tall, red brick apartment buildings 20 to 29 stories tall that may have views of the site

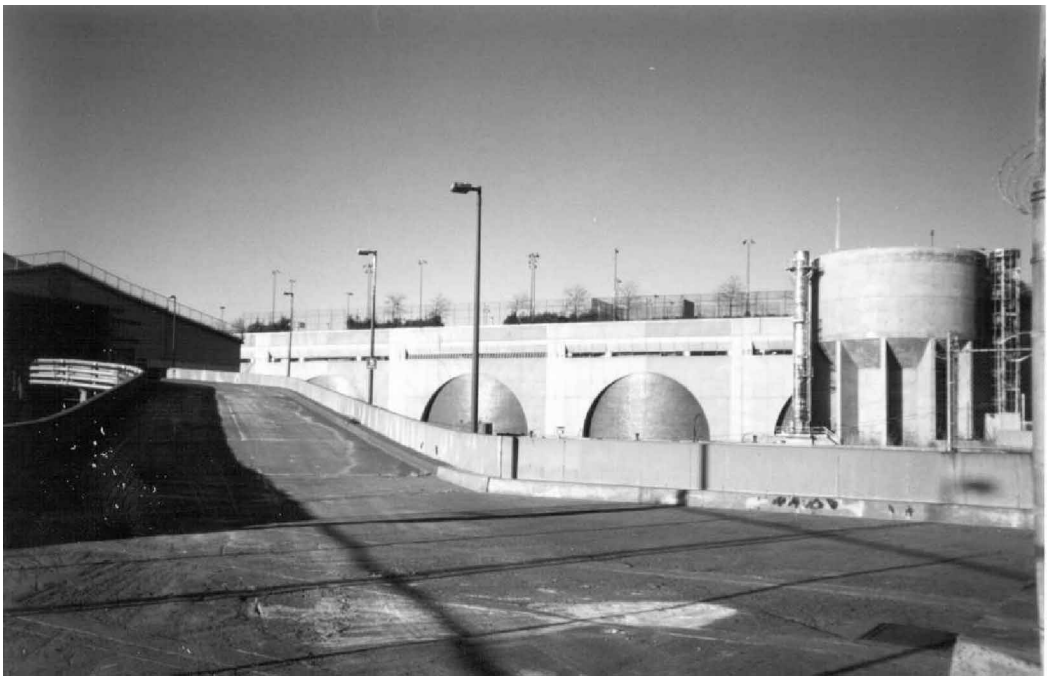

Figure 21.7-3 : View of the North River WPCP and Riverbank State Park, looking north from the site.

Figure 21.7-4 : View looking east from the site. (Photo 2000)

This page intentionally left blank.

The area's landscaping and vegetation are within maintained park areas, Riverbank State Park and portions of Riverside Park, in particular. These park areas are oriented to the land uses east of Twelfth Avenue in terms of access, elevation and location. There is little visual connectivity to the site from the portion of Riverside Park that runs east of the site along Riverside Drive, although the trees in the park are visible from the site.

Just as there are views of the site from some upland residential areas, there are clear views of the site from the ball courts and sitting areas along the entire southern edge of the adjacent Riverbank State Park (seeFigure 21.7-5). The existing MTS does not obstruct views of the river from these locations, however, and it is visually compatible with its adjacent shoreline uses.

The proposed Harlem Piers development site between West 125th and West 135th Streets includes waterfront area by the Fairway parking lot (see Figure 21.7-6). This publicly owned property, which currently is used as a point of public waterfront access, affords views of the site and the North River WPCP to the north (see Figure 21.7-7).

21.7.2 Future No-Build Conditions

Redevelopment of Harlem Piers will be a notable improvement to the urban design of the area by 2006 (see Section 21.2.2). Coupled with the improvements planned by the NYCDPR (see Section 21.5.2), which include enhancement of the bicycle and pedestrian route that follows the water's edge, the Harlem Piers will also provide for a larger visitor population Among the improvements planned by the NYCEDC are the development of a public park area, also featuring retail and passive recreational opportunities. Streetscape improvements, including new streetlights, curbing and sidewalk enhancement, will extend from approximately West 129th Street to West 133rd Street.

This page intentionally left blank.

CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

The site is expected to remain unchanged, however, under Future No-Build Conditions. Though industrial in nature, the design of the existing MTS and the façade treatment of the North River WPCP will provide suitably designed definition to the northward view from the Harlem Piers rather than merely standing as nondescript neighboring industrial facilities.

21.7.3 Potential Impacts with the West 135th Street Converted MTS

21.7.3.1 Visual Quality and Urban Design

The West 135th Street Converted MTS would entail replacement of the existing MTS with a new facility that would include containerization functions and occupy more water-covered area north of the existing platform. Views of the West 135th Street Converted MTS from the elevated residential neighborhoods, the adjacent park or the Harlem Piers area would be similar to existing views, because the West 135th Street Converted MTS would be similar to the existing facility in industrial type and function, physical size, location and operation. While it would be visible from some upland residential and recreational uses, it would not obstruct views of the river. Furthermore, the West 135th Street Converted MTS would be compatible with the existing urban design context of this portion of the Manhattan waterfront, including the proposed Harlem Piers development, and would not result in significant adverse impacts to the urban design and visual quality of the study area.

21.7.3.2 Shadows

According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment were warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.)

Four park and open space resources are located within shadow impact area:

- Riverbank State Park;
- Cherry Walk;
- Riverside Park North; and
- River Walk Path.

Riverbank State Park is located north of the West 135th Street Converted MTS, on the rooftop level of the North River WPCP, approximately 70 feet above the Hudson River on a ½-mile long platform.

Cherry Walk is a pedestrian path from Riverside Drive to the Hudson River, between West 92nd Street and West 134th Street.

Riverside Park North and River Walk Path are both located at-grade, below and shadowed by the elevated structure of the Henry Hudson Parkway.

There are no expected physical changes to the project site or vicinity that might create new shadows on these resources in the Future No-Build Condition. Therefore, the shadow assessment considered only the consequences of the Converted West 135th Street MTS development. During most of the year, shadows generated by the 100-foot tall West 135th Street Converted MTS and 80-foot cranes would completely fall across portions of the Hudson River. Analysis of June 21st and May 6th indicates that shadows would fall across any land for 20 to 30 minutes in the evening hours: from 6:30 p.m. to 7:00 p.m. on June 21st and 6:00 p.m. to 6:20 p.m. on May 6th, and would not touch any portion of the nearby sensitive resources. (See Figure 21.7-8.)

On December 21st, shadows would fall across the base of the North River WPCP in the afternoon, but never climb higher than North River WPCP's portion of the wall. Since no shadows are projected to fall across Riverbank State Park by 2:50 p.m. (approximately one hour before sunset per CEQR guidelines), or on any of the area's other relevant resources, no impacts from shadows are anticipated from the West 135th Street Converted MTS.

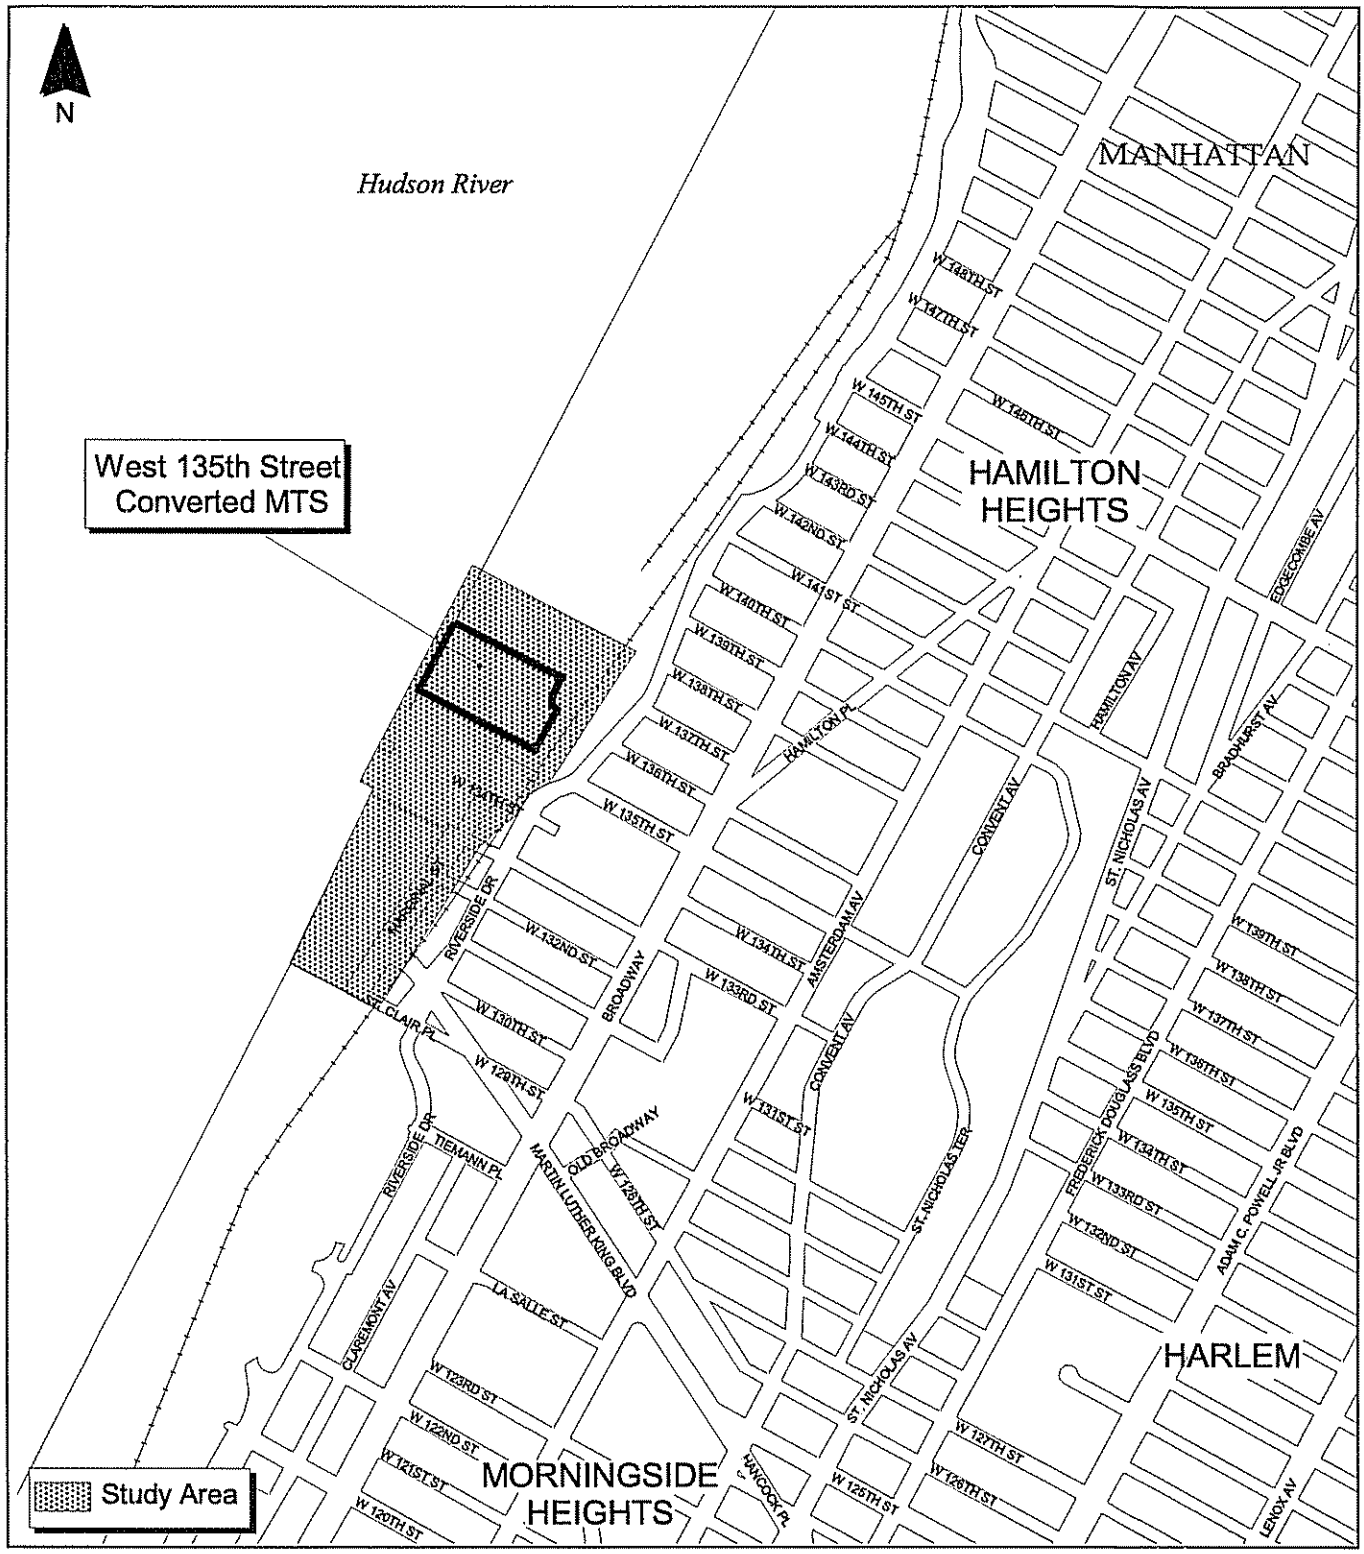
CITY OF NEW YORK
DEPARTMENT OF SANITATION

21.8 Neighborhood Character

21.8.1 Existing Conditions



21.8.1.1 Definition of the Study Area

The site is separated from inland residential neighborhoods by the Henry Hudson Parkway, Riverside Drive and the change in elevation that separates the inland properties from the waterfront. The neighborhood character study area is defined by the visual and physical isolation created by the proximity and scale of surrounding transportation infrastructure and municipal uses. The two major factors contributing to the neighborhood character of the site and surrounding shoreline properties are the unique combination of land uses — large-scale municipal uses, regional park use, public waterfront access, shoreline industrial uses, parking areas and commercial land uses — and the resultant, albeit nondescript, visual quality.

The study area is bounded by the Henry Hudson Parkway to the east and includes the portions of blocks facing Marginal Street south of the site (see Figure 21.8-1). View corridors connecting upland residential areas to the site are also included. The southern edge of the study area is defined by St. Clair Place, the southernmost point of egress from the shoreline within the study area. The northern boundary of the study area includes the southern edge of the elevated Riverbank State Park which, in addition to being adjacent to the site, is the only portion of the park that has direct views of the site.

21.8.1.2 Description of Neighborhood Character

The waterfront development consists of the existing MTS and a Consolidated Edison natural gas pumping facility immediately to the south. The remainder of the shoreline south of the existing MTS is City-owned property. A portion of the land west of Marginal Street is used as a parking lot for the Fairway store between West 132nd and West 133rd Streets. The waterfront is publicly accessible at the southern end of this parking lot, approximating the extension of West 131st Street to the shore. The parking lot is not landscaped, and the area of waterfront access is equally utilitarian, lacking landscaping, seating or decorative elements. North of the site and adjacent to it is the Riverbank State Park, which is at approximately the same elevation as the

Site delineations are approximate
Base Map Source: New York City Department of City Planning

Figure 21.8-1 Neighborhood Location

West 135th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

upland residential areas, east of the Henry Hudson Parkway. The position of the park atop the North River WPCP affords people along the southern edge of the park (where there are ball courts and sitting areas) views down upon the site and virtually the entire study area.

The visual quality in the study area is not one of a consistent character, nor is it aesthetically pleasing near the site, beneath the elevated roadway. Generally speaking, the upland residential areas are characterized by apartment blocks that include active commercial uses along the avenues. Row houses and smaller apartment buildings are found on cross streets. These upland residential areas have no direct connection to the site, except via usage of Riverbank State Park, but they are visible from the site and have views of it and the adjacent shoreline uses.

21.8.2 Future No-Build Conditions

The redevelopment of Harlem Piers by NYCEDC will figure prominently in redefining the neighborhood character of the study area by 2006. The introduction of a new park area as well as complementary commercial activity as part of the Harlem Piers will create a new destination point and in essence extend inland Harlem development efforts westward to the waterfront.

The Hudson River Valley Greenway is also under development, as discussed in Section 21.5. It is reasonable to anticipate increased use of Riverside Park by residents of the surrounding neighborhoods, as bicycling will be encouraged through the Hudson River Valley Greenway development, which will follow the river. NYCDPR is working in cooperation with NYCEDC to ensure that the necessary bicycle and pedestrian ways are developed by the 2006 Build year. Complementary streetscape and sidewalk improvements proposed as part of the Harlem Piers include improved sidewalks, curbing and street lighting. Taken together, these improvements would ensure that the redeveloped area would not exist in limited-access isolation from street activities even though it is adjacent to industrial uses to the north and generally nondescript warehouses under the Hudson River Parkway to the east.

The site would remain DSNY property, and the existing MTS would remain standing.

21.8.3 Potential Impacts with the West 135th Street Converted MTS

No change to the mixed neighborhood character would be expected to result from the reactivation of waste transfer activities at the site. The West 135th Street Converted MTS would be constructed over the water with a similar point of access as the existing MTS, though it would be situated further north, nearer the North River WPCP and Riverbank State Park. Trucks would follow the same route as they did formerly and the operations would feature containerization operations rather than the transport of loose waste by barge.

Riverbank State Park is the nearest destination point attracting people to the neighborhood and near the site. Traffic, air, odor and noise analyses predict no unmitigatible impact on the park or other receptors in the neighborhood character study area (see Sections 21.14, 21.15, 21.16 and 21.17 for detailed discussions of the traffic, air, odor and noise analyses, respectively). Therefore, it is reasonable to conclude that renewed MTS operations would result in no significant adverse impacts to the character of this specific portion of the neighborhood character study area, including the park. (See Section 21.5 for a discussion of potential impacts to parks and open spaces.)

21.9 Natural Resources

21.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Manhattan. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from implementation of the West 135th Street Converted MTS.

21.9.1.1 Definition of Study Area

The study area includes the existing site, including the waterfront section that is located on the Hudson River to the west (see Figure 2.6-1). The existing facility is a platform structure extending out from the shore into the river with a small employee parking area being the only upland feature. As a result, no terrestrial natural resources exist to be discussed. Because Future Build Conditions would include dredging of bottom sediments and construction of a new MTS, a description of the aquatic communities is included.

21.9.1.2 Geology

Boring data from the City of New York Public Works drawing, entitled Record of Borings, Marine Transfer Station W. 135th Street, Manhattan (January 8, 1954), indicates that bedrock was encountered between elevations -153 and –184, based on the Manhattan Borough Datum. The bedrock was described as hard, badly weathered and seamy, dark gray Schist.

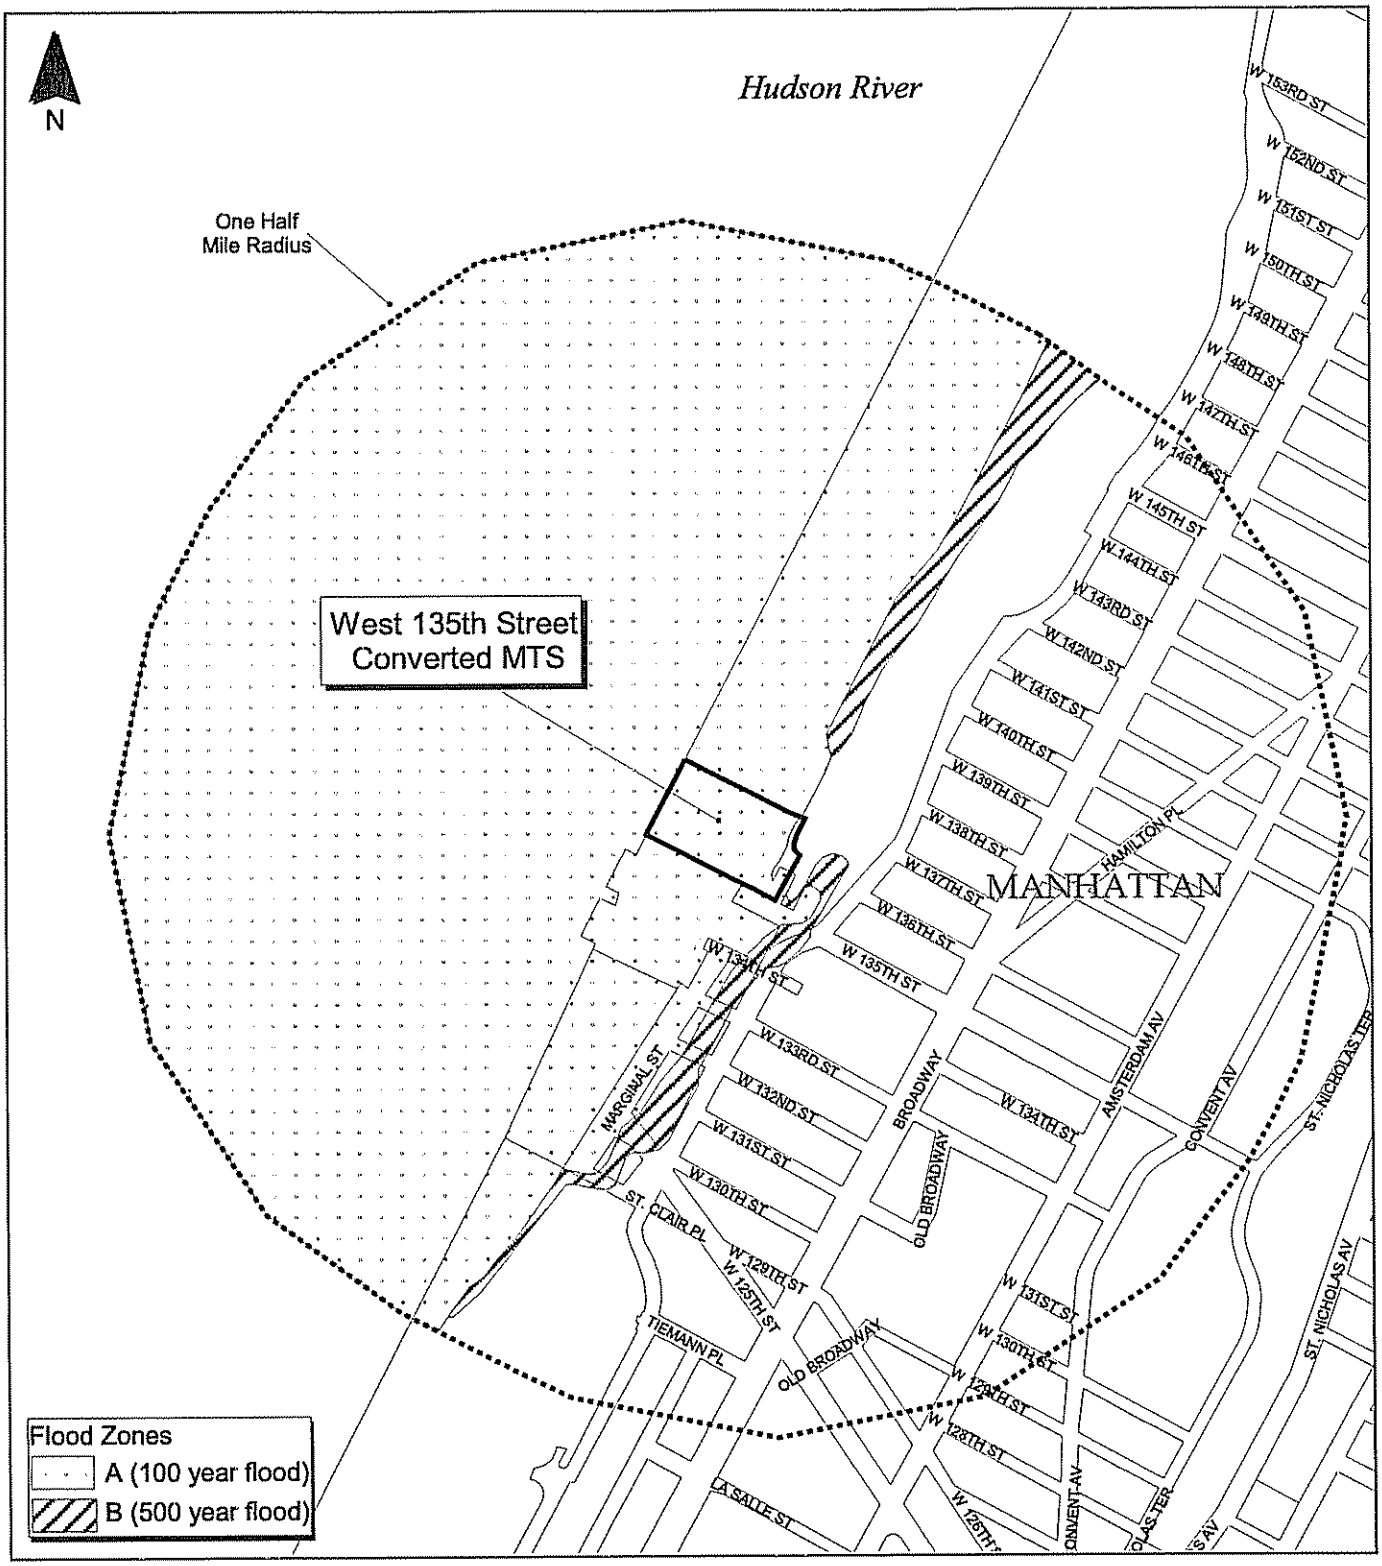
Organic soils were encountered at the mud line and ranged between 20 and 74 feet thick. The organic soils typically consisted of soft, black to gray organic soils with occasional layers of loose gray silty sand. A sand stratum consisting of medium dense to dense, brown to red brown poorly graded sand was encountered underlying the organic soils stratum and ranged from 20 to 41 feet in thickness. Underlying the sand stratum was a silt stratum consisting of stiff, gray to brown silt with sand. This stratum ranged from 4 to 34 feet in thickness. A sand stratum ranging

in thickness from 5 to 55 feet was encountered under the silt stratum and consisted of very dense, red brown silty sand with occasional layers of gravel, silt, and fine sand layers interbedded throughout the unit.

Results of the sediment samples collected for analysis in 2003 show that surficial sediments are composed of 94.3% silt and clay, 5.3% sand and 0.6% gravel.[5] The sediment contains 52,916 mg/kg TOC and was found to be somewhat degraded due to contaminants in the sample material. The three metals with the highest concentrations in the sediment were lead, chromium and barium with concentrations of 76.08 mg/kg, 59.67 mg/kg and 54.83 mg/kg, respectively.

21.9.1.3 Floodplains

The site is constructed within the 100-year coastal floodplain (see Figure 21.9-1). No wetlands, other than the Hudson River, a NYSDEC-designated littoral zone, exist on the site (see Figure 21.9-2).



21.9.1.4 Ecosystems

Because the site is located on an offshore platform, there are no upland natural resources to consider, describe or map. The majority of the approaches leading to the facility are hard surface, devoid of vegetation. A 12-space parking area is the only upland feature of the site.

A field program that took place in 2003 was designed to fully characterize the marine biological resources of the area. The program included monthly sampling for finfish eggs and larvae and water quality, and quarterly sampling for adult finfish, benthic invertebrates and sessile colonizing organisms. Results of the program are presented in the following paragraphs.

The marine communities surrounding the West 135th Street Converted MTS showed signs of ecological stress. Adult finfish and megainvertebrate species richness were amongst the lowest of MTSs sampled. A large number of finfish was collected, but the catch was dominated by a

single species, a sign that indicates environmental stress. Finfish larvae also exhibited low densities in the water column around this structure. The benthic community had a high diversity index, but it had low species abundances and was dominated by pollution-tolerant organisms. A reason for the stressed environmental conditions could be the wastewater treatment plant directly north of the MTS.

A total of 948 adult finfish were collected during the year long study at this MTS. Juvenile Atlantic croaker (*Micropogonias undulatus*) was by far the most abundant species collected, comprising 93% of the total catch. The next most abundant species were striped bass (*Morone saxatilis*) and winter flounder (*Pleuronectes americanus*). There were five adult finfish species collected that have EFH listing. These species were: winter flounder, bluefish (*Pomatomus saltatrix*), Atlantic butterfish (*Peprilus triacanthus*), windowpane (*Scophthalmus aquosus*) and summer flounder (*Paralichthys dentatus*). The most abundant finfish eggs collected at the 135th Street Converted MTS were bay anchovy (*Anchoa mitchilli*). Abundant larval species collected were winter flounder, anchovy spp. and goby spp. (*Gobiosoma* spp.). Two larval species having EFH listing were collected at this MTS – winter flounder and windowpane. There were no EFH-listed eggs collected here.

The most abundant megainvertebrate species collected at the West 135th Street Converted MTS was the sevenspine bay shrimp (*Crangon septemspinosa*). Oligochaetes and polychaetes (worms) were the most abundant benthic organisms collected. Of the eight MTSs studied, abundances of benthic organisms per square meter were second lowest at the West 135th Street Converted MTS. Oligochaetes were 11,000 per square meter and *Streblospio benedicti* and polychates were 4,000 and 3,750 per square meter, respectively. The dominant epibenthic colonizers were *Pleusymtes glaber* (amphipod), *Balanus* sp. (barnacle), *Polydora* sp. (polychaete worm), and hydrozoa, mud and algal film.

It should be noted that the Lower Hudson Reach, in which the study area is located, is a New York State Department of State Division of Coastal Resources and Waterfront Revitalization-designated SCFWH (see Figure 21.9-3). New York State's CMP

includes a specific policy for the protection of fish and wildlife habitats that are determined to be of statewide significance. An inventory of the coastline was conducted to identify the most valuable habitats according to the following criteria: ecosystem rarity, species population levels, support of vulnerable species, human use and replaceability. A numerical rating system using these criteria was applied to more than 300 areas, and approximately 235 have qualified for official designation and mapping as SCFWHs.

NYSDEC's NHP records list the common nighthawk (*Chordeiles minor*) as a species known to be suspected of breeding in the study area. The state legal status of this wild bird is Protected-Special Concern, which includes those species that are not yet recognized as endangered or threatened, but for which documented concern exists for their continued welfare in New York, and that are federally-protected wild birds.

A pesticide survey was conducted in the nearshore sediments. All organic levels were below detection limits (i.e., very low levels) for the USEPA's Toxicity Extraction Procedure, the test in use at the time of the sampling.[6]

21.9.2 Future No-Build Conditions

If the West 135th Street Converted MTS were not to be built, the study area would remain as is. The absence of terrestrial natural resources would remain and the upland portion of the study area would continue to be an ecologically unproductive and stressed urban area. Aquatic natural resources would continue to be present in the waters in and around the study area.

[6] Hudson River Center Site Aquatic Environmental Study Final Report, 1988. Prepared for New York City Public Development Corp. by EEA, Inc.

21.9.3 Potential Impacts with the West 135th Street Converted MTS

21.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

21.9.3.2 Floodplains

Implementation of the West 135th Street Converted MTS would have no effect on the elevation of the study area. The facility would be constructed within the 100-year floodplain, and would not include any provisions for raising any portions of the study area over this level.

21.9.3.3 Ecosystems

Upland impacts to the current natural resources in the study area are expected to be minimal due to the limited size and fully developed condition of the study area.

Removal of the existing facility would presumably be carried out by a barge-mounted crane. During the extraction of the subsurface pilings, the upper organic silts would be disturbed to some degree, resulting in re-suspension of the sediment. However, the amount of re-suspended sediment is expected to be low and the impacts, if any, highly localized. Turbidity and short-term, lower, dissolved oxygen are possible, but not measurable, against normal background fluctuations. The removal of the existing platform will also remove the existing epibenthic community; however, the new expanded platform will result in more surface area for epibenthic communities to colonize the site. This would positively affect the epibenthic communities at the West 135th Street Converted MTS.

Construction of the new pile-supported facility would involve the driving of new piles through the upper organic silts, through the sand layers and to bedrock or sufficient depth for friction support. Penetration of the upper silts may cause small amounts of re-suspension, and dredging will result in an immediate, short-term destruction of the benthic invertebrates in the area.

Because the benthic diversity is high and marine construction causes turbidity and siltation that could smother the benthic organisms, the short-term degree of impact is expected to be high. However, recolonization of the area by benthic invertebrates can be expected to occur within 6 to 12 months after cessation of dredging activities.[7] Given the relatively small size of the project, minimal overall impact to the benthic community is expected at the West 135th Street Converted MTS.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction; flatfish (flounders) are least sensitive. Flounder catch was much higher at the West 135th Street Converted MTS than herring catch, so it can be assumed that this site is not an important herring habitat that will be temporarily impacted. Finfish eggs and larvae are more sensitive to suspended sediment, and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. In addition, larvae will be able to swim away from the impacted environments.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The proposed plan for the West 135th Street Converted MTS is for an increase in 36,089 square feet of pier. This will result in increased shading that will block sunlight and hinder primary production. The enlarged platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[8] Epibenthic communities will have a larger surface area to colonize, and finfish should return to the area with the return of food sources.

---

[7] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

[8] Hudson River Center Site Aquatic Environmental Study Final Report, 1988. Prepared for New York City Public Development Corp. by EEA, Inc.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by EEA in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[9] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as they provide shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. However, because the increase in shading over water is very small, there are not expected to be significant deleterious results. There is a possibility of a slight shift in the finfish community with the addition of over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

According to the Atlas of Breeding Birds in New York State, the common nighthawk (*Chordeiles minor*) regularly nests on flat-roofed structures in cities and towns and feeds upon insects during flight. The West 135th Street Converted MTS is not likely to directly impact any potential nesting habitat or prey species that the nighthawk depends upon.[10]

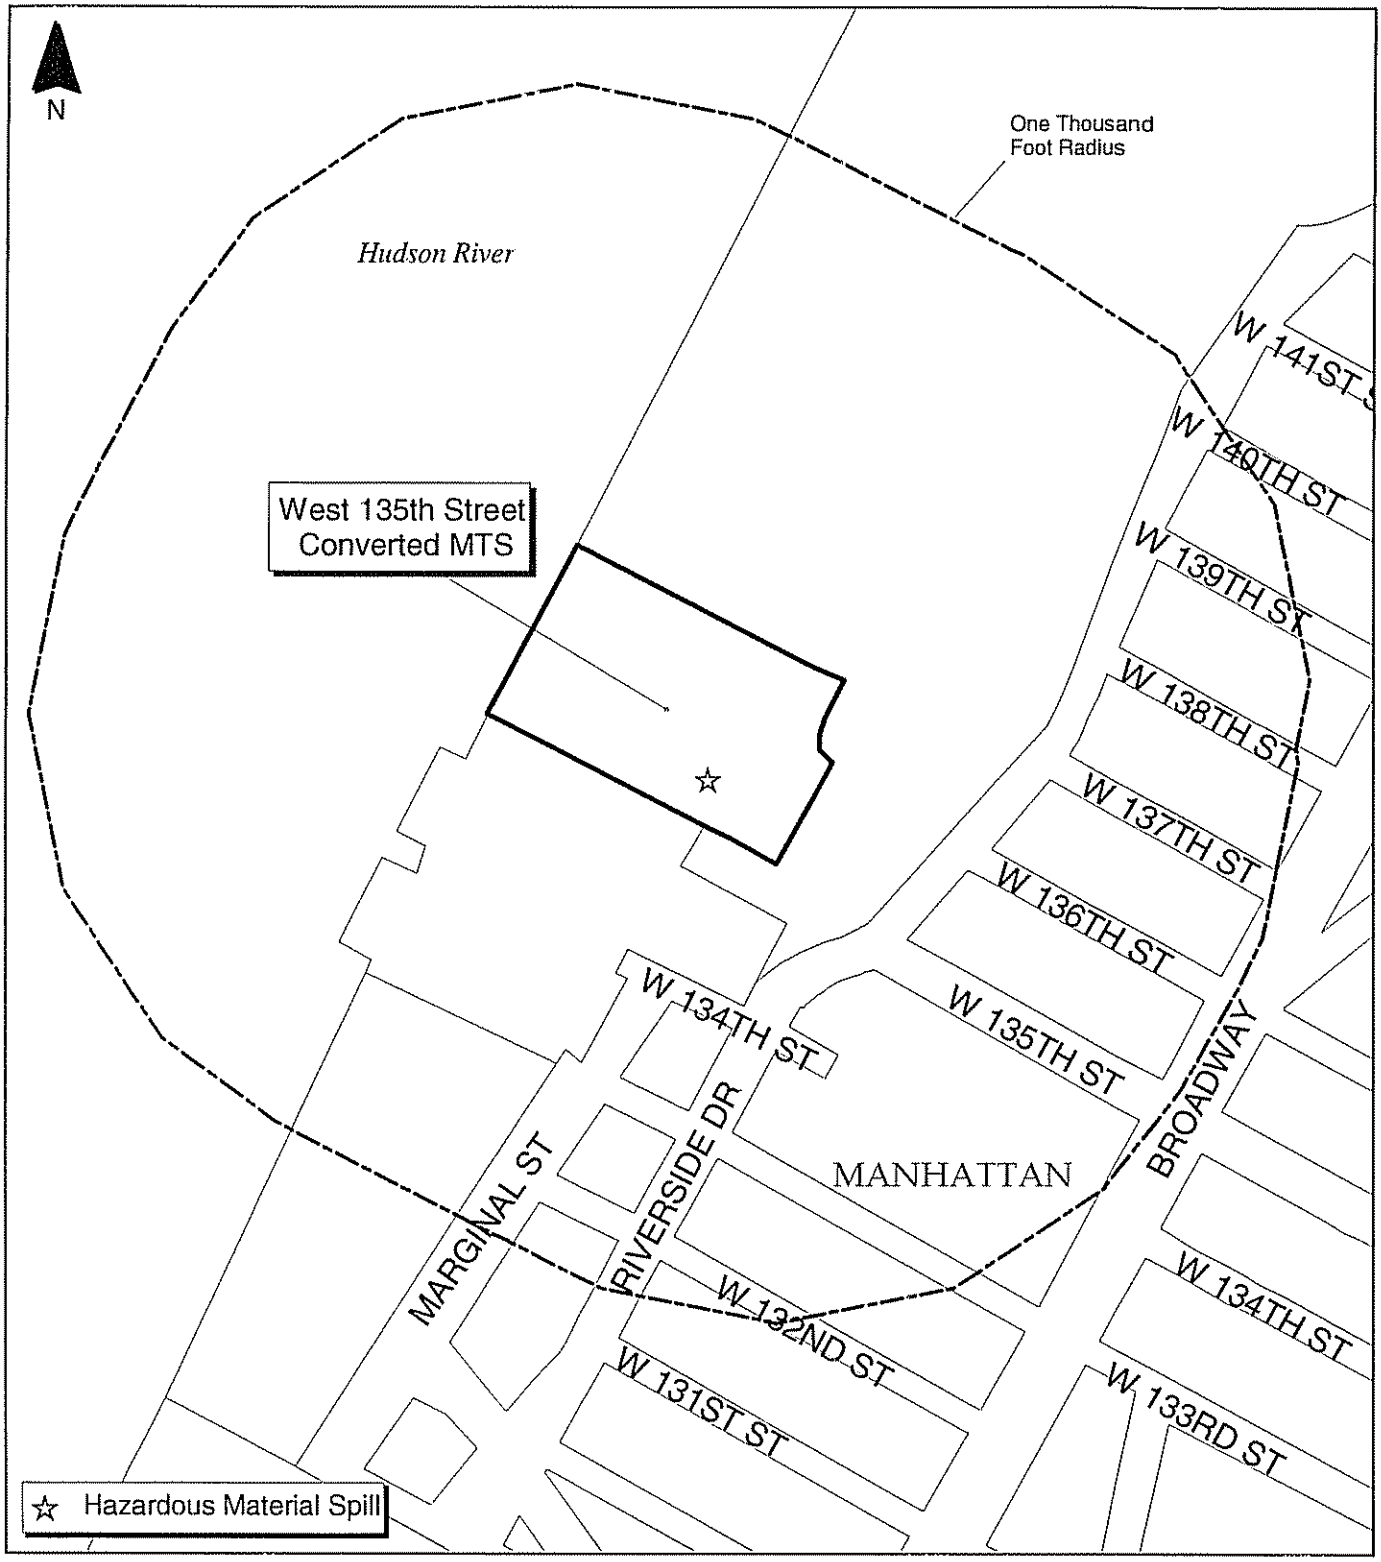
21.10 Hazardous Materials



21.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in April 1999 and updated in February 2003. It included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the FDNY for UST records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted, most recently in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors. Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

21.10.1.1 Definition of Study Area

The study area includes the existing MTS site and neighboring properties within a 1,000-foot radius (see Figure 21.10-1).

Site delineations and study area boundaries are approximate

Figure 21.10-1 Hazardous Material Sites

West 135th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

21.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the ground, groundwater, surface water or structures within the study area where the presence or likely presence of hazardous materials exists and implementation of the West 135th Street Converted MTS could lead to an increased exposure of people or the environment to those materials. No specific areas of concern were identified at this site during the assessment.

21.10.2 Future No-Build Conditions

The site would remain as is. There would be no areas of significant concern with regard to hazardous materials.

21.10.3 Potential Impacts with the West 135th Street Converted MTS

The West 135th Street Converted MTS would not result in adverse impacts. Some benefits may be realized because a new facility would replace the existing MTS. No additional testing would be required other than an asbestos inspection prior to demolition of the existing MTS. If any areas of concern were identified during the demolition or construction phase, an analysis would be made to determine what, if any, mitigation measures should be applied.

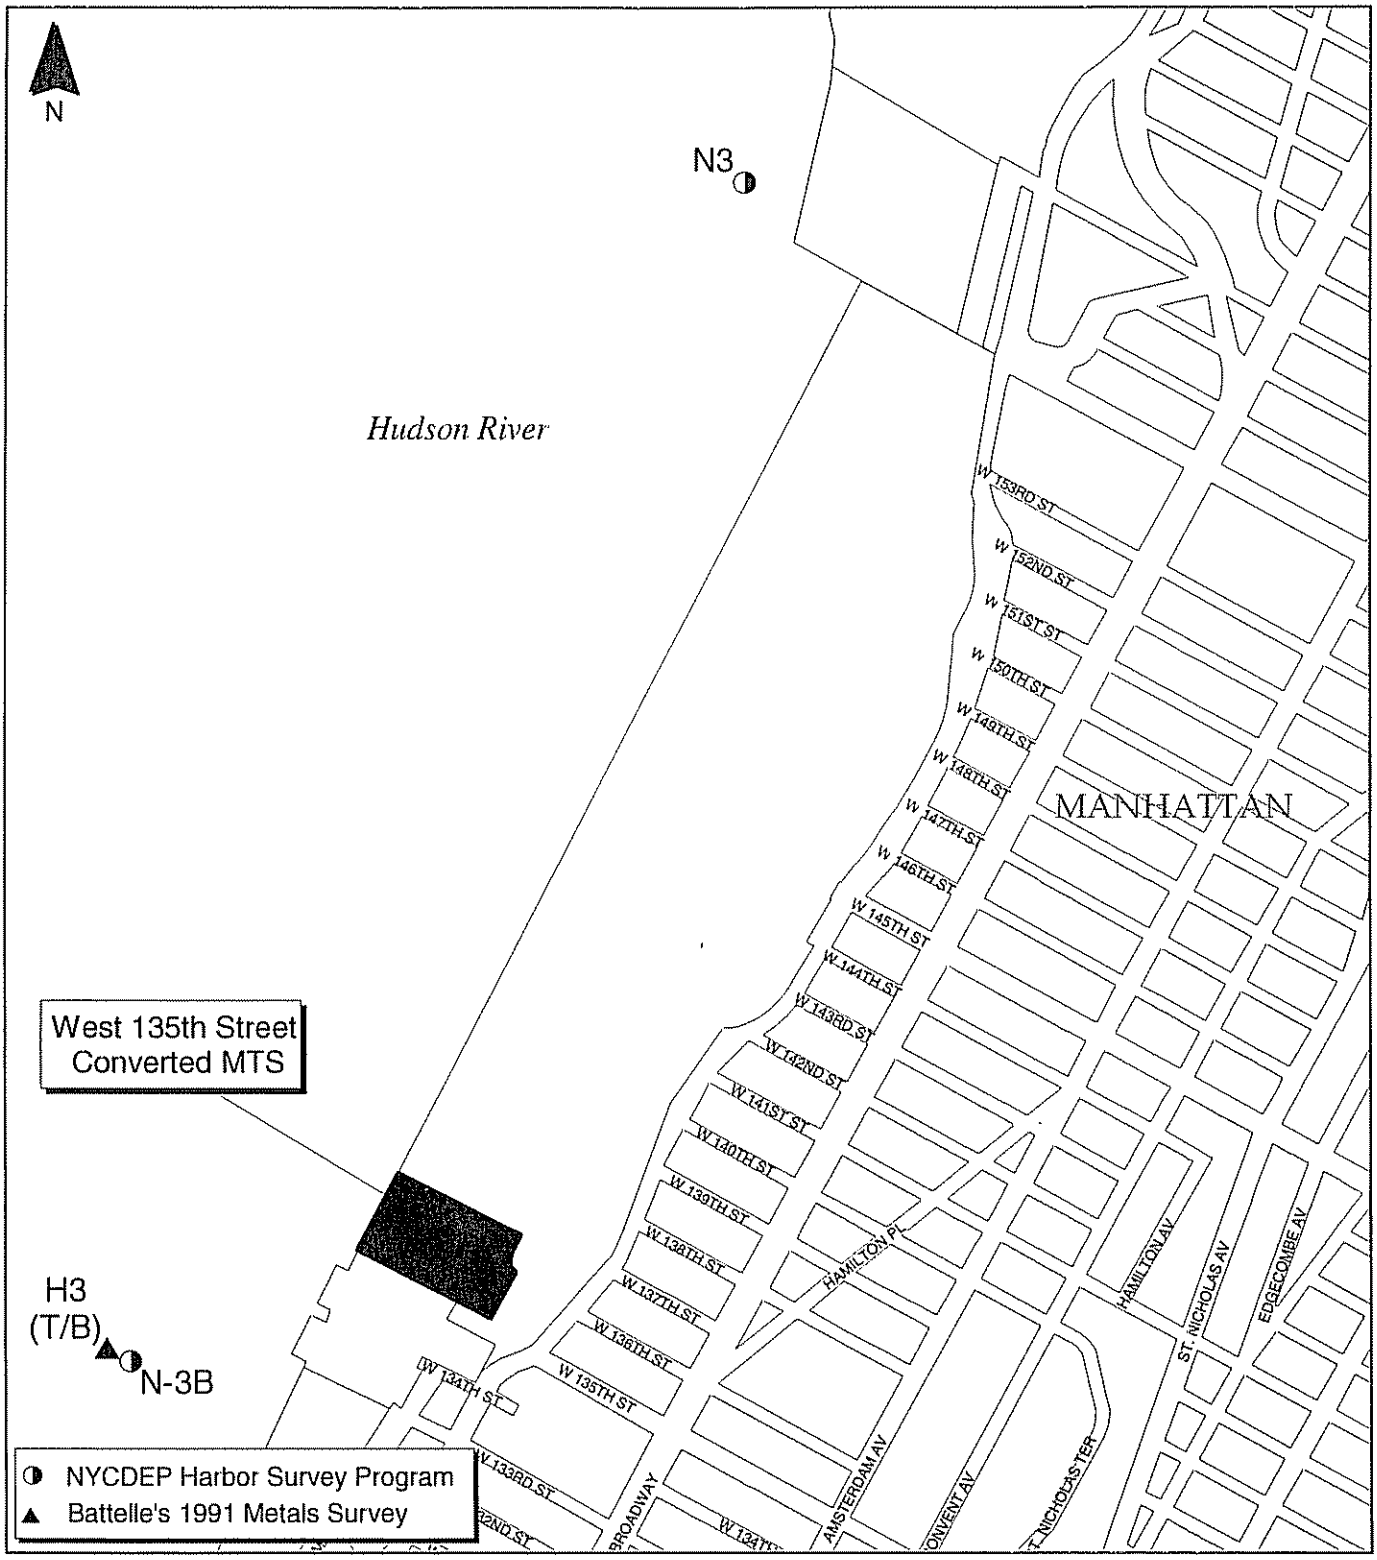
21.11 Water Quality

21.11.1 Existing Conditions

21.11.1.1 Definition of the Study Area

The water quality study area encompasses the Hudson River and includes discharges from CSOs located within ½-mile of the site.

21.11.1.2 Water Quality



The water quality data for the following monitoring stations, shown in Figure 21.11-1, are generally representative of water quality in the study area:

- NYCDEP Harbor Survey Program –Stations N-3 and N-3B in the Hudson River off of Manhattan; and
- Battelle's 1991 Metals Survey –Stations H-3T and H-3B[11] in the Hudson River at mid-Manhattan.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 21.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class I," which indicates water suitable for secondary contact recreation (i.e., fishing and boating).

As shown in Table 21.11-1, on average, NYSDEC standards and guidance values are met. The mercury concentration for Battelle Stations H-3T and H-3B did not conform to the water quality standard for mercury.

[11] Stations H-3T and H-3B are located at the same longitude and latitude. Station H-3T is located at the surface of the Hudson River. Station H-3B is located at the bottom of the Hudson River.

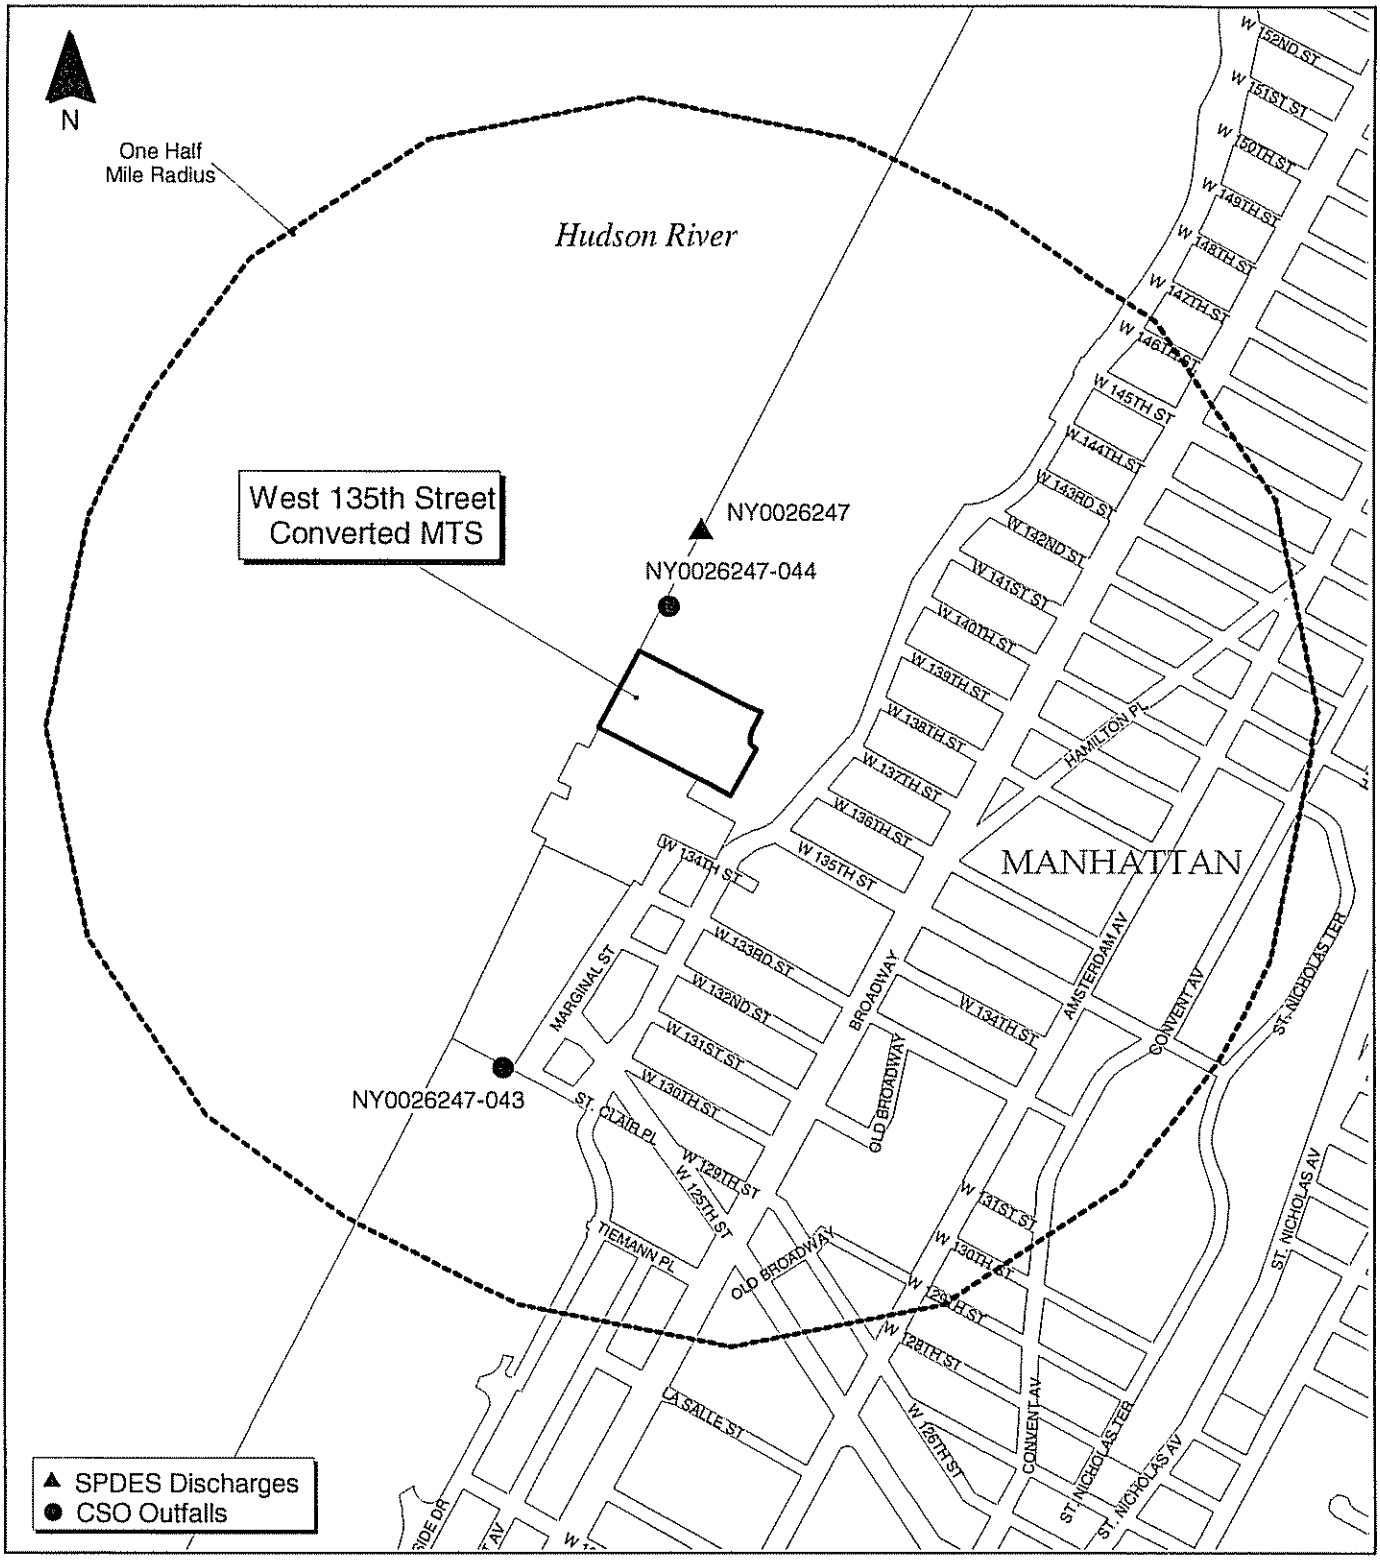
(15) Site-specific chronic and acute criteria for dissolved copper in New York/New Jersey Harbor.
BOD = biochemical oxygen demand
NH_3-N = ammonia
NO_3 = nitrate; NO_2 = nitrite
PO_4 = phosphate
mg/L = milligrams per liter
MPN/100 ml = most probable number per 100 milliliters
MF = membrane filter
µg/L = micrograms per liter

21.11.1.3 Permitted Discharges



A review of the most recently available NYSDEC and USEPA databases indicated that there are several permitted discharges in the vicinity of the site. Those within a ½-mile radius of the West 135th Street Converted MTS site are shown in Figure 21.11-2 and listed in Table 21.11-2. These discharges consist of two CSOs and one point source, all of which are permitted by the NYSDEC. One CSO outfall and the point source are located to the north of the site. The other CSO outfall is located to the south of the site.

21.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, estimates of stormwater pollutant loadings were calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% storage and infiltration. A runoff flow of 0.078 cfs was calculated using the impervious site area (1.30 acres), an average rainfall intensity per storm of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 21.11-3, represent the existing loads at the existing site.

21.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to ongoing water quality improvement programs such as the NYCDEP CSO Abatement Program, which will reduce untreated discharges to receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from the City WPCPs; and other water improvement programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

Site delineations and study area boundaries are approximate.

Notes:
(1) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
(2) Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

21.11.3 Potential Impacts with the West 135th Street Converted MTS

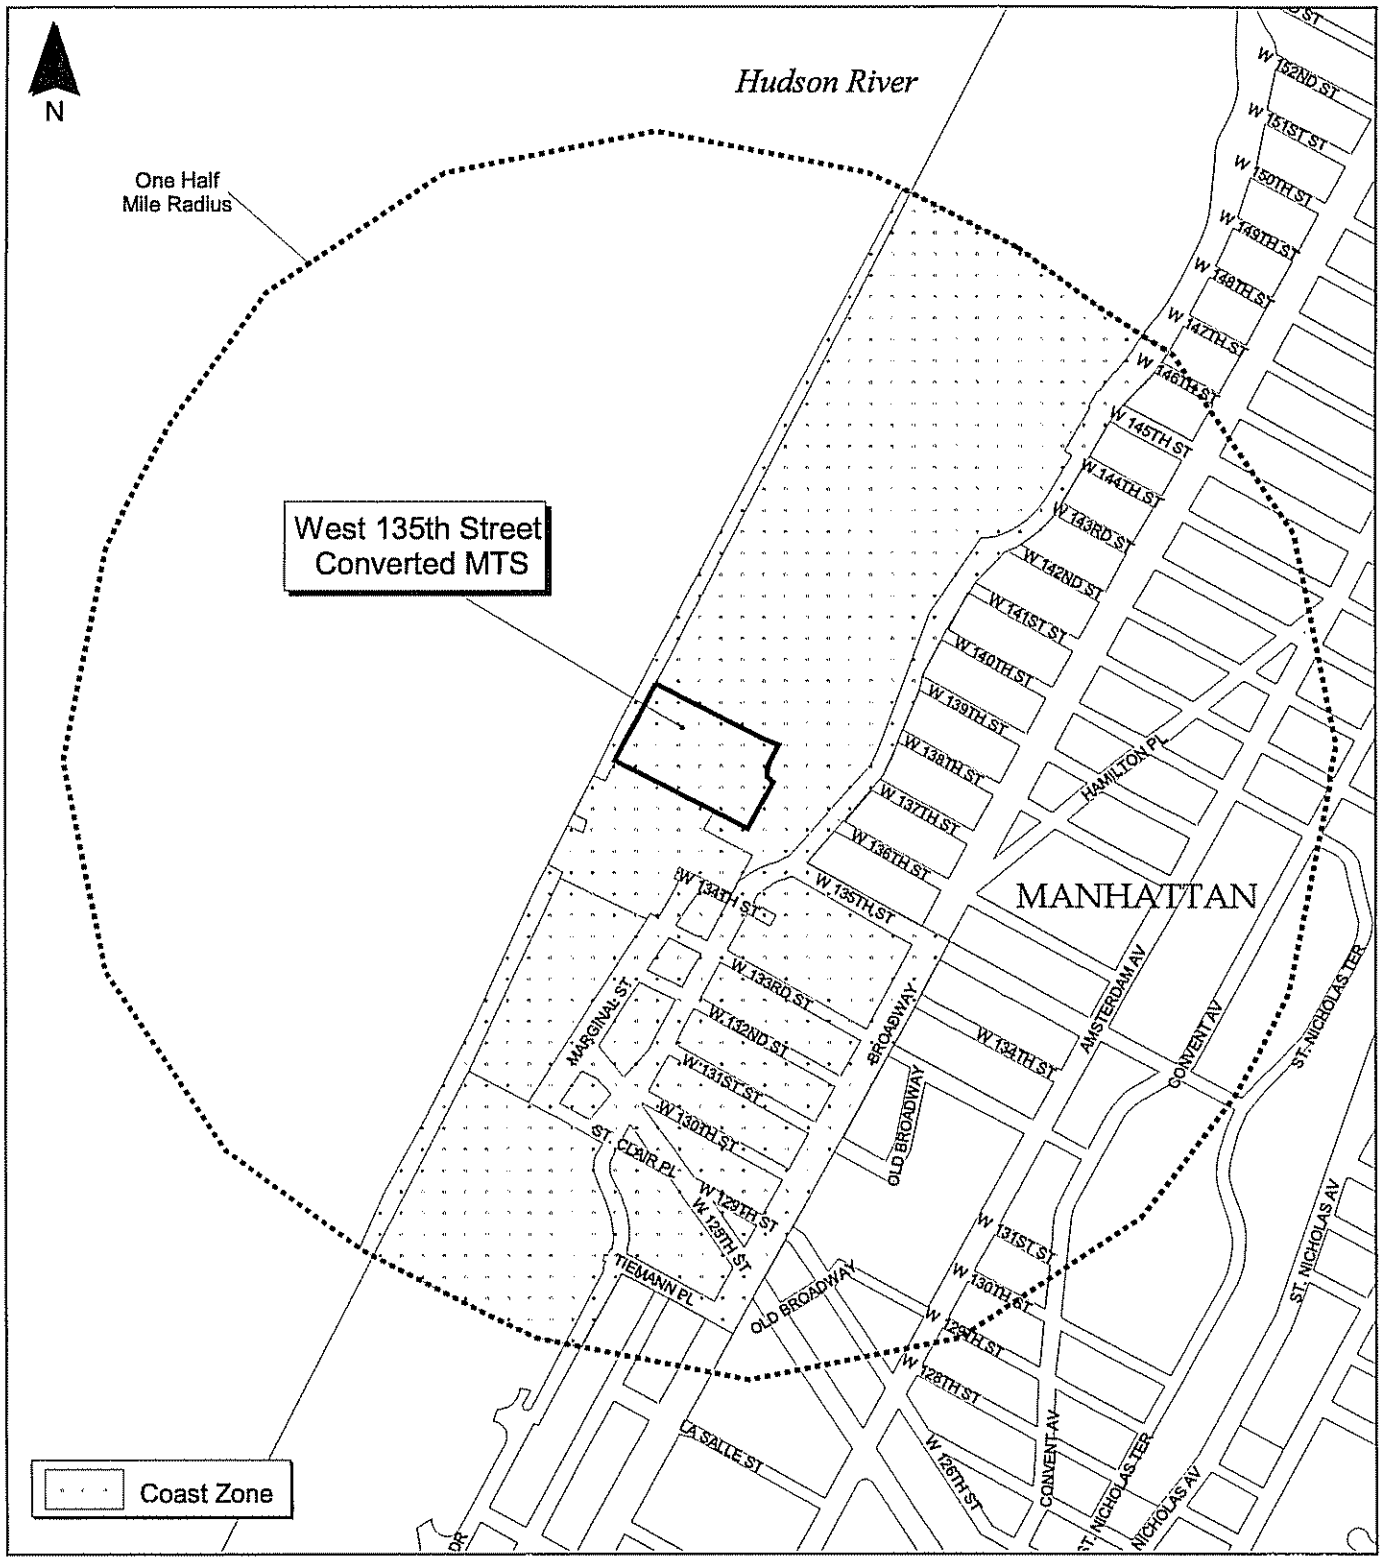
All solid waste processing at the West 135th Street Converted MTS would occur within the proposed structures. All process wastewater from waste handling operations at the facility, such as washdown water, would be routed to an on-site pretreatment system (e.g., oil/water separation). After pretreatment, the process wastewater would be discharged to the municipal sewer system and, ultimately, to the North River WPCP, where it would be treated prior to discharge to the Hudson River and, therefore, would not adversely affect water quality.

With the development and operation of the West 135th Street Converted MTS, there would be an increase in the impervious area and, therefore, an increase in stormwater loadings. Table 21.11-4 shows the existing impervious area, the change in impervious area and the pollutant loads for the West 135th Street Converted MTS. According to the 208 Model, however, these increased loads would have no significant impact on water quality in the adjacent surface waters.

Table 21.11-4
Impervious Area and Estimated Pollutant Loads
West 135th Street Converted MTS

			Estimated Pollutant Loadings/Incremental Change [1]				
Conditions	Total Impervious Area (acres)	Change in Impervious Area (acres)	Fecal Coliform[2]	BOD (lbs/day)	Copper (lbs/day)	Lead (lbs/day)	Zinc (lbs/day)
Existing Conditions	1.30	0 0	14,273/NA	5/NA	0.015/NA	0 012/NA	0.065/NA
Future Build Conditions	2.08	0.78	23,081/8,808	8/3	0 024/0 009	0 019/0 007	0.105/0.040

Notes:
(1) Incremental change refers to the difference in pollutant loading between the Existing Conditions and Future Build Conditions.
(2) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable



The West 135th Street Converted MTS may also require dredging activities to construct the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations, and required permits would be acquired prior to any proposed dredging activities. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant adverse long-term impacts.

21.12 Waterfront Revitalization Program

21.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of the Hudson River, the West 135th Street Converted MTS would be within the City's coastal zone boundary (see Figure 21.12-1). According to "The New Waterfront Revitalization Program," the West 135th Street Converted MTS would be classified as a water-dependent, industrial use. It would be located within Reach 5/Northern Manhattan as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Manhattan Waterfront." It is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The West 135th Street Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These include subpolicies 1.1, 1.2, 2.1, 3.1, 4.4, 6.2, 6.3 and 21.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. Further discussion is provided below for those policies or subpolicies needing more clarification or found to be inconsistent with a component of the West 135th Street Converted MTS. A description of waste handling operations that would occur at the South Bronx Converted MTS is provided in Section 2.4.3.

Site delineations and study area boundaries are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

21.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the West 135th Street Converted MTS. As part of the West 135th Street Converted MTS, connections from the new facility to existing utilities in the vicinity (e.g., sewer and electrical connections, etc.) would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.2 Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.

The West 135th Street Converted MTS would not be located within an SMIA. It would involve the conversion of the existing facility from a truck-to-barge waste transfer station into a TCB transfer station that would transport DSNY-managed Waste to remote out-of-City disposal facilities. The West 135th Street Converted MTS would be largely located at the site of the existing MTS and would extend further north.

The West 135th Street Converted MTS, as described in Section 2.4.3, would involve the complete demolition of the existing MTS to accommodate its expanded function, size and configuration. Waterfront development would involve over-water construction of four primary components: (1) an elevated

access ramp; (2) an enclosed processing building, which would include the tipping floor, loading floor and pier level; (3) an outside gantry crane system; and (4) a barge fendering system and bulkheads. The West 135th Street Converted MTS would largely involve the continuation of an existing industrial and water-dependent use. It would serve to maintain this use while restoring and revitalizing an existing industrial waterfront property, and it would be compatible with existing neighboring industrial uses. Although the West 135th Street Converted MTS would not encourage or facilitate the siting of any additional water-dependent uses, it would represent an expansion and revitalization of an existing water-dependent use and would be compatible with surrounding uses.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The West 135th Street Converted MTS structure would require the complete demolition of the existing MTS to accommodate the expanded function, size and configuration of the new facility. The majority of the construction would occur over the Hudson River. The West 135th Street Converted MTS would be located at the site of the existing MTS and extend further north. Waterfront development would involve four primary components: (1) an elevated access ramp; (2) an enclosed processing building, which includes the tipping floor, loading floor and pier level; (3) an outside gantry crane system; and (4) a barge fendering system and bulkheads. The West 135th Street Converted MTS would be consistent with existing waterfront uses in the vicinity of the site.

The West 135th Street Converted MTS would require dredging to remove accumulated sediments and to provide adequate draft for barges and tugboats once it became operational. All dredging would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The West 135th Street Converted MTS would be located within the Hudson River at the location of the existing MTS. The use of tugboats or its day-to-day operations would not interfere with any maritime industrial, commercial or recreational vessel activities in the area. Activities within the Hudson River resulting from the West 135th Street Converted MTS would be limited to barge loading along the pier level and the periodic swapping of loaded barges at the slips. Four of five barges would be filled on a daily basis. These swapping activities would be similar to previous barge activities at the site. Therefore, no adverse impact to other uses within the water body would be anticipated. The West 135th Street Converted MTS would be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The existing MTS managed solid waste through a truck-to-barge system under which loose waste was placed in open barges. The West 135th Street Converted MTS would be a TCB MTS where waste would be transferred into containers that would be sealed and placed into flat deck barges that would transport DSNY-managed Waste to remote out-of-City disposal facilities. All solid waste handling would be done within an enclosed processing building and, therefore, would be protective of the aquatic environment and surrounding land and water uses. All waste would be placed in sealed containers before leaving the building for loading on barges. Building ventilation would be maintained under negative pressure, which would maintain dust inside the building. Additional dust, odor and vector control systems would also be used to minimize impacts to the surrounding environments. Litter control methods, such as routine sweeping and

washing of the tipping floor, would be implemented at the facility to minimize or eliminate the potential for litter entering surface waters. All process wastewaters would be treated on site prior to being discharged to the municipal sewer system. In addition, any on-site storage of petroleum and handling of unauthorized wastes would be managed in accordance with applicable federal, state and local regulations.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

Based upon a review of SNWAs as described in "The New Waterfront Revitalization Program," as well as Recognized Ecological Complexes and SCFWH information, the site is located within a New York State Department of State Division of Coastal Resources and Waterfront Revitalization-designated SCFWH, specifically the Lower Hudson Reach. The West 135th Street Converted MTS would represent an expansion of a previous use and would not be anticipated to result in any long-term impacts to the natural resources in the vicinity of the site. As described in Section 21.9.2, disturbances to surficial sediments would have short-term and minimal effects on the benthic community found in the immediate vicinity of the site. The West 135th Street Converted MTS would, therefore, be consistent with this subpolicy.

4.2 Protect and restore tidal and freshwater wetlands.

A review of NYSDEC tidal and freshwater wetland and NWI maps was conducted to determine the presence of wetlands. As noted in Section 21.9.1, the site contains no freshwater wetlands. The West 135th Street Converted MTS would be within the Hudson River, which is identified as a littoral zone, a state-

designated wetland. The demolition of the existing MTS and subsequent development of the West 135th Street Converted MTS would not be anticipated to result in any significant long-term impacts to tidal wetlands. Dredging would be required to remove accumulated sediments in order to provide adequate draft for staged barges and tugboats. Potential impacts due to dredging, however, would be minimal and all dredging would be conducted in compliance with applicable federal, state and local regulations. Mitigation for potential impacts, as appropriate and applicable, would be proposed during the environmental review and permitting of the West 135th Street Converted MTS.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

There are no known vulnerable fish or plant species found to be inhabiting areas within the vicinity of the West 135th Street Converted MTS. A review of NYSDEC NHP records list the Common Nighthawk (*Chordeiles minor*) as a known species potentially breeding in the area; it is classified by the state as a Protected-Special Concern species. As noted in Section 21.9.3, the West 135th Street Converted MTS would not impact these species and their habitats.

The West 135th Street Converted MTS would involve the demolition of the existing MTS facility and replacement with a larger, expanded MTS facility. Development of the West 135th Street Converted MTS would involve removal of the existing MTS and its adjoining vehicle ramp and over-water construction of a new, expanded facility. Dredging activities would be required to remove existing piers and structures, install a new pile-supported platform and footings and accommodate barges and tugboats. Potential impacts to plant, fish and wildlife species would be minimal and all dredging would be conducted in compliance with applicable federal, state and local regulations. Required permits would be obtained prior to any dredging activities. In addition, all handling and

containerization of solid waste would be performed inside the processing building, thereby limiting the risk of an introduction of hazardous wastes or other pollutants into the environment that could impact surrounding fish and wildlife resources. Sanitary and process wastewaters would be routed to on-site treatment systems and would then be discharged to the municipal sewer system. Stormwater runoff from the West 135th Street Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The West 135th Street Converted MTS would, therefore, be consistent with this subpolicy.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The West 135th Street Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, all sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site disposal treatment system that would include an oil-water separator, and then be discharged to the municipal sewer system. In addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. Stormwater runoff from the West 135th Street Converted MTS would be managed in accordance with applicable regulations. All handling and containerization of solid waste would be performed inside the processing building, thereby limiting the risk of an introduction of pollutants into the environment.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

During the development and operation of the West 135th Street Converted MTS, BMPs would be used to the extent possible to minimize any nonpoint discharges. The West 135th Street Converted MTS would comply with federal, state and local

requirements concerning the management of stormwater runoff and erosion. During construction, non-structural (such as silt curtains) and, if necessary, structural, measures would be used to manage stormwater runoff and erosion. The West 135th Street Converted MTS would also comply with applicable federal, state and local requirements and would be consistent with this subpolicy.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

The majority of the demolition and construction would occur over the Hudson River. The existing MTS would be demolished and replaced with a new and expanded TCB MTS. Dredging would be necessary during the demolition and construction of pier structures and footings, and would also be necessary to accommodate future barge and tugboat activity. All dredging would be conducted in accordance with applicable federal, state and local permit requirements and would be conducted in a manner that minimizes any impacts to the water quality. Potential impacts to water quality would be short-term and localized. All dredged materials would be disposed of at a permitted upland facility in accordance with applicable federal, state and local regulations.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The West 135th Street Converted MTS would have no adverse impact on the quality or quantity of surface or ground waters at or in the vicinity of its site. No surface or ground waters in the vicinity of the site constitute a primary source of water supply. Applicable and appropriate measures would be implemented at the facility in accordance with federal, state and local regulations. The West 135th Street Converted MTS would be consistent with this subpolicy.

Policy 6. Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to review of the FEMA National Flood Insurance Program maps, the entire West 135th Street Converted MTS site would be located within the 100-year floodplain boundary (Zone A). Redevelopment of the site, however, would not affect the potential for flooding or erosion. All demolition of the existing MTS and construction of new pier structure, platforms and bulkheads would comply with applicable building code requirements and, to the extent practicable and necessary, non-structural (such as silt curtains) or structural measures would be implemented to minimize damage from flooding or erosion.

Policy 7. Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The West 135th Street Converted MTS would involve the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Waste would be transported in airtight, waterproof, sealed containers. All waste handling operations would occur inside an enclosed processing building, which would minimize the escape of litter into the surrounding water body. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours of tipping. Waste processing would be done in accordance with NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the West 135th Street Converted MTS. Radiation detection equipment would be located at the facility, and

contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility. The West 135th Street Converted MTS would not result in adverse impacts and would operate in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

On-site storage of petroleum or hazardous materials related to the operation of the West 135th Street Converted MTS would be minimal and all storage would be in accordance with applicable federal, state and local regulations. Spill prevention and control plans would be used to prevent any hazardous materials from entering the environment.

7.2 *Prevent and remediate discharge of petroleum products.*

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

Public access would generally not be compatible with the principal use of the site due to the existing industrial uses at and in the immediate vicinity of the West 135th Street Converted MTS, such as the North River WPCP. Riverbank State

Park is located above the North River WPCP and currently offers visual and recreational access to the waterfront. Several additional parks located in the area of the West 135th Street Converted MTS providing public access and recreation facilities are discussed in Section 21.5.1.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The West 135th Street Converted MTS would be a stand-alone, water-dependent facility on the Hudson River. Public access would not be compatible with the West 135th Street Converted MTS; however, its development would not preclude any future development of public access along the Hudson River.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

Expansion of the West 135th Street Converted MTS would be compatible and consistent with adjacent properties along the waterfront and would not obstruct or impair visual access to coastal lands, waters or open space. As discussed in Section 21.7.3, visual access to the coastal lands would not be obstructed or impaired. See also response to Subpolicy 9.1

8.4 *Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.*

There are numerous park and open space areas identified in the vicinity of the West 135th Street Converted MTS. Major mapped parklands in the vicinity of the site include Riverbank State Park, Riverside Park (North) and Riverside Park (South), which are north, east and south of the site, respectively. Riverbank State Park is located atop the North River WPCP and would be elevated above the West 135th Street Converted MTS; therefore impacts, if any, would be minimal. Riverside Park (North) is northeast and east of the site and is physically separated

and shielded from the site by the Henry Hudson Parkway. Riverside Park (South) is located south of St. Clair Place and would not be significantly impacted by the West 135th Street Converted MTS. Expansion of the West 135th Street Converted MTS would cause no new significant impacts to these areas and, therefore, is consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The West 135th Street Converted MTS would not result in a significant impact on views, as noted in Section 21.7.3. Based on the information discussed in that section, the West 135th Street Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The West 135th Street Converted MTS would be an expansion and rehabilitation of an existing facility and would pose no new impacts to scenic values associated with natural resources. The West 135th Street Converted MTS would also be compatible with surrounding buildings and, therefore, would be consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

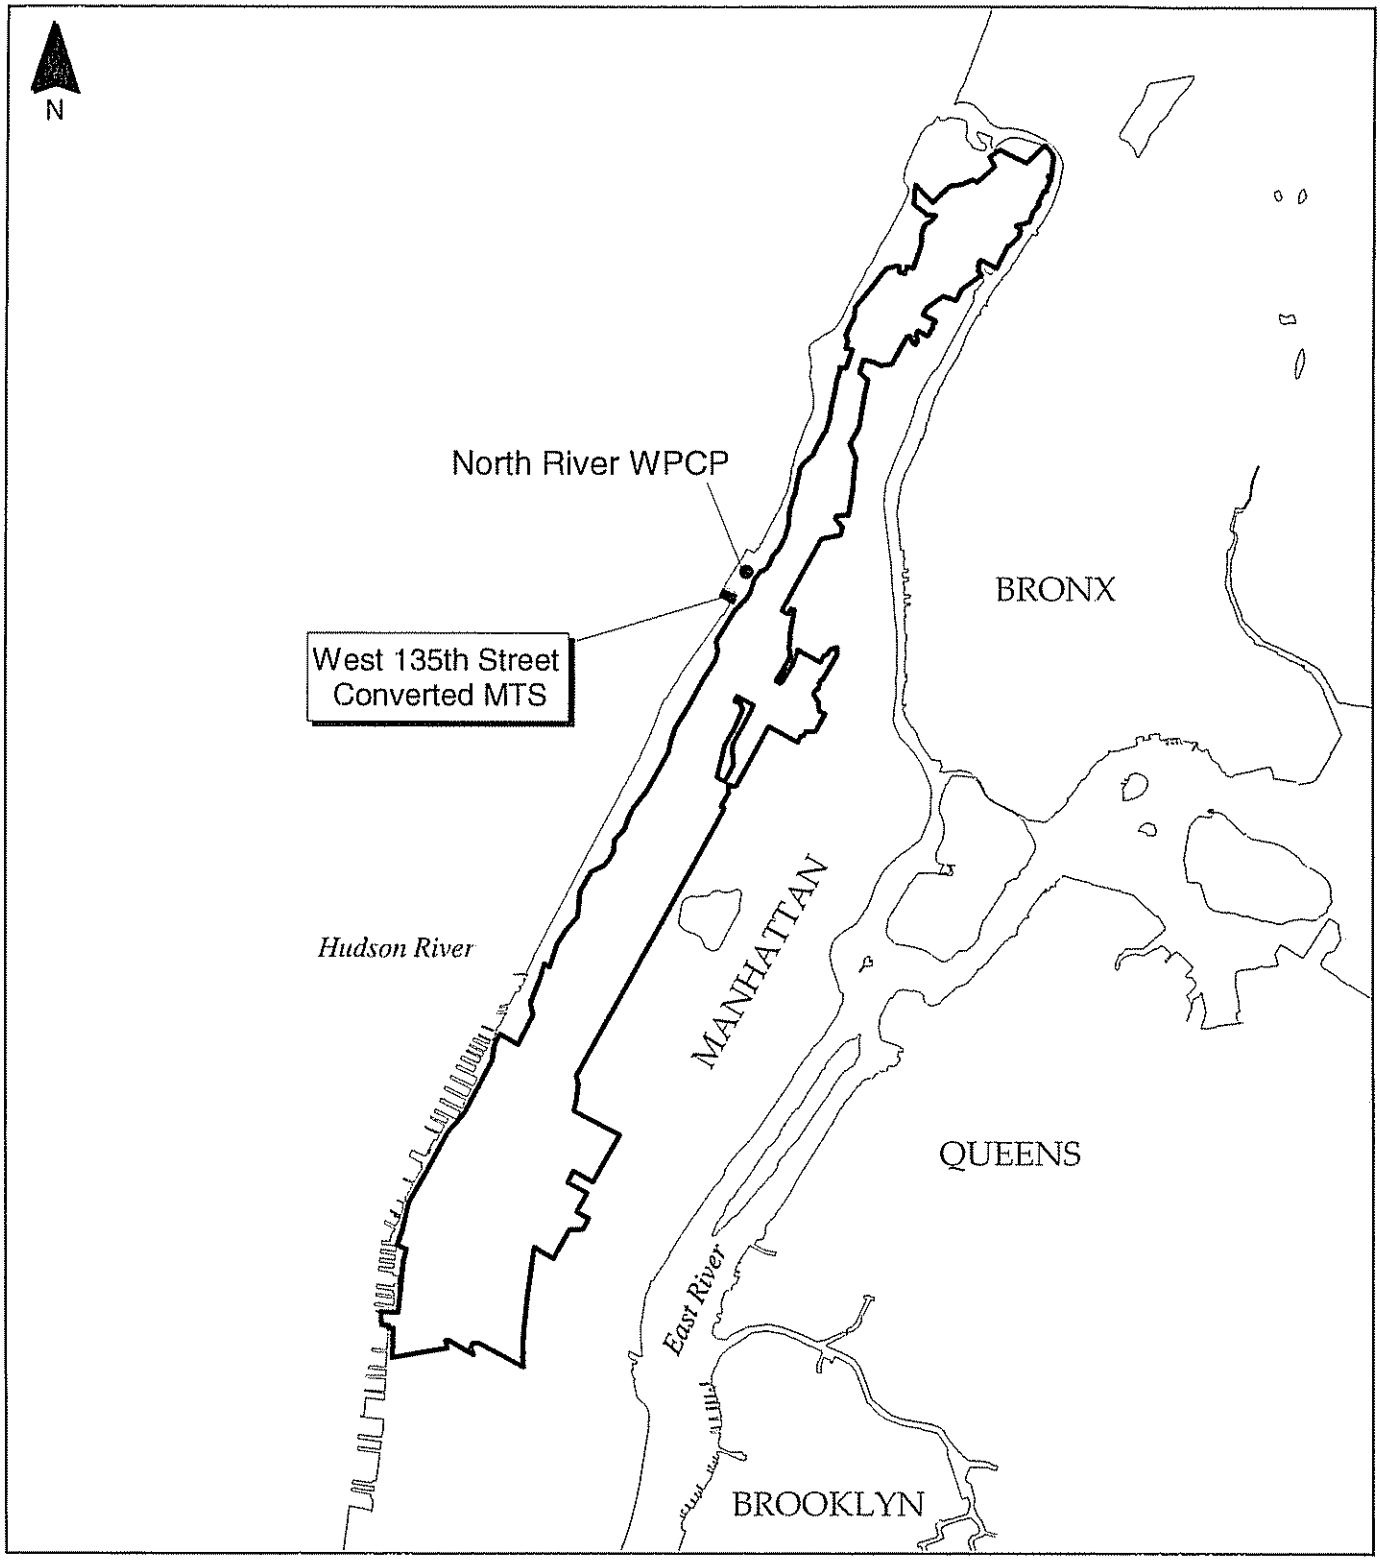
Designated historic resources are found within the study area, as noted in Section 21.6.1. However, the West 135th Street Converted MTS would have no impacts on these resources. Based upon information discussed in Section 21.6.2, the West 135th Street Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

As noted in Section 21.6.3, the site does not have any architectural or archaeological significance, nor are any resources located in its vicinity. The West 135th Street Converted MTS would, therefore, be consistent with this subpolicy.

21.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

21.13.1 Existing Conditions



21.13.1.1 Water Supply

Water is supplied to the existing West 135th Street MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. A 12-inch-diameter pipe in the immediate area of the site at the intersection of West 135th Street and 12th Avenue provides water to the existing potable and fire water systems.

An off-site 6-inch-diameter line along West 135th Street provides potable water for both consumption and sanitary requirements. A second 6-inch-diameter fire water service line located on site provides potable water to charge the fresh water sprinkler system at the existing MTS. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual). To ensure that adequate pressure is provided on site, each water system is currently supplemented with a pump.

21.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the North River WPCP, which serves the western section of Manhattan from Chelsea to Inwood and is located immediately north of the existing West 135th Street MTS. The WPCP drainage area is illustrated in Figure 21.13-1. From July 2002 through June 2003, the North River WPCP treated an average of 124 mgd of wastewater underdry weather flow conditions and an average flow of 133 mgd, which includes the sanitary and stormwater flows by the WPCP during wet weather. (Ssee Table 21.13-1.). The maximum dry weather flow during this period was 130 mgd during August 2002 and June 2003 and the maximum average flow was 149 mdg during June 2003. Effluent from the plant is discharged into the Hudson River and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the North River WPCP is 170 mgd. It is estimated that current on-site employee water usage is about 75 gpd. This estimate is based on the current

Site delineations are approximate.

Notes:
(1) Average flows include the sanitary and stormwater flows received by the plant in wet weather.

staff of three security employees (one employee per shift, three shifts per day) using 25 gallons per person, per day (2001 CEQR Technical Manual). As the facility is currently not accepting waste, no other potable water is used and no operational staff is assigned to the site.

A 12-inch-diameter sewer at West 135th Street and 12th Avenue serves the site. The sewer is connected to a 16-foot, square interceptor line (combined sanitary and storm water system) that runs north along Riverside Drive where waste is directed north to the North River WPCP. Stormwater runoff from the MTS parking area and ramp are routed to catch basins that discharge to the combined sewer system.

21.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each employee at the MTS produces approximately nine pounds of solid waste per week for a facility total of 27 pounds per week (approximately four pounds per day). The solid waste is collected by DSNY personnel and transported by truck to an appropriate licensed solid waste management facility.

21.13.1.4 Energy

Electricity to the facilty is provided by Consolidated Edison of New York. A review of applicable utility plans shows electric lines along 12th Avenue and 135th Street. The MTS service is connected to the Consolidated Edison system on West 135th Street to the west of 12th Avenue. The existing West 135th Street MTS currently utilizes a negligible amount of energy due to low staffing levels providing only security. Currently, no gas is supplied to the facility.

21.13.2 Future No-Build Conditions

The existing West 135th Street MTS would continue to not accept waste. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near Existing Condtions levels for security employees. Wastewater flows to the North River WPCP would continue to increase and would be projected to be 135.1 mgd by 2006.

21.13.3 Potential Impacts with the West 135th Street Converted MTS

21.13.3.1 Water Supply

The West 135th Street Converted MTS would have up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 3,225 gpd above current consumption levels.

The West 135th Street Converted MTS would have no impact on the existing system's ability to supply water reliably. According to Division 6 of the FDNY, the water pressure in the area is about 90 psi. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

21.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,300 gpd for the West 135th Street Converted MTS, the small quantities of wastewater sent to the North River WPCP would not significantly impact the sewage flow rate or the ability of the North River WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 135.1 mgd in 2006, which would be well below the permitted capacity of 170 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

21.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 employees per day, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 444 pounds per week (74 lbs/day) above current waste generation levels. This volume would be managed at the West 135th Street Converted MTS and would not significantly impact the system.

21.13.3.4 Energy

The West 135th Street Converted MTS would require an additional 5.51E+10 BTU/year of electricity to operate the facility. Natural gas heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the West 135th Street Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

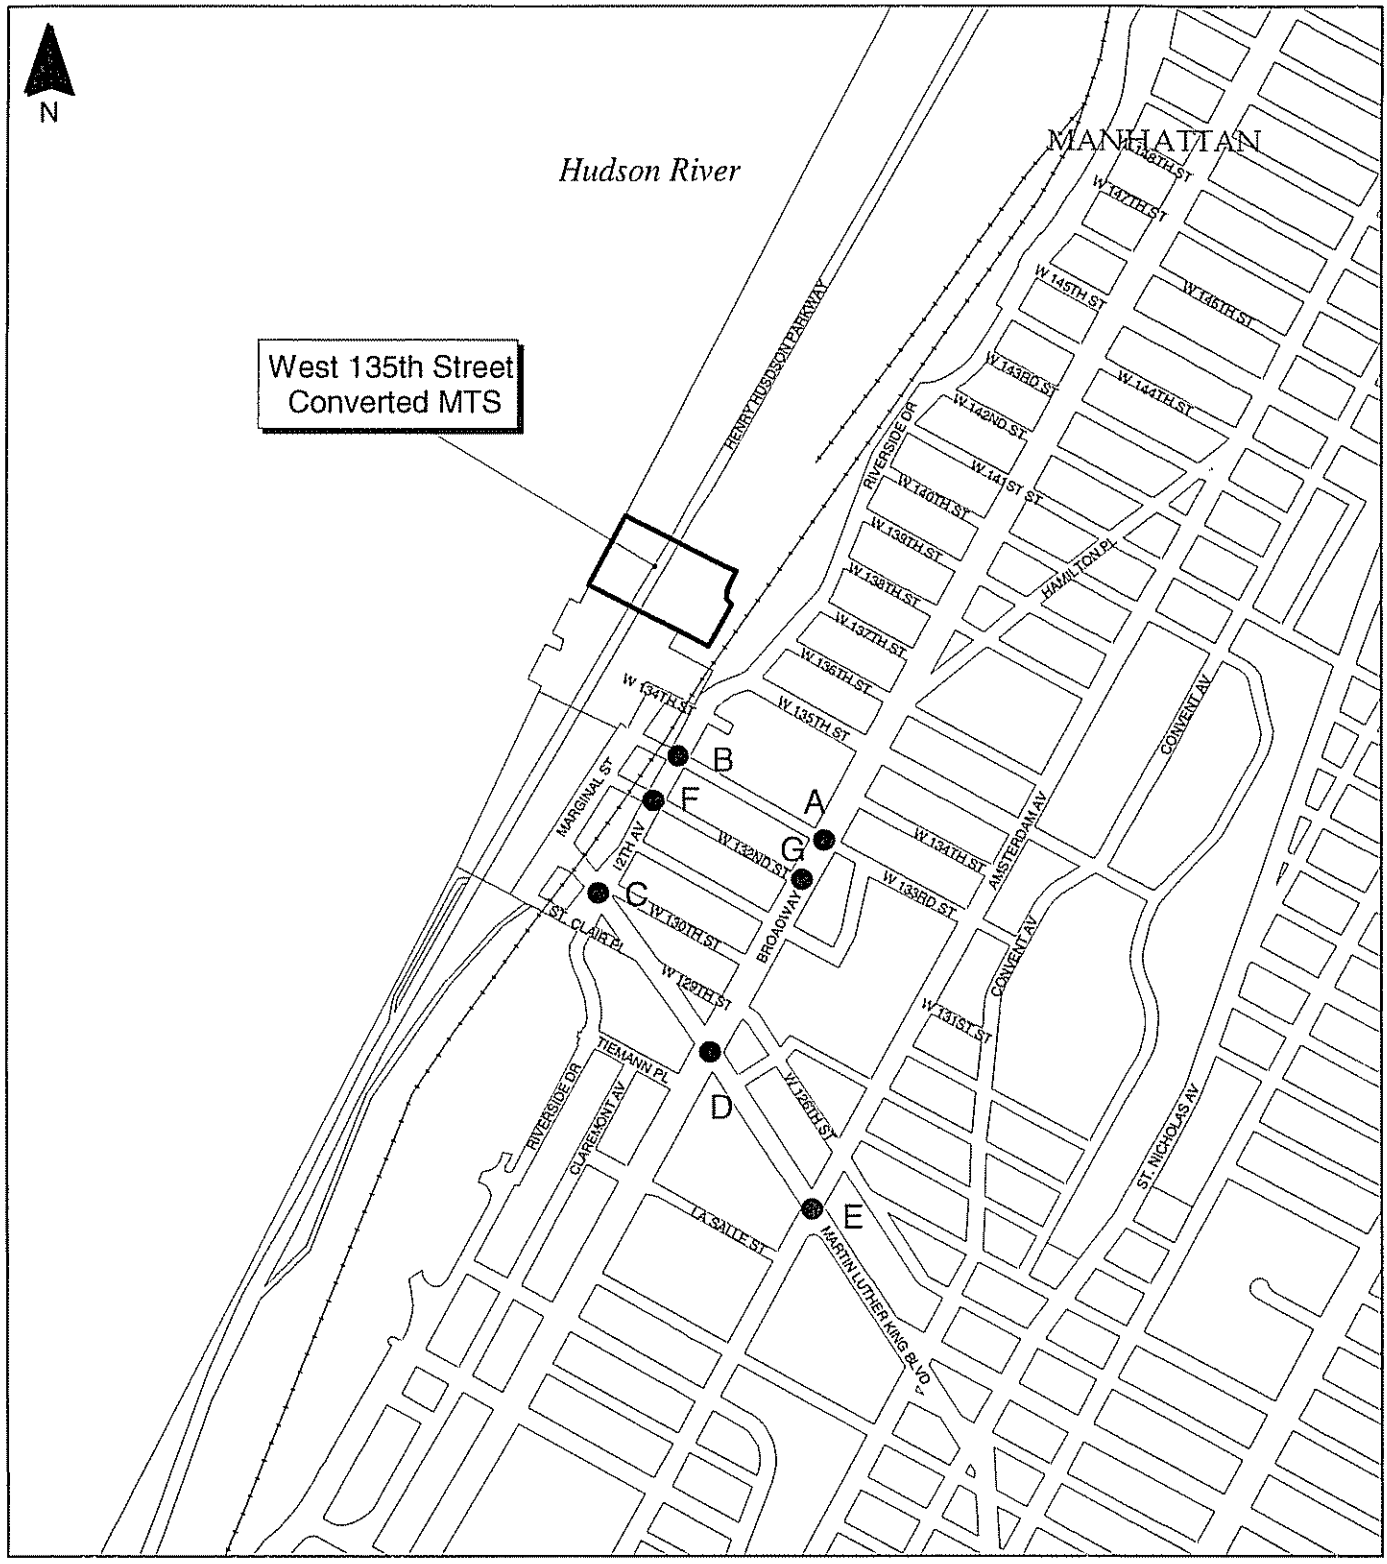
Consolidated Edison was also notified of the natural gas requirements of the West 135th Street Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts.

21.14 Traffic, Parking, Transit, and Pedestrians

21.14.1 Introduction

The West 135th Street Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

21.14.2 Existing Conditions



21.14.2.1 Definition of Study Area

The West 135th Street Converted MTS is located on the Hudson River at West 135th Street. The study area, which is bounded on the east by Amsterdam Avenue, on the south by West 125th Street and on the north by West 135th Street, was defined based upon a determination of the expected concentration of vehicle trips to and from the West 135th Street Converted MTS and also by the configuration of the arterial street network in the site area. The study area is characterized primarily by mixed commercial and residential land uses with some light industrial.

The major roadways in the study area include 12th Avenue, Broadway, West 125th Street and Amsterdam Avenue. Figure 21.14-1 shows the locations of the intersections selected for analysis (locations A through G). (Intersections analyzed were selected using the procedures defined in Section 3.16). Section 21.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the West 135th Street Converted MTS.

21.14.2.2 Surface Network

Trucks are required by NYCDOT Title 34 to travel on truck routes directly to the site or the intersection nearest the site if adjacent streets are not designated truck routes. A map showing all major truck routes and local truck routes in Manhattan is provided in Section 3.16 (see Figure 3.16-4).

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The primary truck access routes between the West 135th Street Converted MTS and CDs M9, M10 and M12 and their associated garages are Broadway, Amsterdam Avenue and West 125th Street. Broadway and Amsterdam Avenue are major north/south Manhattan arterials. Broadway extends throughout the length of Manhattan and is a two-way arterial in the study area. The NYCT Broadway/7th Avenue Local No. 1/9 line runs on an elevated structure over Broadway in the study area. Amsterdam Avenue is also a two-way arterial in the study area. West 125th Street is a two-way major east-west commercial corridor extending from the east to the west shorelines of Manhattan. Direct access to the site is provided by 12th Avenue and a short segment of West 135th Street. 12th Avenue is a short street segment in the study area extending generally between West 125th Street and West 135th Street. Riverside Drive is on an elevated structure over 12th Avenue. Ramps to northbound Route 9A and to and from southbound Route 9A are located in the study area.

DSNY and other agency collection vehicles traveling to the West 135th Street Converted MTS from the north on Broadway can turn west on West 133rd Street to gain access to 12th Avenue and then proceed to the site. Vehicles coming from the north along Amsterdam Avenue would proceed to West 125th Street and then to 12th Avenue. Vehicles approaching from the south on Broadway or Amsterdam Avenue would use West 125th Street to gain access to 12th Avenue and then West 135th Street by the Converted MTS. DSNY and other agency collection vehicles exiting the West 135th Street Converted MTS and returning north along Broadway must use West 132nd Street in order to turn north onto Broadway. A height restriction due to an NYCT bridge located above Broadway at West 133rd Street prevents DSNY and other agency collection vehicles from making a left onto Broadway from West 133rd Street. Other exiting vehicles travel south along 12th Avenue to West 125th Street and then proceed to a designated truck route to return to their respective CDs. Figure 21.14-2 depicts NYCDOT designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

21.14.2.3 Existing Traffic Operations

The seven intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the West 135th Street Converted MTS. All are on major arterials and/or collection vehicle routes. Diagrams of the following intersections are included in technical backup submitted to NYCDOT.

- Broadway and West 133rd Street – Signalized Intersection (see Figure 21.14-1, Location A)
- 12th Avenue and West 133rd Street – Signalized Intersection (see Figure 21.14-1, Location B)
- 12th Avenue and West 125th Street – Signalized Intersection (see Figure 21.14-1, Location C)
- Broadway and West 125th Street – Signalized Intersection (see Figure 21.14-1, Location D)
- Amsterdam Avenue and West 125th Street – Signalized Intersection (see Figure 21.14-1, Location E)
- 12th Avenue and West 132nd Street – Signalized Intersection (see Figure 21.14-1, Location F)
- Broadway and West 132nd Street – Signalized Intersection (see Figure 21.14-1, Location G)

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement and ATR counts were conducted primarily in November 2002 with some additional counts conducted in March 2003. Figures 21.14-3, 21.14-4 and 21.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 8:00 a.m. and 9:00 a.m., the Facility peak between 9:00 a.m. and 10:00 a.m., and the PM peak between 5:00 p.m. and 6:00 p.m. Table 21.14-1 presents the v/c ratio, delay and LOS for the seven study intersections during the AM, Facility, and PM peaks.

LT = left through movement L = left movement

TR = through right movement

Existing truck traffic on the major streets in the study area is substantial in the AM and mid-day periods, but less during the PM peak. Heavy vehicles generally consist of 10% to 15% of the total traffic on Broadway, Amsterdam Avenue and West 125th Street during the AM and mid-day periods; and range from 5% to 10% on Amsterdam Avenue and Broadway, and less than 3% on West 125th Street during the PM peak period.

The intersection of Amsterdam Avenue with West 125th Street has been identified as a high pedestrian accident location. Thirteen accidents involving pedestrians were reported at this intersection in the year 2000. Overall, 51 accidents occurred at the intersection in 2000, of which 26 were reportable and 17 involved personal injury. There were no fatalities reported over the last three-year period, but the total number of accidents and the number of injury accidents have increased over the period.

21.14.2.3.1 LOS at Signalized Intersections

Table 21.14-1 shows that the study signalized intersections generally operated at an overall LOS of B or C with the following exceptions. During the AM peak period both West 125th Street at Amsterdam Avenue and West 125th Street at Broadway operated at LOS D. These two intersections also operated at LOS D during the PM peak hour, as did the intersection of West 133rd Street at 12th Avenue.

Overall, most of the individual lane groups at each intersection generally operate at LOS D or better during each analysis period, with some exceptions. At the intersection of West 133rd Street at 12th Avenue, the westbound left, through and right lane group operates at LOS F during the PM peak hour. The westbound left turn lane group operates at LOS F during the AM peak hour at the intersection of 125th Street and Amsterdam Avenue and during the PM peak hour, the northbound left, through and right turn lane group operates at LOS E. Lastly, the northbound left turn lane group and the northbound left, through and right turn lane group at the intersection of 125th Street and Broadway operates at LOS E during the AM peak hour and LOS F during the PM peak hour.

21.14.2.3.2 LOS at Unsignalized Intersections

No unsignalized intersections were analyzed.

21.14.2.4 Existing DSNY-Related Traffic

MSW generated by Manhattan CDs M9 and M10 is currently transported under the Manhattan interim export program to American Ref-Fuel, a commercial vendor located at 183 Raymond Boulevard in Newark, New Jersey. MSW generated by Manhattan CD M12 is currently transported to ACS PEN PAC-Eastern located at 30-35 Fulton Street in Paterson, New Jersey. In all instances, MSW is transported from Manhattan to New Jersey in collection vehicles.

21.14.2.5 Public Transportation

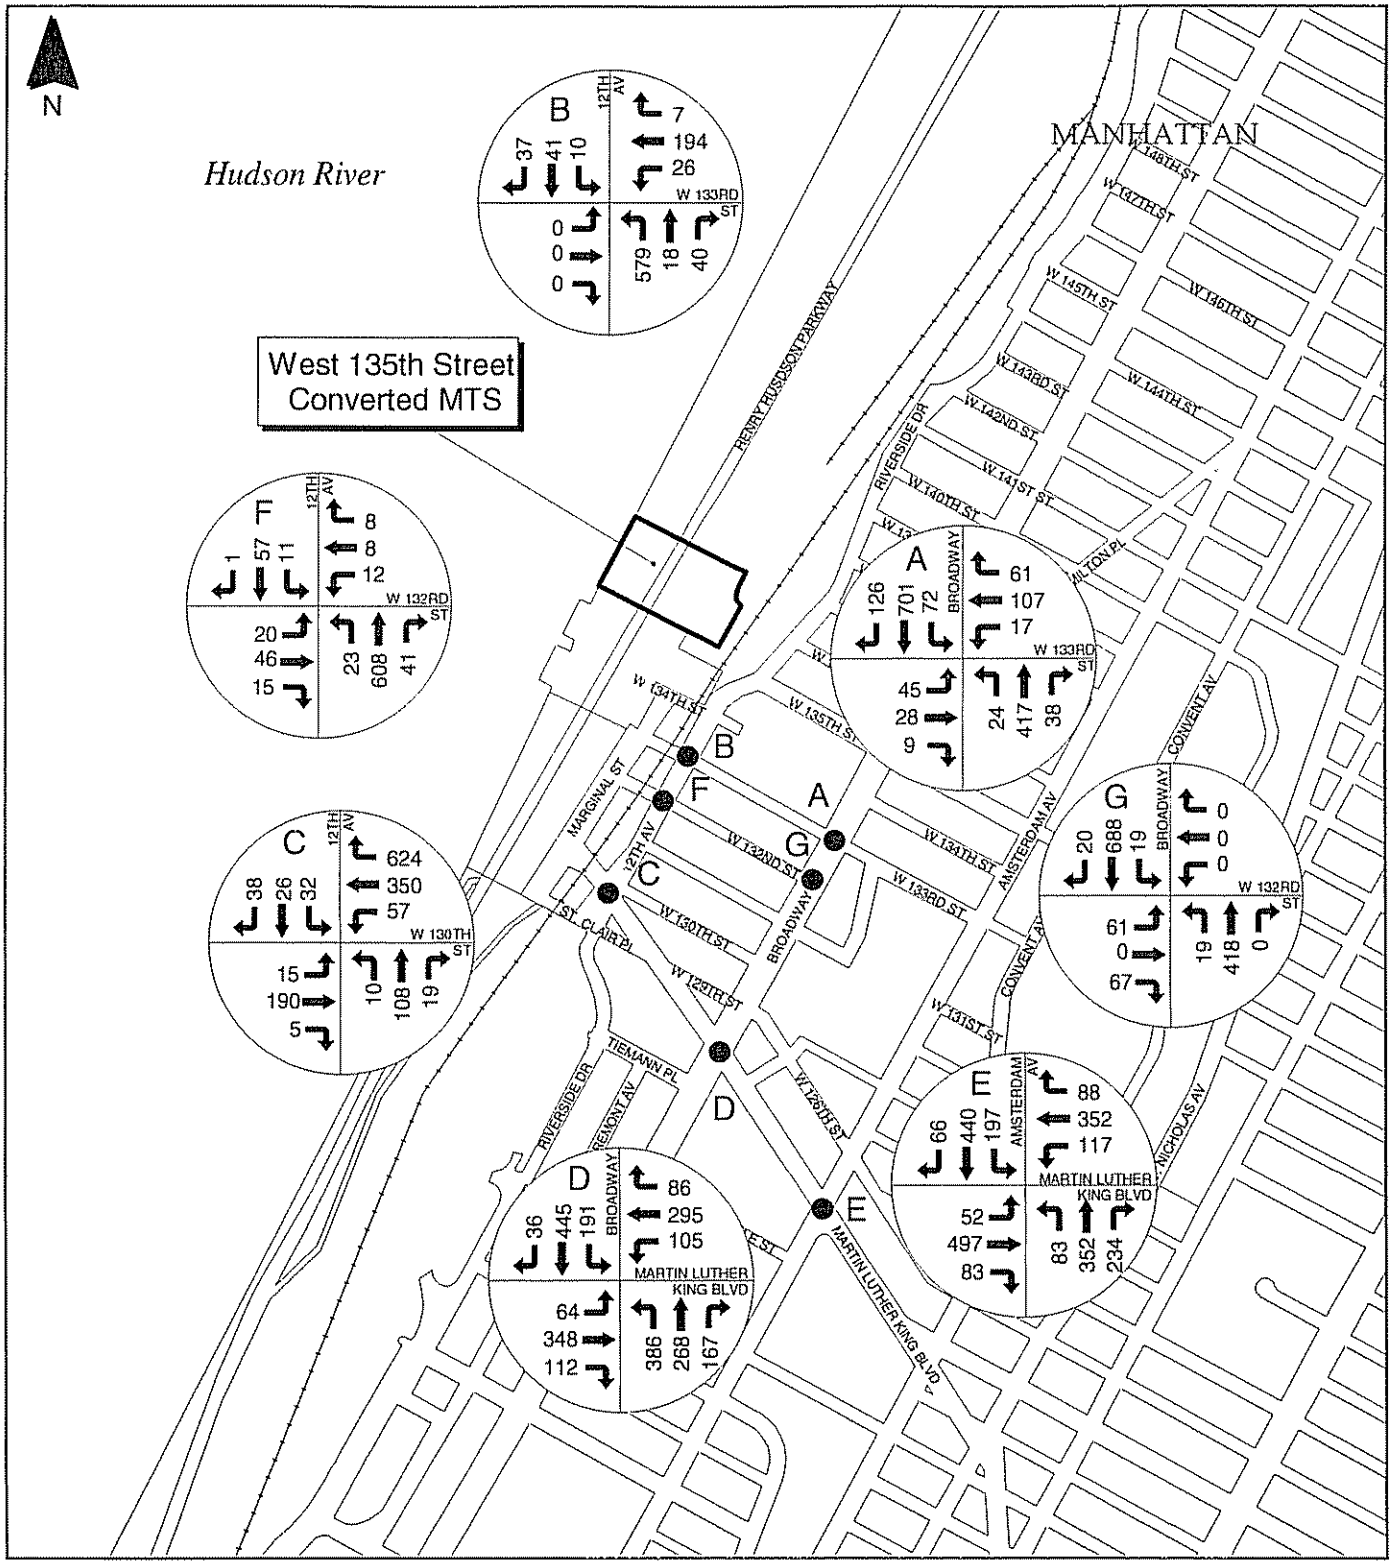
Within the study area, NYCT bus and subway systems provide public transportation service. The Broadway-7th Avenue Local No. 1/9 subway line runs north/south on Broadway through the study area with station stops at West 125th Street and West 137th Street. There are also a number of NYCT bus routes that traverse the study area as follows:

- Bx15: Harlem to Fordham in the Bronx serving West 125th Street within the study area.
- M4: Midtown to Washington Heights through the Upper East Side and Harlem. Service is provided along Broadway within the study area.
- M5: Greenwich Village to Washington Heights. Service is provided along Broadway, Riverside Drive and 5th Avenue.
- M11: Greenwich Village to Riverbank State Park making stops in the study area along Amsterdam Avenue.
- M100: East Harlem crosstown and into Inwood. Within the study area, service is provided along West 125th Street and Amsterdam Avenue.
- M101: East Village to Washington Heights through both East Harlem and Harlem, servicing West 125th Street and Amsterdam Avenue within the study area.
- M104: Murray Hill crosstown and into Harlem. Within the study area, stops are made along West 125th Street and Amsterdam Avenue.

21.14.2.6 Pedestrian Activity

Pedestrian activity is substantial along Broadway, West 125th Street and Amsterdam Avenue, but is significantly less in the western part of the study area, such as along 12th Avenue. The highest pedestrian volumes were identified at the intersection of Amsterdam Avenue and West 125th Street, where counts exceeded 300 pedestrians per hour crossing a crosswalk. Slightly lower pedestrian volumes were counted at the intersection of Broadway and West 125th Street. In contrast, fewer than 20 pedestrians per hour on each crosswalk were identified along 12th Avenue.

21.14.3 Future No-Build Conditions



21.14.3.1 Traffic Conditions

The following assumptions and traffic assignments were applied in the development of Future No-Build traffic volumes:

- Continued operation of the Manhattan interim export program with MSW delivered to the vendors noted above.
- Discrete assignment of auto and truck trips expected to be generated by the West Harlem Master Plan Waterfront Development Complex, which is expected to be completed by 2006, and the redevelopment of the Studebaker Building at 615 West 131st Street as a 35,000-square-foot office building.
- Background traffic growth of 0.5% per year in accordance with the 2001 CEQR Technical Manual.

Figures 21.14-6, 21.14-7 and 21.14-8 provide the AM, Facility, and PM peak hour Future No-Build traffic volumes for the intersections analyzed in conjunction with this site.

Table 21.14-2 provides the Future No-Build v/c ratio, delay and LOS for each study intersection. As shown, the study intersections will operate at a LOS B or C during most time periods. During the AM peak hour, however, the intersections of both West 125th Street and Amsterdam Avenue, as well as West 125th Street and Broadway, will operate at LOS D. During the PM peak hour,

Notes for Table 21.14-2:
(1) HCM output is included in technical backup submitted to the NYCDOT.
DFL = defacto left
LTR = left, through and right movements
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
L = left movement
TR = through right movement

the intersection of West 133rd Street and 12th Avenue will operate at LOS E, as would the intersection of West 125th Street and Broadway. Also, the intersections of West 125th Street and Amsterdam Avenue as well as West 133rd Street and Broadway would operate at LOS D.

The individual movements generally would operate at LOS D or better with a few exceptions. At the intersection of West 125th Street and Amsterdam Avenue, the westbound left turn lane group would operate at LOS F during the AM peak hour, LOS E during the Facility peak hour and LOS D during the PM peak hour, and the northbound approach would operate at LOS E during the PM peak hour. The westbound left, through and right turn lane group would operate at LOS F during the PM peak hour at the intersection of West 133rd Street and 12th Avenue. At the intersection of West 125th and Broadway, the northbound approach would operate at LOS E or worse during the AM and PM peak hours.

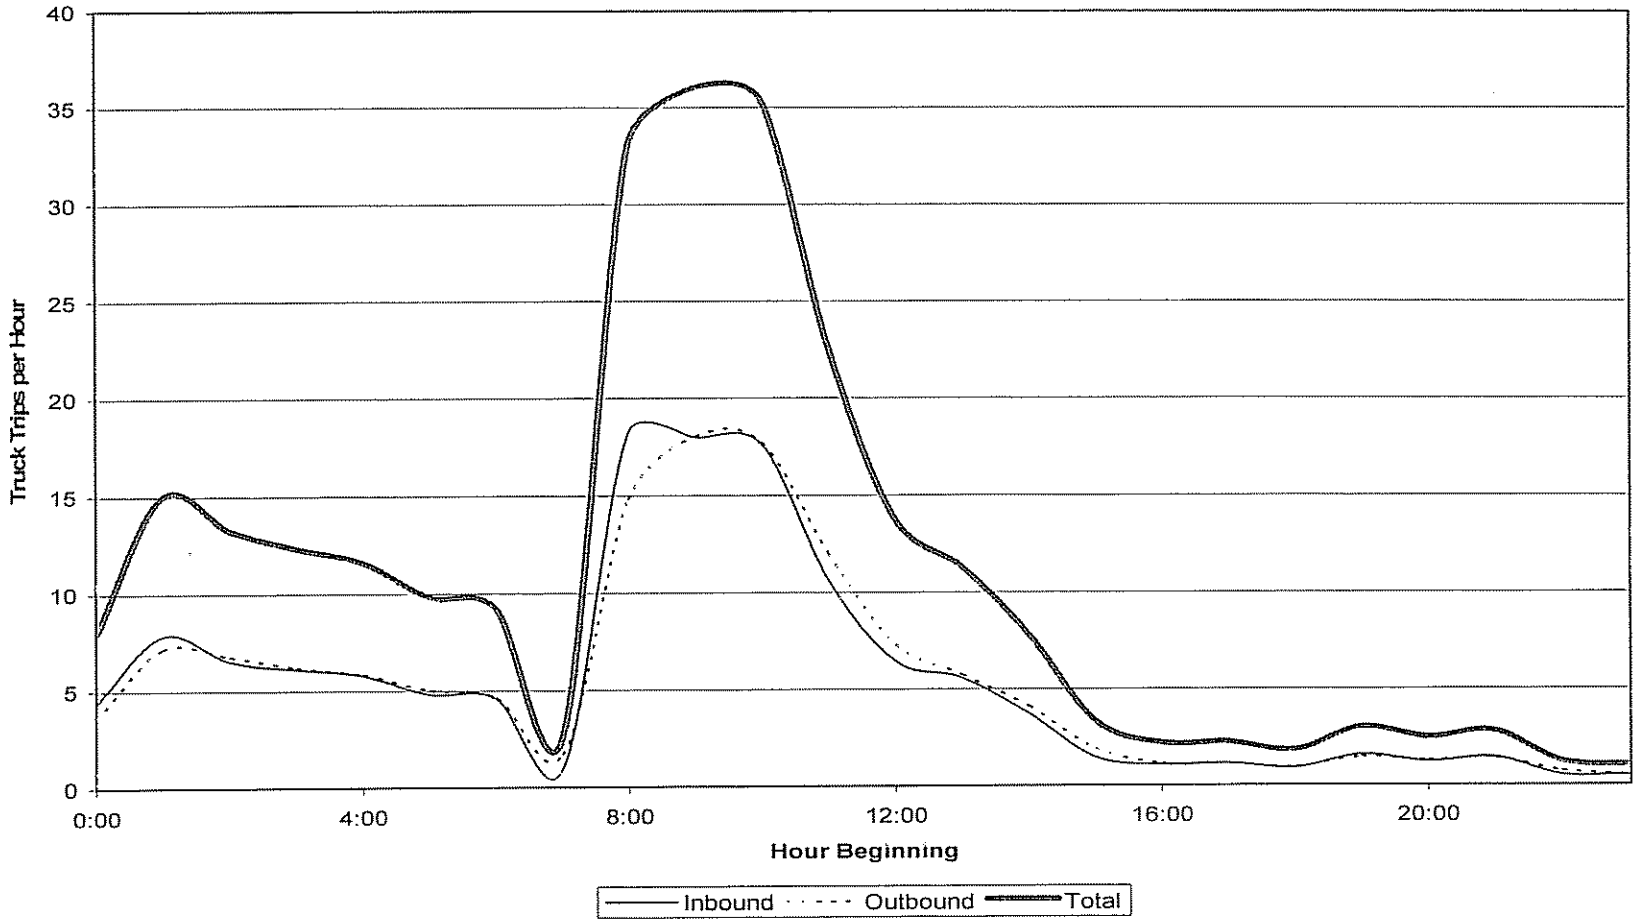
21.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

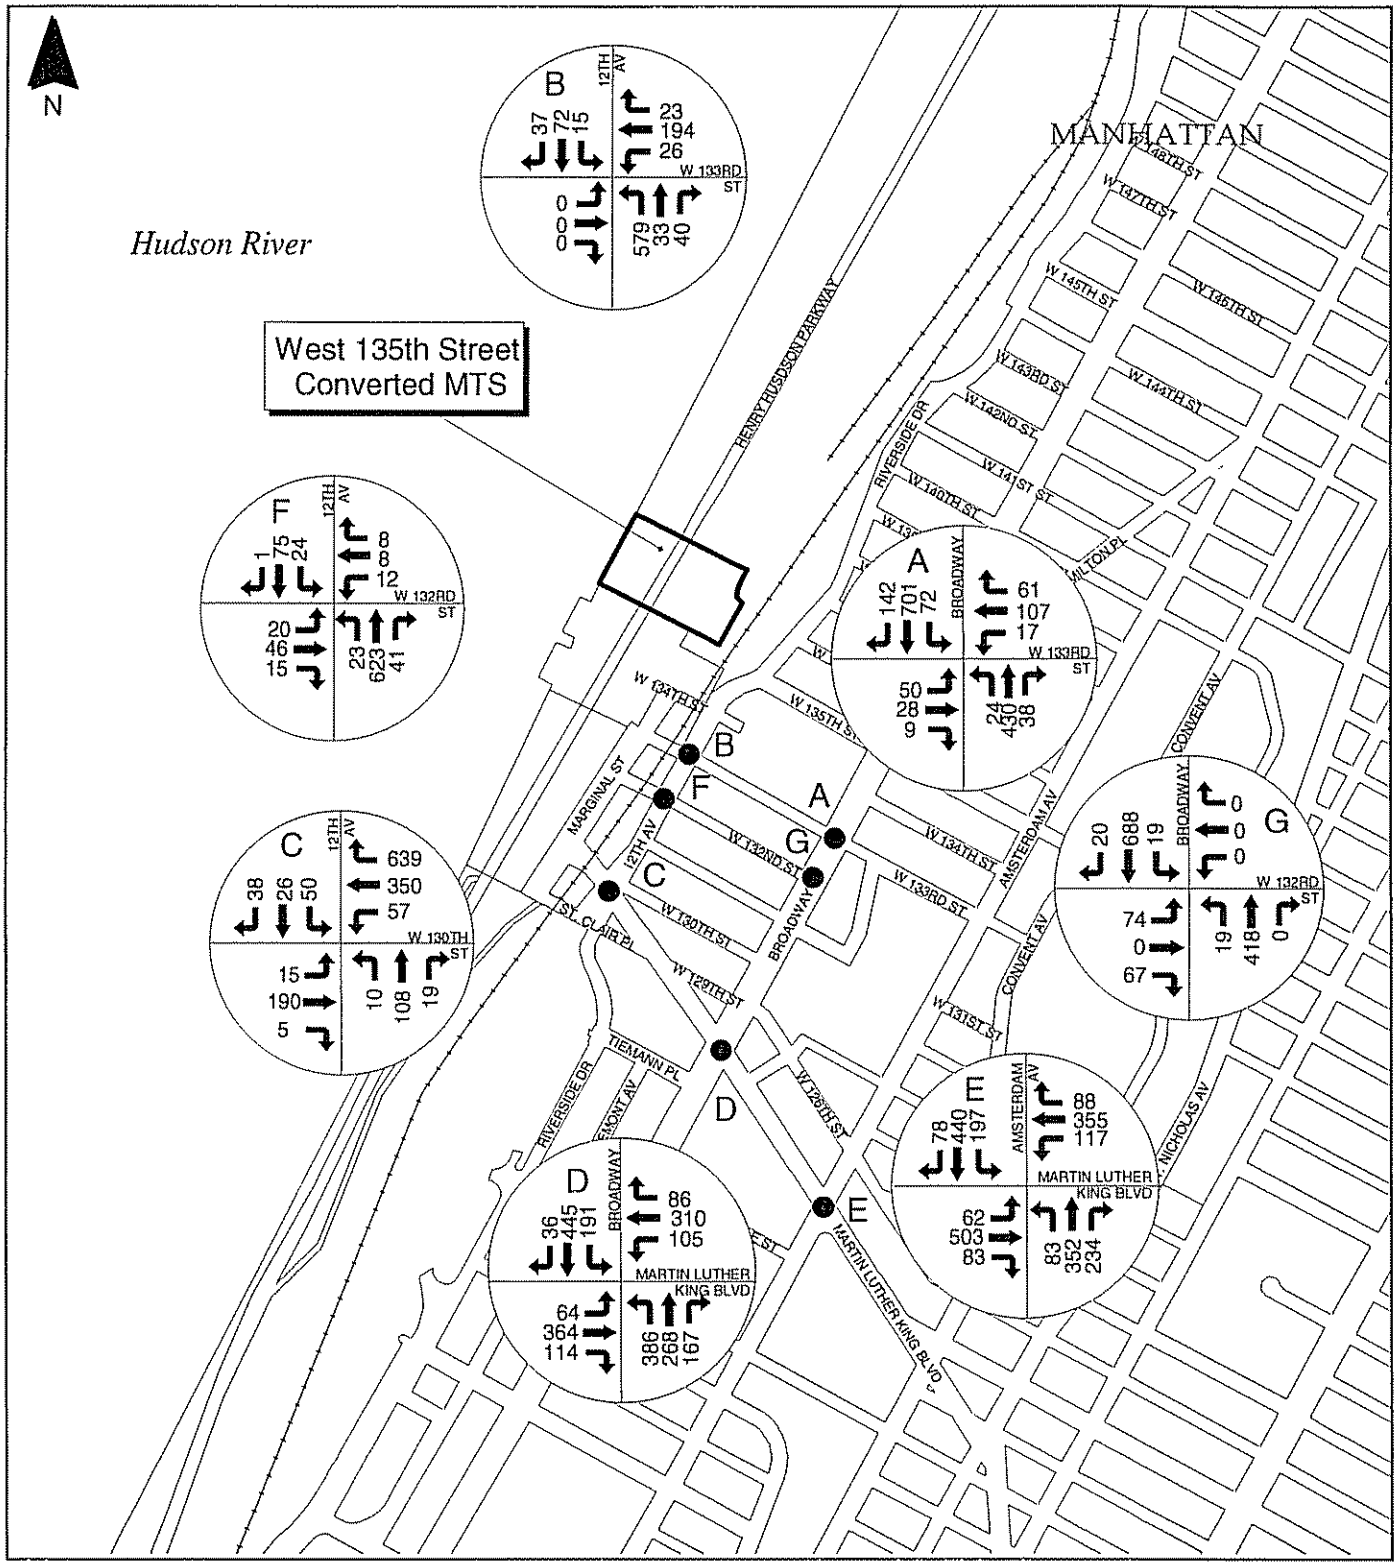
21.14.3.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

21.14.4 Potential Impacts with the West 135th Street Converted MTS



The West 135th Street Converted MTS would receive municipal waste from CDs M9, M10 and M12 in Manhattan. Additionally, employee trips to and from the site may result in traffic impacts during the AM peak hour.



21.14.4.1 2006 Future Build Traffic Conditions

2006 Future Build Traffic Conditions assume that the West 135th Street Converted MTS would generate 222 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site to the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the West 135th Street Converted MTS are shown in Figure 21.14-2.

Figure 21.14-9 presents the average peak day temporal distribution of collection vehicles for the West 135th Street Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicle trips generated by the West 135th Street Converted MTS is expected to vary between 2 to 25 truck trips per hour in the late evening/early morning; approximately 15 to nearly 60 truck trips per hour in the mid-morning/early afternoon; and 5 to 15 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle trips (60) occurs during both 9:00 a.m. and 10:00 a.m. and 10:00 a.m. to 11:00 a.m. Figures 21.14-10, 21.14-11 and 21.14-12 depict the Future Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Figures 21.14-13, 21.14-14 and 21.14-15 depict the net future traffic volumes added to the Future No-Build Conditions to generate Future Build Conditions for AM, Facility, and PM peaks at the intersections analyzed.

DEPARTMENT OF SANITATION

Employee person trips generated as a result of the West 135th Street Converted MTS are expected to be about 44 per shift (22 coming in and 22 leaving). There are three employee shifts per day: 8:00 a.m. to 4:00 p.m.; 4:00 p.m. to 12:00 a.m.; and 12:00 a.m. to 8:00 a.m. It is assumed that employees would arrive about ½-hour before the start of a shift and leave about ½-hour after the end of a shift. With these projections, employee trips are expected to occur between 7:30 a.m. and 8:30 a.m.; 3:30 p.m. and 4:30 p.m.; and 11:30 p.m. and 12:30 a.m. Because only the AM peak (8:00 to 9:00 a.m.) coincided with a projected employee shift change (7:30 to 8:30 a.m.), employee trips both to and from the West 135th Street Converted MTS during the shift change (44) were considered as part of the net increase in site-generated traffic.

Figures 21.14-10, 21.14-11 and 21.14-12 illustrate the 2006 Build Condition traffic volumes, which are a combination of Future No-Build and 135th Street MTS traffic volumes at the study intersections. A two-stage process was used to derive these traffic volumes. First, the truck trips generated by the existing interim export program were subtracted from the truck trips expected to be generated by the West 135th Street Converted MTS. These net trips were added to the Future No-Build traffic volumes along the paths specified in Figure 21.14-2. In the case of the West 135th Street Converted MTS, there was no overlap of truck trips generated by the interim export program with that expected to be generated by the West 135th Street Converted MTS.

Figures 21.14-13, 21.14-14 and 21.14-15 illustrate the resulting net change in traffic at each study intersection. The highest net increase in truck trips occurred at the intersection of 133rd Street and 12th Avenue. All of the trucks proceeding to and from the West 135th Street Converted MTS would pass through this intersection.

As noted in Section 21.14.2.3, the intersection of West 125th Street and Amsterdam Avenue was identified as a high pedestrian accident location and the overall number of accidents at this intersection has been increasing over the last three-year period. As also noted in Section 21.14.2.6, the highest pedestrian crossing volumes were identified in the study area at this intersection. High pedestrian volumes, coupled with turning movement volumes ranging from 50 to nearly 260 vehicles per hour and only a short lag-protected green phase for the southbound Amsterdam Avenue approach, likely result in a level of pedestrian/vehicle conflict that is contributory to the high number of pedestrian accidents. The maximum volume of collection vehicles that would pass through this intersection proceeding to and from the West 135th Street Converted MTS during one hour is estimated at 30. This represents less than 2% of the total

traffic flow that would enter the intersection under Future Build Conditions and should not represent a measurable change in safety. The provision of additional split phases to separate pedestrian and turning traffic should be investigated at this intersection.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 70% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 94% of weekday traffic volumes. Table 21.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the West 135th Street Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 21.14-3
Weekday and Weekend Traffic
West 135th Street Converted MTS

DSNY and Other Agency Collection Vehicle Traffic		**Background Traffic NB and SB on Broadway (1)**	
Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday Average Vehicles/Day	Weekend Average Vehicles/Day
222	153	26,501	25,043

Note:
(1) NB and SB traffic data collected from ATR counts taken on Broadway between 133rd Street and 134th Street from September 11 to 17, 2003.

Table 21.14-4 provides the v/c ratio, delay and LOS for each analyzed signalized intersection under the Future Build with the West 135th Street Converted MTS. Overall, 2006 Build intersection traffic operations, expressed in terms of delay, would deteriorate very minimally and except during the facility peak hour at the intersection of 133rd Street and Broadway, the LOS does not change at any intersection. While there are no changes in the LOS at most signalized intersections, a significant traffic impact, as defined by the 2001 CEQR Technical Manual and listed in Section 3.16, was identified for the westbound left turn lane group at the intersection of 125th Street and Amsterdam Avenue during the AM peak hour. Suggested mitigation for this impact is discussed below.

Notes for Table 21.14-4:
(1) HCM output is included in technical backup submitted to the NYCDOT.
LTR = left, through and right movements
DFL = defacto left
NB = northbound
WB = westbound
EB = eastbound
SB = southbound
L = left movement
TR = through right movement

During the AM peak hour, an impact was identified on the westbound left turn lane group at the intersection of West 125th Street and Amsterdam Avenue. As shown, the westbound left turn lane group remains at LOS F, but the delay increases from 120.1 seconds to 125.7 seconds. Currently, the existing signal operates as a three-phase signal. The mitigation proposed is as follows:

- Increase eastbound/westbound green time to 31 seconds; and
- Reduce northbound/southbound exclusive left turn green time to 9 seconds.

This would reduce the westbound left turn lane group, with LOS F, from a delay of 125.7 seconds to 104.5 seconds. This would not generate any impacts for the southbound exclusive left turn lane group and it would provide adequate clearance time for pedestrian crossings.

21.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

21.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

21.15 Air Quality

21.15.1 Definition of the Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the West 135th Street Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersections listed in Section 21.15.4.2.

21.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest the study area are shown in Table 21.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 21.15-1
Representative Ambient Air Quality Data
West 135th Street Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO	P.S. 59	8-Hour	2,978 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	5,268 $\mu g/m^3$	40,000 $\mu g/m^3$
NO_2	P.S. 59	Annual	71 $\mu g/m^3$ (1)	100 $\mu g/m^3$
PM_{10}	P.S. 59	Annual	34 $\mu g/m^3$ (2)	50 $\mu g/m^3$
		24-Hour	88 $\mu g/m^3$ (2)	150 $\mu g/m^3$
SO_2	P.S. 59	3-Hour	186 $\mu g/m^3$ (1)	1,300 $\mu g/m^3$
		24-Hour	123 $\mu g/m^3$ (1)	365 $\mu g/m^3$
		Annual	37 $\mu g/m^3$ (1)	80 $\mu g/m^3$

Notes:
Source: NYCDEP, April 2003 & USEPA Air data – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.

21.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build air quality conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

21.15.4 Potential Impacts with the West 135th Street Converted MTS

21.15.4.1 On-Site Analysis

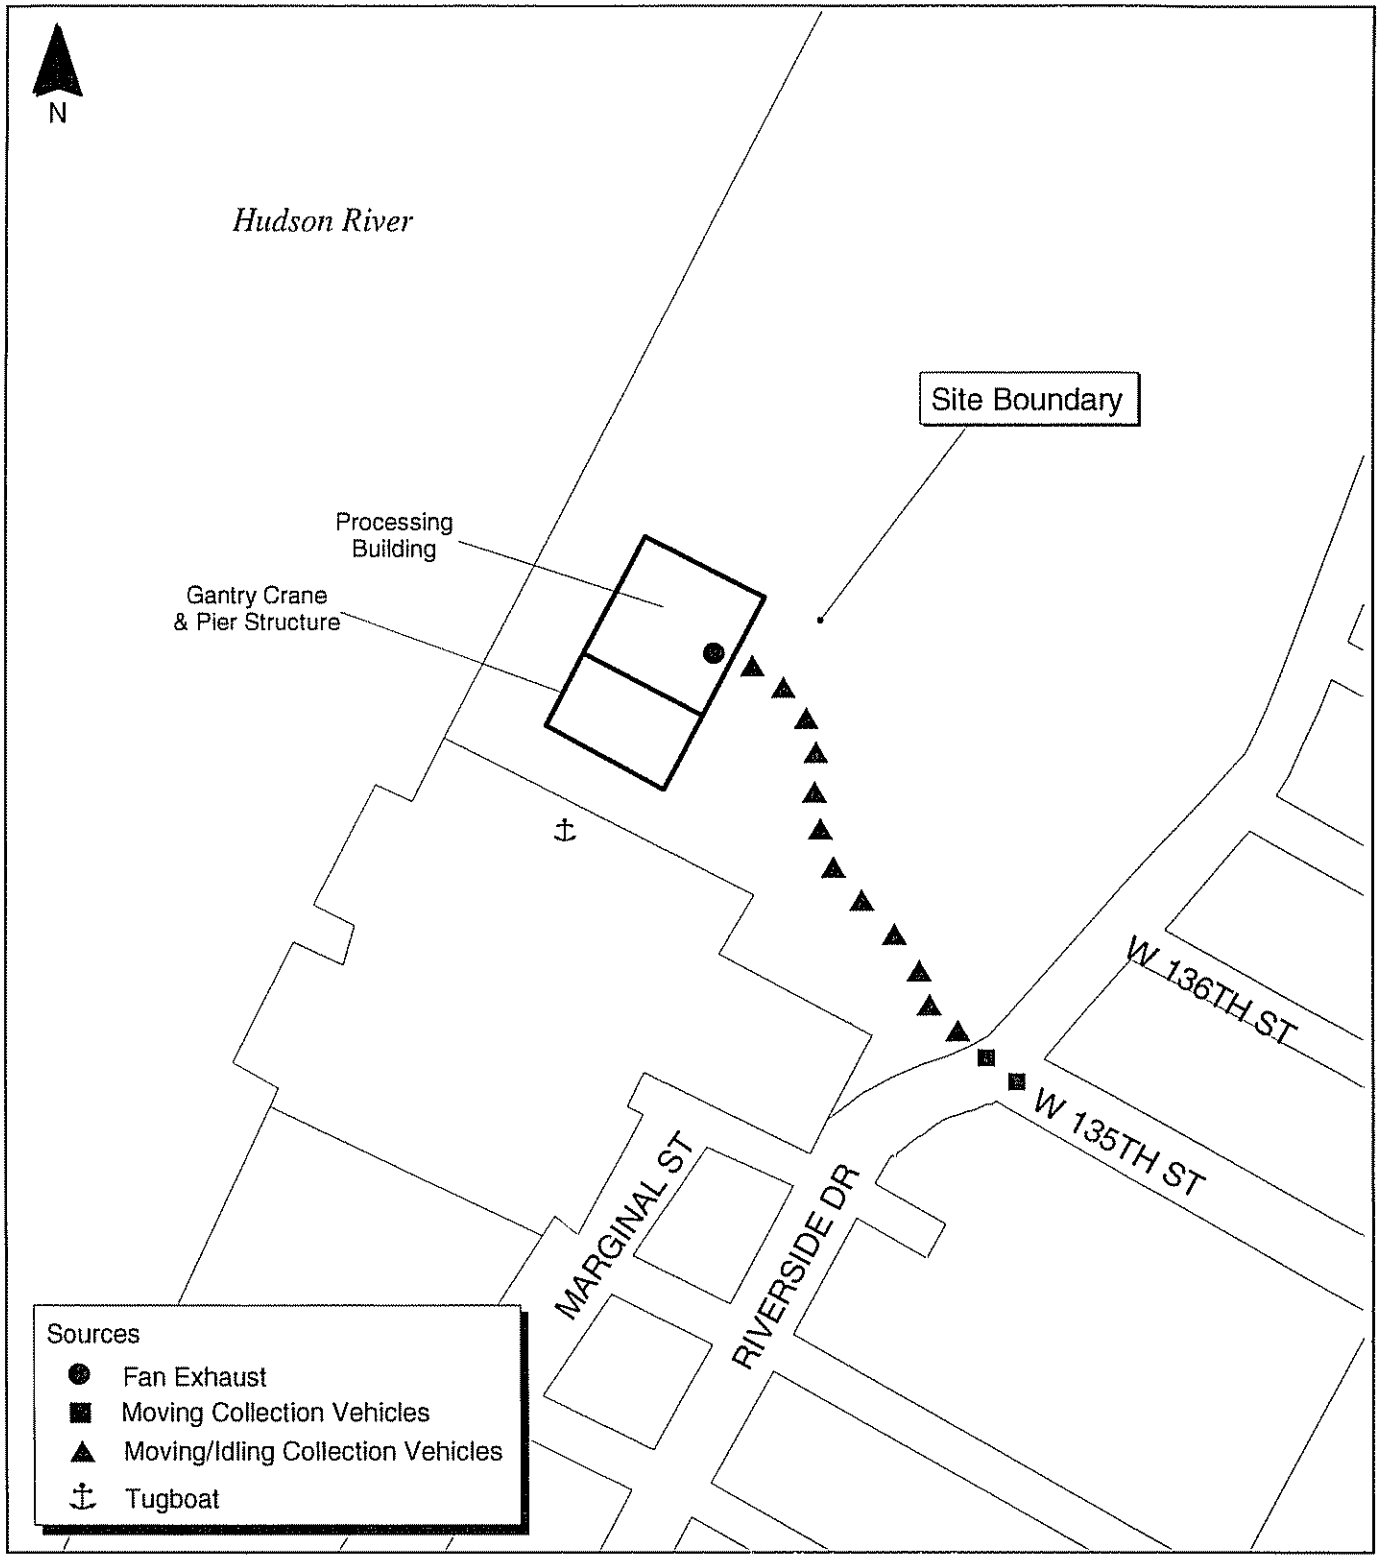
21.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that is anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 21.15-2. Figure 21.15-1 shows the locations of these sources within the site.

21.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 21.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from West 135th Street Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 21.15-3, are below the STVs. The West 135th Street Converted MTS would not, therefore, significantly impact air quality in the area.

Table 21.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
West 135th Street Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	46	18
Space Heaters	10	10
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	46	18
Queuing Collection Vehicles[3]	17 in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup ~~provided to the NYCDEP~~to be provided upon request.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) The peak 8-hour and 3-hour average number of queuing collection vehicles outside of the processing building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (17), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

Site delineations are approximate
Base Map Source: New York City Department of City Planning
Note: These are modeled source locations used in the on-site air quality analysis and do not represent individual collection vehicles

	Annual	1	~~34~~ 37	~~35~~ 38	80	NA

Notes:
(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.
(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~on February 18, 2005.
(3) NAAQS = National Ambient Air Quality Standard.
(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.
(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.
(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.
(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.
NA = Not Applicable

21.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 21.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the West 135th Street Converted MTS are not considered to be significant.

21.15.4.2 Off-Site Analysis

21.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines that are outlined in Section 3.17. Following these guidelines, the following detailed mobile source analyses were conducted for the applicable (i.e., worst-case) time periods:

- An analysis of the intersections of 12th Avenue and West 133rd Street, and Broadway and West 133rd Street to determine whether West 135th Street Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 24-hour and annual $PM_{2.5}$ STVs; and
- An analysis of the same two intersections, to determine whether West 135th Street Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 21.15-2.

Notes to Table 21.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC.

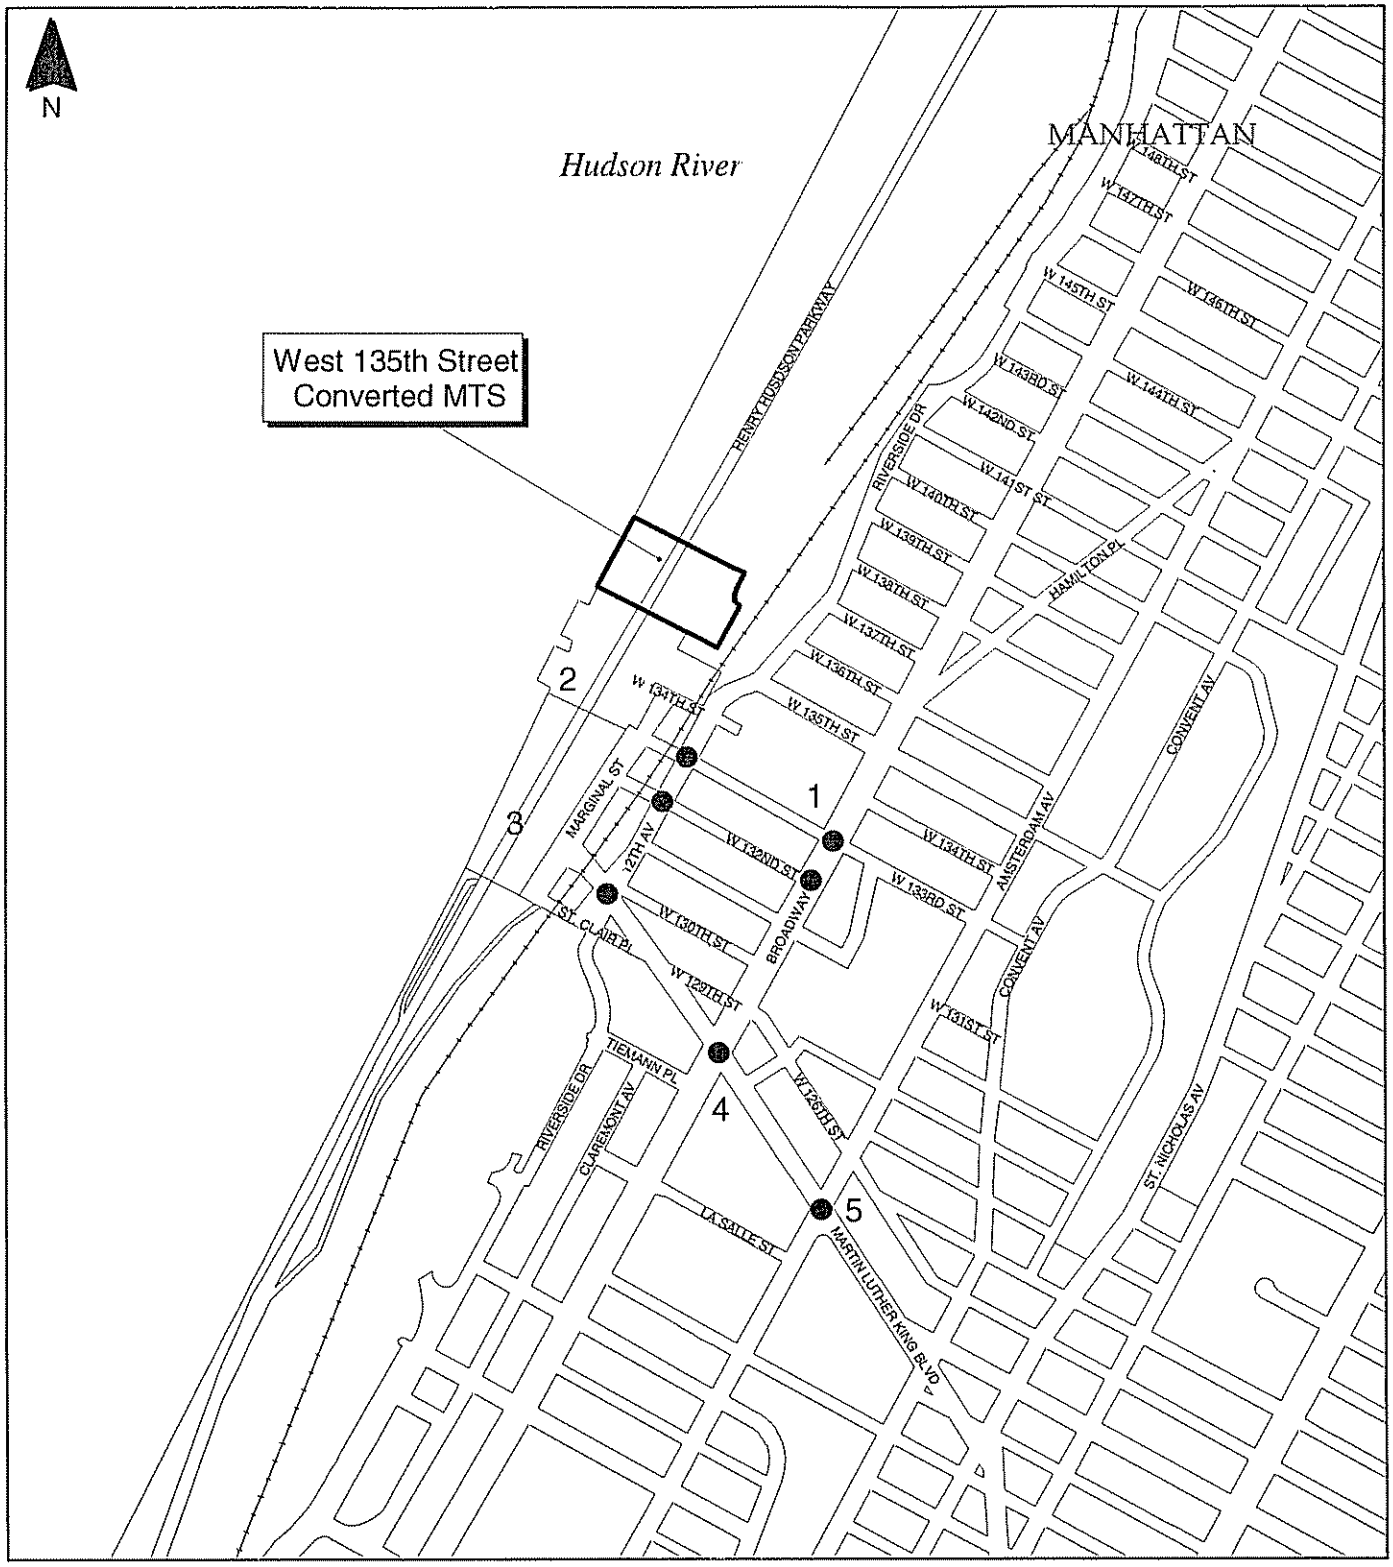
(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

NA = Not Applicable

Figure 21.15-2 Off-Site Air Quality Intersections Studied West 135th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

21.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 21.15-5, are all within (less than) the applicable state and federal ambient air quality standards, STVs (for $PM_{2.5}$) and/or de minimus impact values (for CO). The West 135th Street Converted MTS would not, therefore, significantly impact air quality in the area.

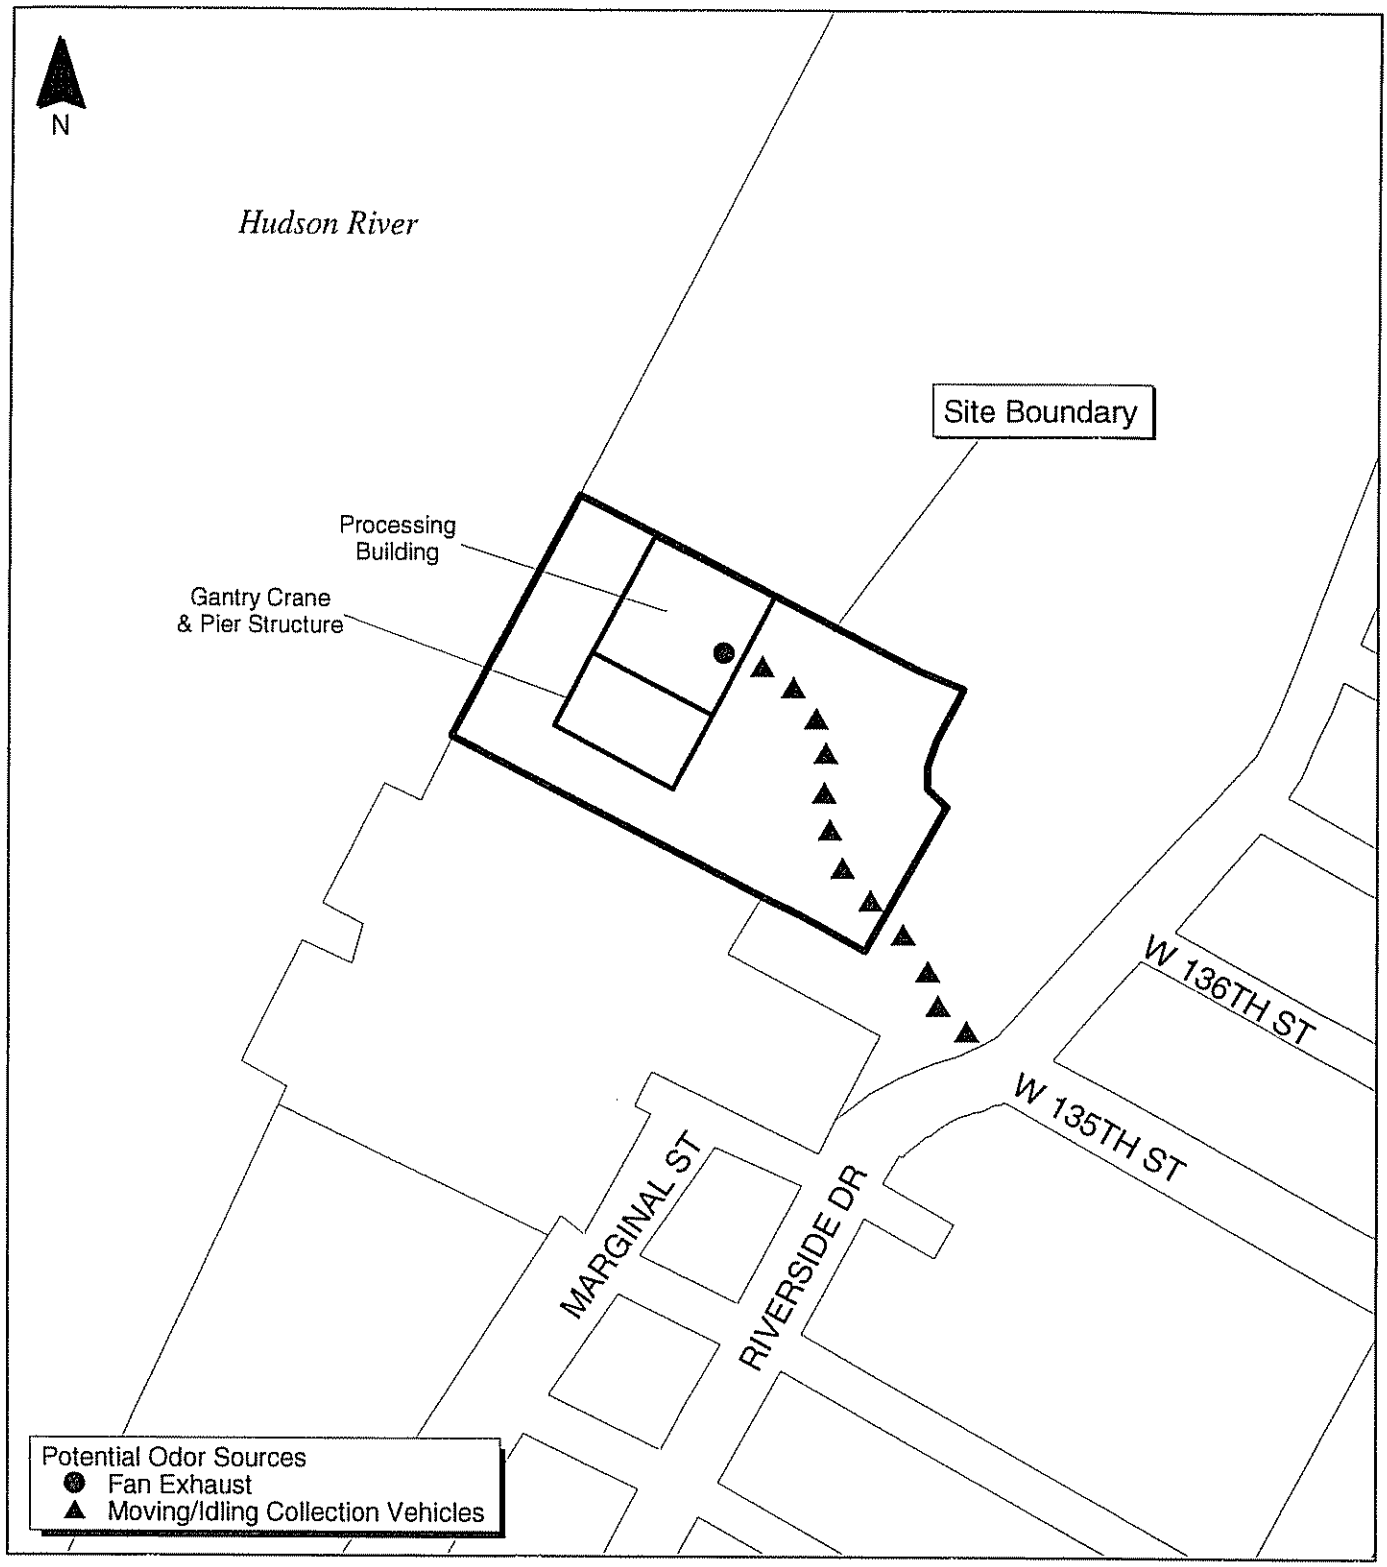
21.16 Odor

21.16.1 Existing Conditions

The existing MTS is not in operation, and there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is the Riverbank State Park located approximately 60 feet from the site boundary.

21.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the West 135th Street Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



21.16.3 Potential Impacts with the West 135th Street Converted MTS

21.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the West 135th Street Converted MTS are provided in Table 21.16-1. Figure 21.16-1 shows the locations of these sources within the site.

Table 21.16-1
Odor Sources Included in Odor Analysis

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the West 135th Street Converted MTS.

21.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 21.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the West 135th Street Converted MTS at any nearby sensitive receptor is less than 1, so odors from the West 135th Street Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 21.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
West 135th Street Converted MTS

Parameter	Resulting Odor Unit (1)
Estimated Detectable Concentration	5.0
Highest Result	0.31
Type of Receptor	Discrete Receptor
Receptor(2)	On Land

Type of Receptor	Riverbank State Park
Distance to Receptor	~~60~~ 90 Feet

Notes:

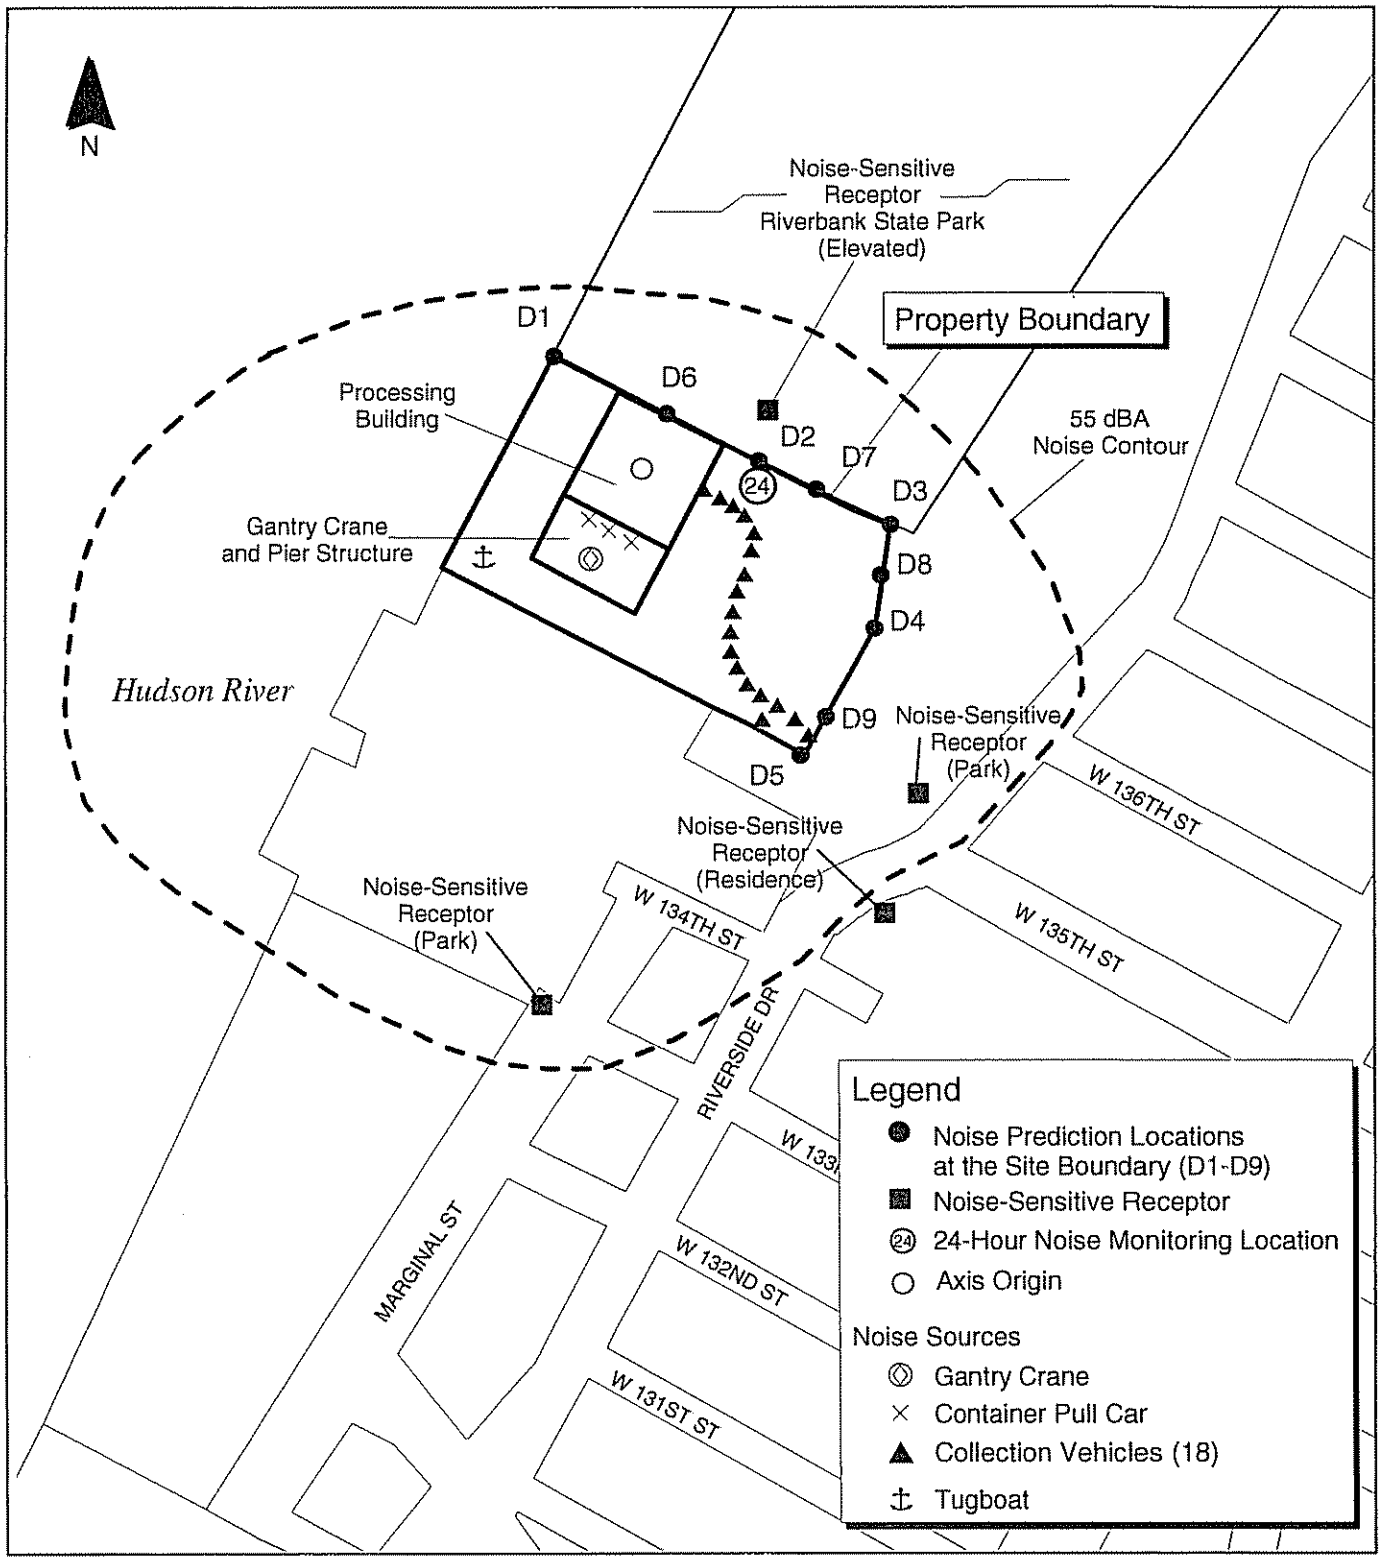
(1) Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.

(2) Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.

~~(1) D/T ratio is dimensionless.~~

~~(2) Measured from the site boundary.~~

~~(3) Measured from the site property line.~~



21.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from West 135th Street Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

21.17.1 Existing Conditions

21.17.1.1 Introduction

Figure 21.17-1 shows the location of the West 135th Street MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptors are Riverbank State Park, located adjacent to the elevated West Side Highway approximately 27 meters (90 feet) north of the property boundary; Riverside Ramparts, located on Riverside Drive approximately 67 meters (220 feet) southeast of the property boundary; an apartment building located on the corner of Riverside Drive and West 135th Street, approximately 99 meters (325 feet) southeast of the property boundary; and Harlem Piers Park, located approximately 183 meters (600 feet) from the property boundary. The other noise-sensitive land uses within the study area are residential areas on top of the bluff across the West Side Highway, where traffic noise from the elevated highway dominates the ambient acoustic environment and obscures noise from the site. No other noise-sensitive land uses are found nearby.

Site delineations are approximate

CITY OF NEW YORK
DEPARTMENT OF SANITATION

21.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptors. Noise monitoring data recorded hourly included $L_{eq(1)}$, L_{min} and L_{max},[12] and the statistical metrics of L_{10}, L_{50} and L_{90}[13] Table 21.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 2:00 a.m. and 3:00 a.m. and had an $L_{eq(1)}$ of 61.6 dBA on March 18, 2003. Activities and events that contribute to the on-site noise levels are as follows:

- Traffic noise from the elevated West Side Highway; and
- Occasional watercraft on the Hudson River.

21.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the West 135th Street Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required and, therefore, off-site noise monitoring was conducted. Table 21.17-2 presents monitored noise levels near noise-sensitive receptors during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) based on first-level screening.

[12] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[13] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

Table 21.17-1
Existing Hourly (Monitored) Noise Levels On Site[1]
West 135th Street Converted MTS

Time of Measurement	$L_{eq(1)}$ (dBA)	L_{90} (dBA)	L_{50} (dBA)	L_{10} (dBA)	L_{min} (dBA)	L_{max} (dBA)

8:00-9:00 p.m.	65.2	63.6	64.8	66.2	61.1	77.7
9:00-10:00 p.m.	64.4	62.6	63.8	65.4	60.1	77.7
10:00-11:00 p.m.	64.1	61.7	63.1	65.0	59.8	80.6
11:00 p.m.-12:00 a.m.	63.7	62.2	63.4	64.7	60.3	75.1

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

Table 21.17-2
Existing Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor for Off-Site Analysis
West 135th Street Converted MTS

Location	Existing Noise Levels During Quietest Hour (dBA)[1][2]
West 132nd Street between 12th Avenue and Broadway	71.3
West 133rd Street between 12th Avenue and Broadway	66.1

Notes:
(1) The noise level reading was measured at the closest noise-sensitive receptor during the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest).
(2) The existing noise levels were measured on June 16, 2004 at 3:00 a.m. for West 132nd Street and July 31, 2003 at 1:00 a.m. for West 133rd Street.

21.17.2 Future No-Build Conditions

21.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

21.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 21.17-3 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 21.17-3
Off-Site Noise Traffic Volume
West 135th Street Converted MTS

Location	Hour	Existing Traffic Volume[1] (Vehicles / Hour)	Future No-Build Traffic Volume[2] (Vehicles / Hour)
West 132nd Street between 12th Avenue and Broadway	2:00 a.m.	16	16
West 132nd Street between 12th Avenue and Broadway	8:00 a.m.	100	104
West 133rd Street between 12th Avenue and Broadway	2:00 a.m.	41	42
West 133rd Street between 12th Avenue and Broadway	10:00 a.m.	237	247
West 125th Street between Broadway and Amsterdam	2:00 a.m.	225	228
West 125th Street between Broadway and Amsterdam	10:00 a.m.	1,001	1,016

West 125th Street between Broadway and 12th Avenue	3:00 a.m.	152	154
West 125th Street between Broadway and 12th Avenue	9:00 a.m.	1,070	1,086
Broadway between West 132nd Street and West 133rd Street	2:00 a.m.	225	228
Broadway between West 132nd Street and West 133rd Street	10:00 a.m.	1,001	1,016

Notes:
[1] Existing Traffic Volumes are based on ATR data
[2] Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates

21.17.3 Potential Impacts with the West 135th Street MTS

21.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the West 135th Street Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 21.17-4. Spectral noise levels used in the Performance Standards analysis are shown in Table 21.17-5. The number and types of equipment assumed for this analysis were based on the West 135th Street Converted MTS's peak design capacity. Shown earlier, Figure 21.17-1 indicates the West 135th Street layout, the locations of the points along its property boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

21.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the West 135th Street Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 79 meters (260 feet) from the property boundary in the direction of Riverbank State Park, which is approximately 27 meters (90 feet) away from the property boundary. Similarly, the 55 dBA contour line is approximately 84 meters (275 feet) from the property boundary in the direction of the apartment building on Riverside Drive, which is 99 meters (325 feet) away from the property boundary; approximately 98 meters (320 feet) from the property boundary in the direction of Riverside Ramparts, which is approximately 67 meters (220 feet) away from the property boundary; and approximately 229 meters (750 feet) from the property boundary in the direction of Harlem Piers Park, which is approximately 183 meters (600 feet) away from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that ~~three of the four~~ there are noise-sensitive receptors ~~are~~ located within the 55 dBA contour line (see Figure 21.17-1). Therefore, an on-site noise analysis, including noise monitoring at Riverbank State Park, Riverside Ramparts, Riverside Drive Apartment Building and Harlem Piers Park, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Table 21.17-4
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
West 135th Street Converted MTS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Tip Floor Wheel Loaders type CAT 966G (2)	80.6
Mini Loader type CAT 908 (1)	69.3
Tamping Cranes type CAT 325 (1)	81
Spreader Crane/Hoist (1)	70
Skid Steer Loader (Bobcat S300) (1)	76
Vacuum Sweeper (1)	64.3
Moving/Queuing DSNY Collection Vehicles (7)	79
Outdoor	
Container Shuttle Cars (3)	45
Gantry Crane (1)[3]	67
Harbor Tug Bboat (1)[4])	69
Moving/Queuing DSNY Collection Vehicles (18)[5]	67

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.
(3) Noise level will be specified for the gantry crane in DSNY's plans and specifications for construction of the converted MTS's.
(4) Noise level will be specified for the harbor tug boat in DSNY's plans and specification for construction of the converted MTS's.
(5) Quantity includes one truck queuing on the outbound scale.

Noise monitoring was conducted at the noise-sensitive receptors during the quietest hour based on monitoring data provided in Table 21.17-1 above. Table 21.17-6 below identifies the existing monitored background noise levels. The table shows the distance from the West 135th Street Converted MTS to the noise-sensitive receptors, the monitored existing background noise level at the noise-sensitive receptors, West 135th Street Converted MTS-related predicted noise levels at the noise-sensitive receptors, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptors. This difference represents the predicted incremental change in noise level from the West 135th Street Converted MTS. Because this incremental change is ~~less~~ greater than the CEQR threshold of 3 dBA, at one of the

noise-sensitive receptors, since the existing background noise level is 62 dBA or greater at all of the noise-sensitive receptors analyzed, there is ~~no~~ a predicted impact that would be caused by the West 135th Street Converted MTS on-site operations.

The data presented in this section is for the analyses performed to date. If this facility is chosen to be part of the new SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

21.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points representative of the West 135th Street Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (assuming tugboats are transportation facilities) (see Table 21.17-7). Based on this analysis, ~~no~~ exceedances to the Performance Standards are predicted.

The data presented in this section is for the analyses performed to date. If this facility is chosen to be part of the new SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 21.17-6
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
West 135th Street Converted MTS

Noise-Sensitive Receptor ~~ID~~	Distance from Facility (meters/ feet)	Existing Noise Levels During Quietest Hour (dBA)[1]~~[2]~~	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]~~[4]~~	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise ~~Levels~~ Level (dBA)	Impact[4]~~[5]~~ (yes or no)

~~Harlem Piers Park~~Riverside Ramparts Park	67/200	62 ~~24~~	59.0	~~64.6~~ 64.0	1.6	No
Riverside Drive ~~Ramparts~~Apartment	~~67 / 200~~ 119/389	58.0	~~58.5~~ 58.0	~~63.9~~ 61.8	~~1.5~~ 2.5	No
Harlem Piers Park	183/600	62.2	~~60.1~~ 61.0	~~64.3~~ 64.5	~~2.1~~ 2.3	No

Notes:

(1) Twenty-minute noise level readings measured at the nearest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

(2) Existing noise levels at the proposed Harlem Piers Park were measured July 16, 2004 at 10:15 a.m. Existing noise levels at Riverside Ramparts were measured at August 18, 2004 at 10:40 a.m. Existing noise levels at Riverbank State Park were measured on April 16, 2003 at 2:45 p.m. Existing noise levels at Riverside Drive Apartment were measured on May 9, 2003 at 2:30 a.m.

(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.

(4) According to CEQR, an increase of 3 dBA during the daytime if the existing noise level is greater than 62 dBA is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the West 135th Street Converted MTS with the quietest background noise levels that occur during its operation. Only an analysis during the quietest daytime noise level was performed since the parks are not expected to be open during nighttime hours.

21.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the West 135th Street Converted MTS boundary (D1, etc.) to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 21.17-8. Based on this conservative analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analyses performed to date. If this facility is chosen to be part of the new SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 21.17-8
Current Noise Code Analysis
West 135th Street Converted MTS

Bold = Exceedance

21.17.3.6 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the West 135th Street Converted MTS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 21.17-9.

Because the screening results presented above showed that the PCEs would double on a roadway due to DSNY and other agency collection vehicles coming to or going from the West 135th Street Converted MTS, a detailed off-site noise analysis was performed at that roadway using TNM for the hour expected to receive the largest change in noise levels (when the difference between

Table 21.17-9

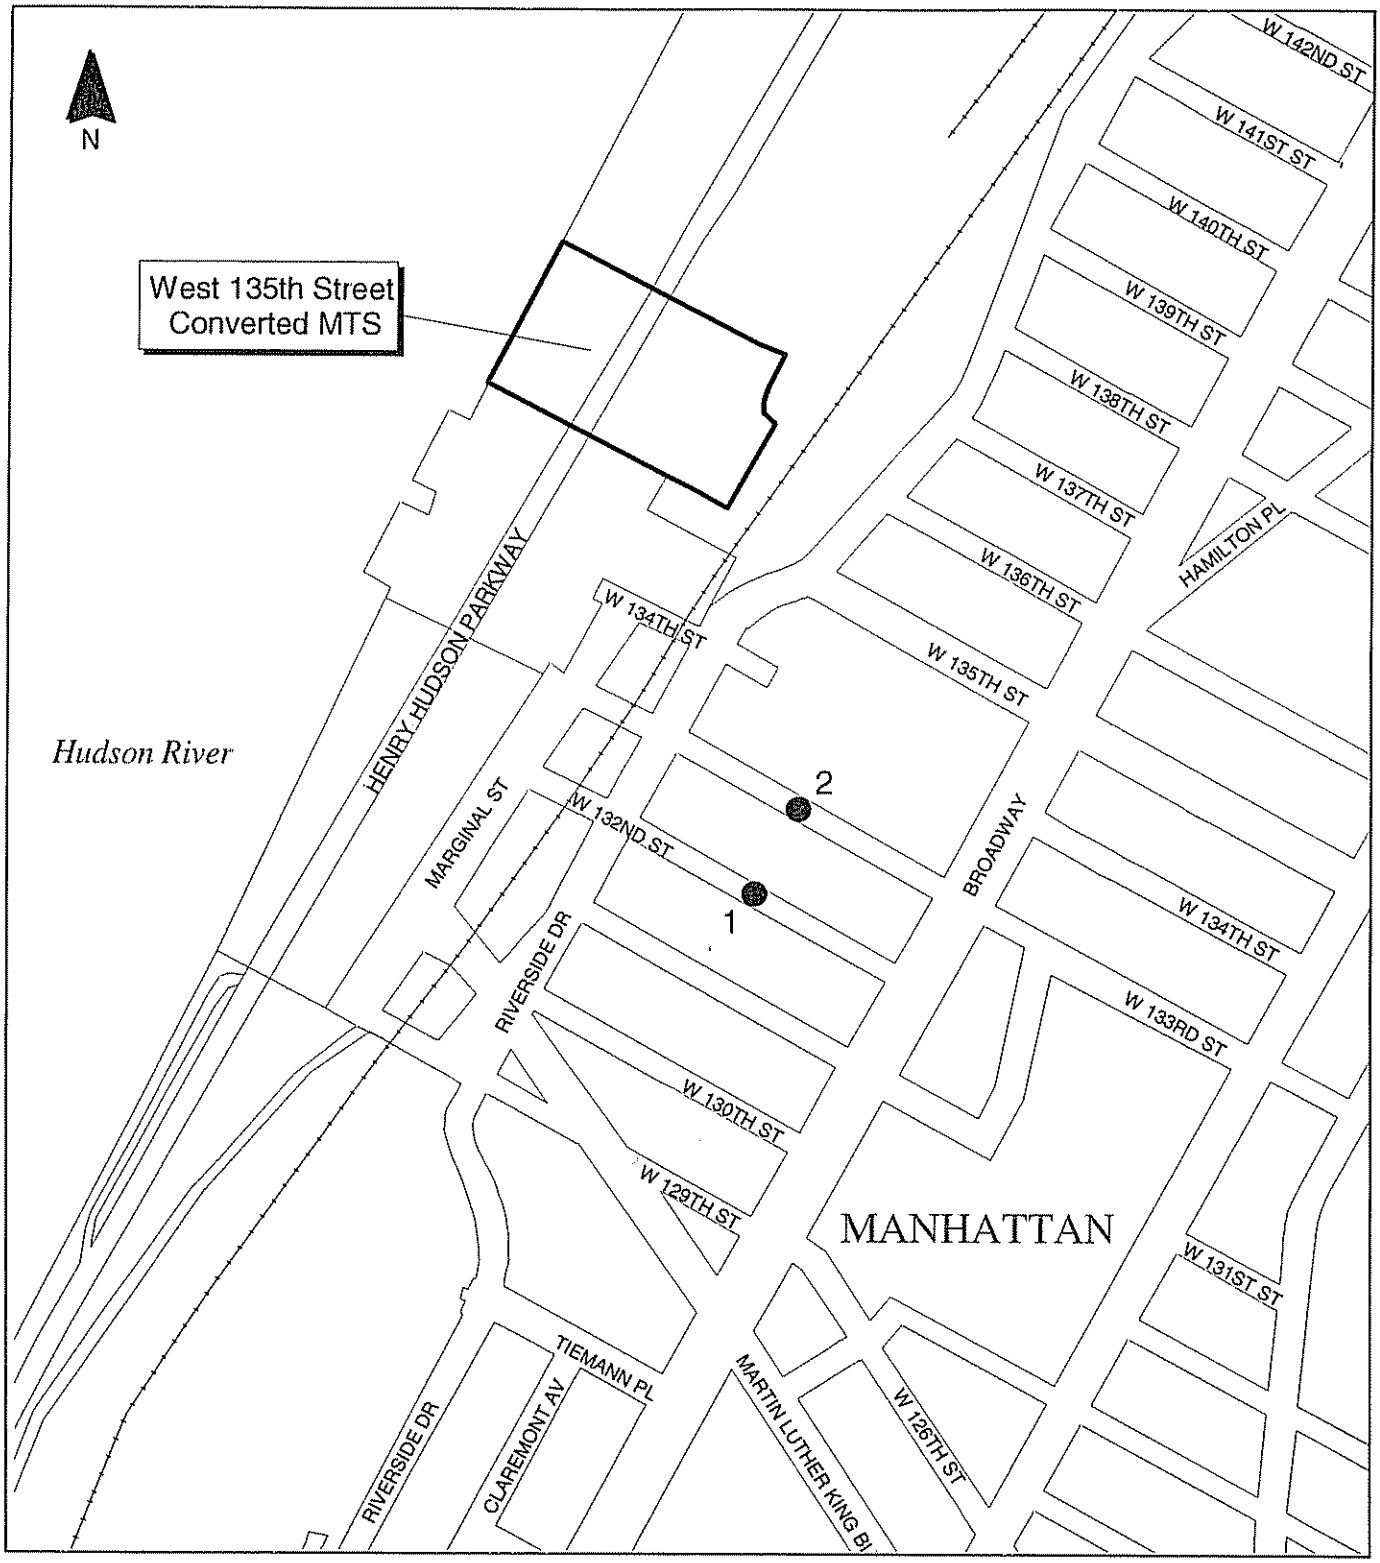
West 135th Street Converted MTS



Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net Collection Vehicle PCEs[1][2]	Future Build PCEs[1][2]	Possible Impact[3]
West 132nd Street between 12th Avenue and Broadway	2:00 a.m.	16	6	0	282	298	Yes
West 132nd Street between 12th Avenue and Broadway	8:00 a.m.	248	13	0	611	859	Yes
West 133rd Street between 12th Avenue and Broadway	2:00 a.m.	42	5	0	235	277	Yes
West 133rd Street between 12th Avenue and Broadway	10:00 a.m.	344	15	0	705	1,049	Yes
West 125th Street between Broadway and Amsterdam	2:00 a.m.	616	12	0	564	1,180	No
West 125th Street between Broadway and Amsterdam	10:00 a.m.	3,935	30	0	~~5,345~~ 1410	5,345	No
West 125th Street between Broadway and 12th Avenue	1:00 a.m.	626	13	0	611	1,237	No
West 125th Street between Broadway and 12th Avenue	3:00 a.m.	577	12	0	564	1,141	No
West 125th Street between Broadway and 12th Avenue	9:00 a.m.	2,226	30	0	1,410	3,636	No
Broadway between West 132nd Street and West 133rd Street	2:00 a.m.	616	11	0	517	1,133	No
Broadway between West 132nd Street and West 133rd Street	10:00 a.m.	3,935	30	0	1,410	5,345	No

Notes:

(1) Total PCEs are rounded to the nearest whole number.

(2) Future Build PCEs include West 135th Street Converted MTS-related DSNY and other agency collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted using a factor of 1.

(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime. Figure 21.17-2 depicts the location of the roadways when a detailed off-site noise analysis was performed.

TNM results for locations/hours that indicated an impact based on a second-level screening are presented in Appendix E of this FDEIS. Because the incremental noise-level change, which is calculated by obtaining the difference between the TNM-predicted Future Build noise level and the TNM-predicted Future No-Build noise level, is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, an impact is predicted by TNM from the West 135th Street Converted MTS-related collection and employee vehicles.

To determine if these TNM-predicted impacts were accurate, site-specific truck simulations were conducted at the noise-sensitive receptor site. The truck simulation analysis provides a more realistic determination of DSNY and other agency collection vehicle noise impacts based on the proposed number of DSNY and other agency collection vehicles expected to travel through the roadways analyzed during the nighttime hours. Truck simulations were conducted with DSNY collection vehicles, as described in Section 3.19.7.2, for each roadway and hour that the first-level screening analysis resulted in potential impacts. For this procedure, two sets of noise measurements were taken, one with and one without DSNY trucks, by routing a set number of DSNY trucks during the affected nighttime hours past the noise-sensitive receptor. Tables 21.17-10 and 21.17-11 below contain the results of the site-specific DSNY collection vehicle simulations.

A comparison of the simulation results for the hour resulting in an impact and the TNM results for this hour for the same traffic conditions and background noise levels estimated from recordings during the simulations is provided in Appendix E of this FDEIS. Based on this comparison, it is determined that TNM over-predicted the incremental change. The over-prediction can be attributed to the default assigned noise level for each type of vehicle, which appears to be greater than the actual noise levels that would be emitted by the West 135th Street Converted MTS-related collection vehicles.

The results of the site-specific truck simulations show that an impact would not be caused at a noise-sensitive receptor by the West 135th Street Converted MTS-related collection vehicles.

Notes:
(1) Existing background noise levels were estimated from noise monitoring performed during the simulations.
(2) Simulations for hours 1:00 a.m. to 5:00 a.m. were performed on June 16, 2004. Simulations for hours 8:00 a.m. to 11:00 a.m. were performed on May 25, 2004.

21.17.3.6 Combined On-Site and Off-Site Noise Levels

An on-site and off-site noise analysis was performed for the West 135th Street Converted MTS. Since the potential impacts of these analyses can affect the same noise-sensitive receptor, a screening analysis was conducted to determine if a combined noise analysis would be required for the operations at the West 135th Street Converted MTS. The combined analysis study area was defined by the 55 dBA isopleth contours from the on-site source and the bottom driveway entrance to the site. The other limits for the combined analysis study area were defined by the first row of buildings along the roadway between the 55 dBA contour and the driveway entrance to the site. The results of the screening analysis show that the West 132nd Street apartment building and West 133rd Street apartment building noise-sensitive receptors are located within the study area that can be impacted by both on-site and off-site West 135th Street Converted MTS operations; therefore, a combined noise analysis, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptors during the quietest hour based on the off-site analysis discussed in Section 21.17.3.5 above. Tables 21.17-12 and 21.17-13 show the distance from the West 135th Street Converted MTS to the noise-sensitive receptors, the monitored existing background noise level at the noise-sensitive receptors, West 135th Street Converted MTS-related predicted noise levels at the noise-sensitive receptors, and the predicted off-site noise levels at the noise-sensitive receptors. The table also provides the combined on-site and off-site noise levels and the difference between these combined noise levels. This difference represents the predicted incremental change in noise level from the West 135th Street Converted MTS on-site and off-site operations at the noise-sensitive receptor. Because this incremental change is not greater than the CEQR threshold of 3 dBA during nighttime hours for the West 132nd Street apartment building and West 133rd Street apartment building noise-sensitive receptors analyzed, there is ~~no~~ a predicted impact that would be caused by the West 135th Street Converted MTS combined on-site operations and off-site operations.

The data presented in this section is for the analyses performed to date. If this facility is chosen to be part of the new SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

21.18 Commercial Waste to the West 135th Street Converted MTS

21.18.1 Existing Conditions

No commercial waste is delivered to the West 135th Street MTS site under Existing Conditions. Commercial waste generated in Manhattan is taken directly out of the City to remote disposal locations.

21.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the West 135th Street Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

21.18.3 Potential Impacts of Sending Commercial Waste to the West 135th Street Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

21.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the West 135th Street Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 4,290 tpd (see Sections 21.15, 21.16 and 21.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

21.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the West 135th Street Converted MTS were evaluated in Sections 21.14, 21.15 and 21.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 21.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 30 (inbound trip ends) per hour, which occurred during the AM peak. These 30 DSNY and other agency collection vehicles are also more than the 22 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the West 135th Street Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 30 DSNY and other collection agency vehicles at the West 135th Street Converted MTS. Therefore, the addition of the 22 DSNY and other agency collection vehicles and commercial waste hauling vehicles at the West 135th Street Converted MTS during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 30 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 30 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24 hour period. Results showed there would be no unmitigatible significant adverse environmental impacts. Consequently, because the 22 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can be processed at the West 135th Street Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the West 135th Street Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 1,029 tons (or 95 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

CHAPTER 22 ENVIRONMENTAL REVIEW: WEST 59TH STREET CONVERTED MTS

22.1 Introduction

The results of the environmental analyses of the West 59th Street Converted MTS are presented in the following sections:

22.2 Land Use, Zoning, and Public Policy
22.3 Socioeconomic Conditions
22.4 Community Facilities and Services
22.5 Open Space
22.6 Cultural Resources
22.7 Urban Design, Visual Resources, and Shadows
22.8 Neighborhood Character
22.9 Natural Resources
22.10 Hazardous Materials
22.11 Water Quality
22.12 Waterfront Revitalization Program
22.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
22.14 Traffic, Parking, Transit, and Pedestrians
22.15 Air Quality
22.16 Odor
22.17 Noise
22.18 Commercial Waste to the West 59th Street Converted MTS

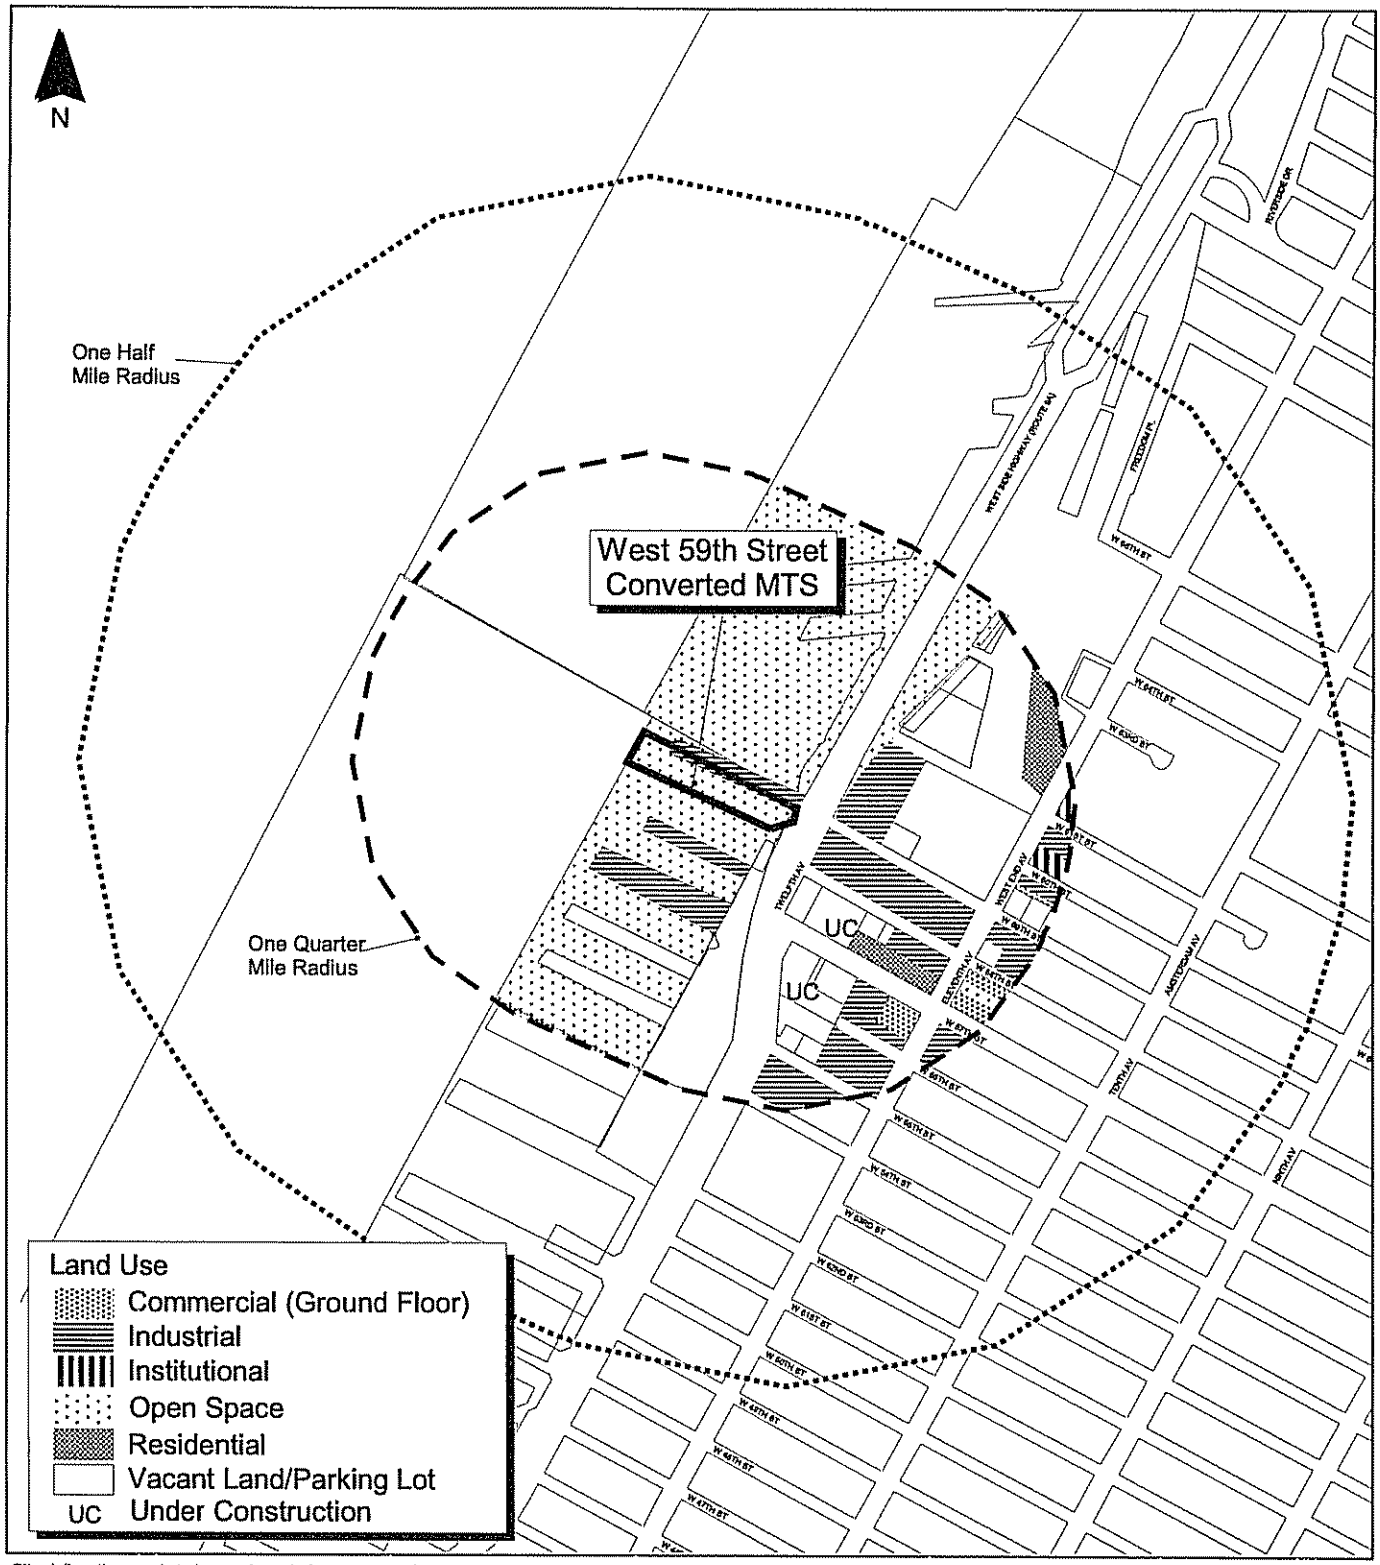
Section 2.7 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

22.2 Land Use, Zoning, and Public Policy

22.2.1 Existing Conditions

22.2.1.1 Definition of the Study Areas

The primary study area for the land use, zoning, and public policy analyses is defined as the area within ¼-mile of the site (see Figure 22.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (see Figure 22.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.7 provides information on existing land uses and operations on the site.



22.2.1.2 Land Use Patterns

22.2.1.2.1 General Context

Set in the larger context of Manhattan's changing Hudson River waterfront, west of the Clinton/Lincoln Center neighborhoods, the site is surrounded by a large surface parking lot, construction sites, industrial activities, and the elevated West Side (Miller) Highway.

22.2.1.2.2 Land Uses in the Primary Study Area

The primary study area is characterized by active industrial uses, municipal operations, and transportation infrastructure, as well as extensive construction activity. The elevated Miller Highway itself dominates the study area immediately surrounding the site, as it touches down to grade at West 57th Street, as does the massive generating plant across Twelfth Avenue and the large surface parking lot north of West 59th Street. In addition to the plant, Consolidated Edison occupies Pier 98 (at the terminus of West 58th Street), immediately south of the MTS site, which is used for fuel transfer operations. Just south of this pier is Pier 97, which DSNY utilizes for vehicle parking and various storage operations. Piers 95 and 96 (at the terminus of West 55th and West 56th Streets, respectively), which are under construction as part of the

Hudson River Park's "Clinton Cove Park" will feature a boathouse and other waterfront amenities. This section of park is scheduled to open in 2005. (Pier 97 is also planned to be rehabilitated in the future as part of the Clinton Cove Park and may include passive and active recreational areas.)

East of Twelfth Avenue between West 58th and West 57th Streets is the expansive ArtKraft Sign Corp. factory, as well as other industrial activities located along the side streets. Interspersed with these one- and two-story warehouses are parking garages and surface lots. A large site has been cleared for the new DSNY District (4, 4A and 7) Garage construction across Twelfth Avenue, spanning West 56th Street (from West 55th to West 57th Streets). It is due to be completed by 2007. Further east, the land use pattern changes with a mix of century-old low-rise tenement buildings and recent high-rise apartment towers that have come to characterize the Clinton neighborhood.

Directly north of the site is an unbuilt section of Riverside Park South, which will connect the developing upland residential and commercial development north of West 59th Street to the waterfront under the elevated Miller Highway structure. The northern section, between West 65th and West 72nd Streets, is already completed and features expansive lawn areas, landscaped waterfront walkways, seating and a new 750-foot pier (West 70th Street). The park segment between West 62nd and West 65th Streets (Phase 3) is actively under construction and due to be completed in 2005. The planned park terminates at West 59th Street, where the upland area is restricted to street right-of-way, such that the adjacent bicycle/pedestrian path is the only physical and visual link between Riverside Park South and the emerging Hudson River Park to the south.

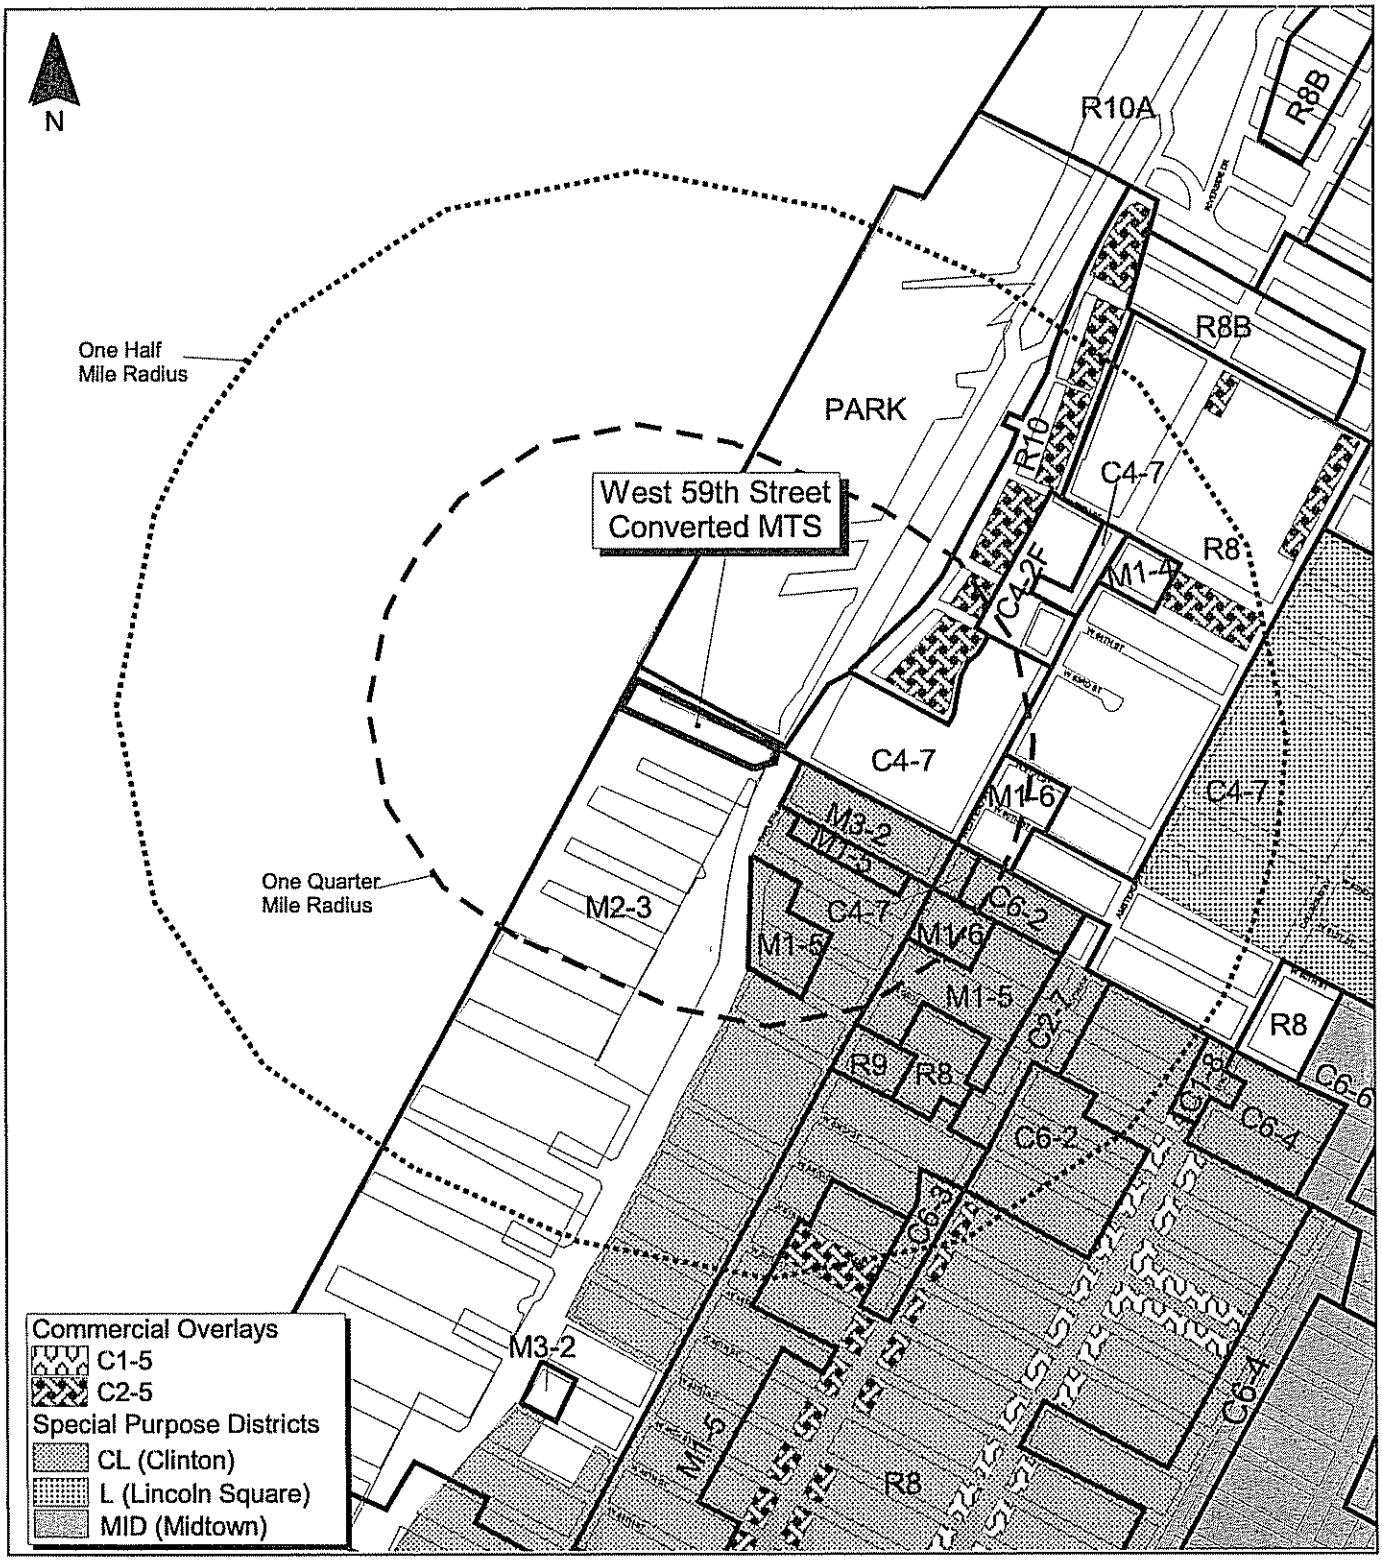
The West End Towers Park is a relatively new park that is privately owned, though open to the public on West End Avenue, between West 63rd and West 64th Streets. De Witt Clinton Park is located south of the site, between West 52nd and West 54th Streets and Eleventh and Twelfth Avenues.

The Riverside South Development will ultimately extend from West 59th to West 72nd Streets on the site of the former Penn Central Yards. In conjunction with the park, the northern segments – between West 65th and West 72nd Streets – were completed first. Construction continues as a new ABC studio building is rising at West 66th Street.

Further northeast of the site (along West End/Eleventh Avenue and Amsterdam/Tenth Avenue), the Upper West Side mix of high-rise residential buildings, institutions and neighborhood shopping has moved steadily southward, though upscale car dealership and headquarters still remain, particularly on Eleventh Avenue (and West 57th Street).

22.2.1.2.3 Land Uses in the Secondary Study Area

Fairly discrete concentrations of industrial, residential, commercial and institutional uses characterize the secondary study area. In addition to Riverside South, whose residential towers line the west side of West End Avenue north of West 61st Street, residential uses can also be found concentrated between Tenth and Eleventh Avenues north of West 63rd Street, south of West 56th Street, and east of Tenth Avenue between West 56th and West 63rd Streets. Large new residential developments have recently opened in the secondary study area, including the Westport (500 West 56th Street) with more than 300 apartments and ground-floor retail; and the Clinton Parkview Apartments (555 West 52nd Street) with 96 apartments and space for a community garden and offices. The Clinton Parkview Apartments is the first entirely income-restricted building to be constructed in Clinton since 1981. Otherwise, the blocks between Tenth and Eleventh Avenues are mostly industrial and institutional in nature, featuring uses such as John Jay College of Criminal Justice, Fordham University at Lincoln Center and St. Luke's/Roosevelt Hospital Center. New residential buildings are proposed or under construction within the area as well. Commercial uses are concentrated south of West 58th Street.



DeWitt Clinton Park is a nearly six-acre City park, located approximately ¼-mile south of the site, between Eleventh and Twelfth Avenues and West 52nd and West 54th Streets. South of the park, the remainder of the study area is largely residential with small-scale, ground-floor commercial properties lining both sides of Eleventh Avenue southward.

22.2.1.3 Current Zoning On and Near the Site

22.2.1.3.1 Zoning Within the Primary Study Area

The site is located at the northern edge of an M2-3 manufacturing zone, which extends south along the Hudson River waterfront to the Gansevoort Peninsula and then continues south again to Battery Park City. Adjacent to the site's northern boundary, ~~is a large R10 district that covers the waterfront~~ the water (extending to the Pierhead line) comprises an area of mapped parkland, which extends inland to between Miller Highway and Riverside Drive, where R10 residential zoning covers ~~and~~ the residential portion of the new Riverside South Development. Directly northeast of the site is a C4-7 zoning district and an M1-6 district.

Southeast of the site, the immediate area is predominantly zoned for a range of industrial uses (M1-5 and M3-2). There are also two small recently-rezoned commercial districts, east of West End Avenue, between West 59th and West 60th Streets. This rezoning allows the construction of a 31-story apartment building and underground garage. This is one of several rezoning actions since 1999 that allows land uses and building forms that are compatible with the context of the blocks north and northwest of West End Avenue. The Clinton Special Purpose District also extends south of West 59th Street and west to Twelfth Avenue in the primary study area. This zoning district was established in 1974 to preserve the residential character of the community, located between the waterfront on the west and the growing CBD on the east. (See Figure 22.2-3.)

Site delineations and study area boundaries are approximate.

Figure 22.2-3 Zoning

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

22.2.1.3.2 Zoning Within the Secondary Study Area

As in the primary study area, the shoreline south of the site is zoned M2-3. Northeast of the site is a mix of zoning, with mostly commercial (C4-2F, C4-7) and high-density residential districts (R10 and R8). There are a couple of discrete industrial zones on West End Avenue (M1-6 and M1-4), but largely it is zoned for residential and commercial activities. The Lincoln Square Special Purpose District extends into the secondary study area between West 60th and West 65th Streets. This district was created to protect and promote the unique cultural and architectural character of the Lincoln Center area. Southeast of the site is a mix of commercial (C6-2, C2-7, C6-3), industrial (M1-6 and M1-5) and residential (R8 and R9) districts, including a portion of the Clinton Special Purpose District.

22.2.1.4 Plans and Policies

The site lies right at the border of CD 4 (south of West 59th Street) and CD 7 (to the north). In the FY 2004 CDNS prepared by CD 4, the Governing Board of the CDs lists criteria for new development proposed for the Clinton Urban Renewal Area, which covers the mixed-use community between West 50th and West 56th Streets and Tenth and Eleventh Avenues southeast of the site, to protect residents and businesses from displacement. A 197-a Plan is currently being prepared for the South Hell's Kitchen (Chelsea) area. The statement urges the relocation of the DSNY garage and salt storage to another pier in the CD to minimize potential conflict with the proposed Hudson River Park in which the West 59th Street converted MTS site is located. In the statement, the Governing Board supports improvement and maintenance of DeWitt Clinton Park and the improvement of the West 59th Street Recreation Center, a former bath house structure with pool located between West 59th and West 60th Streets east of Eleventh Avenue.

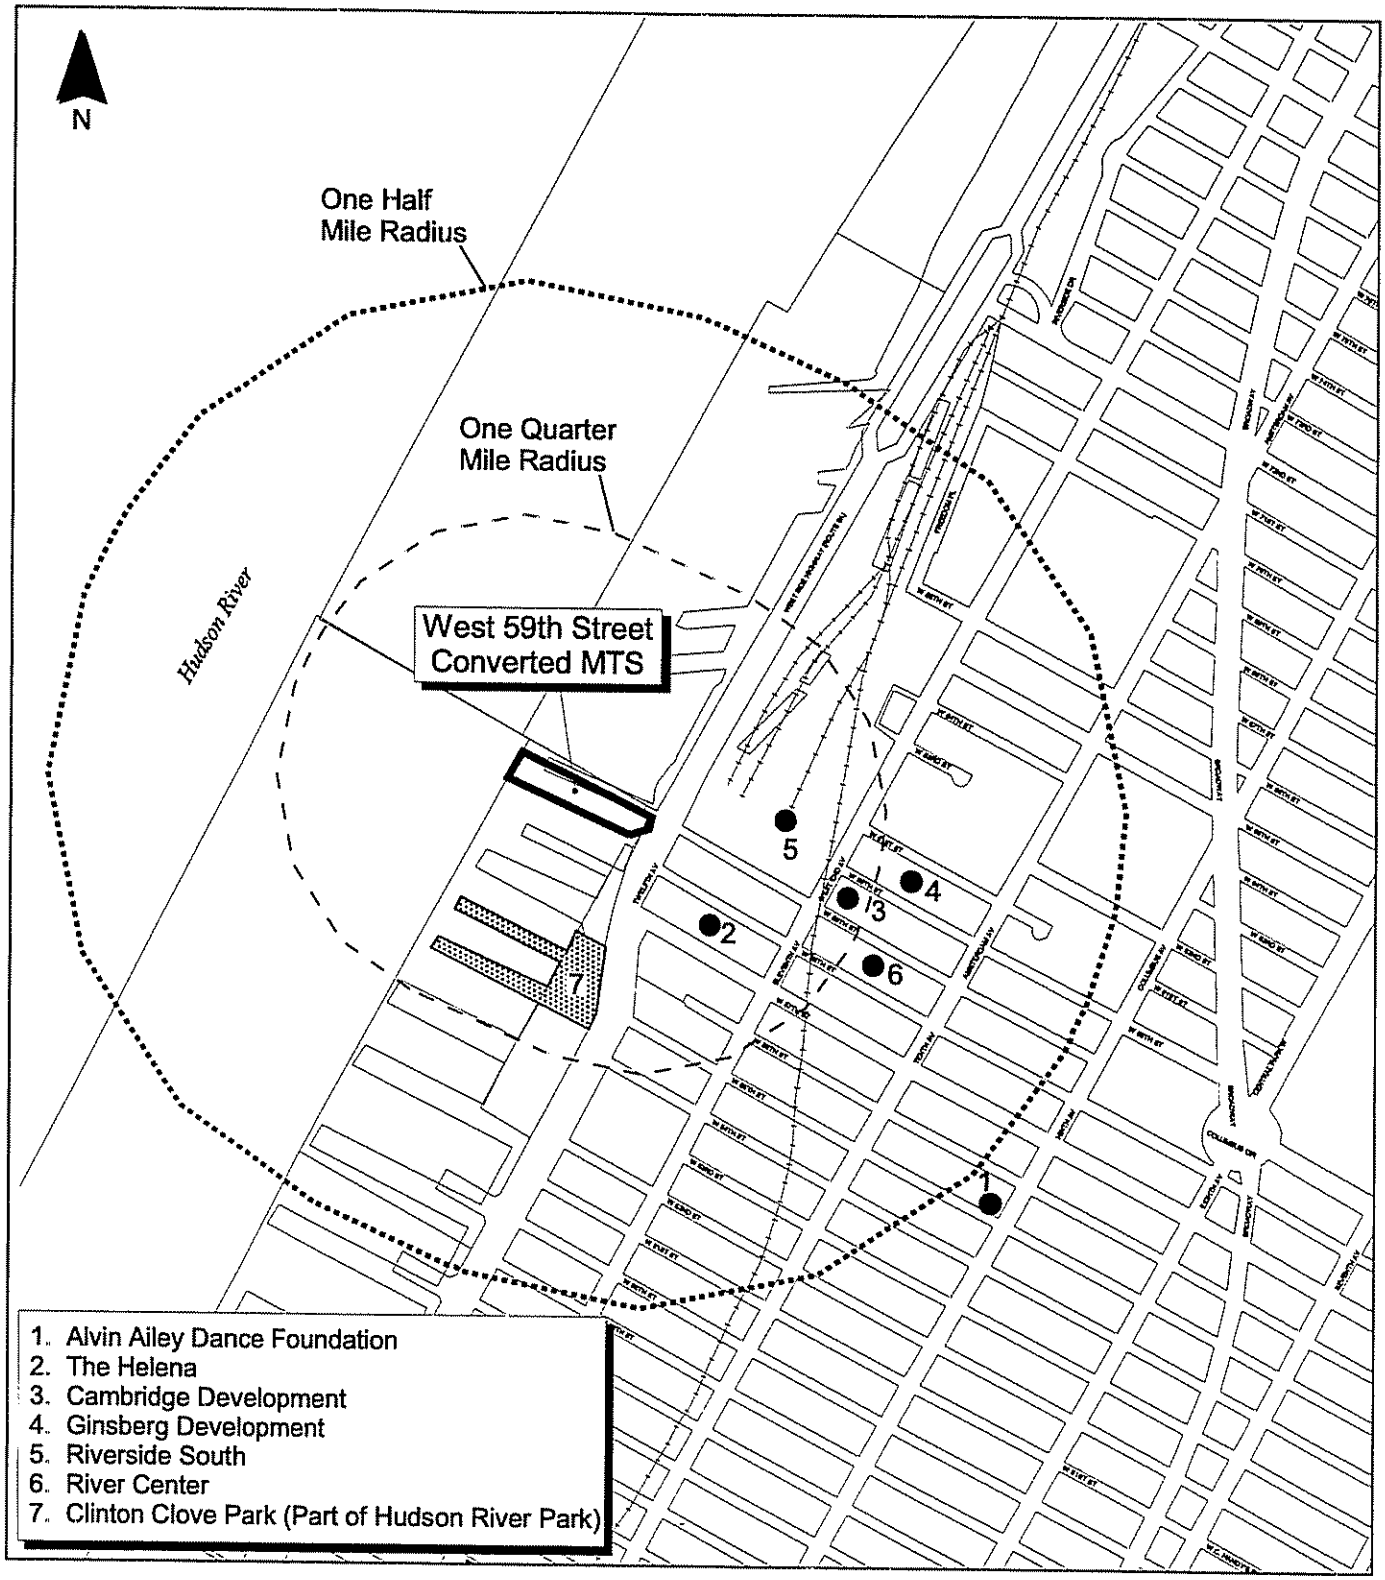
In its 2004 CDNS, CD 7 expressed general concerns of its generally residential district. There are no statements referring to DSNY, the site or its environs.

The Plan for Reach 3, which includes the site and extends south from West 59th Street to several blocks below Canal Street, makes no recommendations pertinent to the West 59th Street Converted MTS. The site and the Consolidated Edison Pier (Pier 98) to the south are working waterfront sites, though Pier 97 is recommended as a public access site and a continuous "esplanade" is recommended for part of the "Hudson River Valley Greenway", Twelfth Avenue throughout the study area. In the intervening years, the bikeway/pedestrian path along Route 9A has been constructed.

22.2.2 Future No-Build Conditions

- The new ABC Studio in Riverside South, is are currently under construction on West End Avenue between West 64th and West 66th Streets. It is scheduled to be completed in 2005. Other development parcels (residential and mixed use) within The Riverside South project area are expected to be under construction in 2006.

- Clinton Cove Park (part of Hudson River Park) is currently under construction on Piers 95 and 96. It will include a large grassy area and feature a boathouse and kayak launch on Pier 96, and a passive open space near the river on Pier 95. It is due to be completed in Spring 2005. Pier 97, which currently functions as a DSNY storage pier, will ultimately be rehabilitated for active recreation and historic ships when it is redeveloped as part of the Hudson River Park (schedule unknown).



- The Alvin Ailey Dance Foundation is currently completing construction of a 25,970-square-foot studio and 5,000-square-foot theater at West 55th Street and Ninth Avenue. It is expected to open in late 2004.

- River Center is a mixed-use project proposed (and approved) for a site located between 58th and 59th Streets and Tenth and Eleventh Avenues. It will contain 1,200 dwelling units; 166,000 square feet of retail space; 900,000 square feet of community facility space; and 655 associated parking spaces.

- Construction is underway on The Helena - a Durst Organization apartment building, located between West 57th and West 58th Streets and Eleventh and Twelfth Avenues. The 300,000-square-foot luxury residential tower stands 31 stories and will be ready for occupancy by late 2004.

- Cambridge Development has proposed the construction of 224 to 309 dwelling units combined with up to 20,000 square feet retail space on West End Avenue at West 59th Street. It is assumed to be completed in 2005.

These planned development sites are shown in Figure 22.2-4.

Site delineations and study area boundaries are approximate.

Figure 22.2-4 Planned Development Sites
West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

The Passenger Ship Terminal located on Piers 88, 90 and 92 (at the southern end of, and beyond, the secondary shady area) is planned for internal site circulation and signage improvements to upgrade pedestrian and vehicular movements within the terminal. Pier 94 (at 54th Street) would continue to function as a venue for trade shows in the future.

In the future No-Build Condition, the site will remain DSNY property and the existing MTS will continue to be used for the transfer of paper recyclables from truck to barge.

22.2.3 Potential Impacts with the West 59th Street Converted MTS

22.2.3.1 Land Use and Zoning

The West 59th Street Converted MTS would entail replacing the existing MTS with a new facility that would feature containerization functions. It would represent a slight physical upgrading of the site itself. The facility's processing operation would be designed to containerize waste and prepare containers for transfer to barge for disposal outside of the City. The existing MTS, which extends over the water, would be demolished and the new, larger one would be built in almost precisely the same place, still extending as a linear pier, with a footprint resembling those of neighboring piers. The location of the entrance to the site would remain unchanged.

The addition of waste containerization and associated truck traffic to ongoing recycling activities on the site would not be a change in on-site land use, nor would it encourage similar types of land uses or discourage other types of land use in the study areas, (e.g. residential, commercial and parkland development) which have already been redefining the area West of West End/10th Avenue. Therefore, no significant adverse impacts to land use or zoning in the primary or secondary study areas would result.

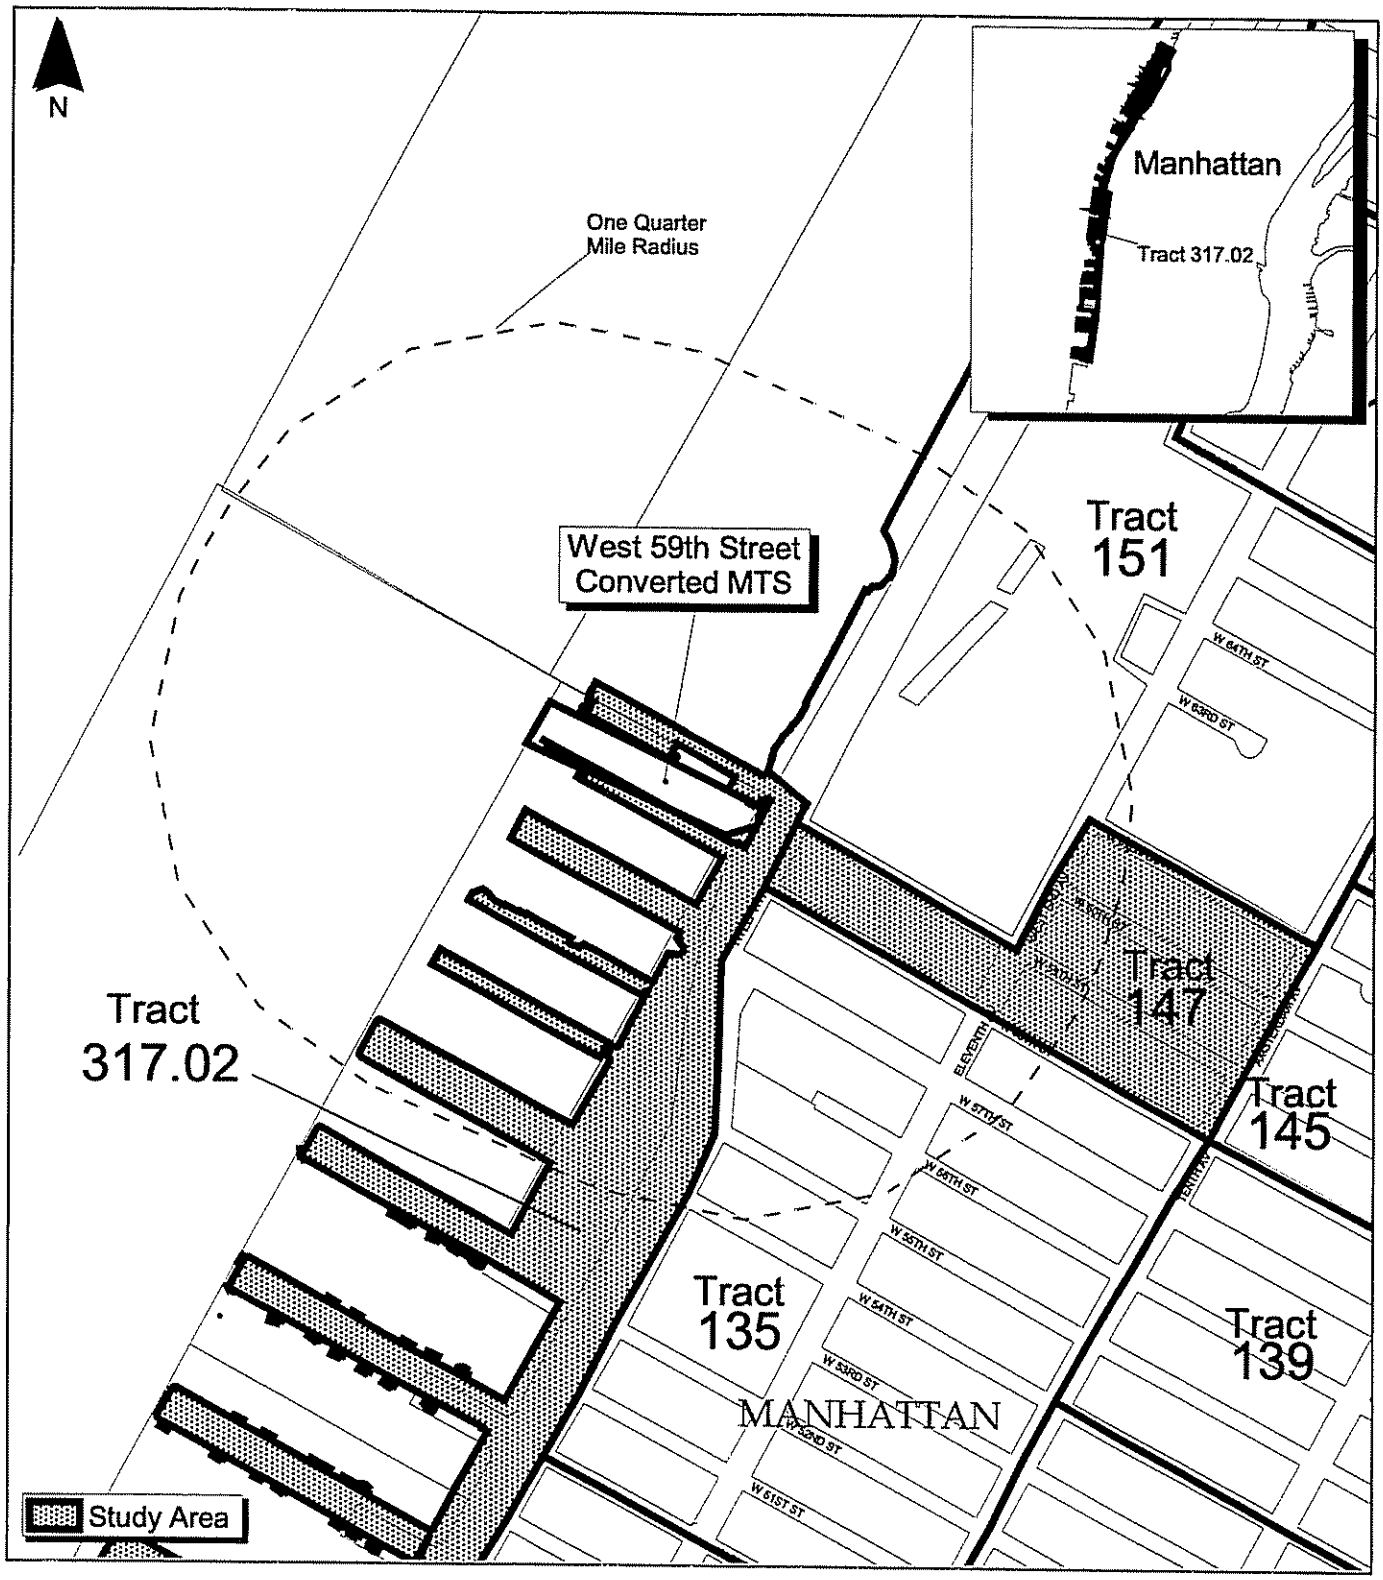
22.2.3.2 Consistency with Public Plans and Policies

With the exception of park development (Riverside Park South) to the north and the Hudson River Park, and completion of the Hudson River Valley Greenway further south (the pedestrian/bike path alongside the MTS), there are no recommendations or objectives stated in relevant plans or policies that specifically relate to the site, study area or West 59th Street Converted MTS. Continued municipal waste transfer activity on the site is a permitted use noted in the Hudson River Park Act Plan and would therefore not conflict with its implementation. The Converted MTS would similarly have no effect on the completion or use of Riverside Park South to the north. The adjacent bike/pedestrian path segment is already in place and will continue to serve as a connection to the parks north and south of the site's industrial sub-area.

22.3 Socioeconomic Conditions

22.3.1 Existing Conditions

22.3.1.1 Definition of the Study Areas



Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site, and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) The demographic study area is comprised of Census Tracts 147 and 317.02 (see Figure 22.3-1), which include the waterfront south of West 59th Street and an area along West 59th Street inland to Tenth Avenue. For comparison purposes, both 1990 and 2000 census data were gathered at the borough and City levels. The study area for the assessment of potential impacts on economic conditions extends as far north as West 69th Street, as far south as West 49th Street, and far enough east to include Tenth Avenue.

Detailed socioeconomic information referred to in the text but not presented in table form may be found in Appendix B.

22.3.1.2 Demographic Characteristics

22.3.1.2.1 Population

The total 2000 study area population was 2,198 persons (see Table 22.3-1). In terms of total population growth from 1990 to 2000, the study area experienced a considerably greater percentage increase (72%) than did the borough (3%) and the City (9%) during the same period.

Site delineations and study area boundaries are approximate.

Figure 22.3-1 Census Tracts

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The age-sex distribution was slightly different from the population distribution of the borough and the City, with an even greater proportion of females to males within the study area. The study area contained a slightly greater percentage of children and teenagers than the borough but less than the City; approximately 23% of the study area population was under the age of 20, compared to 19% for the borough and 27% for the City.

Table 22.3-1
-1990-2000 Population

	Study Area	Manhattan	City
2000	2,198	1,537,195	8,008,278
1990	1,278	1,487,536	7,322,564
Percent Change	+72.0%	+3.3%	+9.4%

Source: U.S. Census 1990, 2000

22.3.1.2.2 Racial and Ethnic Characteristics

The 2000 study area population had a far smaller proportion (6%) of people of Hispanic origin (all races) than did Manhattan or the City (27%). Of the 94% not of Hispanic origin, 9% were Black, 23% were Asian and 64% were White. In Manhattan and the City, Blacks represented approximately 21% and 33% of the non-Hispanic populations, respectively; Asians represented 13% at both levels and Whites represented 63% and 48%, respectively.

From 1990 to 2000, the number of study area residents of Hispanic origin decreased by 50% while this population grew proportionally in the borough (10%) and in the City (24%) during the same period. Because the 2000 Census introduced the option for respondents to identify themselves as two or more races, racial categories are not directly comparable with 1990.

22.3.1.2.3 Families and Households

There were 326 families in the study area in 2000 and the percentage of these families that had children under the age of 18 (about 40%) was slightly smaller than those families in Manhattan (43%) and in the City (49%). There was a considerably larger percentage of married-couple families in the study area (71%) than in the borough (62%) and the City (62%), and 51% of these families had children, greater than Manhattan (39%) but about the same as the City (48%).

Eighteen percent of the families in the study area were headed by a female householder. This percentage is lower than that in the borough or the City (both 30%). Only 7% of the female householder families in the study area had children under the age of 18, far less than the percentages in the borough (53%) and the City (55%).

There were 789 households in the study area in 2000, with an average household size of 1.7 persons, less than Manhattan (2.0 persons) or the City (2.6 persons).

From 1990 to 2000, the number of households in the study area increased by 30%, far greater than the 3% increase in the borough and 7% increase in the City.

22.3.1.2.4 Employment

Within the study area, 71% of persons aged 16 and older participated in the labor force in 2000, greater proportionally than the 64% in Manhattan and 58% in the City. The majority of these people in all three areas were employed as private wage and salary workers.

Five percent of employed persons 16 and over were government workers, compared to Manhattan (10%) and the City (16%). Moreover, 3% of the study area's working population was self-employed, less than that of Manhattan (9%) and the City (6%).

From 1990 to 2000, the number of employed persons within the study area increased by 101%, while the number of employed persons in the borough and the City remained approximately the same. Among employed persons, those engaged in government jobs decreased by 21%, compared to a 15% decrease in the borough and a 10% decrease in the City.

Current forecasts indicate that about 280,288 employees worked in Manhattan CDs 4 and 7 in 2005.[1]

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

22.3.1.2.5 Housing

Most housing units in the study area were constructed in two periods – 1970 to 1979 and 1995 to 2000 – while the majority of housing units in both Manhattan and the City were built before 1960. As of 2000, there were 866 housing units in the study area with a vacancy rate of about 3.7%, lower than either the borough (8%) or the City (6%). Nearly all the housing units were renter-occupied (96%), considerably greater than the rate in the borough (74%) or the City (66%). Median monthly rent ($1,174) was far higher than in the borough ($796) or the City ($705).

The turnover in the study area (63%) from 1995 until 2000 was greater than that of the borough (45%) and the City (43%) in the same period.

From 1990 to 2000, a total of 344 housing units were added in the study area, representing a 66% increase, markedly greater than the borough (2%) or the City (7%).

22.3.1.2.6 Education

Although the proportion of children in the study area was similar to that of the larger areas, the rate of school enrollment (49%) was approximately twice that of the borough (24%) or the City (29%). Of those enrolled in school within the study area in 2000, 8% were enrolled in elementary school or high school and 89% were enrolled in college or beyond. In Manhattan, 51% were enrolled in elementary or high school and 39% in college or beyond, while 62% of the City's enrolled population were in elementary or high school and 27% in college or beyond.

The study area witnessed a 388% increase in the number of persons enrolled in school from 1990 to 2000, with the largest increase in enrollments occurring at the college level (804%), whereas the borough experienced an 8% increase in enrollees and, of that, a 98% increase in pre-primary students, comparable to the City (18% and 150%, respectively).

The study area had a far higher educational attainment level than either the borough or the City. A markedly larger proportion (94%) of the study area population aged 25 and over had a college degree or some college education, compared to Manhattan (65%) and the City (48%). The study area had a smaller percentage of people with only high school diplomas (4%) compared to the borough (14%) and a considerably smaller percentage than that of the City (24%).

Consistent with the higher educational levels, from 1990 to 2000 the study area witnessed rising levels of educational attainment. The number of college graduates increased 74%, and the same trend was evident in the borough and the City, which experienced increases of 20% and 29%, respectively. Meanwhile, the number of people with less than a college education declined significantly in the study area overall.

22.3.1.2.7 Income and Poverty

In 2000, both median household income ($68,750) and median family income ($93,164) were far higher than in Manhattan ($47,030 and $50,229, respectively) and the City ($38,293 and $41,887, respectively). Compared to the larger two areas, a greater percentage of study area households were concentrated at the highest income levels, with the majority of annual household incomes (64%) above $50,000. Only 10% of households in the study area had incomes of $25,000 or below, compared with 30% in the borough and 35% in the City.

Within the study area, the percentage of families living below the poverty level (2%) was far less than that of Manhattan (18%) or the City (19%). However, there were no families living below the poverty level with children under the age of 18, which contrasts greatly with Manhattan (48%) and the City (55%).

There were no people either under the age of 18, or 65 and older, living below the poverty level in the study area as compared to 32% and 19% for the borough, and 30% and 18% for the City, respectively.

22.3.1.3 Economic Conditions

The portion of Manhattan's West Side within approximately ½-mile of the site contains light industrial development, including waterfront piers, warehouses and television studios. Ground-floor commercial establishments serving the neighborhood line Eleventh Avenue, along with several of Manhattan's major automobile retail establishments.

22.3.2 Future No-Build Conditions

22.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Manhattan CDs 4 and 7 will remain about the same as current conditions,[2] although some new residential population growth is anticipated due to the ABC Studio on Riverside South (mixed-use development), River Center (mixed-use development), the Helena (Residential Tower), and the Cambridge Development residences (See Section 22.2.2). The NYMTC-projected total net change for the two CDs is an increase of about 3,500 people (about 1.20 percent) between 2003 and 2006. The planned developments were considered in all analyses, both as potential sensitive receptors and as potential generators of transit and traffic; no impacts were found to result assuming these planned developments. It is reasonable to assume that new retail establishments will follow to serve the new residential population.

22.3.2.2 Economic Conditions

The current paper recycling transfer operations at the existing MTS are expected to continue in the Future No-Build Conditions.

~~Several new developments are predicted for the area by 2006, with the primary changes to the socioeconomic landscape being the introduction of additional residential space and some retail. The second phase of the Riverside South development will be under way or complete, replacing much of the parking lot and vacant land east of the site on West End Avenue between West 59th~~

[2] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.

~~and West 60th Streets with new residential and mixed-use towers. It is reasonable to assume that new retail establishments will follow to serve the new residential population.~~

Regional projections indicate that employment in Manhattan CDs 4 and 7 will remain about the same as current conditions.[3]

22.3.3 Potential Impacts with the West 59th Street Converted MTS

The West 59th Street Converted MTS represents the reactivation of solid waste transfer operations on the site with added containerization operations. Therefore, it would not result in socioeconomic changes in the study area. No significant direct or indirect impacts are anticipated related to socioeconomic conditions.

22.3.3.1 Residential Impacts

No direct residential displacement would occur as a result of the West 59th Street Converted MTS, and land use and neighborhood character analyses predict no adverse impacts. (See Sections 22.2.3.1 and 22.8.3, respectively.)

22.3.3.2 Direct Business and Institutional Impacts

The West 59th Street Converted MTS would not result in the direct displacement of businesses or institutional uses. The transfer of paper recyclables from truck to barge that would continue in the Future No-Build Condition would continue as part of the West 59th Street Converted MTS.

22.3.3.3 Indirect Business and Institutional Impacts

The West 59th Street Converted MTS would not result in indirect impacts to study area businesses or institutions since local truck routes follow busy avenues and side streets that will remain predominantly industrial in nature. No traffic, air or noise impacts or neighborhood character impacts are predicted.

---

[3] Ibid.

22.3.3.4 Employment Impacts

The West 59th Street Converted MTS is expected to generate a total of 85 jobs, including supervisors, equipment operators, mechanics, laborers and clerical personnel. In addition to the direct positive employment impacts (likely to reach beyond the study area), the new workers would generate a minor amount of indirect economic benefits in the study area through local spending.

22.4 Community Facilities and Services

22.4.1 Existing Conditions

22.4.1.1 Definition of the Study Areas

The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼- and ½-mile of the site.

22.4.1.2 Summary of Community Facilities and Services

There is one community facility in the primary study area and 24 in the secondary study area. These facilities and others serving the site, but located outside the secondary study area, are listed in Table 22.4-1 and shown on Figure 22.4-1.

22.4.2 Future No-Build Conditions

There are no known changes planned for the community facilities and services within the primary and secondary study areas by 2006. Therefore, anticipated Future No-Build Conditions are expected to remain fundamentally the same as Existing Conditions.

22.4.3 Potential Impacts with the West 59th Street Converted MTS

The West 59th Street Converted MTS would not create any significant new demand on services and community facilities and would not displace facilities or disrupt services. The NYFD states that it would have no problem supporting the reactivation of the site (see Appendix A). No significant adverse impacts to service delivery are expected.

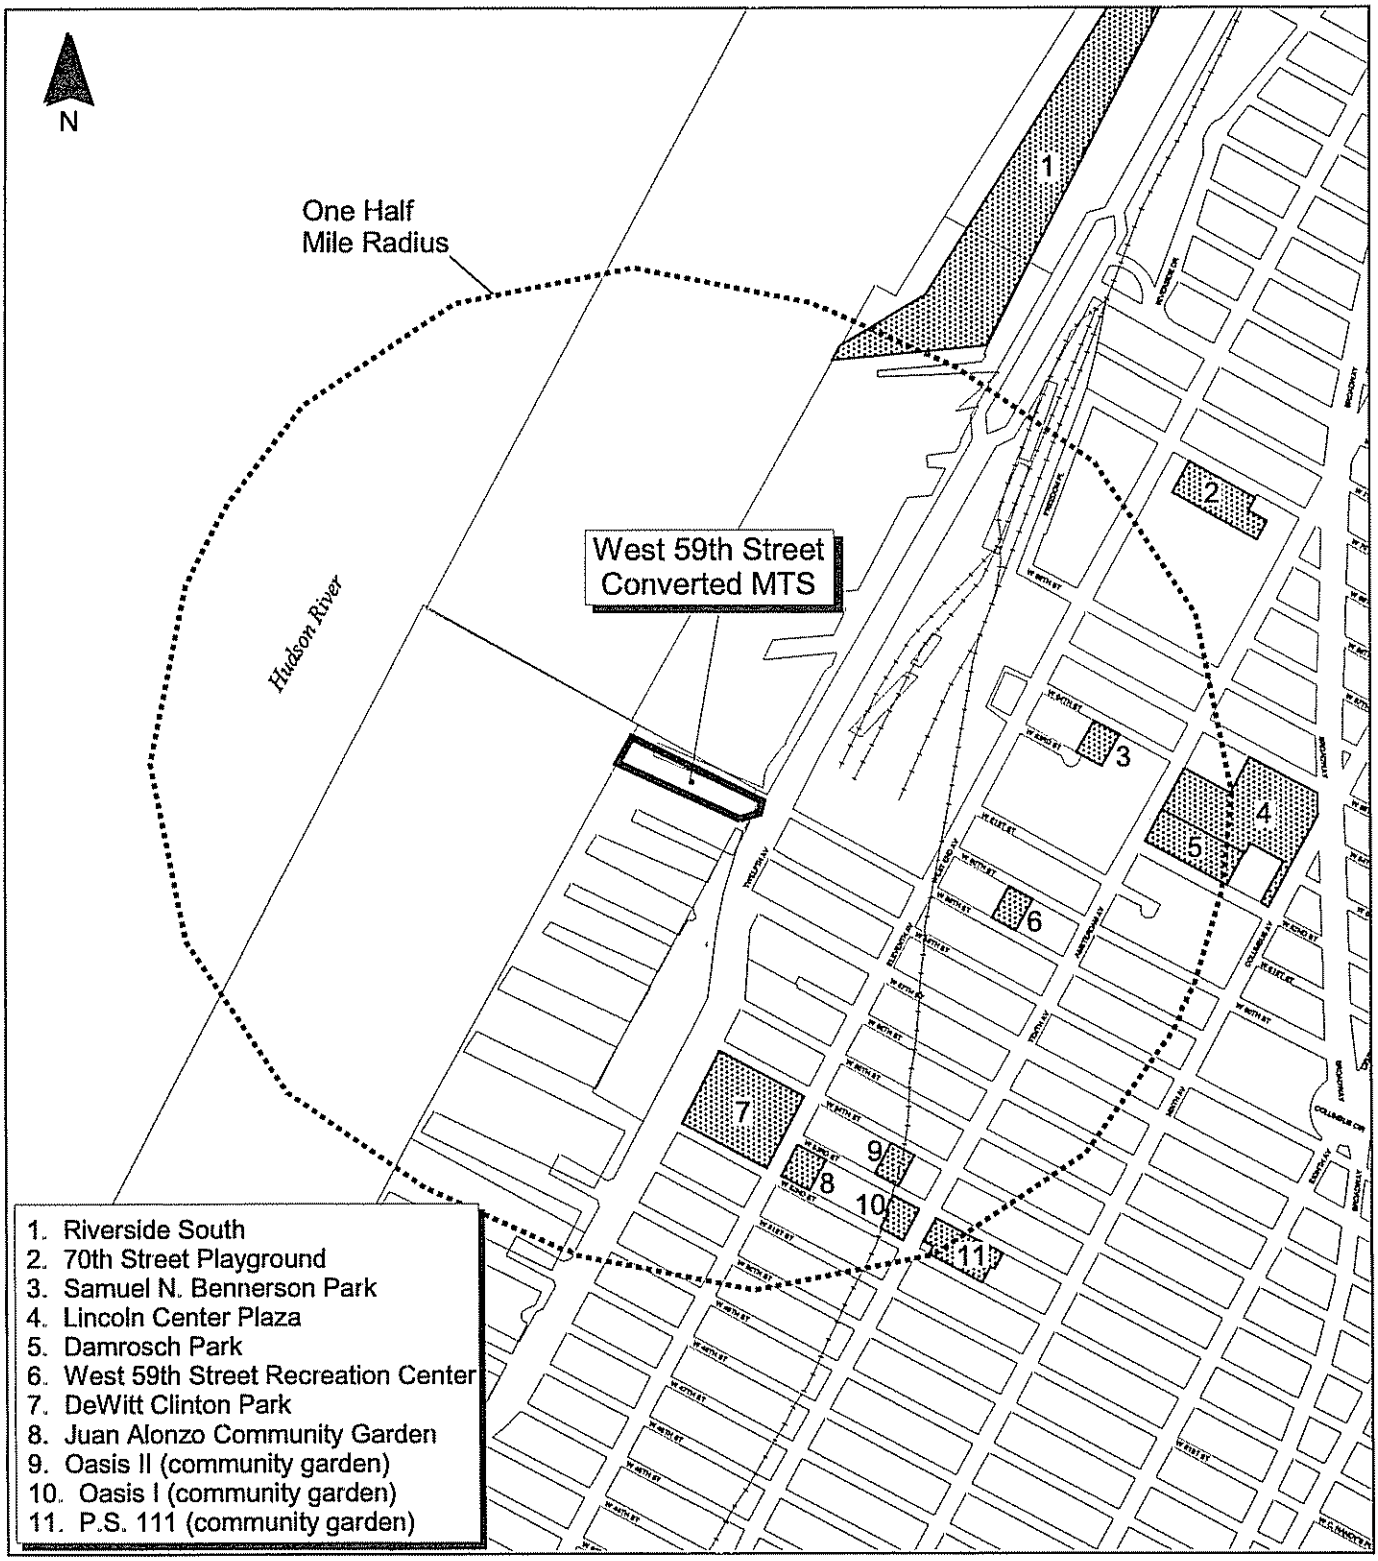
22.5 Open Space

22.5.1 Existing Conditions

22.5.1.1 Definition of the Study Area



The study area for open space is defined as being the area within a ½-mile radius of the site.

22.5.1.2 Summary of Open Space in the Study Area

There are 10 public parks and open spaces within the study area, and one just outside to the north. They are listed in Table 22.5-1 and shown on Figure 22.5-1.

Table 22.5-1

Figure 22.5-1 Open Space/Parkland
West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

In addition to the typical urban parks and open spaces serving the study area, is the linear Hudson River Valley Greenway. The Hudson River Valley Greenway comprises a pedestrian and bicycle pathway stretching along the Hudson River in Manhattan and the Bronx, and a greenway of developed waterfront parkland extending from Battery Place to about West 181st Street in Manhattan. In 1998, the Hudson River Park Act authorized that an approximately 550-acre park to be built in phases along a five-mile stretch from West 59th Street to Battery Place. The park, which is delineated to include the West 59th Street Converted MTS, is designed to reserve extensive portions of the waterfront exclusively for public recreation and to significantly limit the types and locations of commercial activities allowed. The act also designated the river itself as an estuarine sanctuary, and it requires that every dollar earned within the park be directed to fund the park's construction, maintenance, or operations.

Along the Hudson River from West 59th to West 72nd Street, the privately funded Riverside Park South is being constructed in phases and will ultimately fall under NYCDPR jurisdiction. As Riverside Park South and adjacent waterfront park areas are developed, they host an interim multi-use path, including the Route 9A Bikeway (part of the Greenway), which was implemented by the NYSDOT as part of the reconstruction of Route 9A (also known as Joe DiMaggio Highway/West Street/West Side Highway). This multi-use path, which will become permanent when park construction is complete, lies roughly 150 feet inland and travels directly beneath the elevated West Side Highway from West 70th Street to West 65th Street. To the east, future phases of Riverside South residential buildings will be developed, while the first two phases of waterfront parkland to the west of the path are already open for public use (West 65th to West 72nd Streets).

South of West 59th Street where the West Side Highway returns to street level, the path lies directly adjacent to the highway, passing a mixture of waterfront uses to the west.

The multi-use path is divided south of West 57th Street, where a pedestrian promenade hugs the waterfront to the west and the main path remains adjacent to the West Side Highway. To the south, at West 56th and West 55th Streets, construction of Clinton Cove Park is underway on Piers 95 and 96 as part of Hudson River Park. At West 55th Street, the promenade merges back into the bikeway, which continues south, ultimately connecting to the Battery Park City esplanade.

22.5.2 Future No-Build Conditions

Segment 7 of Hudson River Park, which stretches from West 44th Street to West 59th Street, is currently in final design stages, with construction underway and set to be completed by 2005. Segment 7 will include Clinton Cove Park which will feature a boat and kayak lunch and provide passive recreational opportunities at the waterfront. Phase I interior reconstruction of the nearby West 59th Street Recreation Center (between Eleventh and Twelfth Avenues) is likely to be complete by 2006. Additional Riverside South development construction is expected to be underway by 2006, and will entail the reconstruction of that portion of the bike path north of the site, running beneath the elevated West Side Highway.

22.5.3 Potential Impacts with the West 59th Street Converted MTS

Due to the West 59th Street Converted MTS's industrial location within the Hudson River Park, adjacent to the developing Riverside South Park and in the vicinity of several other public parks, air quality, odor, noise and traffic studies were conducted to determine what the environmental consequences would be on these sensitive uses; no significant adverse impacts were found. Due to site constraints, the angle for the existing site entrance will remain unchanged and therefore the existing hazard created for southbound bicyclists would not be eliminated. Any increase in MTS truck traffic, therefore, could potentially worsen the safety conditions on the bike path. Appropriate measures, developed in coordination with the NYCDPR, would likely resolve this conflict.

22.6 Cultural Resources

22.6.1 Existing Conditions

22.6.1.1 Definition of the Study Area

The cultural resources study area is defined as that area within ½-mile of the site.

22.6.1.2 Development History of the Area

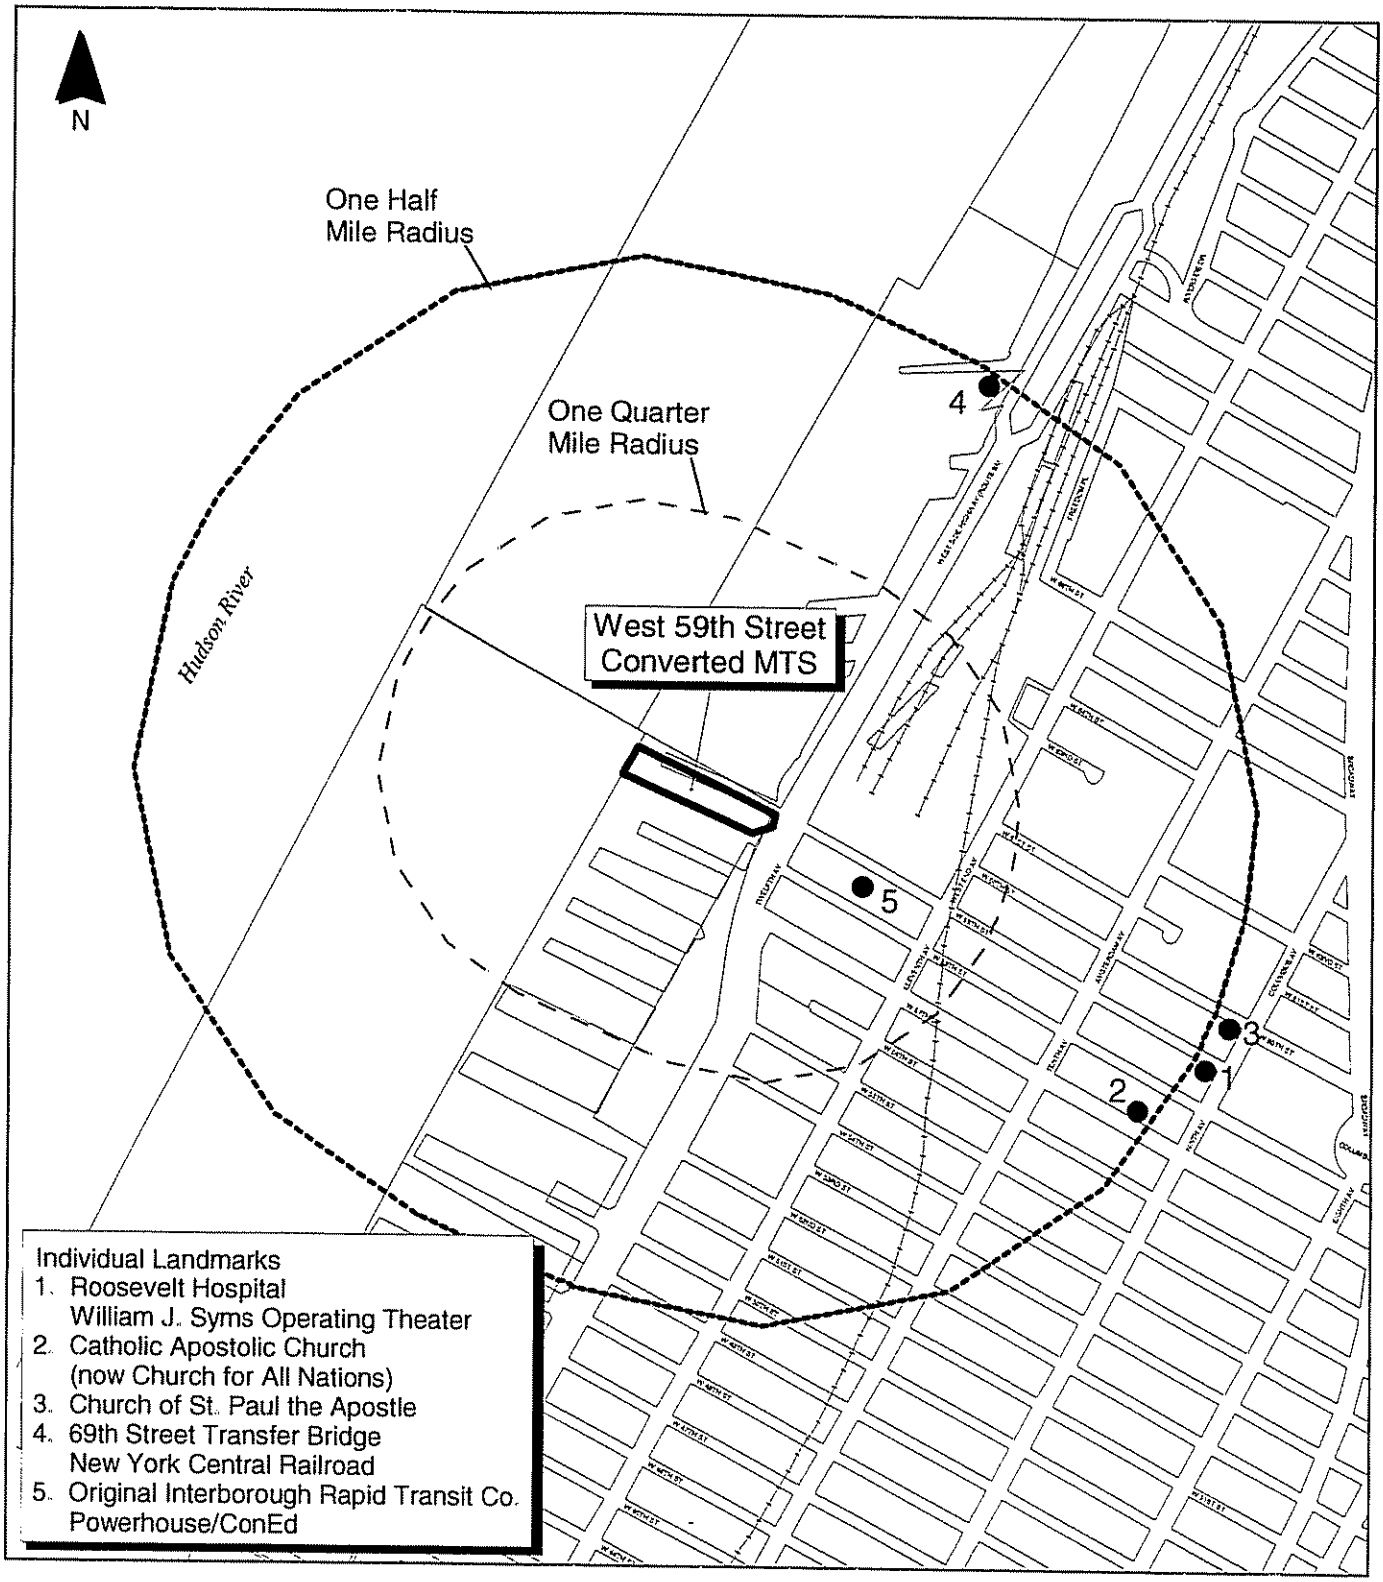
The study area straddles two neighborhoods: Clinton (formerly Hell's Kitchen), which is located south of West 59th Street; and a portion of the Upper West Side, which is located north of West 59th Street and includes the Lincoln Center Urban Renewal area and Riverside South development on the former Penn Central railyards.

As with much of Manhattan north of its southern tip, the study area was farmland and forest during the Colonial period and only later, in the early 1800s, was it divided into developable lots. In 1851, the New York and Hudson River Railroad began steam rail service along the east side of the Hudson River, connecting Manhattan with the Bronx and the rest of the mainland. Its terminal was located on Eleventh Avenue at West 30th Street, south of the study area. This rail line was the first to carry freight directly into Manhattan and, as such, it played a significant role in the Upper West Side's development. Related industries and activities sprang up around the route, as did worker housing.

During the mid-19th century, the study area was populated largely by Irish immigrants. The predominant land uses were slaughterhouses, freightyards, warehouses, lumberyards, factories and many adjacent blocks of tenements. At the end of the Civil War, Hell's Kitchen was known as one of the City's worst slums and the home of notorious gangs. With the advent of the Ninth Avenue El in the 1880s (along Columbus Avenue), more tenements were built west of Broadway.

After 1900, new populations immigrated and migrated to the area, beginning with Greeks and other eastern Europeans early in the century, followed by Blacks migrating from the south and Hispanics from Puerto Rico in the 1940s. Many of the area's earlier social problems remained.

Large areas of tenements were demolished during the first half of the 20th century to make way for large public works projects, such as the West Side Highway, Lincoln Tunnel, the New York Central Railroad West Side Improvement Project and the Port Authority Bus Terminal. Slums were cleared for urban renewal projects as well, such as Lincoln Towers, Lincoln Center and Fordham University in the 1960s. With the decline of the ocean liner industry, the piers in the area were abandoned and the neighborhood close to the waterfront further declined.



At about this same time, Hell's Kitchen was renamed Clinton (after nearby DeWitt Clinton Park) to improve its image and distance itself from its violent past. Later, during the 1980s and 1990s, new private and public residential construction and housing redevelopment efforts were undertaken to rejuvenate the area.

22.6.1.3 Cultural Resources on the Site

There are no elements of architectural or archaeological significance within the site. The bulkhead within the vicinity of the site may be eligible for listing on the SRHP and NR.

22.6.1.4 Historic Resources Within the Study Area

There are five historic properties located within the study area, representing development from the late-19th century to the mid-20th century (see Figure 22.6-1). These properties are listed in Table 22.6-1. In addition, the Hudson River Park Trust (HRPT) has indicated that the bulkhead in the vicinity of the site may be eligible for listing on the State and National Registers of Historic Places, therefore, if the West 59th Street Converted MTS were selected as part of the Proposed Plan, additional consultation of SHPO, LPC and the HRPT may be appropriate.

Cultural Resources in the Study Area

Name	Location	Designation
Riverside Park	West 72nd to West 129th	NRHP/SRHP, NMCL
Original IRT (Interborough Rapid Transit) Power House (now Consolidated Edison Generating Plant)	Streets, 58th-59th Streets, Eleventh to Twelfth Avenues	Eligible for listing on the SRHP
William J. Syms Operating Theater, Roosevelt Hospital	64th Street (west of Tenth Avenue), 400 West 59th Street	NYCL
Church of St. Paul the Apostle	415 West 59th Street	SRHP/NRHP
69th Street Transfer Bridge, New York Central Railroad	69th Street and Hudson River	Eligible for listing on the SRHP

Notes:
SRHP= New York State Register of Historic Places
NR= National Register of Historic Places
NYCL= New York City Landmark

22.6.2 Future No-Build Conditions

Two properties within the study area, the IRT Power House and 69th Street Transfer Bridge, have been determined to be eligible for listing on the ~~State Register of Historic Places~~SRHP; and the bulkhead in the vicinity may be eligible for listing on the SRHP and NR. Except for these properties, there is no reason to anticipate the designation of other resources in this area in the near future. Even with their potential designation, anticipated Future No-Build Conditions are assumed to be essentially the same as Existing Conditions.

22.6.3 Potential Impacts with the West 59th Street Converted MTS

Based upon its review, SHPO has stated that the West 59th Street Converted MTS will have no impact upon cultural resources in, or be eligible for inclusion in, State and National Registers of Historic Places. The LPC has stated that the site contains no architectural or archeological significance (see Appendix A). The West 59th Street Converted MTS would not result in adverse impacts to cultural resources and no mitigation measures would be warranted.

22.7 Urban Design, Visual Resources, and Shadows

22.7.1 Existing Conditions

22.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area. The neighborhood character study area is bounded by West 64th Street on the north, West 52nd Street on the south, Tenth Avenue (Amsterdam Avenue) on the east and the Hudson River on the west (see Figure 22.8-1). The site has been developed in a manner consistent with the uses of the adjacent properties, although new residential development as near as ¼-mile northeast and southeast of the site is changing the general character of the area. The site is separated from upland areas by the West Side Highway, which itself obstructs some street-level views to the waterfront throughout the area. There is, however, the bikeway that runs alongside Twelfth Avenue below the elevated West Side Highway, connecting Riverside Park South to Hudson River Park below West 59th Street. This feature and surrounding park facilities are sensitive to potential urban design and visual quality impacts.

22.7.1.2 Description of the Site

The existing MTS is unique among such facilities as it is the only one featuring a neon light installation, which was designed by the artist Stephen Antonakos as part of the its renovation in 1990. As such, the MTS makes a unique and positive contribution to the otherwise bleak visual quality of the immediate area. The neon is installed on the interior of the MTS and is visible outside through frosted plastic panels. It provides architectonic definition to the eastern facades of the station and adjacent office, with red light framing alternating windows on the northern elevation. The entrances are further emphasized with a neoclassical arch added to the eastern side of the MTS property, framing the MTS on the waterfront in the background (see Figure 22.7-1).

The artistically enhanced MTS façade is visible on land from the elevated West Side Highway, Twelfth Avenue, and the bikeway, and to some extent from points on West 59th Street approximately as far east as Tenth Avenue.

This page intentionally left blank.

This page intentionally left blank.

lining the streets, while Tenth Avenue in the study area features stylishly designed large-scale commercial establishments, such as automobile showrooms, and small-scale groceries and restaurants defined by their signage and window treatments.

Construction of Clinton Cove Park is underway on Piers 95 and 96 (at West 55th and West 56th Streets) approximately 600 feet south of the site. This park will provide a boat launch and recreational open space on the river.

22.7.2 Future No-Build Conditions

There are no plans for the site or immediate environs that would lead to substantial changes in urban design or visual quality conditions of most of the study area by 2006. However, the southern extent of the Riverside South development, which is set to be under construction or complete by 2006, will substantially transform the landscape north of West 59th Street and west of Eleventh Avenue. Several new towers are planned for the area, currently occupied by a large surface parking lot. The sleek continuum of residential towers characteristic of Eleventh Avenue north of West 61st Street would thus be extended to transform the visual quality and urban form of the southward land immediately inland of the site, east of the elevated West Side (Miller) Highway.

Riverside Park South Phase III (West 62nd to West 65th Streets) is due to be completed by 2005, which will include extended timber walkways (with two additional overlooks), landscaped areas, and a major plaza at West 64th Street. The proposed park area immediately adjacent to the site would not yet be redeveloped.

The site would remain DSNY property and the existing MTS would remain in operation for the transfer of paper recyclables.

22.7.3 Potential Impacts with the West 59th Street Converted MTS

22.7.3.1 Visual Quality and Urban Design

Development of a containerization facility at the site would alter the visual quality or urban design of the changing waterfront. The new facility would be approximately 70 feet tall (about 20 feet taller than the existing MTS structure, but similarly sited on the linear pier. Transfer activities would resemble the ongoing waterborne transport of recyclables, though containerized waste would result in a slight improvement in aesthetics. Electric cranes used to load containers, which would be filled inside the new facility onto waiting barges, would be situated on the south side of the facility and stand approximately 80 feet tall. This loading activity would be screened by the active Consolidated Edison Pier (to the south). The existing neon ornament found on the MTS would not be incorporated into the proposed facility design, though the entrance portal will remain undisturbed. Overall, the larger new facility would not create notable changes to the urban design and visual quality of the site or study area, and no significant adverse impacts are predicted.

22.7.3.2 Shadows

According to the 2001 CEQR Technical Manual, an impact area should be drawn around the site to encompass the maximum project shadow in order to determine if any sensitive resources nearby might be affected, and consequently, if a full shadow impact assessment is warranted. (This shadow impact area is calculated by multiplying the height of the proposed structure by 4.3 to estimate its longest possible shadow.) If this site were chosen and a noise wall used as the preferred mitigation, a supporting analysis would be conducted.

While there are three mapped open space/parkland resources within the shadow impact area, only one facility – the bicycle/pedestrian path extending from Riverside Park South – is near enough to the site to be potentially affected by shadows. This path is generally used for active recreation, including bicycling, pedestrian activities, rollerblading, etc. (See Figure 22.7-5.)

There are no expected physical changes to the project site or vicinity that might create new shadows on these resources in the Future No-Build Condition. Therefore, the shadow assessment considered only the consequences of the West 59th Street Converted MTS development.

During most of the year, shadows generated by the 71-foot-tall West 59th Street Converted MTS and 84-foot-tall cranes would completely fall across portions of the Hudson River. Analysis of December 21st indicates that the walkway would not be affected by shadows. During the three other analysis periods, approximately 40 feet in length of the bicycle/pedestrian path would be affected by shadow, for approximately one hour during each period. On June 21st, shadows would fall over the bicycle/pedestrian path from 5:50 p.m. to 7:00 p.m.; on March 21st, from 3:40 p.m. to 4:30 p.m.; and on May 6th, from 5:20 p.m. to 6:20 p.m. As shadows would only affect 40 feet of the walkway for approximately one hour during three periods, and since the walkway is not dependent upon direct sunlight for its active uses, the West 59th Street Converted MTS is not considered to cause a significant shadow impact.

This page intentionally left blank.

Figure 22.7-5 Shadow Diagram

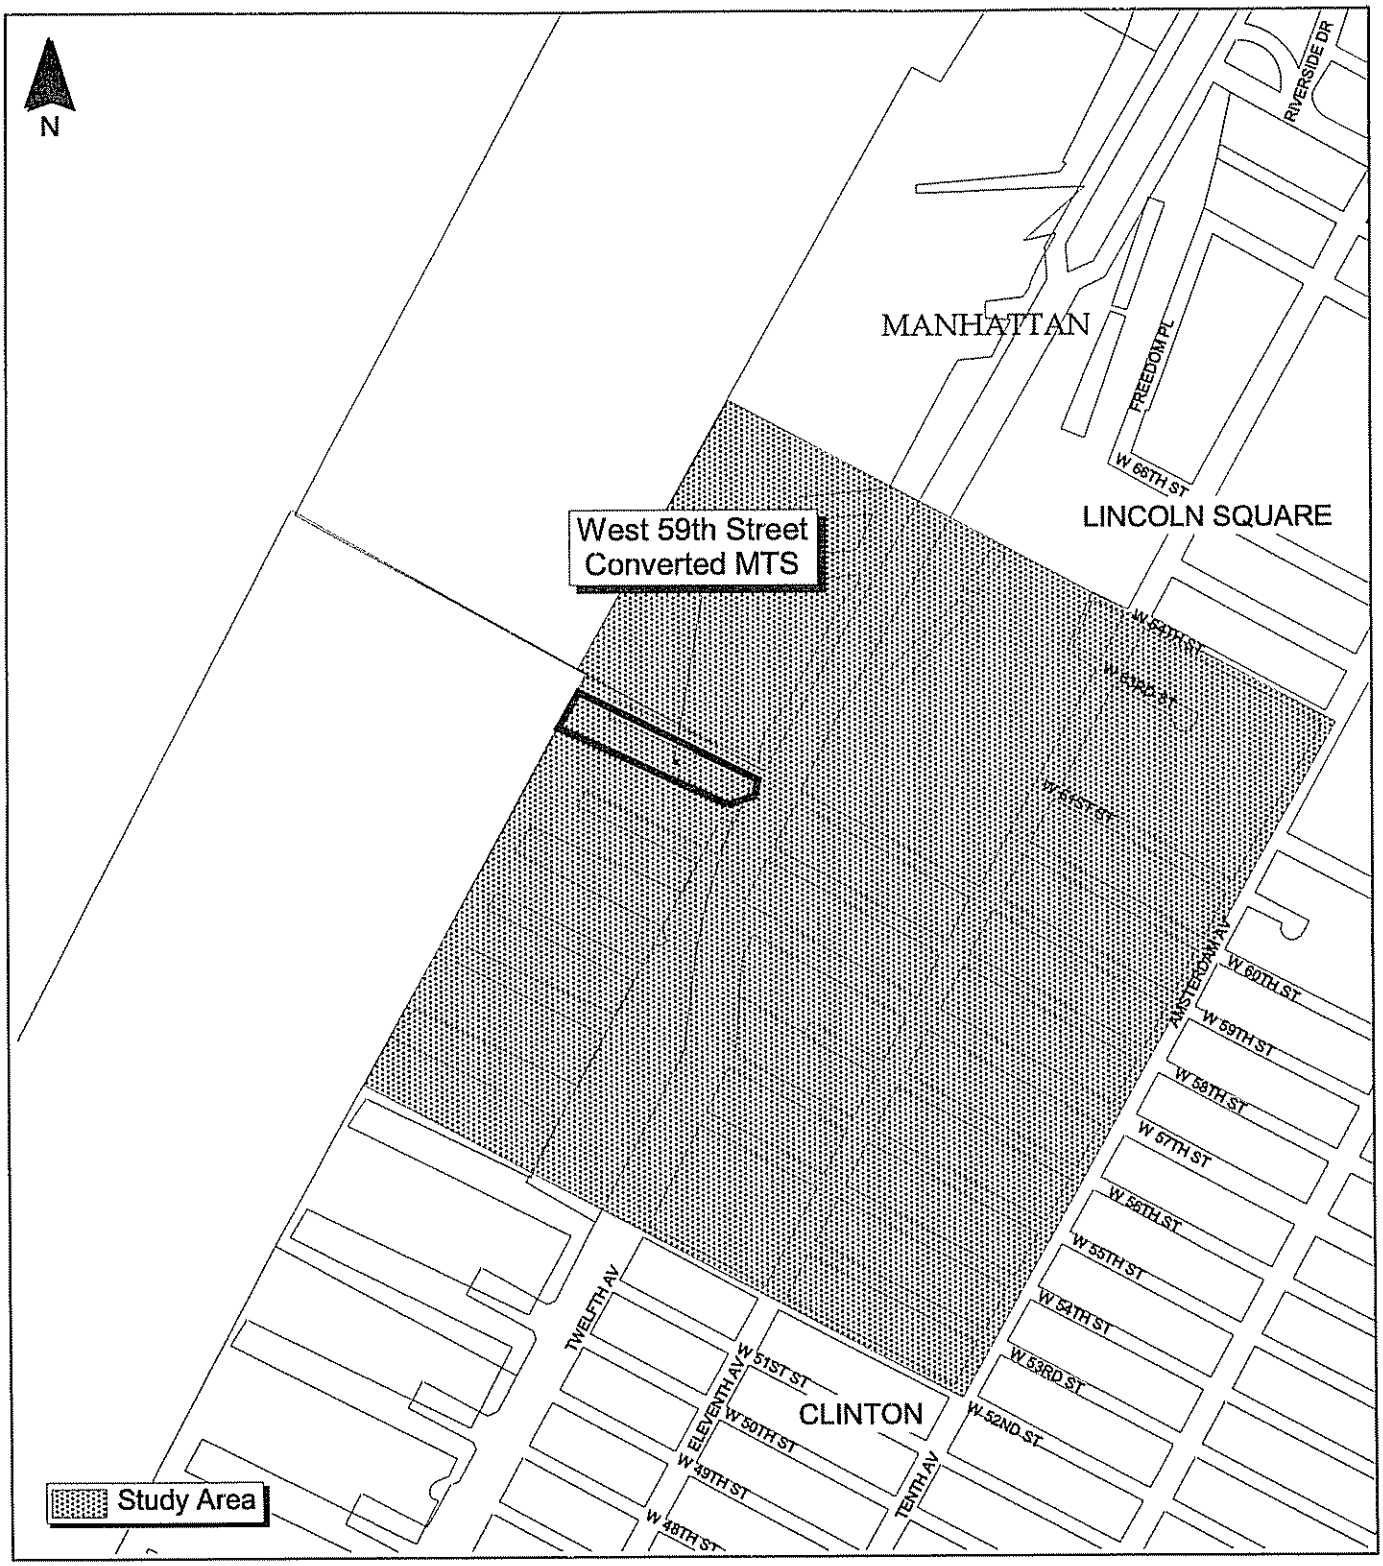
CITY OF NEW YORK
DEPARTMENT OF SANITATION

This page intentionally left blank.

22.8 Neighborhood Character



22.8.1 Existing Conditions

22.8.1.1 Definition of the Study Area

The site is surrounded by industrial uses and is effectively separated from inland blocks by the elevated West Side (Miller) Highway (West 59th to West 72nd Streets) and vacant land beneath it or in its immediate vicinity. Although there is a concentration of institutional uses, including Lincoln Center and John Jay College of Criminal Justice several blocks east of the site, the industrial uses and dense urban nature development inland are the major factors contributing to the neighborhood character. This is especially true near the West Side (Miller) Highway where a large Consolidated Edison generating plant is located one block inland of the site. Riverside South residential towers have recently been built, introducing a major new physical element to an area north of the site, but this residential development currently shares no direct connectivity to the site at this point, and is separated from it by the elevated West Side Highway, and the large parking lot between the two. The neighborhood character study area is bounded by West 64th Street on the north, West 52nd Street on the south, Tenth Avenue (Amsterdam Avenue) on the east and the Hudson River shore on the west (see Figure 22.8-1).

22.8.1.2 Description of Neighborhood Character

The general neighborhood character of the study area is mixed and changing, as described in the previous sections, though remains industrial immediately surrounding the site to the east and south. Industrial uses on densely-built blocks along with the presence of the elevated West Side (Miller) Highway, inhibit views to the waterfront from inland blocks in the study area, especially along West 59th Street. While construction is underway on several surrounding sites (to create waterfront parks to the north and south, a new sanitation garage, new large-scale residential and commercial developments), the character of the immediate environs remains largely industrial and transportation-oriented. There is no destination in the immediate area of the site that would attract anyone but workers employed in the warehouses and industries. The nearest destination points include the John Jay College of Criminal Justice, and St. Lukes/Roosevelt Hospital Center, east of Tenth Avenue — two blocks east of the site — and the DeWitt Clinton Park along the southern boundary of the study area, both of which would attract people from outside and within the study area.

Site delineations are approximate.

HDR URBITRAN EEA Cambridge Environmental Inc HYDROQUAL PB

Figure 22.8-1 Neigborhood Location
West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

The new residential towers of Riverside South stand about ¼-mile northeast of the site and an additional parcel (ABC studios) is under construction nearby. Together with Riverside Park South, whose Phase III is scheduled to open in 2005, these developments will introduce physical characteristics and visual resources unlike those currently associated with the Hudson River waterfront in this vicinity.

22.8.2 Future No-Build Conditions

Nearly all the proposed development expected to be complete or under way by 2006 will be located within the neighborhood character study area. The two developments nearest the site would be: (1) the extension of the Riverside South development, which entails construction of several residential and mixed-use towers north of the large surface parking lot across Twelfth Avenue, from the site and parkland along the waterfront north of West 59th Street; and (2) the Helena (Durst Organization) residential tower south of West 58th Street, east of Twelfth Avenue, to open later in 2004. (The new DSM District 4, 4A and 7 Garage is soon to be under construction on Twelfth Avenue, between West 55th and West 57th Streets, though not scheduled to open until 2007). While the Riverside South and associated park development will substantially alter the character of the waterfront west of the elevated West Side (Miller) Highway, north of the site, the remainder of the study area is expected to resemble Existing Conditions, particularly due to the continued presence of the monumental Consolidated Edison Power Plant, the West Side (Miller) Highway and neighboring industrial/municipal uses. The site will remain DSNY property and the existing MTS will continue to be used for transfer of paper recyclables from truck to barge.

22.8.3 Potential Impacts with the West 59th Street Converted MTS

The West 59th Street Converted MTS is not expected to result in significant impacts on neighborhood character since it would be a reactivation of waste transfer facilities on a site formerly used for that purpose and currently used for the transfer of recyclable paper from truck to barge. Traffic, air quality, odor and noise studies all indicated that nearby sensitive receptors would not experience significant adverse impacts. (See Sections 22.14, 22.15, 22.16 and 22.17.)

Because DSNY trucks currently run through the study area (along West 59th and West 57th Streets, as well as Twelfth, Eleventh and Tenth Avenues south of West 59th Street) and the site is somewhat buffered from the new residential and park uses to the north by the elevated Miller Highway, potential operational impacts from the facility would be largely contained to the immediate vicinity. (See Section 22.5 for a discussion of potential impacts to open space.)

The Converted MTS and barge movements will be partly visible from Riverside Park South to the north, particularly from the planned overlooks now under construction between West 62nd and West 65th Streets, and from the Clinton Cove Park some 600 feet south of the site, as part of the developing Hudson River Park. However, given the industrial nature of the immediate area, the impacts to neighborhood character would not be significantly adverse. Rather, the immediate industrial character would be reinforced and visual quality upgraded with the containerization facility, as opposed to the previous open barge transfer.

22.9 Natural Resources

22.9.1 Existing Conditions

Existing Conditions include stressed aquatic and terrestrial communities that are typical of this area of Manhattan. Conditions associated with the presence of natural resources, including water resources and endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise from implementation of the West 59th Street Converted MTS.

22.9.1.1 Definition of Study Area

The study area includes the existing MTS and the waterfront section that is bounded by the Hudson River to the west (see Figure 2.7-1). The existing MTS is a platform structure extending out from the shore into the river. As a result, no terrestrial natural resources exist to be discussed. Because Future Build Conditions would include dredging of bottom sediments and construction of a new MTS, a description of the aquatic communities is included.

22.9.1.2 Geology

Previous borings performed along the length of the existing MTS site ranged from 62 to 110 feet in depth.[4] These borings reference the water surface (Elevation 0.0 feet) as the top of the borings. Four borings terminated at rock between –57 and –110 feet. Bedrock generally dips to the west, as the two westernmost borings did not encounter bedrock at –110 feet. The uppermost layer generally consisted of organic soil, with shells and vegetation present within this stratum. At the bulkhead along 12th Avenue, riprap and boulders were present. In addition, occasional pieces of timber were encountered in this stratum beneath the existing pier. Below the organic soil, the surface of quartz-mica schist was encountered between –57 and –90 feet. The bedrock

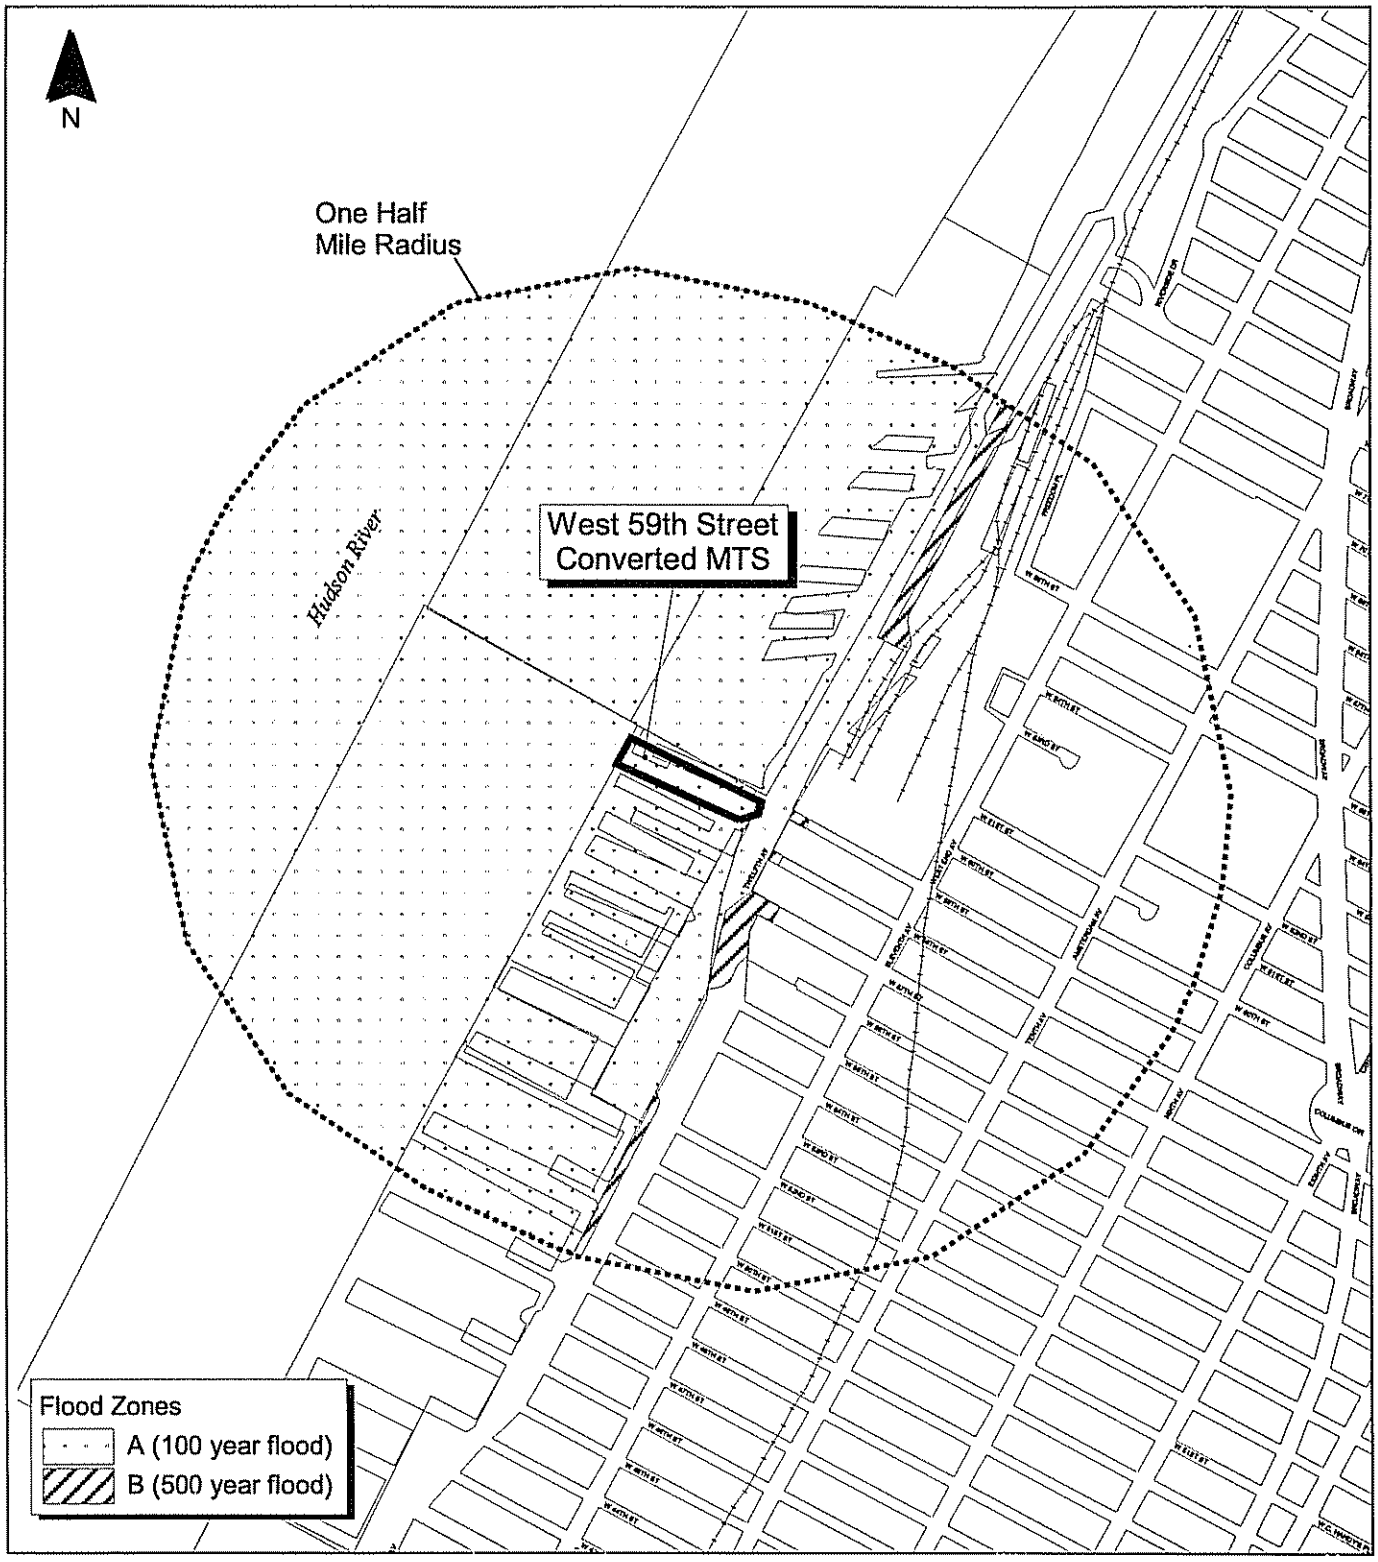
[4] Geology discussion based on "Report of Subsurface Evaluation of West 59th Street (Manhattan) Marine Transfer Station, City of New York Department of Sanitation," September 1983, by Woodward-Clyde Consultants, Inc., as cited in the *MTS Conversion Conceptual Design Report*, April 2003, by Greeley and Hansen, LLC.

was described as soft to moderately hard, seamy, slightly weathered schist. Overlaying this schist are river sediments deposited over time that are characterized as dark to grey-brown hard clay with some silty sand, with approximately 38,250 mg/kg of TOC. The sediment surrounding the MTS was made up of 91.6% silt and clay, 8.0% sand and 0.6% gravel.[5] Sediment was found to be somewhat degraded due to contaminants in the sample material. The three metals with the highest concentrations in the sediment were lead, chromium and barium, with 91.77 mg/kg, 67.75 mg/kg and 55.42 mg/kg, respectively.

22.9.1.3 Floodplains

The site is located within the 100-year coastal floodplain (see Figure 22.9-1). No wetlands, other than the Hudson River, a NYSDEC-designated littoral zone, exist on the site (see Figure 22.9-2).

22.9.1.4 Ecosystems



Because the site is located on an offshore platform, there are no upland natural resources to consider, describe or map. The majority of the approaches leading to the facility are hard surfaced and devoid of vegetation.

A field program that took place in 2003 was designed to fully characterize the marine biological resources of the study area. The program included monthly sampling for adult finfish, finfish eggs and larvae and water quality, and quarterly sampling for benthic invertebrates and sessile colonizing organisms. Results of the program are presented in the following paragraphs.

The West 59th Street Converted MTS was determined to support one of the more biologically productive marine communities. It had one of the highest species richnesses of adult finfish and megainvertebrates and the highest total catch of both. It supported six EFH-listed adult finfish species and three larval species. It also had the highest concentration of finfish eggs.

---

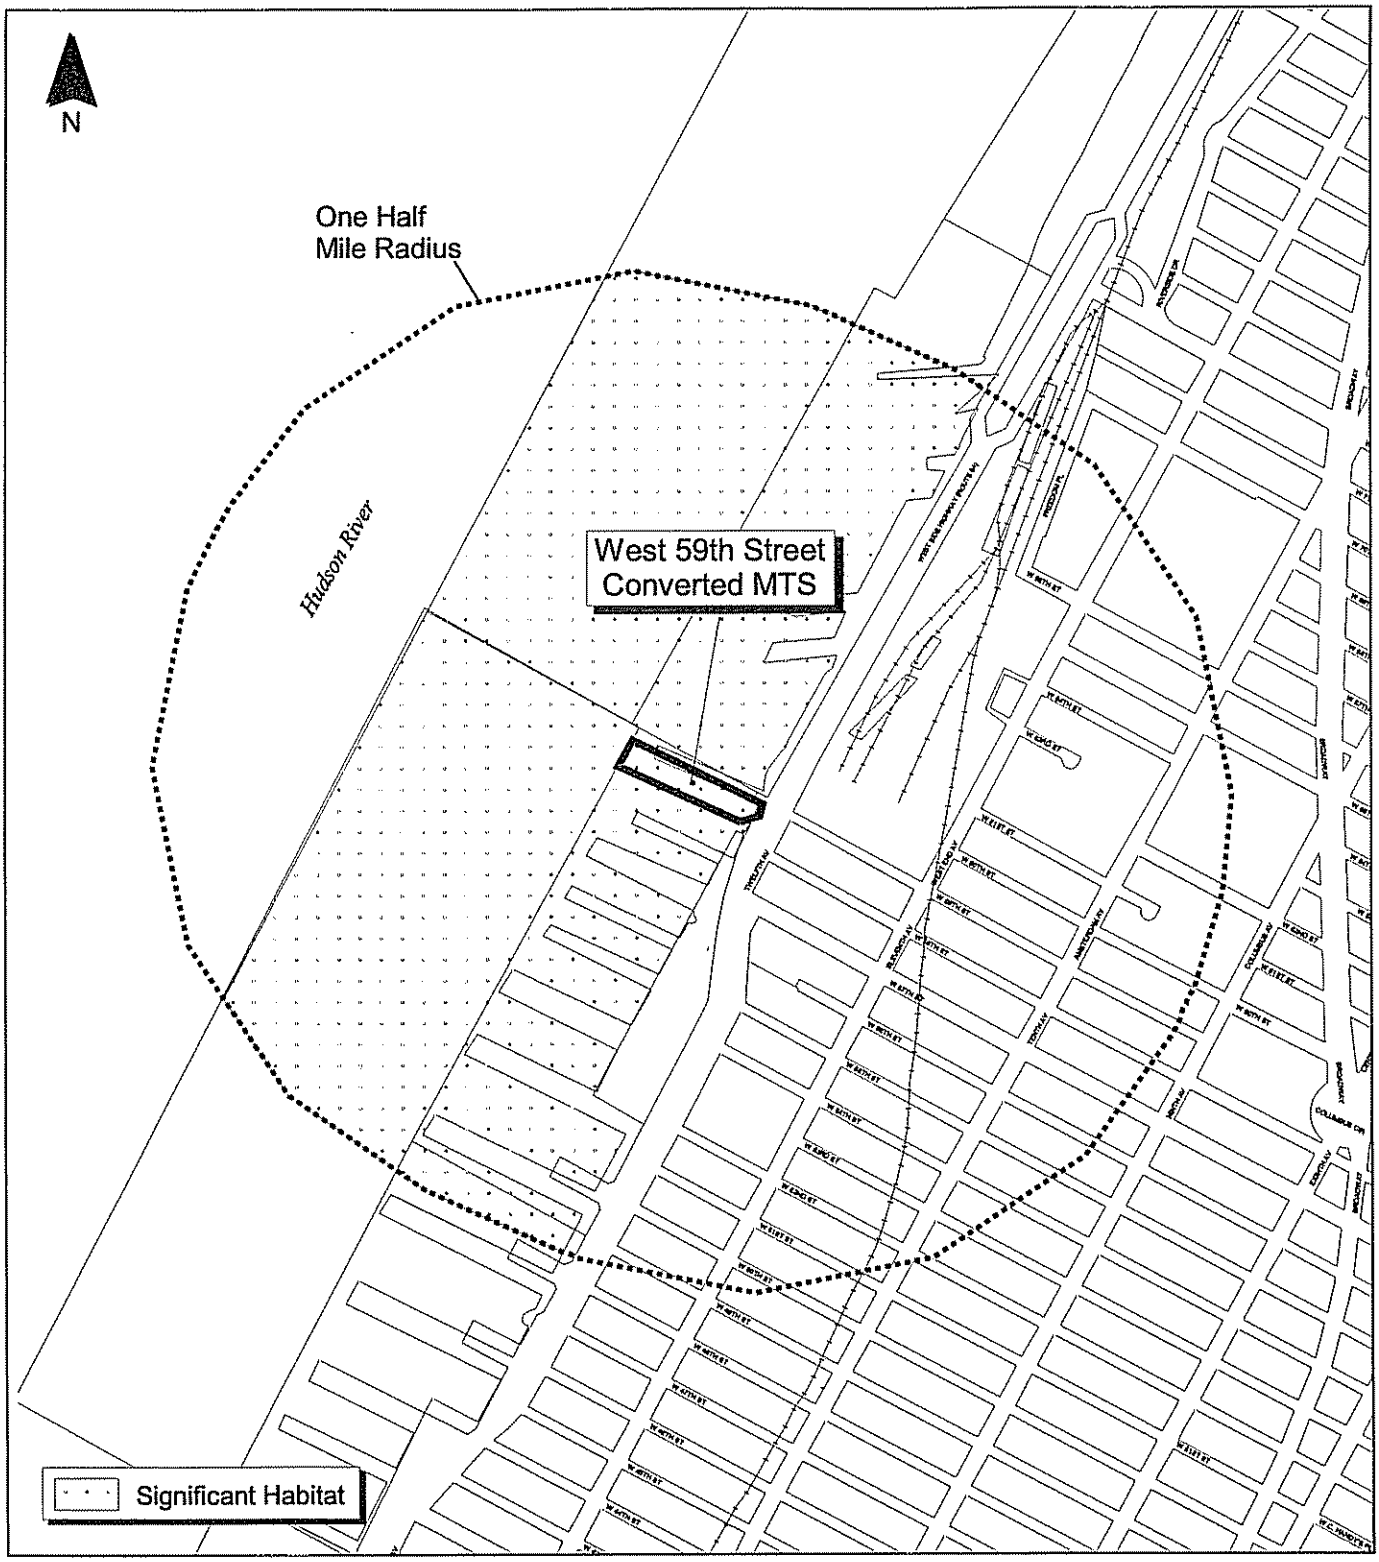
Figure 22.9-2 Wetlands

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION



THE CITY OF NEW YORK DEPARTMENT OF SANITATION

A total of 1,390 adult finfish were collected at the West 59th Street Converted MTS, the highest catch of the eight MTSs studied.[6] The most abundant species collected was striped bass (*Morone saxatilis*), followed by hogchoker (*Trinectes maculates*), Atlantic tomcod (*Microgadus tomcod*), weakfish (*Cynoscion regalis*) and bay anchovy (*Anchoa mitchilli*). There were six EFH-designated species collected: windowpane (*Scophthalmus aquosus*), Atlantic butterfish (*Peprilus triacanthus*), winter flounder (*Pleuronectes americanus*), summer flounder (*Paralichthys dentatus*), Atlantic herring (*Clupea harengus*) and bluefish (*Pomatomus saltatrix*). Finfish eggs and larvae were least diverse at the West 59th Street Converted MTS. The most abundant finfish egg collected at this MTS was bay anchovy. Anchovy spp., winter flounder and goby spp. (*Gobiosoma* spp.) larvae were also abundant. Winter flounder and windowpane, both EFH listed, eggs and larvae were present at the West 59th Street Converted MTS.

Sevenspine bay shrimp (*Crangon septemspinosa*) and eastern mudsnail (*Ilyanassa obsoleta*) were the most abundant megainvertebrates collected from the West 59th Street Converted MTS. The fewest number of benthic invertebrates and lowest abundances were collected at this facility. Oligochaetes were the most abundant, followed by polychaetes. The West 59th Street Converted MTS also had a high number of species in common with the other MTSs sampled, suggesting that it is less distinct in its community composition. The most abundant epibenthic colonizers collected were *Pleusymtes glaber* (amphipods), *Polydora* sp. (polychaete worms), *Balanus* sp. (barnacles), and hydrozoa, mud and algal film.

It should be noted that the Lower Hudson Reach, in which the study area is located, is a New York State Department of State Division of Coastal Resources and Waterfront Revitalization-designated SCFWH (see Figure 22.9-3). New York State's CMP includes a specific policy for the protection of fish and wildlife habitats that are determined to be of statewide significance. An inventory of the coastline was conducted to identify the most valuable habitats according to the following criteria: ecosystem rarity, species population levels, support of vulnerable species, human use and replaceability. A numerical rating system using these criteria was applied to more than 300 areas and approximately 235 have qualified for official designation and mapping as SCFWHs.

Figure 22.9-3 Significant Habitat

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

NYSDEC's NHP records list the common nighthawk (*Chordeiles minor*) as a species suspected of breeding in the study area. The state legal status of this wild bird is Protected-Special Concern, which includes those species that are not yet recognized as endangered or threatened but for which documented concern exists for their continued welfare in New York, and that are federally-protected wild birds.

22.9.2 Future No-Build Conditions

If the West 59th Street Converted MTS were not to be built, the study area would remain as is. The absence of terrestrial natural resources would remain, as the study area does not contain any upland features. Aquatic natural resources would continue to be present in the waters in and around the study area.

22.9.3 Potential Impacts with the West 59th Street Converted MTS

22.9.3.1 Geology

The geology of the study area would not be changed other than by the removal of dredge material to accommodate the barges and tugboats. The dredging activity would remove layers of sediments deposited over time and further alter the submarine ecological features of the study area, but would not result in any significant impact.

22.9.3.2 Floodplains

Implementation of the West 59th Street Converted MTS would have no effect on elevation of the study area. It would be constructed within the 100-year floodplain, and would not include any provisions for raising any portions of the study area over this level.

22.9.3.3 Ecosystems

Construction of the West 59th Street Converted MTS would involve installing piles for the foundation supports and dredging to accommodate the deeper draft of the coastal barges, resulting in an immediate, short-term destruction of the benthic invertebrates in the area. Because the benthic diversity had a medium rank and marine construction causes turbidity and siltation that could smother the benthic organisms, the short-term degree of impact is expected to be medium to high. However, recolonization of the area by benthic invertebrates can be expected to occur within 6 to 12 months after cessation of dredging activities.[7] Given the relatively small size of the project, minimal overall impact to the benthic community is expected at the West 59th Street Converted MTS. The removal of the existing platform will also remove the existing epibenthic community; however, the new expanded platform will result in more surface area for epibenthic communities to colonize the site. This would positively affect the epibenthic communities at the West 59th Street Converted MTS.

The pile-driving and dredging activity during the construction will cause adult finfish to avoid the site. Fish in the herring family are most sensitive to the suspended sediment and noise from construction; flatfish (flounders) are least sensitive. Flounder catch was much higher at the West 59th Street Converted MTS than herring catch, so it can be assumed that this site is not an important herring habitat that will be temporarily impacted. Finfish eggs and larvae are more sensitive to suspended sediment, and those that settle to the harbor floor may be smothered by sediment. Swift currents may sweep eggs and larvae past the construction site, but the short exposure time should not significantly harm the ichthyoplankton. In addition, larvae will be able to swim away from the impacted environments. Winter flounder eggs were found at the West 59th Street Converted MTS, but construction impacts are expected to be negligible.

Operational impacts will last the entire lifespan of the facility. The major impact is the footprint of the pier over water. The proposed plan for the West 59th Street Converted MTS is for an increase in 25,631 square feet of pier. This will result in increased shading that will block

[7] U.S. Army Corps of Engineers, 1999. The New York District's Biological Monitoring Program for the Atlantic Coast of New Jersey, Asbury Park to Manasquan Section Beach Erosion Control Project, Draft. Phase II-III. During Construction and 1st Year Post-Construction Studies.

sunlight and hinder primary production. The enlarged platform, however, will not adversely impact the ichthyoplankton, benthic, epibenthic or adult finfish communities. A field study conducted on the Hudson River reported no statistical difference in benthic populations in interpier and underpier areas in New York Harbor waters.[8] Epibenthic communities will have a larger surface area to colonize, and finfish should return to the area with the return of food sources.

Experts have differing opinions regarding the effects of shading on finfish. Studies conducted by EEA in the late 1980s showed similar finfish communities in the interpier and underpier environments in a large-scale program on the East River. There were, however, slight differences in the dominant finfish in the populations. Studies by Able *et al.* showed caged juvenile winter flounder (*Pseudopleuronectes americanus*) to have depressed feeding on the benthos beneath piers as compared to feeding activity alongside and between piers.[9] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as they provide shelter and surfaces for food to grow. While the field tests appear to be contradictory, there is no doubt that finfish inhabit at least the interface of platforms. However, because the increase in shading over water is very small, there are not expected to be significant deleterious results. There is a possibility of a slight shift in the finfish community with the addition of over-water pier coverage; however, because finfish are transient, this shift may be hard to measure.

According to the Atlas of Breeding Birds in New York State, the common nighthawk (*Chordeiles minor*) regularly nests on flat-roofed structures in cities and towns and feeds upon insects during flight. The West 59th Street Converted MTS is not likely to directly impact any potential nesting habitat or prey species on which the nighthawk depends.[10]

22.10 Hazardous Materials

22.10.1 Existing Conditions

Existing Conditions associated with the presence of hazardous materials in soil, groundwater and building components/equipment were investigated within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527). The assessment was performed in February 2003 and included a historical land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps for the study area, if available, and a Freedom of Information Law request to the NYFD for UST records. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A written request to NYCDEP was made to solicit records pertaining to hazardous or toxic materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted in February 2003. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers and unusual stains and odors. Topographic maps, visual observations and readily available geologic information sources were reviewed if off-site potential sources of contamination were identified.

22.10.1.1 Definition of Study Area

The study area includes the site and neighboring properties within a 1,000-foot radius.

22.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the ground, groundwater, surface water or structures within the study area where the presence or likely presence of hazardous materials exists and implementation of the West 59th Street Converted MTS could lead to an increased exposure of people or the environment to those materials. No specific areas of concern were identified at this site during the assessment.

22.10.2 Future No-Build Conditions

The existing MTS would continue to be used for the transfer of paper recyclables from truck to barge. There would be no areas of significant concern with regard to hazardous materials.

22.10.3 Potential Impacts with the West 59th Street Converted MTS

The West 59th Street Converted MTS would not result in adverse impacts. No additional testing would be required. If any areas of concern were identified during the construction phase, an analysis would be made to determine what, if any, mitigation measures should be applied.

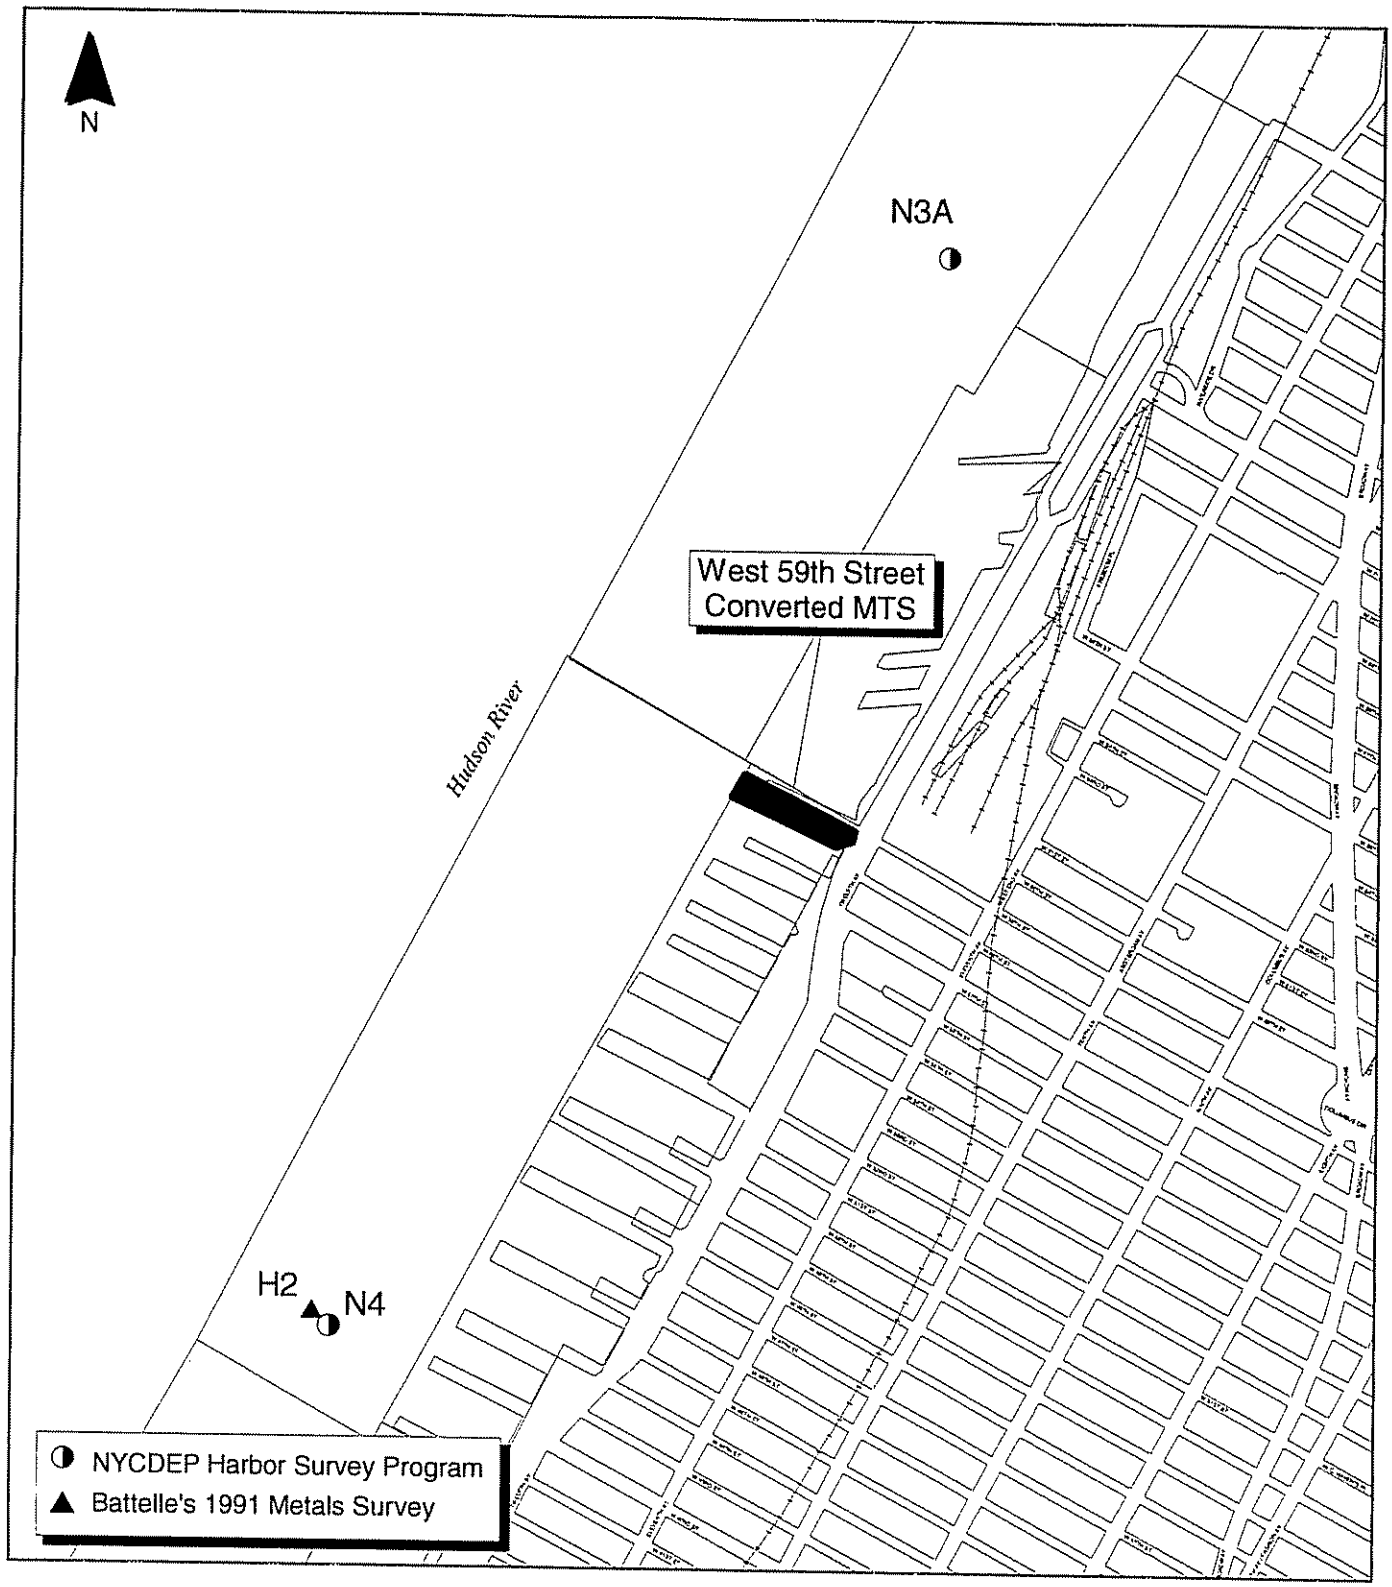
22.11 Water Quality

22.11.1 Existing Conditions

22.11.1.1 Definition of the Study Area

The water quality study area encompasses the Hudson River and includes discharges from CSOs located within ½-mile of the site.

22.11.1.2 Water Quality



The water quality data for the following monitoring stations, shown in Figure 22.11-1, are generally representative of water quality in the study area:

- NYCDEP Harbor Survey Program – Stations N-3A, located one-third of the distance from the Manhattan shore at West 72nd Street to the New Jersey shore; and N-4, located one-third of the distance from the Manhattan shore at West 42nd Street to the New Jersey shore.
- Battelle's 1991 Metals Survey – Station H-2T and H-2B[11] located one-third of the distance from the Manhattan shore at West 42nd Street to the New Jersey shore.

These data, along with NYSDEC's water quality standards and guidance values, are presented in Table 22.11-1. The standards and guidance values for the waters in the vicinity of the site correspond to "Class I," which indicates waters suitable for secondary contact recreation (i.e., fishing and boating).

As shown in Table 22.11-1, on average, NYSDEC standards and guidance values are met. The mercury concentration for Battelle Stations H-2T and H-2B did not conform to the water quality standard for mercury.

[11] Stations H-2T and H-2B are located at the same longitude and latitude. Station H-2T is located at the surface of the Hudson River. Station H-2B is located at the bottom of the Hudson River.

Site delineations are approximate

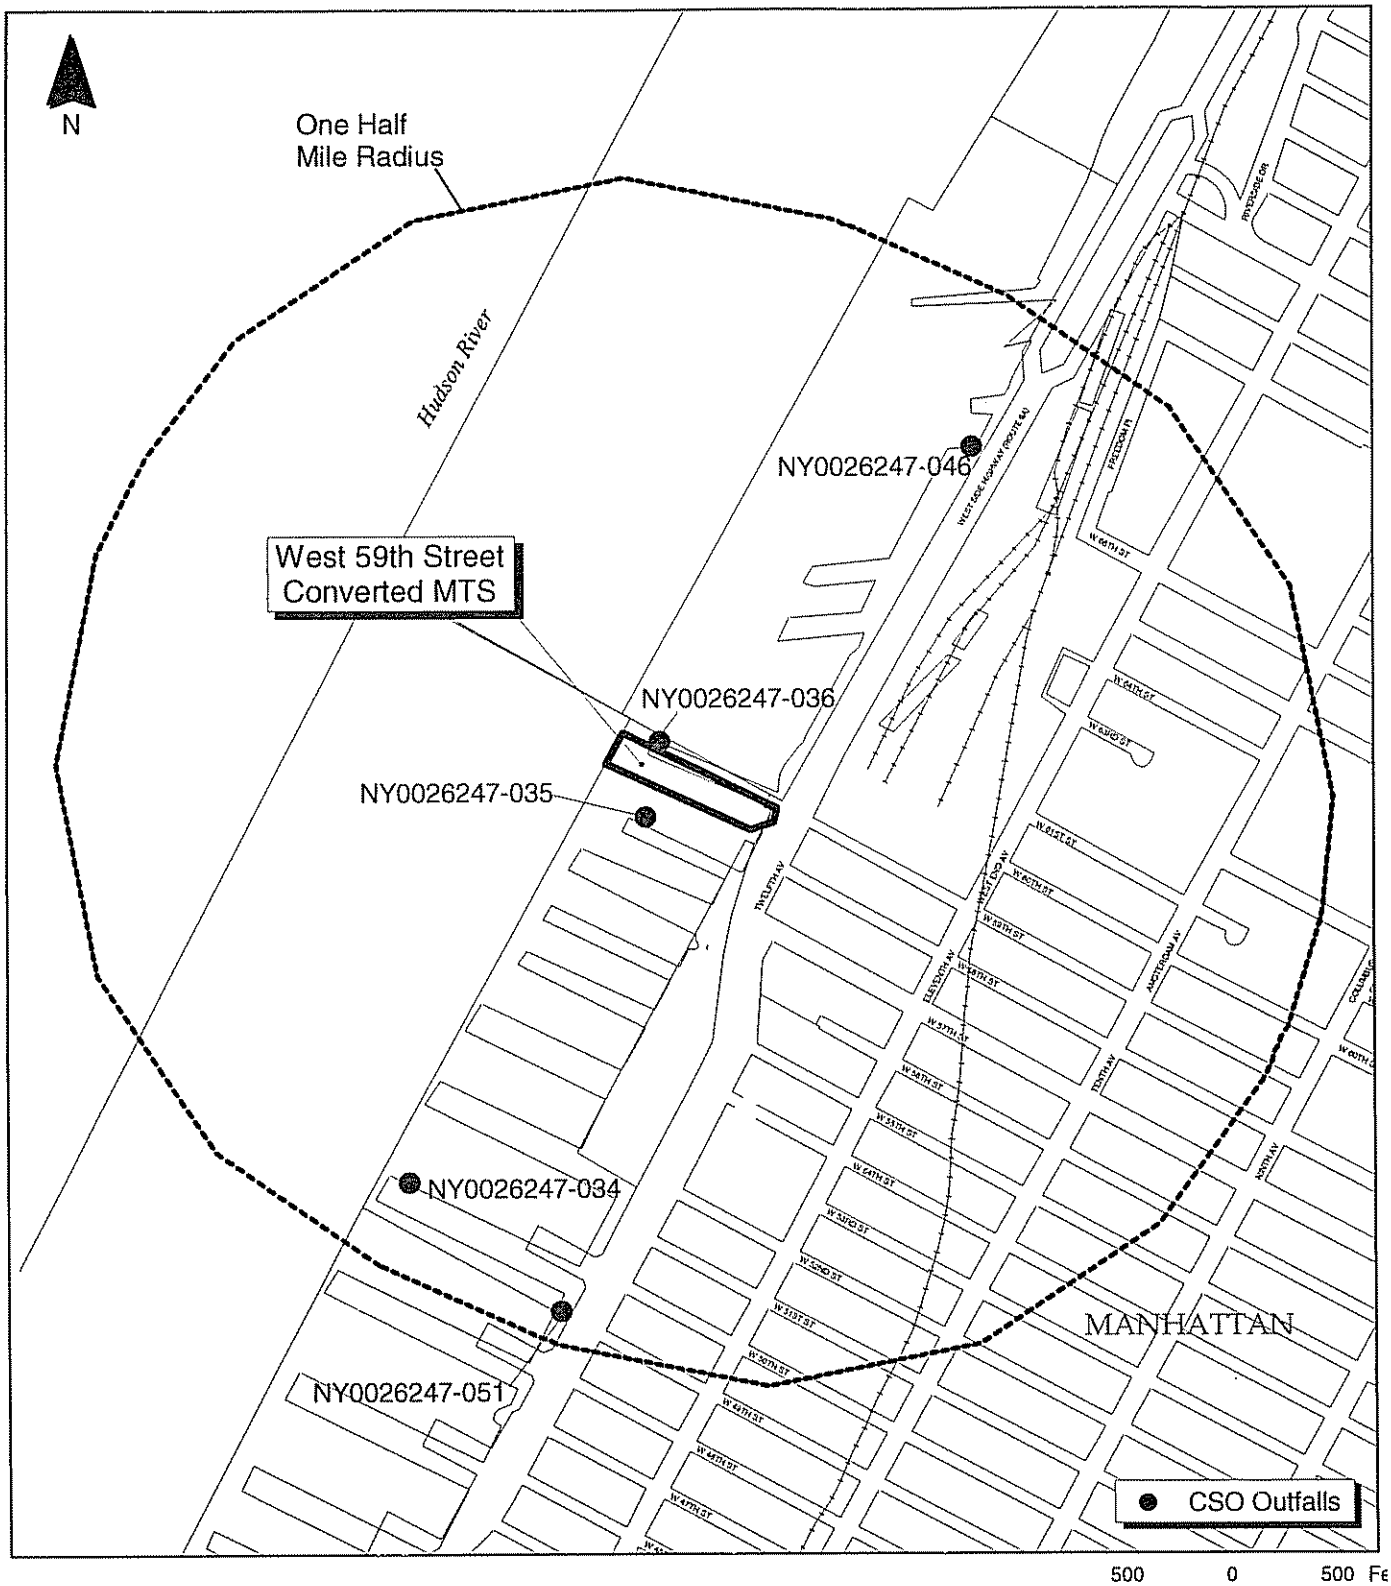
µg/L = micrograms per liter

22.11.1.3 Permitted Discharges



A review of the most recently available NYSDEC and USEPA databases indicated that there are five permitted discharges in the vicinity of the site. The existing discharges within a ½-mile radius are listed in Table 22.11-2 and shown in Figure 22.11-2. These discharges consist of five CSOs, all of which are permitted by the NYSDEC.

Table 22.11-2

West 66th Street/North River	NY0026247-046	New York	Hudson River
West 49th Street/North River	NY0026247-051	New York	Hudson River

22.11.1.4 Existing Pollutant Loads and Stormwater Runoff

Using available databases on stormwater pollutant concentrations and local precipitation data, an estimate of existing stormwater pollutant loadings was calculated. The existing paved areas were assumed to be completely impervious, and the existing unpaved areas were assumed to have 100% infiltration and/or storage. A runoff flow of 0.093 cfs was calculated using the impervious site area (1.55 acres), an average rainfall intensity of 0.06 inches/hour and a runoff coefficient of 1. The resulting stormwater loads, shown in Table 22.11-3, represent the existing loads at the West 59th Street site.

Site delineations and study area boundaries are approximate.
Base Map Source: New York City Department of City Planning

Figure 22.11-2 Permitted Outfalls and CSO Locations

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

Table 22.11-3

Heavy Metals		
Copper µg/L	35	0.018
Lead µg/L	28	0.014
Zinc µg/L	154	0.077
Total Impervious Area (acre) = 1.55		Runoff Coefficient (C) = 1.00
Average Rainfall Intensity per Storm (inch/hour) = 0.06[2]		Runoff Volume (cfs) = 0.093

Notes:
(1) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
(2) Based on Central Park Rain Data (1969-2002); The National Climatic Data Center.

22.11.2 Future No-Build Conditions

Water quality would be expected to remain the same or improve. Water quality improvements would be due to the NYCDEP CSO Abatement Program, which will reduce untreated discharges to receiving waterways; nitrogen removal activities, which will reduce nitrogen loads from City WPCPs; and other programs. Stormwater loads from the existing site would not be expected to change, so no significant water quality impacts would be expected.

22.11.3 Potential Impacts with the West 59th Street Converted MTS

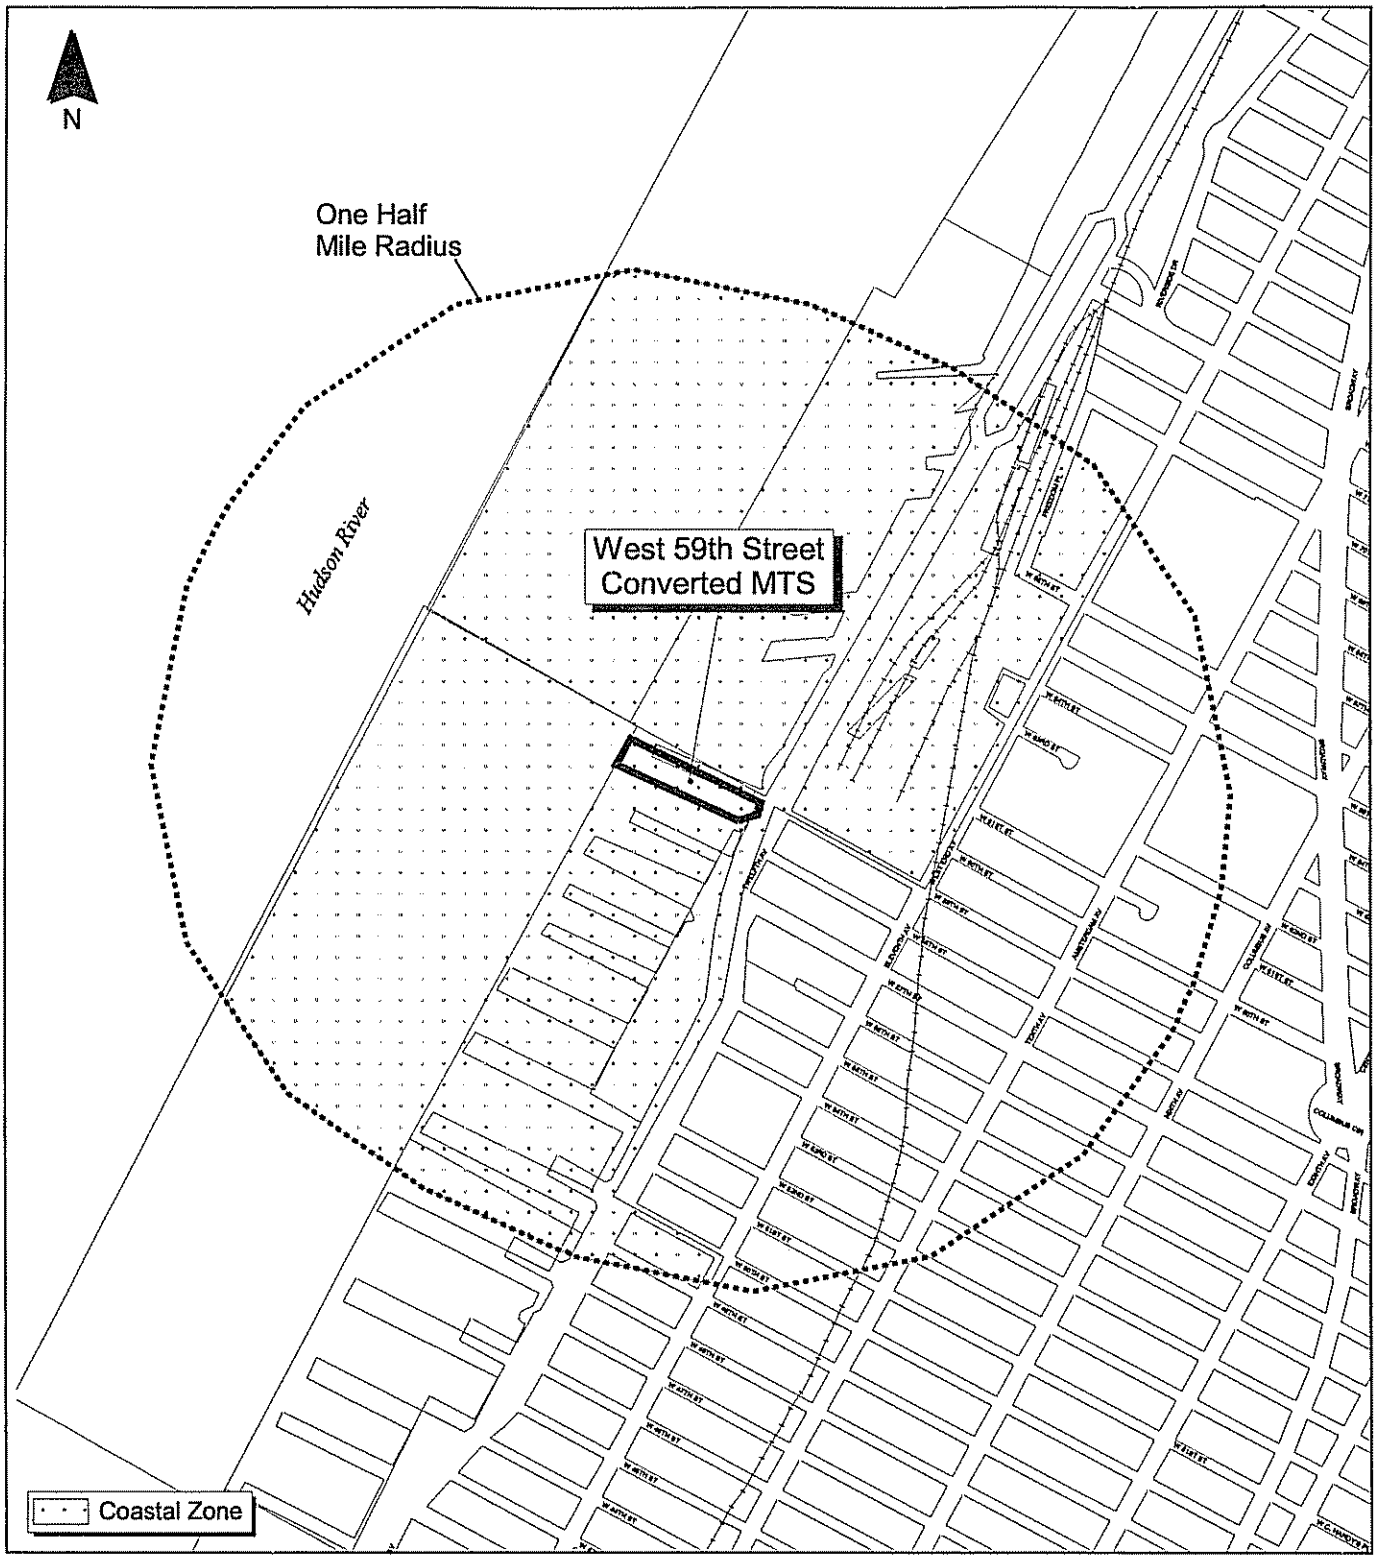
All solid waste processing at the West 59th Street Converted MTS would occur within structures on the site. All process wastewater from waste handling operations in the facility, such as washdown water, would be routed to an on-site pretreatment system (e.g., oil/water separation). After treatment, the process wastewater would be discharged to the municipal sewer system and, ultimately, to the North River WPCP, where it would be treated prior to discharge to the Hudson River and, therefore, would not adversely affect water quality.

Stormwater loads and impervious area, shown in Table 22.11-4 would be expected to increase above Existing Conditions. According to the 208 Model, however, the increased loads would have no significant impact on water quality in the adjacent surface waters.

Table 22.11-4
-Impervious Area and Estimated Pollutant Loads
West 59th Street Converted MTS

			Estimated Pollutant Loadings/Incremental Change[1]				
Conditions	**Total Impervious Area (acres)**	**Change in Impervious Area (acres)**	**Fecal Coliform[2]**	**BOD (lbs/day)**	**Copper (lbs/day)**	**Lead (lbs/day)**	**Zinc (lbs/day)**
Existing Conditions	1.55	0	17,010/NA	6/NA	0.018/NA	0.014/NA	0.077/NA
Future Build Conditions	2.19	0.64	24,044/7,034	8/2	0.025/0.007	0.020/0.006	0.109/0.032

Notes:
(1) Incremental change refers to difference in the pollutant loading between the Existing Conditions and Future Build Conditions.
(2) Coliform loads are not shown in lbs/day. Loading comparable to MPN/100 ml.
NA = Not Applicable



Unimpeded operation of the West 59th Street Converted MTS may also require dredging activities to construct the waterfront structures and improve existing water depths in the immediate vicinity of the site. All dredging activities would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any proposed dredging activities. Applicable and appropriate measures (e.g., closed clamshell buckets, silt curtains, etc.) would be implemented during any and all dredging activities to minimize and/or eliminate any short-term impacts to local water quality. Short-term impacts could include an increase in turbidity during active dredging operations; however, dredging would not result in any significant long-term impacts.

22.12 Waterfront Revitalization Program

22.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of the Hudson River, the West 59th Street Converted MTS would be within the City's coastal zone boundary (see Figure 22.12-1). According to "The New Waterfront Revitalization Program," the West 59th Street Converted MTS would be classified as a water-dependent, industrial use. The site is not within a designated SNWA or SMIA; it would be located within Reach 3/The West Side as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Manhattan Waterfront." The West 59th Street Converted MTS is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The West 59th Street Converted MTS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.1, 3.1, 4.4, 6.2, 6.3 and 8.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14.1. In instances where a component of the West 59th Street Converted MTS required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below. A description of waste handling operations that would occur at the West 59th Street Converted MTS is provided in Section 2.7.

Site delineations and study area boundaries are approximate.

22.12.2 Consistency Assessment

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the new West 59th Street Converted MTS. As part of the West 59th Street Converted MTS, connections from the new facility to existing utilities in the vicinity (e.g., sewer and electrical connections, etc.) would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.2 Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.

The existing West 59th Street MTS is not currently located within an NYCDCP-designated SMIA. The development of the West 59th Street Converted MTS would involve the demolition of the existing MTS and the development of a new, expanded processing building in approximately the same location. The West 59th Street Converted MTS would involve the conversion of the existing facility from a truck-to-barge waste transfer station into a TCB transfer station that would transport DSNY-managed Waste to remote out-of-City disposal facilities. Paper recycling activities allowing for the transport by barge to recycling facilities would also be incorporated.

The site redevelopment, as described in Section 2.7.2, would enhance existing waterfront industrial property and would be generally compatible with existing manufacturing, industrial and maritime uses in the vicinity. The majority of reconstruction activities would occur over water and would consist of four primary components: (1) an expanded, enclosed processing building which would include a tipping floor, loading floor and pier level; (2) a new elevated access ramp with accompanying retaining walls to the truck gallery; (3) a gantry crane, outside of the processing building along the southern waterfront of the proposed pier; and (4) new bulkheads and fendering systems that may be required for the new facility. The West 59th Street Converted MTS would generally be consistent with existing land uses along the waterfront and with the "Plan for the Manhattan Waterfront," which recommends the continued industrial use of the pier. Although it would not encourage or facilitate the siting of any additional water-dependent uses, the West 59th Street Converted MTS would represent an expansion and revitalization of an existing water-dependent use and would be compatible with surrounding uses. Therefore, the West 59th Street Converted MTS would be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The West 59th Street Converted MTS would involve the demolition of the existing MTS and the subsequent development of a new TCB transfer station at the site. Its development would allow for the truck delivery of waste to the MTS, where it would be transferred into sealed containers, loaded onto DSNY barges and transported by barges to out-of-City disposal facilities. In addition, once construction efforts were completed, paper recycling activities would continue in a manner similar to existing paper recycling operations at the site.

Waterfront development would be comprised of four primary components: (1) an expanded, enclosed processing building which would include a tipping floor, loading floor and pier level; (2) a new elevated access ramp with accompanying

retaining walls to the truck gallery; (3) a gantry crane, outside of the processing building along the southern waterfront of the proposed pier; and (4) new bulkheads and fendering systems that may be required for the new facility.

The West 59th Street Converted MTS would require dredging to improve existing water depths at and in the immediate vicinity of the site and allow for the unimpeded operation of barges and tugboats once it became operational. All required dredging would be conducted in compliance with applicable federal, state and local regulations and required permits would be acquired prior to any proposed dredging activities.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

Development of the West 59th Street Converted MTS would involve the expansion of an existing waterfront use and would not interfere with any maritime industrial, commercial or recreational vessel activities in the area. Activities resulting from the West 59th Street Converted MTS within this portion of the Hudson River would be limited to barge loading along the pier level and the periodic swapping of loaded barges along the southern bulkhead of the new MTS. Approximately four or five barges would be filled on a daily basis. These swapping activities would be in close proximity to the West 59th Street Converted MTS. Therefore, there would be no anticipated impact on other uses within the water body. In addition, barge movements associated with paper recycling operation at the westernmost portion of the pier would be comparable to current activities. Therefore, the West 59th Street Converted MTS would be consistent with this subpolicy.

3.3 Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The West 59th Street Converted MTS would involved the conversion of an existing truck-to-barge system where loose waste was placed in open barges, into a TCB transfer station where waste was transferred into containers that would be sealed and placed into flat deck barges that would transport DSNY-managed Waste to out-of-City disposal locations and, therefore, would be protective of the aquatic environment and surrounding land and water uses. All solid waste handling would occur within an enclosed processing building. All waste would be placed in sealed containers before leaving the building for loading on barges. Paper recycling activities would continue in a manner similar to existing paper recycling operations at the site. Paper would be placed in open-top barges, netted and transported to recycling facilities.

Inside the facility, several measures would be taken to minimize the potential for environmental degradation as a result of the facility. Building ventilation would be maintained under negative pressure, which would maintain dust inside the enclosed processing building. Additional dust, odor and vector control systems would be used to minimize impacts to the surrounding environment. Litter control methods, such as routine sweeping and washing of the tipping floor, would be implemented to minimize or eliminate the potential for litter entering surface waters. All process wastewaters generated on site (e.g. washdown waters, etc.) would be treated prior to their discharge to the municipal sewer system. In addition, on-site storage of petroleum products and hazardous materials related to the operation of the West 59th Street Converted MTS would be done in accordance with applicable federal, state and local regulations. The West 59th Street Converted MTS would be consistent with this subpolicy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 *Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.*

Based upon a review of SNWAs, as described in "The New Waterfront Revitalization Program", as well as Recognized Ecological Complexes, the West 59th Street Converted MTS would not be within a designated area. SCFWH information maintained by the New York State Department of State indicates that the West 59th Street Converted MTS would be located with the Lower Hudson Reach SCFWH.

The development of the West 59th Street Converted MTS would involve the demolition of the existing MTS and development of a new, expanded processing building that would incorporate existing paper recycling operations at the site. Construction of the Converted MTS would include dredging within the Hudson River to improve existing water depths at and in the immediate vicinity of the site in order to allow for unimpeded barge and tugboat operations. The West 59th Street Converted MTS would represent an expansion of an existing previous use and would not be anticipated to significantly impact natural resources in the vicinity of the site. The West 59th Street Converted MTS would, therefore, be consistent with this subpolicy.

4.2 *Protect and restore tidal and freshwater wetlands.*

A review of NYSDEC tidal and freshwater wetland maps was conducted in order to determine the presence of wetlands within the project site. As noted in Section 22.14.1, the West 59th Street Converted MTS would be located on the Hudson River, a NYSDEC-designated littoral zone. No freshwater wetlands exist on the site. The West 59th Street Converted MTS would involve the demolition and subsequent construction of a TCB transfer station that would incorporate the existing paper recycling operation. Dredging would also be required to improve

existing water depths at and in the immediate vicinity of the site to allow for the unimpeded operation of barges and tugboats. Dredging activities associated with the construction of the new facility would result in limited, short-term impact to these tidal wetlands.

The West 59th Street Converted MTS is not anticipated to have significant impacts on wetland areas in the vicinity due to existing water depths in excess of six feet at mean low water, previous and ongoing activities at and in the vicinity of the site and previous dredging activities that have historically occurred at the existing MTS. Mitigation for potential impacts would be proposed during the environmental review and permitting of the West 59th Street Converted MTS. This mitigation, if required, would address potential impacts that may occur due to the West 59th Street Converted MTS and would effectively restore these wetlands and their associated value. The West 59th Street Converted MTS would, therefore, be consistent with this subpolicy.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

A review of the NYSDEC NHP database indicated the Common Nighthawk (*Chordeiles minor*) as a species suspected of breeding in the vicinity of the site. The Common Nighthawk is classified by the state as a Protected Special Concern species.

As part of the West 59th Street Converted MTS, the existing MTS and its support pilings would be removed as part of the demolition activities. Dredging will be necessary to allow for the unimpeded operation of barges and tugboats. As stated in Section 22.13.3, modifications to the site would pose little, if any, adverse ecological impacts or loss of habitat for rare or endangered species due to previous and ongoing industrial and dredging activities at and in the vicinity of the site. Sanitary and process wastewaters would be routed to on-site treatment

systems and would then be discharged to the municipal sewer system. Stormwater runoff from the West 59th Street Converted MTS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. Further, the West 59th Street Converted MTS would not introduce hazardous wastes or other pollutants into the environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The West 59th Street Converted MTS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site treatment system, which would consist of oil/water separators, etc., discharging eventually to the municipal sewer system. In addition, the slope of the tipping floor would prevent the build-up of free liquids by directing all liquids to drains. Stormwater runoff from the West 59th Street Converted MTS would be managed in accordance with all applicable federal, state and local regulations.

In addition, the majority of activity associated with the West 59th Street Converted MTS would be conducted within an enclosed processing building. Only sealed, air- and watertight containers would be transferred to barges outside of the processing building by gantry cranes installed at the pier level. Inside the facility, several measures would be taken to minimize the potential for environmental degradation as a result of the facility. Building ventilation would be maintained under negative pressure, which is intended to keep dust inside the enclosed processing building. Litter control methods such as routine sweeping and washing of the tipping floor would be implemented to minimize or eliminate the potential for litter entering surface waters. Therefore, the West 59th Street Converted MTS would be consistent with this subpolicy.

5.2 *Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.*

BMPs would be used to the extent possible during all phases of construction and operation of the West 59th Street Converted MTS in order to minimize any nonpoint discharges. The West 59th Street Converted MTS would comply with federal, state and local requirements concerning the management of stormwater runoff and erosion. All handling and containerization of solid waste would be conducted within an enclosed processing building. During construction, non-structural and, if necessary, structural, measures would be used to minimize nonpoint source pollution.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

Dredging would be necessary to provide sufficient water depths for unimpeded operations once the West 59th Street Converted MTS were operational, as well as to construct its expanded pier structure. Any dredging done as part of construction would result in temporary impacts and would be conducted in a manner to minimize siltation, erosion and other short-term impacts to water quality. To the extent practical, non-structural and, if necessary, structural, measures would be used to minimize siltation and potential adverse impacts to tidal wetlands in the vicinity. All dredged materials would be disposed of at a permitted upland facility in accordance with applicable federal, state and local regulations. Therefore, the West 59th Street Converted MTS would be consistent with this subpolicy.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The West 59th Street Converted MTS would have no impact on the quality or quantity of surface or ground waters. Process wastewaters (e.g. washdown

waters, etc.) would be conveyed to an on-site treatment system and would then discharge to the municipal sewer system. Stormwater runoff from the facility would be managed in accordance with all applicable federal, state and local regulations. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer or water supply. The West 59th Street Converted MTS would be consistent with this policy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

According to a review of the FEMA National Flood Insurance Program maps, the West 59th Street Converted MTS would be is located in a section of Zone C (outside of the 100-year and 500-year floodplains). The existing MTS would be demolished and the West 59th Street Converted MTS would be constructed at approximately the same location. Dredging would be required as part of the activity to allow for unimpeded barge operations at the site. Improvements to the existing bulkhead may also be required. Construction of the West 59th Street Converted MTS would not affect the potential for flooding or erosion. All structures would comply with applicable building code requirements. To the extent practicable, non-structural and, if necessary, structural, measures would be used to minimize damage from flooding and erosion during the demolition of the existing MTS and subsequent construction of the West 59th Street Converted MTS.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The West 59th Street Converted MTS would not involve the storage, treatment or disposal of hazardous waste, but would facilitate the management and processing of solid waste through a TCB system and marine transport to out-of-City disposal sites. Recyclable paper would also continue to be handled by the facility. Unless emergencies close the facility, solid waste would generally be containerized within 24 hours of tipping. All solid waste handling operations would be conducted in accordance with NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the West 59th Street Converted MTS. The majority of activities would occur within an enclosed processing building. Only sealed, air- and watertight containers would be utilized outside of the facility. Radiation detection equipment would be located at the facility, and contingency plans would be in place in the event of unauthorized waste and/or other situations that could disrupt the operation of the facility.

On-site storage of petroleum or hazardous materials related to the operation of the West 59th Street Converted MTS would be minimal. All storage would be in accordance with applicable federal, state and local regulations. The West 59th Street Converted MTS would be operated in a manner to ensure that there would be no impact to ground and surface water supplies, significant fish and wildlife habitats, recreational areas and scenic resources.

7.2 Prevent and remediate discharge of petroleum products.

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

Due to the existing industrial uses at and in the immediate vicinity of the West 59th Street Converted MTS, public access would not be compatible with the principal use of the site. Therefore, this subpolicy is not applicable.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The West 59th Street Converted MTS would be a stand-alone, water-dependent, industrial facility on the Hudson River. Public access would not be compatible with the West 59th Street Converted MTS; however, its development would not preclude any future development of public access at other locations along the Hudson River that have been identified for potential public access sites.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

The West 59th Street Converted MTS site would be considered an expansion of an existing waterfront use and would not impair visual access to coastal lands, waters or open space. See also response to Subpolicy 22.1.

8.4 Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

Due to its isolated location to the west of the West Side Highway, it is not anticipated that the West 59th Street Converted MTS would have a significant impact on any open space resources within the study area. Furthermore, the development of the West 59th Street Converted MTS would not preclude development of waterfront parks to either the north or south. Therefore, it would be consistent with this subpolicy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The West 59th Street Converted MTS would be an expansion and rehabilitation of an existing waterfront use and would be compatible with the existing urban design context and visual conditions of this portion of the Hudson River Waterfront, as noted in Section 9.7. Based on the information presented in that section, the West 59th Street Converted MTS would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The West 59th Street Converted MTS would pose no impact to scenic values associated with natural resources. Therefore, this subpolicy is not applicable.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

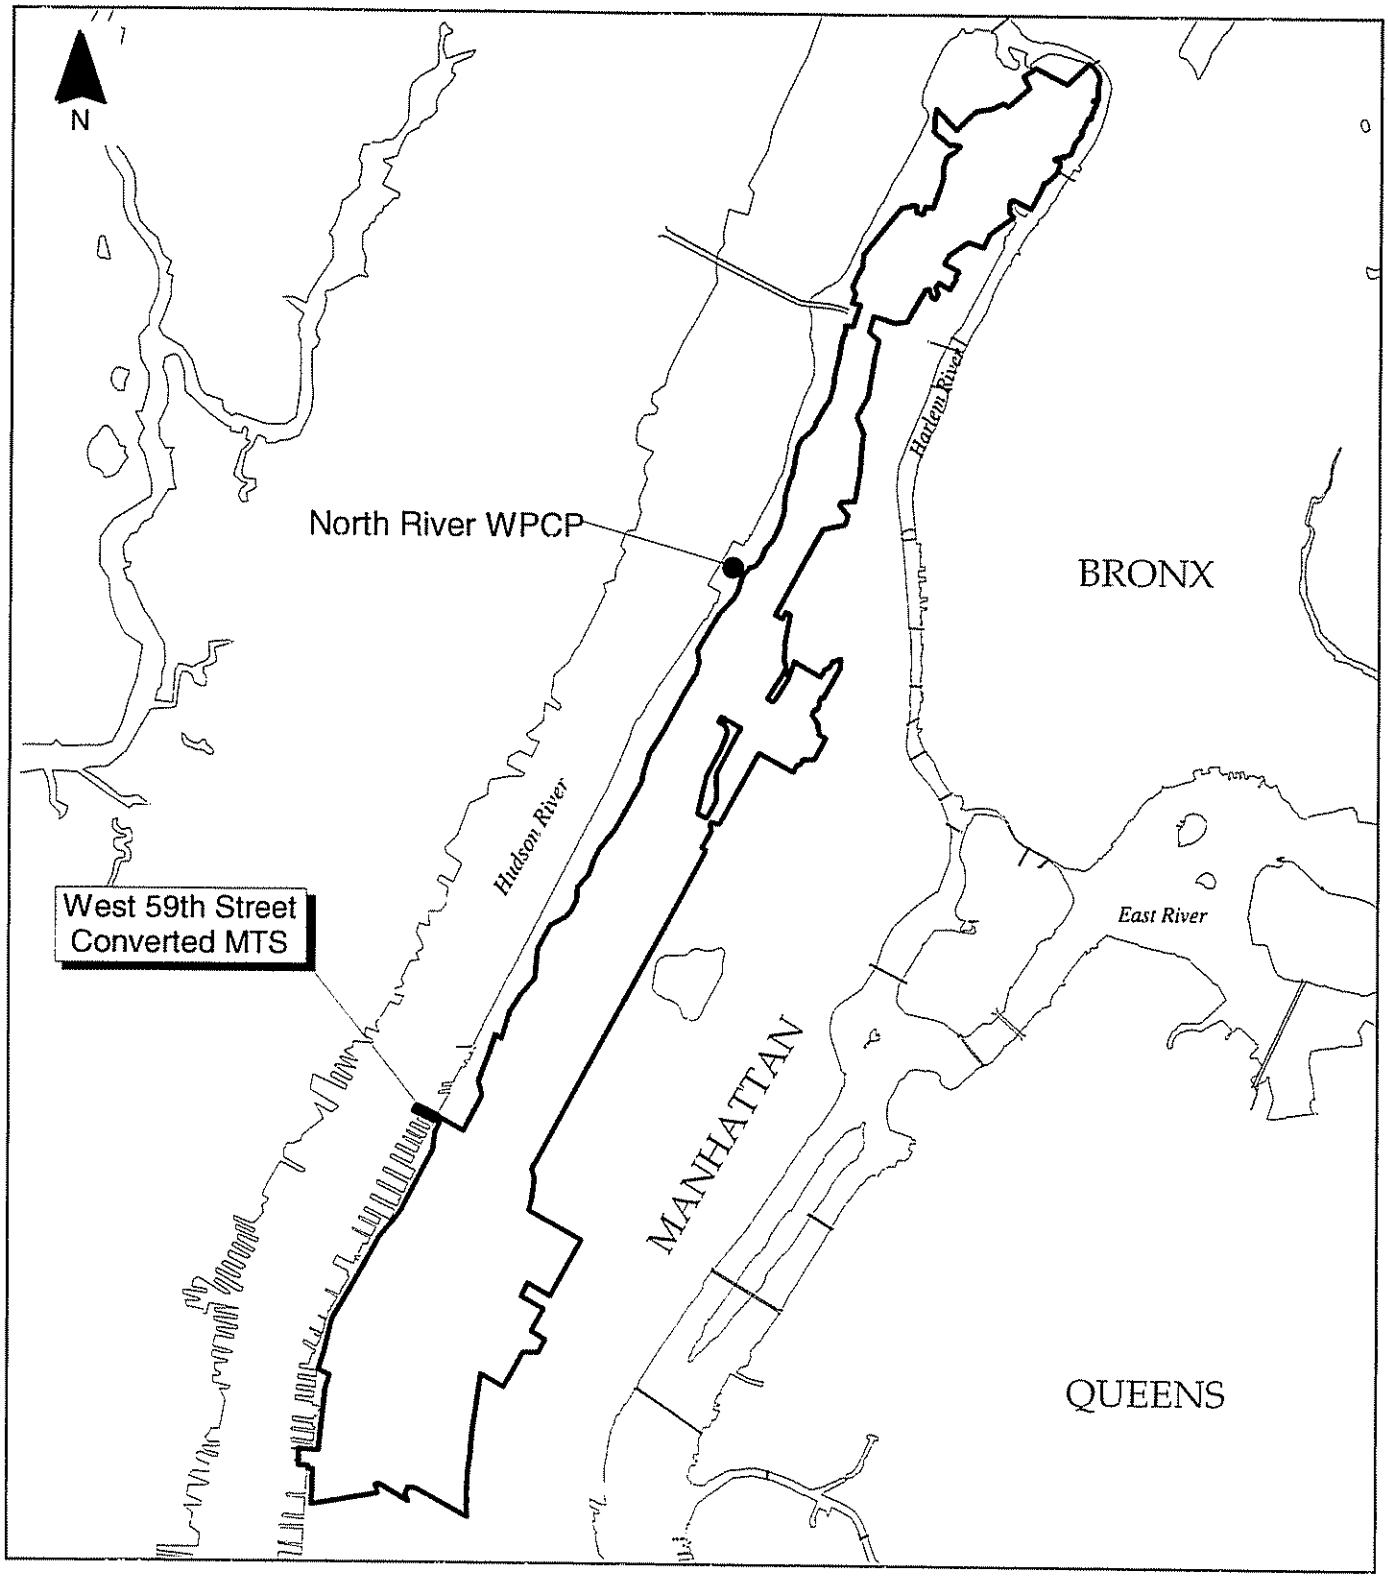
10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

The West 59th Street Converted MTS would have no effect on any cultural resources on or near the site, as noted in Section 22.6.3. Based on the information presented in that section, the West 59th Street Converted MTS would be consistent with this subpolicy.

10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site or in the study area. This subpolicy, therefore, is not applicable.

22.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



Existing Conditions

22.13.1.1 Water Supply

Water is supplied to the existing West 59th Street MTS from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. A 16-inch-diameter pipe along West 59th Street provides potable water for both consumption and sanitary requirements. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual). To ensure that adequate pressure is provided on site, the potable and fire water systems are currently supplemented with a pump.

22.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the North River WPCP, which serves west Manhattan from Chelsea to Inwood. The WPCP drainage area is illustrated in Figure 22.13-1. From July 2002 through June 2003, the North River WPCP treated an average of 124 mgd of wastewater under dry weather flow conditions and an average flow of 133 mgd which include the sanitary and stormwater flows received by the WPCP during wet weather (see Table 22.13-1). The maximum dry weather flow during this period was 130 mgd during August 2002 and June 2003 and the maximum average flow was 149 mdg during June 2003. Effluent from the plant is discharged into the Hudson River and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the North River WPCP is 170 mgd. It is estimated that current on-site employee water usage is about 475 gpd. This estimate is based on the current staff of 19 employees using 25 gallons per person, per day (2001 CEQR Technical Manual). In addition, approximately 180 gpd of potable water is used for tipping floor washdown and dust control. Total existing water usage is approximately 655 gpd.

Site delineations are approximate

Average Monthly Dry Weather and Average Flows
North River Water Pollution Control Plant
Fiscal Year 2003

Month	Dry Weather Flow (mgd)	Average Monthly Flow-(1) (mgd)
July 2002	127	129
August	130	137
September	124	135
October	121	140
November	118	130
December	120	128
January 2003	119	125
February	125	129
March	122	130
April	128	134
May	122	129
June	130	149
Average Effluent	**124**	**133**

Note:
(1) Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

A 12-inch-diameter sewer on West 59th Street and 12th Avenue serves the site. The sewer is connected to a 10.5-foot, square interceptor line (combined sanitary and stormwater system) that runs north along Riverside Drive where waste is directed to the North River WPCP. Stormwater runoff from the existing MTS parking area and ramp are routed to catch basins that discharge to the combined sewer system.

22.13.1.3 Solid Waste

Based on solid waste generation information from the 2001 CEQR Technical Manual, it was estimated that each employee at the existing MTS produces approximately nine pounds of solid waste per week for a facility total of 171 pounds per week (approximately 25 pounds per day). The solid waste is collected by DSNY personnel and transported by truck to an appropriately licensed solid waste management facility.

22.13.1.4 Energy

Electricity to the facility is provided by Consolidated Edison of New York. A review of applicable utility plans shows lines along West 59th Street and 12th Avenue with the existing MTS service connected to the Consolidated Edison system at the intersection of 12th Avenue and West 59th Street. The West 59th Street MTS utilized 0.24E + 10 BTU during FY 2002 (i.e., July 2001 through June 2002) based on operations information provided by DSNY. No gas is currently supplied to the facility.

22.13.2 Future No-Build Conditions

The existing West 59th Street MTS would continue to operate as it does today. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near Existing Conditions levels for security employees. Wastewater flows to the North River WPCP would continue to increase and would be projected to be 135.1 mgd by 2006.

22.13.3 Potential Impacts with the West 59th Street Converted MTS

22.13.3.1 Water Supply

The West 59th Street Converted MTS would have a total of up to 60 employees working three shifts per day. They would require approximately 1,500 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. The combined total usage of 3,300 gpd of potable water would represent an increase of 2,645 gpd above current consumption levels.

The West 59th Street Converted MTS would have no impact on the existing system's ability to supply water reliably. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

22.13.3.2 Sanitary Sewage

Based on the estimated water usage of 3,300 gpd for the West 59th Street Converted MTS, the small quantities of wastewater sent to the North River WPCP would not significantly impact the sewage flow rate or the ability of the North River WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 135.1 mgd in 2006, which would be well below the permitted capacity of 170 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in combined sewer overflows (CSO).

22.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 60 facility employees per day, 468 pounds of solid waste would be generated per week (78 lbs/day) and would represent an incremental increase of approximately 297 pounds per week (approximately 50 lbs/day) above current waste generation levels. This volume would be managed at the West 59th Street Converted MTS and would not significantly impact the system.

22.13.3.4 Energy

The West 59th Street Converted MTS would require an additional 5.48E+10 BTU/year of electricity to operate the facility. Natural gas heating would be used with an estimated demand of 2.00E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the West 59th Street Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity.

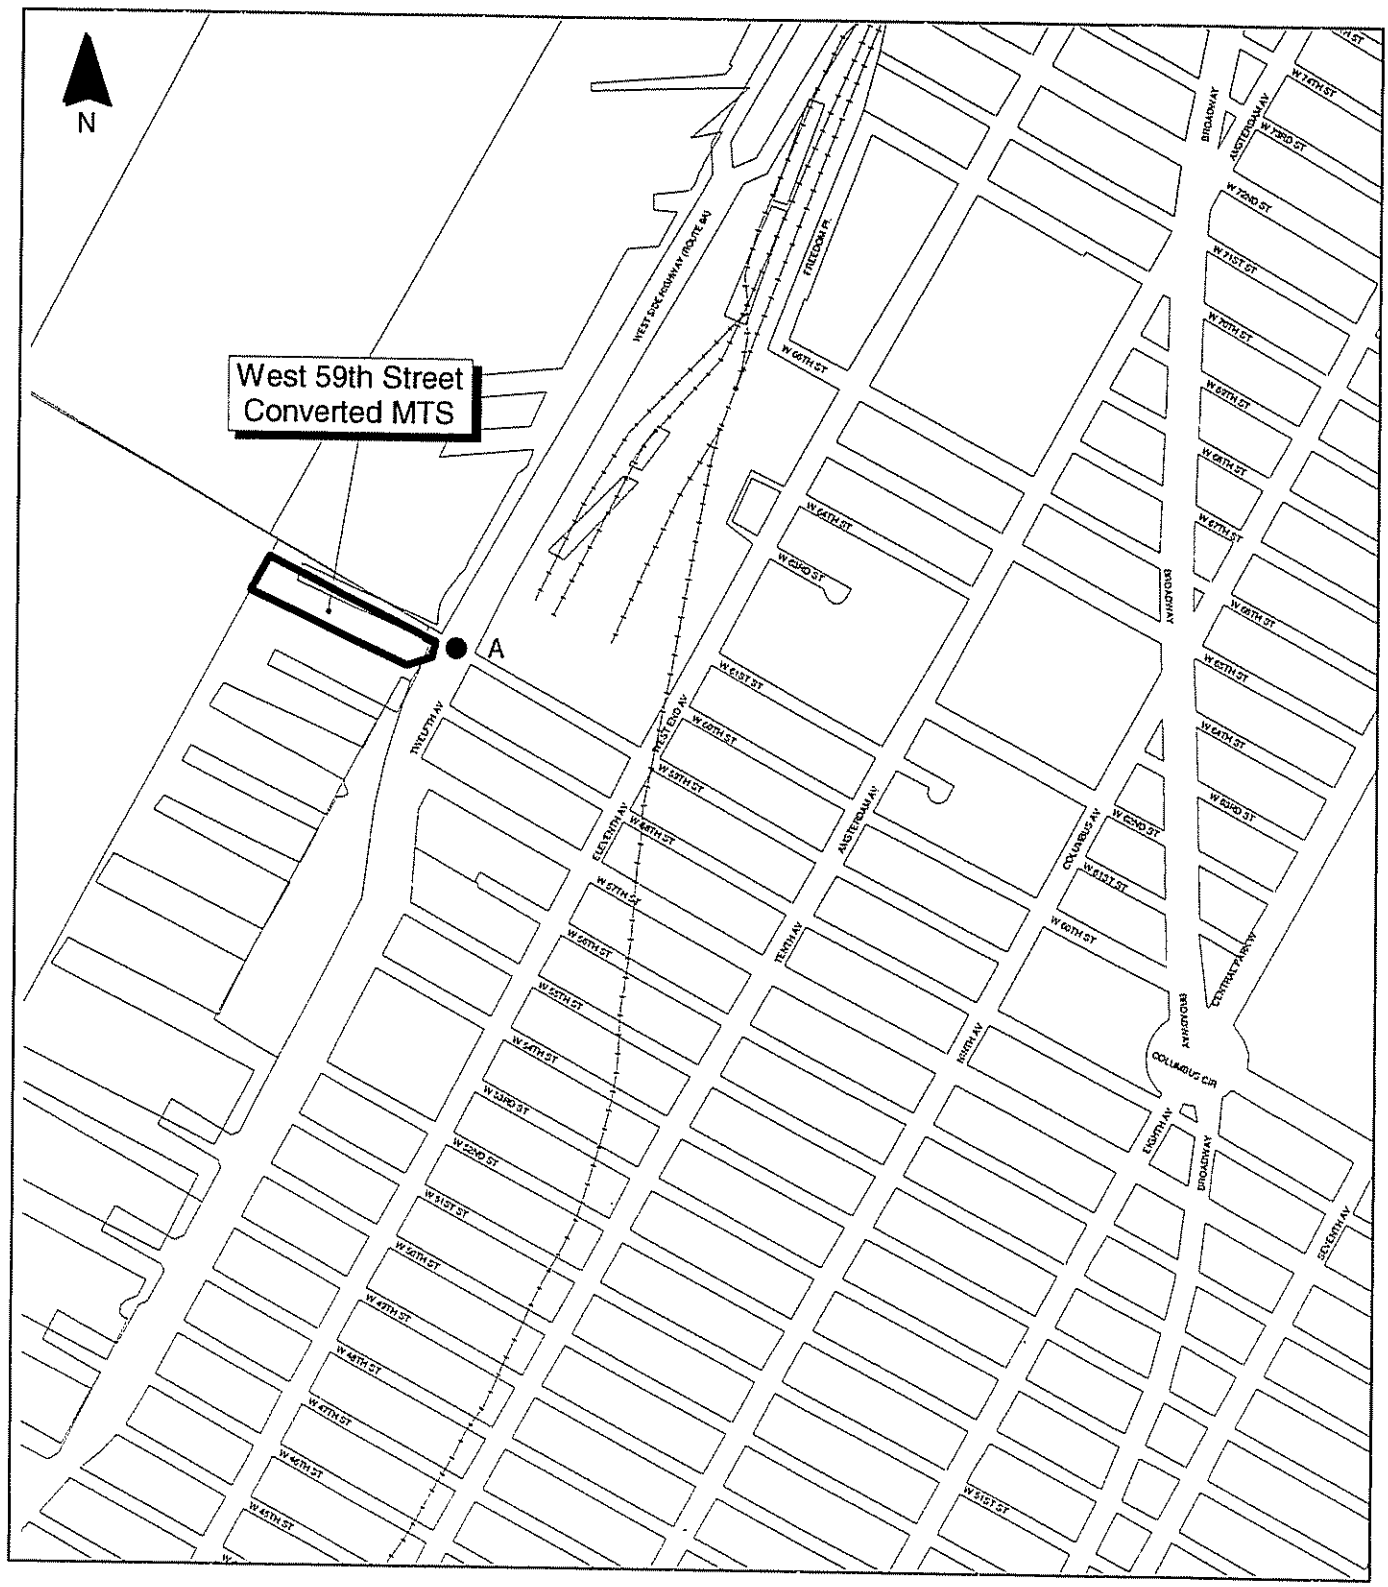
Consolidated Edison was also notified of the natural gas requirements of the West 59th Street Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts to the utility.

22.14 Traffic, Parking, Transit, and Pedestrians

22.14.1 Introduction

The West 59th Street Converted MTS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

22.14.2 Existing Conditions



22.14.2.1 Definition of Study Area

Based on the number of anticipated DSNY and other agency collection vehicles using this site, the traffic analysis study area is limited, and is focused primarily along 12th Avenue (Route 9A). This study area is a mix of light industrial, commercial and residential uses. There are no CEQR-defined areas of concern located within the study area. Figure 22.14-1 shows the locations of the intersections selected for analysis (location A). The intersections analyzed were selected using the procedures defined in Section 3.16.

All collection vehicles must access the site from West 59th Street. Westbound collection vehicles would approach the site along West 59th Street. Northbound collection vehicles would approach from the south via 12th Avenue and turn west onto West 59th Street. Section 22.14.2.2 further discusses the specific routes used by DSNY and other agency collection vehicles to access the West 59th Street Converted MTS.

22.14.2.2 Surface Network

One major highway, the West Side Highway/Henry Hudson Parkway (Route 9A), services the study area. Tenth Avenue, 11th Avenue, 12th Avenue and West 57th Street are local truck routes that provide access to and from the site. A map showing all major truck routes and local truck routes in Manhattan is provided in Section 3.16 (see Figure 3.16-4).

Site delineations are approximate

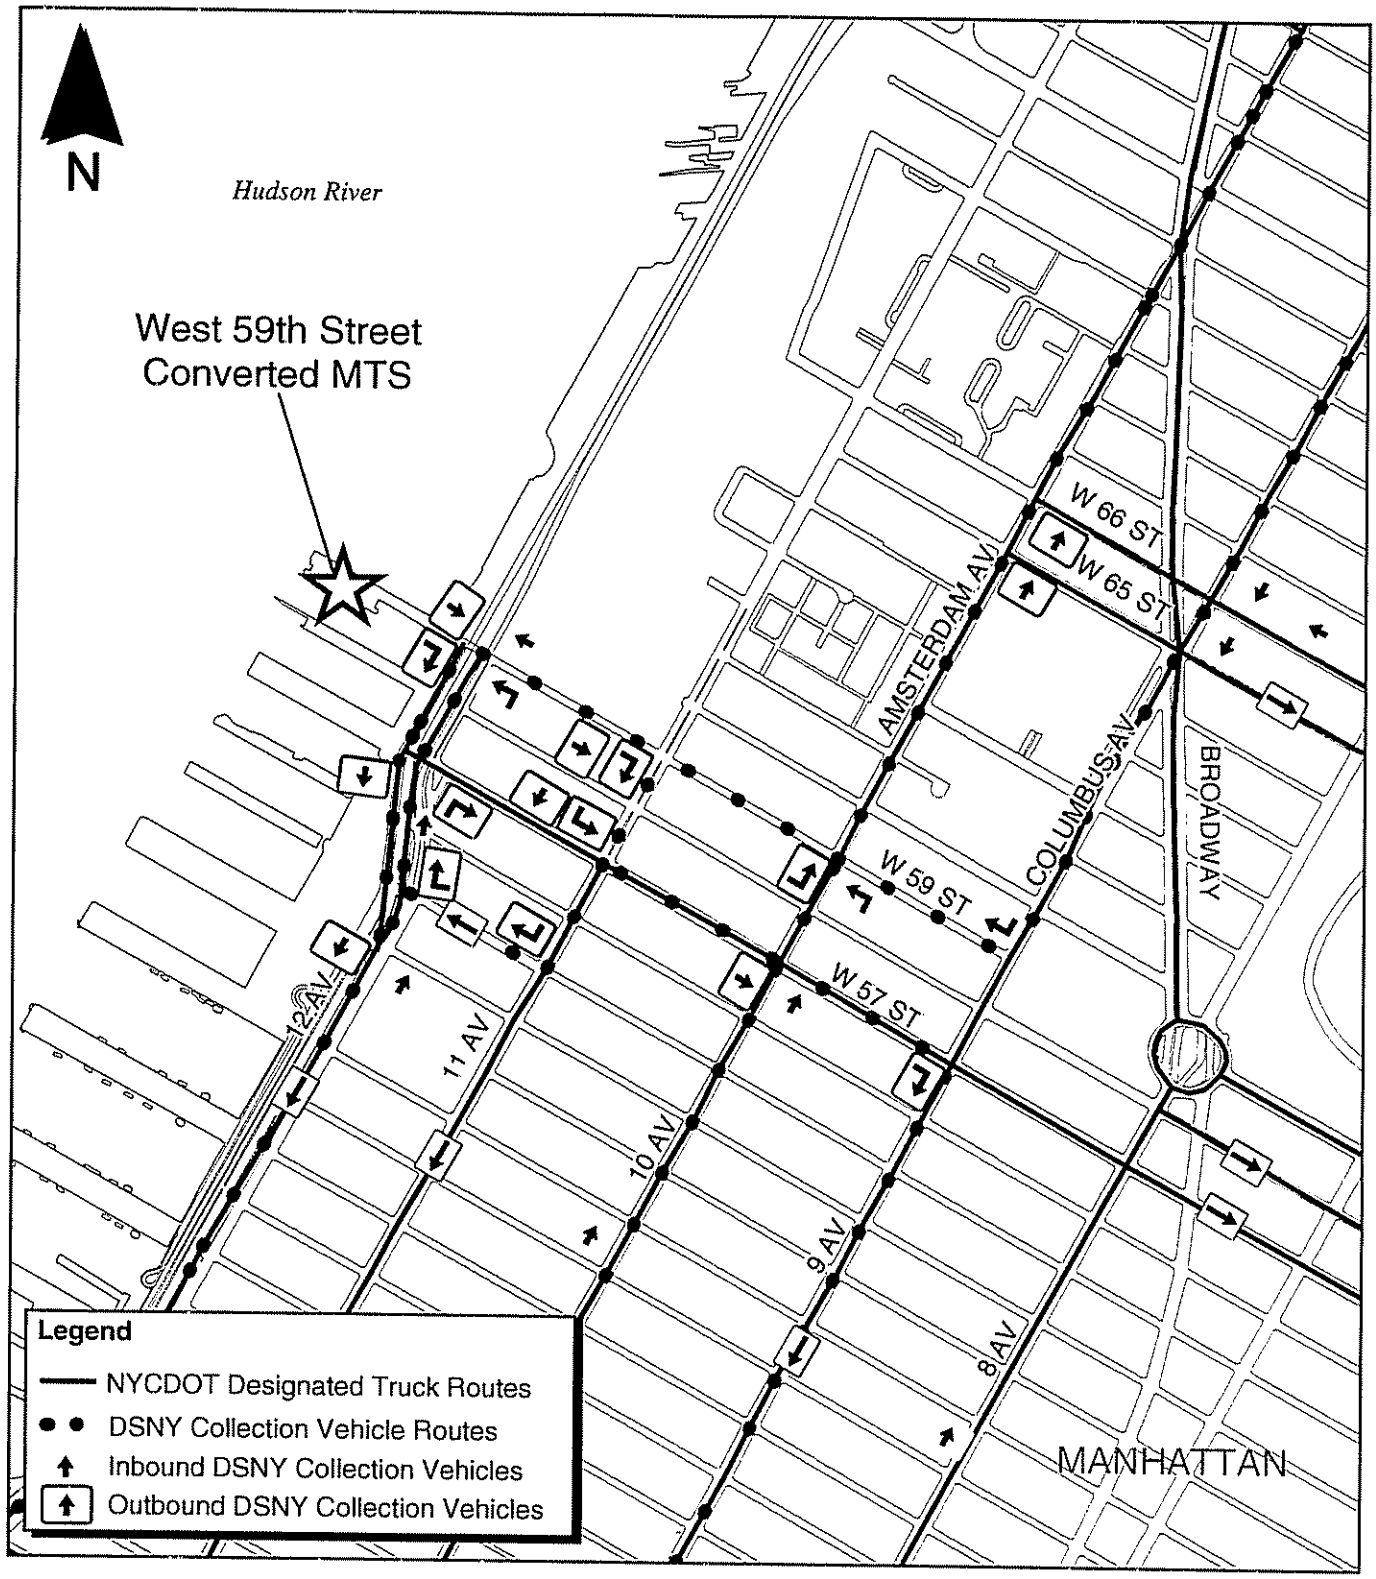
Figure 22.14-1 Traffic Analysis Study Area
West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION



Twelfth Avenue (West Side Highway – Route 9A) is a principal arterial that is the major west side access route from downtown Manhattan to all points north. West 59th Street is an east-west collector road for local traffic. Ninth Avenue, 11th Avenue and Columbus Avenue run southbound only in the vicinity of the site and 8th Avenue, 10th Avenue and Amsterdam Avenue run northbound only.

DSNY and other agency collection vehicles traveling north to the facility from lower Manhattan would use Route 9A and exit onto 12th Avenue at West 57th Street. Twelfth Avenue is divided in the vicinity of the site by Route 9A as it ramps up into an elevated highway. Vehicles traveling north to the facility from more local areas would follow 10th Avenue north to West 59th Street and then turn west to enter the facility. Vehicles traveling south to the facility would follow Columbus Avenue to West 59th Street. All vehicles entering the facility pass through the intersection of 12th Avenue (northbound and southbound) and West 59th Street. All exiting vehicles pass through the intersection of West 59th Street and 12th Avenue (southbound). DSNY and other agency collection vehicles returning north follow West 59th Street east to Amsterdam Avenue and then turn north. Vehicles returning to lower Manhattan turn south at the exit of the facility onto 12th Avenue and merge onto Route 9A near West 55th Street, while vehicles returning to local areas south of the Converted MTS follow West 59th Street east to either 11th Avenue or 9th Avenue and then proceed south. Figure 22.14-2 depicts NYCDOT designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

22.14.2.3 Existing Traffic Operations

The intersections listed below were identified for analysis because they are the most likely to be impacted from an increase in DSNY and other agency collection vehicle traffic to the West 59th Street Converted MTS. Both are on major arterials and/or collection vehicle routes. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Twelfth Avenue northbound and West 59th Street – Unsignalized Intersection (see Figure 22.14-1 – location A)
- Twelfth Avenue southbound and West 59th Street – Unsignalized Intersection (see Figure 22.14-1 – location A)

Twelfth Avenue (West Side Highway – Route 9A) is a principal arterial that is the major west side access route from downtown Manhattan to all points north. West 59th Street is an east-west collector road for local traffic.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted between February 11 and February 13, 2003, while ATR counts were conducted between February 10 and February 14, 2003. Figures 22.14-3 and 22.14-4 depict the existing traffic volumes for AM and PM peaks at the intersections analyzed (the Facility peak coincides with the AM peak, thus only two peak hours were analyzed for this site). The AM peak generally occurred between 8:45 a.m. and 9:45 a.m. and the PM peak between 3:45 p.m. and 4:45 p.m. Table 22.14-1 presents the v/c ratio, delay and LOS for the two intersections during the AM and PM peaks.

Existing truck traffic through these intersections was relatively low. The percentage of trucks was 9% during the morning hours, then decreased to 4% or lower during the PM peak hours.

EB = eastbound
WB = westbound

22.14.2.3.1 LOS at Signalized Intersections

No signalized intersections were analyzed.

22.14.2.3.2 LOS at Unsignalized Intersections

Table 22.14-1 shows that the unsignalized intersections generally operated at an overall LOS of A or B.

22.14.2.4 Existing DSNY-Related Traffic

The existing DSNY-related traffic in the vicinity of the West 59th Street Converted MTS is generated by DSNY and related facilities in the immediate study area, most notably the DSNY Manhattan CD 7 garage (West 57th Street at 12th Avenue). Within the study area, DSNY-related traffic is routed primarily along West End/11th Avenue, Amsterdam Avenue/10th Avenue, and West 57th Street.

22.14.2.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The "59th Street/Columbus Circle" station, located approximately ¾-mile to its east, is the closest subway stop to the site. Subway service on MTA's A, B, C, D, 1 and 2 lines is provided at this station. Two MTA bus lines, M31 and M57, provide service primarily along West 57th Street/York Avenue and West 57th Street/West End Avenue, respectively. There are no bus routes or bus stops located at either study intersection.

22.14.2.6 Pedestrian Activity

Pedestrian activity is generally moderate within the study area. Striped crosswalks are provided at major pedestrian crossings, including the bicycle/pedestrian path that is a part of the Hudson River Park.

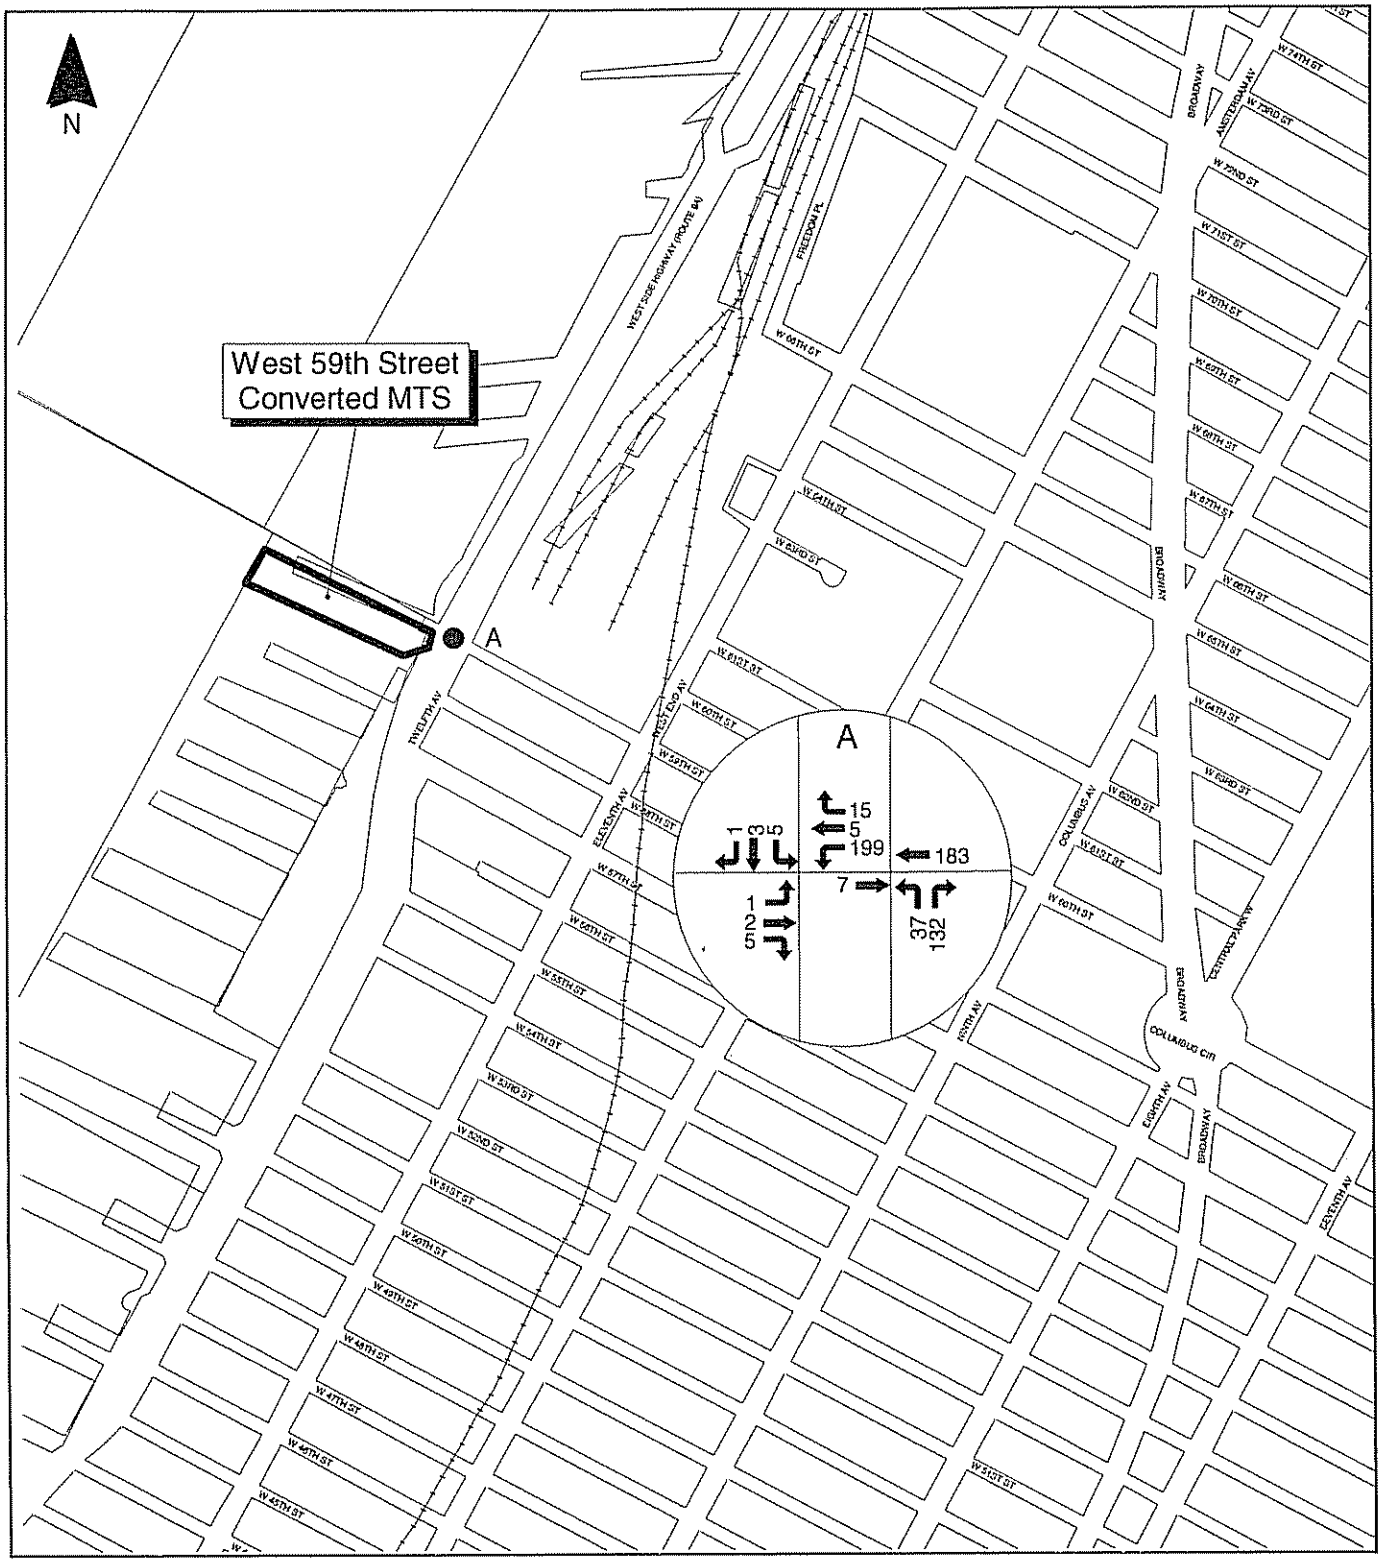
22.14.3 Future No-Build Conditions

22.14.3.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 0.5% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. In addition, additional traffic generated by proposed developments in the study expected to be completed by the Future No-Build year (2006) was also included. The following is a listing of the approved or in-process developments that are expected to generate significant volumes of traffic through the study area, and thus were specifically accounted for as part of this analysis:

- Hearst Tower (retail and offices);
- AOL Time Warner (residential, retail, offices, hotel and theater);
- Alvin Ailey Dance Foundation (studio/showroom and theater);
- River Center (residential, retail and community facility);
- Durst Organization, Scheme "C" (residential, retail, office and studio/showroom);

- Cambridge Development: 2 West End Avenue (residential and retail);
- Ginsberg Development: West 60th to West 61st Streets (residential);
- Glenwood Management: 1926 Broadway (residential and retail);
- Riverside South: West End Avenue, between 59th Street and 60th Street (residential, retail, community facility, park and studio/showroom);
- Sidney Fetner Associates: southwest corner of 10th Avenue and West 42nd Street (residential);
- Chinese Embassy: West 43rd Street between 10th and 11th Avenues (residential);
- 345 West 42nd Street (residential and retail);
- J.D. Carlyle Development: 12th Avenue and West 42nd Street (office);
- Douglas Durst: northeast corner of 9th Avenue and West 42nd Street (residential and retail);
- National Video Studio expansion: 10th Avenue and West 42nd Street (office); and
- Milstein: 8th Avenue and West 42nd Street (office).

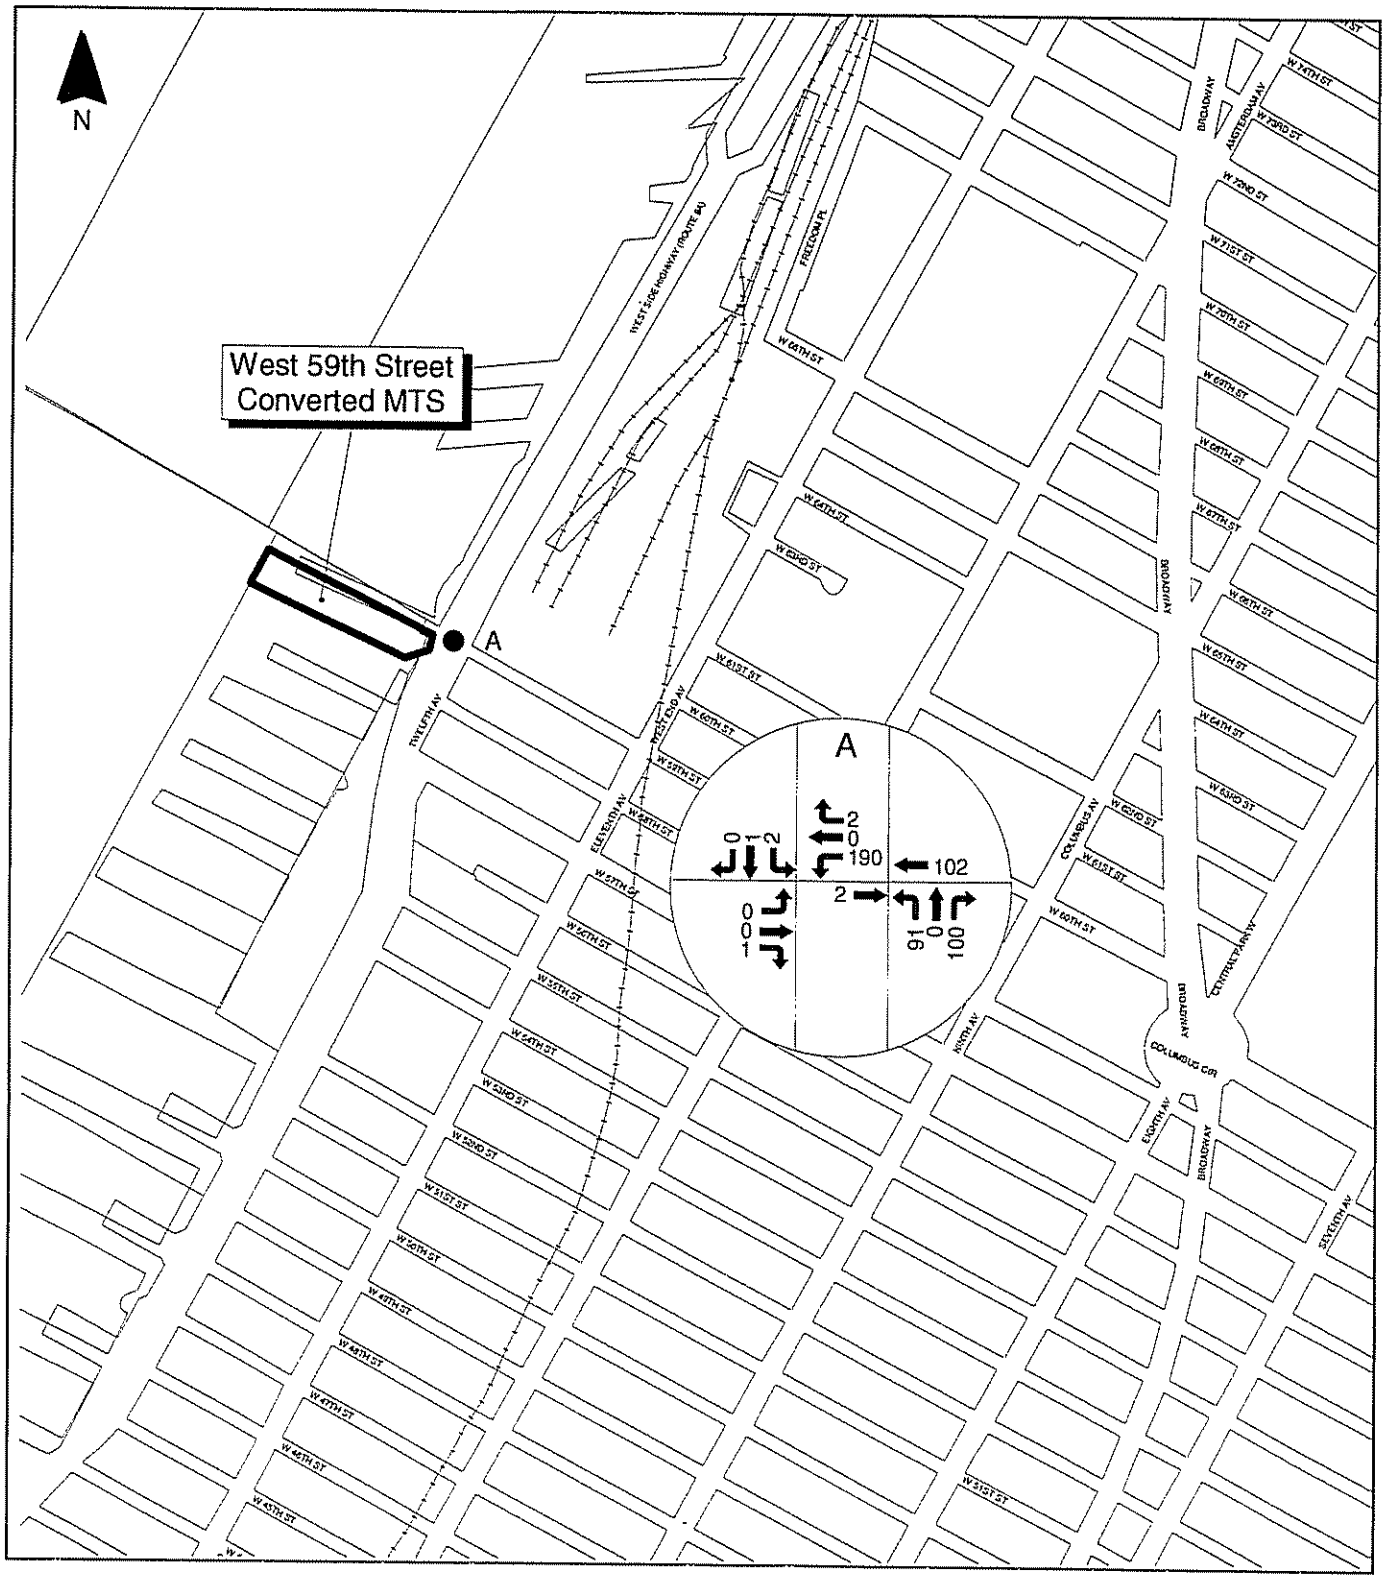


Figures 22.14-5 and 22.14-6 depict the Future No-Build traffic volumes for the AM and PM peaks at the intersections analyzed. Table 22.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, unsignalized intersections experienced relatively small increases in delay (less than 5 seconds) and are projected to remain at their existing condition LOS.

22.14.3.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

22.14.3.3 Pedestrian Activity



~~Future No-Build Conditions are expected to remain the same as Existing Conditions.~~Given imminent plans for completing Riverside Park South and for the construction of a greenway link between the Hudson and East River at Battery Park, it seems highly likely that more pedestrians and cyclists will travel through this area. ~~the West 59th Street Converted~~

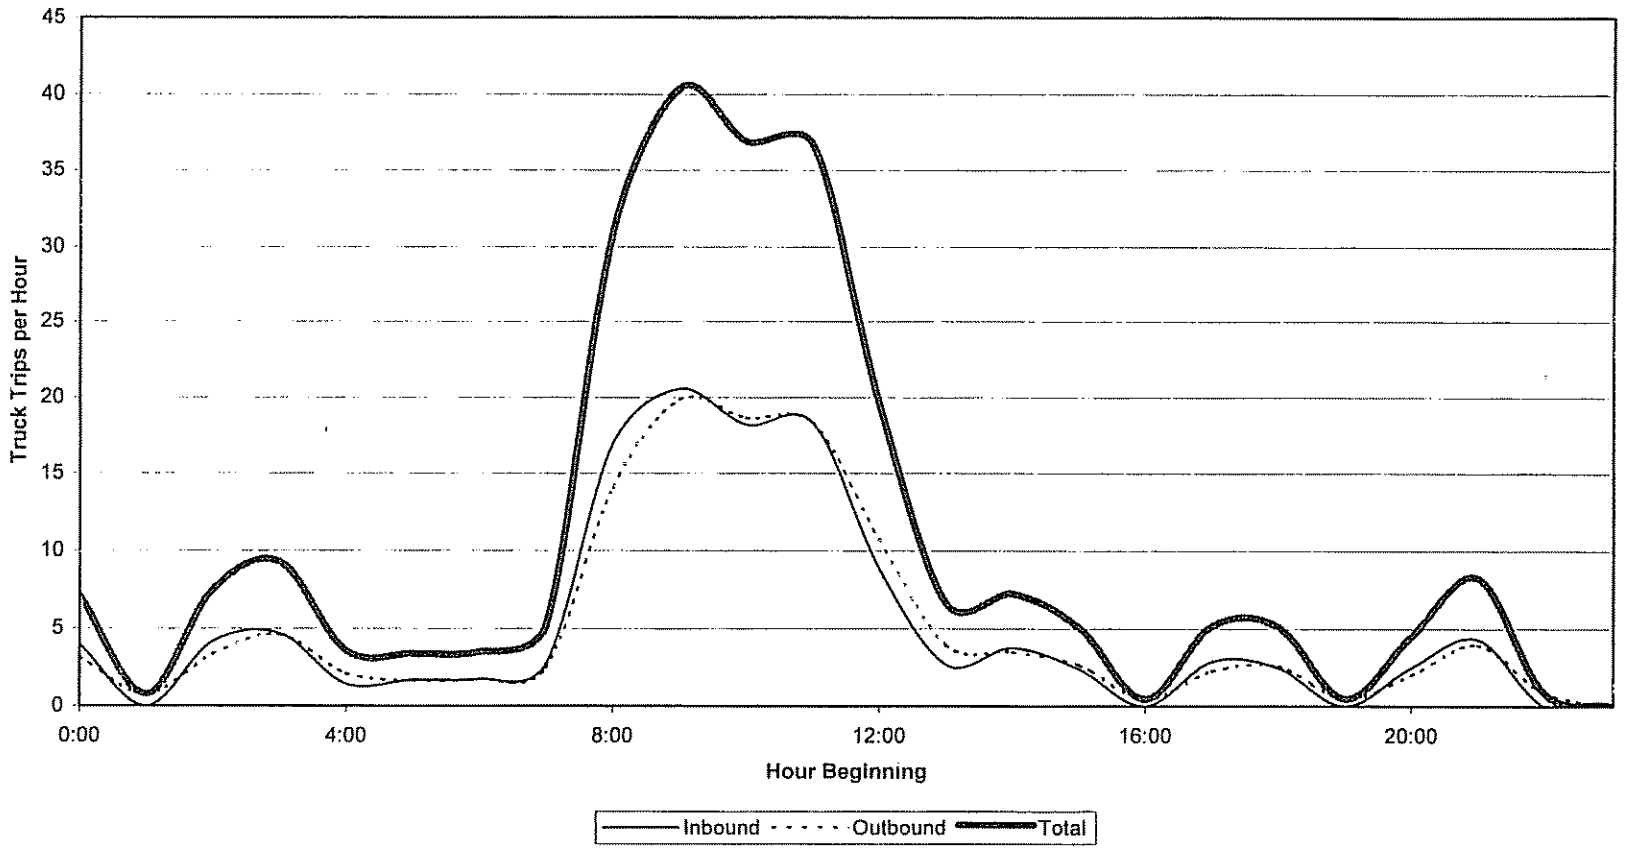
22.14.4 Potential Impacts with the West 59th Street Converted MTS



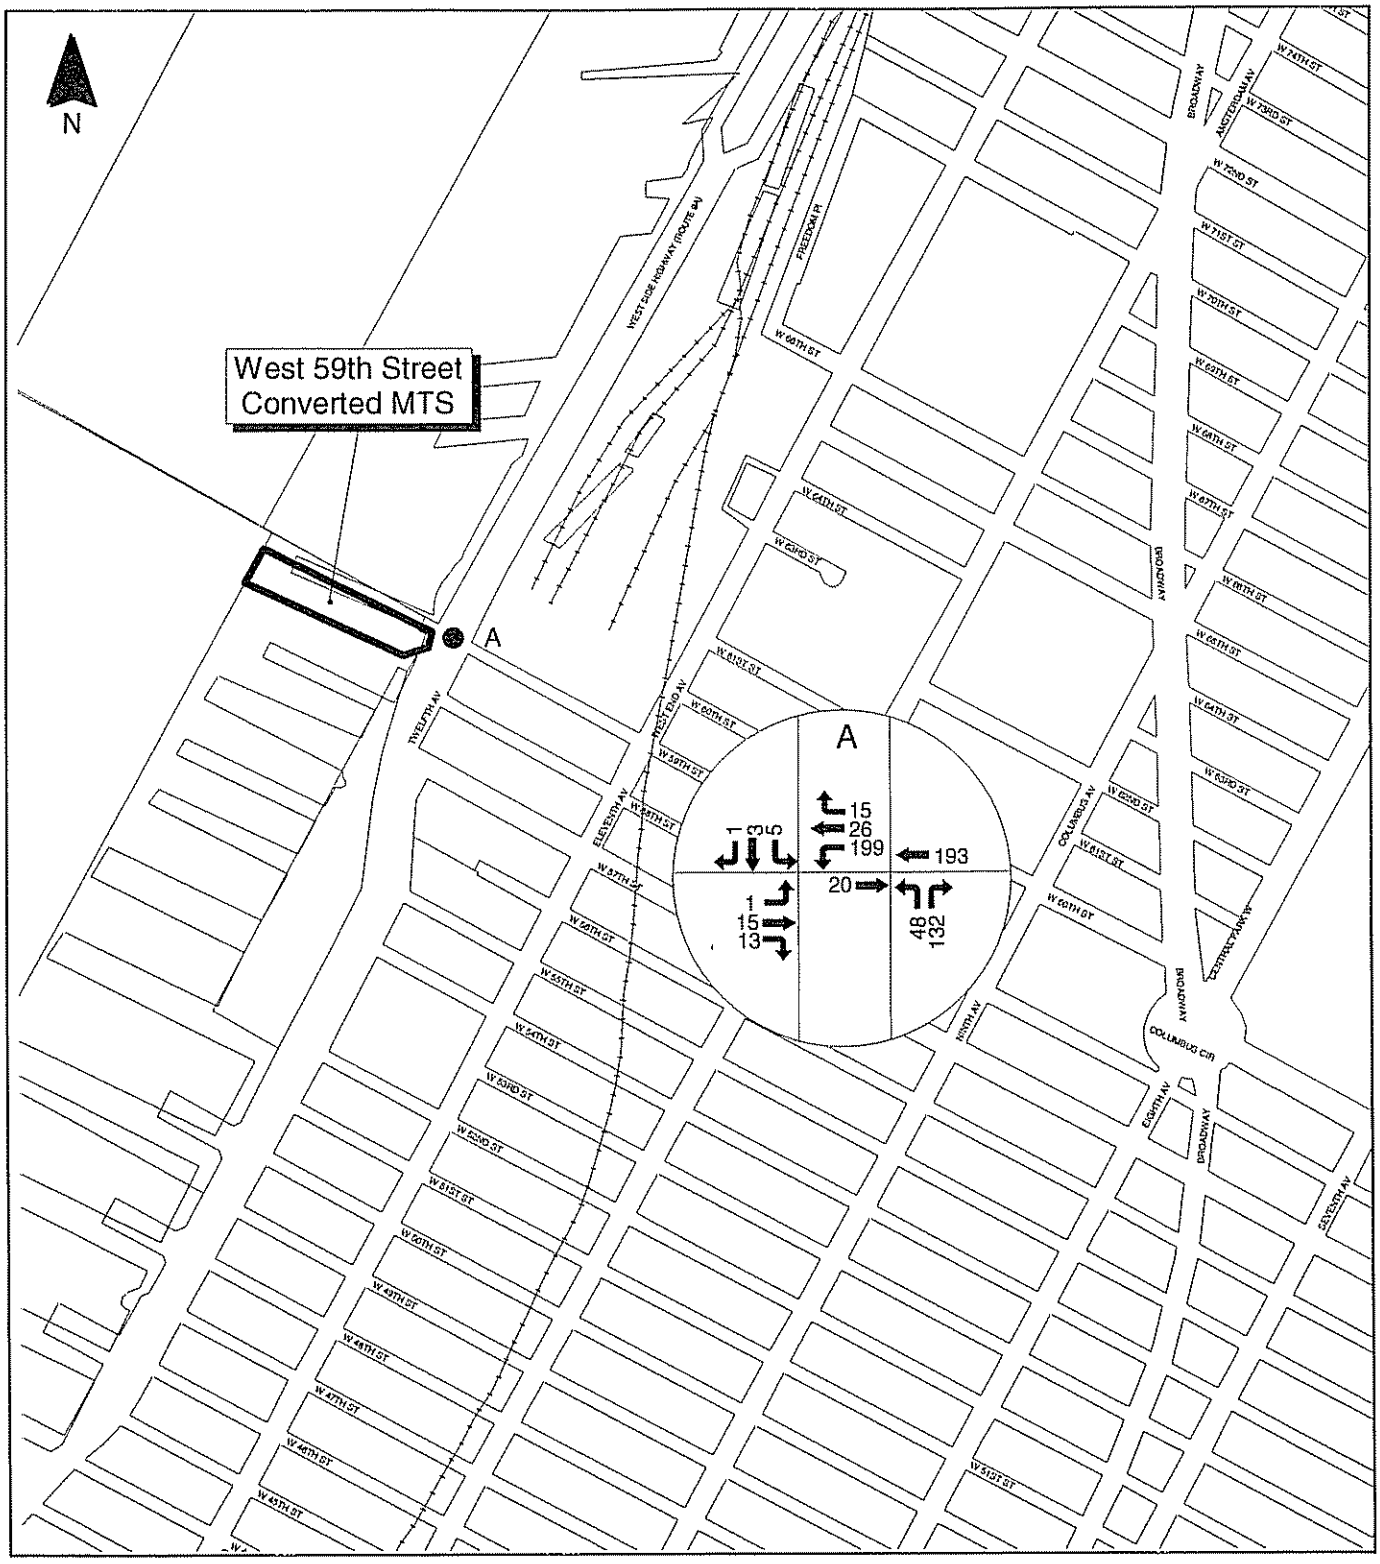
The West 59th Street Converted MTS would receive waste from five CDs in Manhattan - Manhattan CDs MN01 through MN04 and MN07. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours.

22.14.4.1 2006 Future Build Traffic Conditions

The 2006 Future Build Traffic Conditions assume that the West 59th Street Converted MTS would generate 124 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site or the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the West 59th Street Converted MTS are shown in Figure 22.14-2.

Figure 22.14-7 presents the average peak day temporal distribution of collection vehicles for the West 59th Street Converted MTS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the West 59th Street Converted MTS is expected to vary from approximately 0 to 10 truck trips per hour in the late evening/early morning, 5 to 42 truck trips per hour in the mid-morning/early afternoon, and 0 to 10 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (42) occurs at approximately 9:00 a.m.

Figure 22.14-7
Truck Trips per Hour
West 59th Street Converted MTS



Figures 22.14-8 and 22.14-9 show the intersections analyzed with the Future Build traffic levels. Figures 22.14-10 and 22.14-11 depict the net future traffic volumes added to the Future No-Build Conditions to generate Future Build Conditions for AM and PM peaks at the intersections analyzed. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the West 59th Street Converted MTS. These projected net increases were routed through the intersections for the AM and PM peak hours. The highest net increase in trucks in the ingress or egress direction was 21. The highest net increase at any one intersection was 42 trucks. Both of these net increases occurred at the intersection of 12th Avenue southbound and West 59th Street.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 69% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 81% of weekday traffic volumes. Table 22.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the West 59th Street Converted MTS would not operate on Sundays. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 22.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM and PM peak times associated with the West 59th Street Converted MTS. Overall, unsignalized intersections experienced relatively small increases in delay (less than five seconds) and are projected to remain at their Future No-Build condition LOS, with the following exception:

- During the AM peak hour, the delay of the southbound approach at the intersection of 12th Avenue southbound and West 59th Street increased from 15.0 to 16.5 seconds (LOS B to LOS C)

Although the West 59th Street Converted MTS would remain within the vicinity of several parks, no air quality, odor, noise or traffic impacts are predicted to result. Due to site constraints, the angle for the existing site entrance will remain unchanged. The existing hazard created for southbound bicyclists will not be eliminated. Any increase in West 59th Street Converted MTS truck traffic, therefore, could potentially worsen the safety conditions on the bike path. Appropriate measures developed in coordination with NYCDPR would likely resolve this conflict.

22.14.4.2 Impacts and Mitigation

No traffic impacts are expected to occur as a result of Future Build Conditions.

22.14.4.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

22.14.4.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

22.15 Air Quality

22.15.1 Definition of the Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the West 59th Street Converted MTS. The study area for the off-site air quality analysis is defined as the area or intersections listed in Section 22.15.4.2.

22.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest the study area are shown in Table 22.15.1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 22.15-1
Representative Ambient Air Quality Data
West 59th Street Converted MTS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO[(1)]	P.S.59	8-Hour	2,978µg/m^3	10,000 µg/m^3
		1-Hour	5,268µg/m^3	40,000 µg/m^3
NO_2[(1)]	P.S. 59	Annual	71 µg/m^3	100 µg/m^3
PM_{10}	P.S. 59	Annual	34 µg/m^3	50 µg/m^3
		24-Hour	88 µg/m^3	150 µg/m^3
SO_2[(1)]	P.S. 59	3-Hour	186 µg/m^3	1,300 µg/m^3
		24-Hour	123 µg/m^3	365 µg/m^3
		Annual	37 µg/m^3	80 µg/m^3

Notes:
Source: NYCDEP, April 2003& USEPA Airdata – Monitor Values Report (http://oaspub.epa.gov/airdata)
(1) Values are the highest pollutant levels recorded during the 2003 calendar year.

22.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build air quality conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

22.15.4 Potential Impacts with the West 59th Street Converted MTS

22.15.4.1 On-Site Analysis

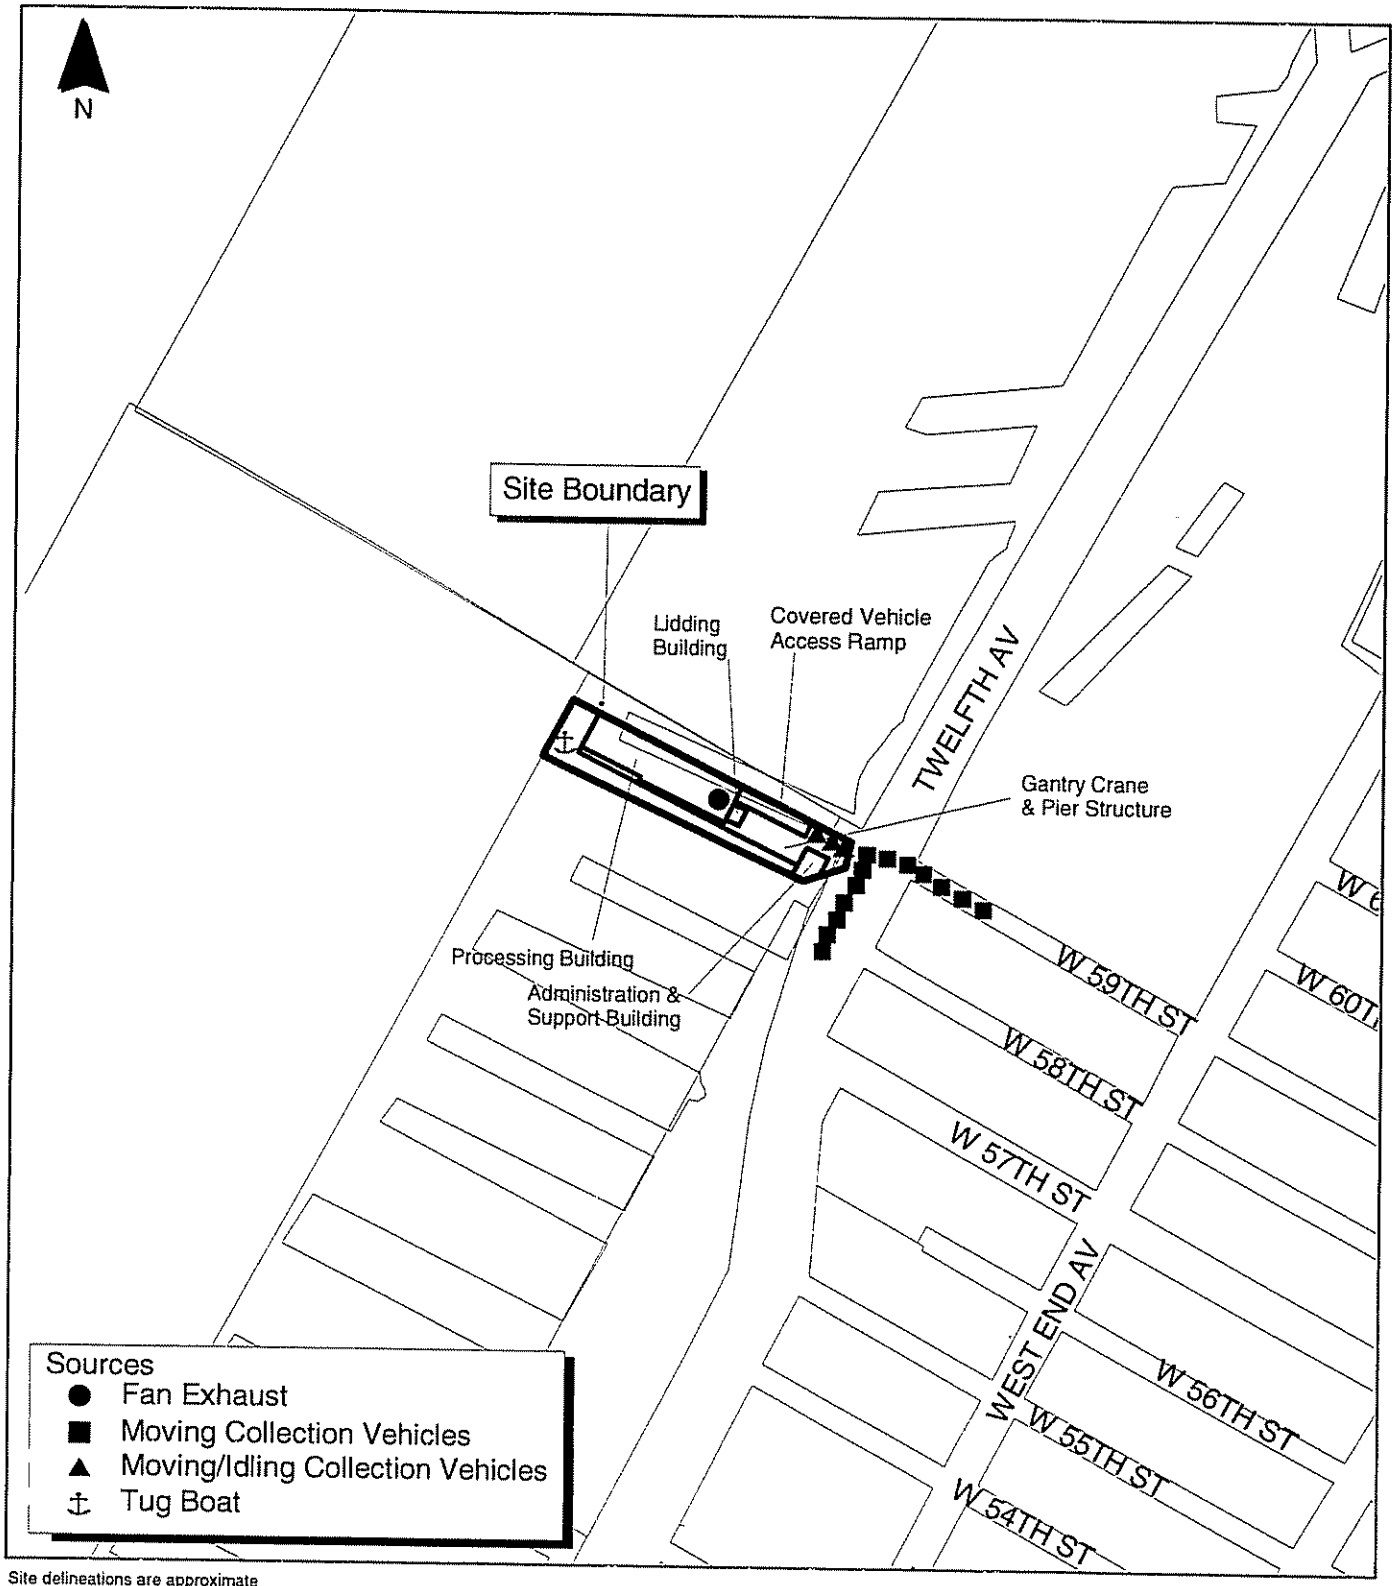
22.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 22.15-2. Figure 22.15-1 shows the locations of these sources within the site.

22.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 22.15-3. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual PM_{25} concentrations from West 59th Street Converted MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 22.15-3, are below the STVs. The West 59th Street Converted MTS would not, therefore, significantly impact air quality in the area.

Table 22.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
West 59th Street Converted MTS



Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Wheel Loaders	2	1
Mini Loaders	1	1
Tamping Cranes	1	1
Mini-Sweepers	1	1
Vacuum Sweepers	1	1
Moving/Queuing Collection Vehicles	51	13
Space Heaters	10	3
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	51	13
Queuing Collection Vehicles[3]	4 in, 1 out	3 in, 1 out
Oceangoing Tugboats	1	1

Notes:

(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.

(2) This is based on design capacity of the Converted MTS, not analyzed truck arrival rates.

(3) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 4, the same as peak 1 hour value.

Site delineations are approximate

	24-hour[6]	2	139	141	365	NA
	Annual	0.3	~~34~~37	~~34~~37	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~ memorandum dated February 18, 2005..

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM^{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.

NA = Not Applicable

22.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 22.15-4. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the West 59th Street Converted MTS are not considered to be significant.

22.15.4.2 Off-Site Analysis

22.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY and other agency collection vehicles were identified using 2001 CEQR Technical Manual guidelines that are outlined in Section 3.17. Following these guidelines, the following detailed mobile source analyses were conducted for the applicable (i.e., worst-case) time periods:

- An analysis of the intersections of 12th Avenue and West 59th Street, and Route 9A and West 57th Street to determine whether West 59th Street Converted MTS-generated traffic has the potential to cause exceedances of NYCDEP's 24-hour and annual $PM_{2.5}$ STVs; and
- An analysis of the intersections of 12th Avenue and West 59th Street, and Route 9A and West 57th Street to determine whether West 59th Street Converted MTS-generated traffic has the potential to cause exceedances of the 24-hour and annual PM^{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 22.15-2.

Notes to Table 22.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC

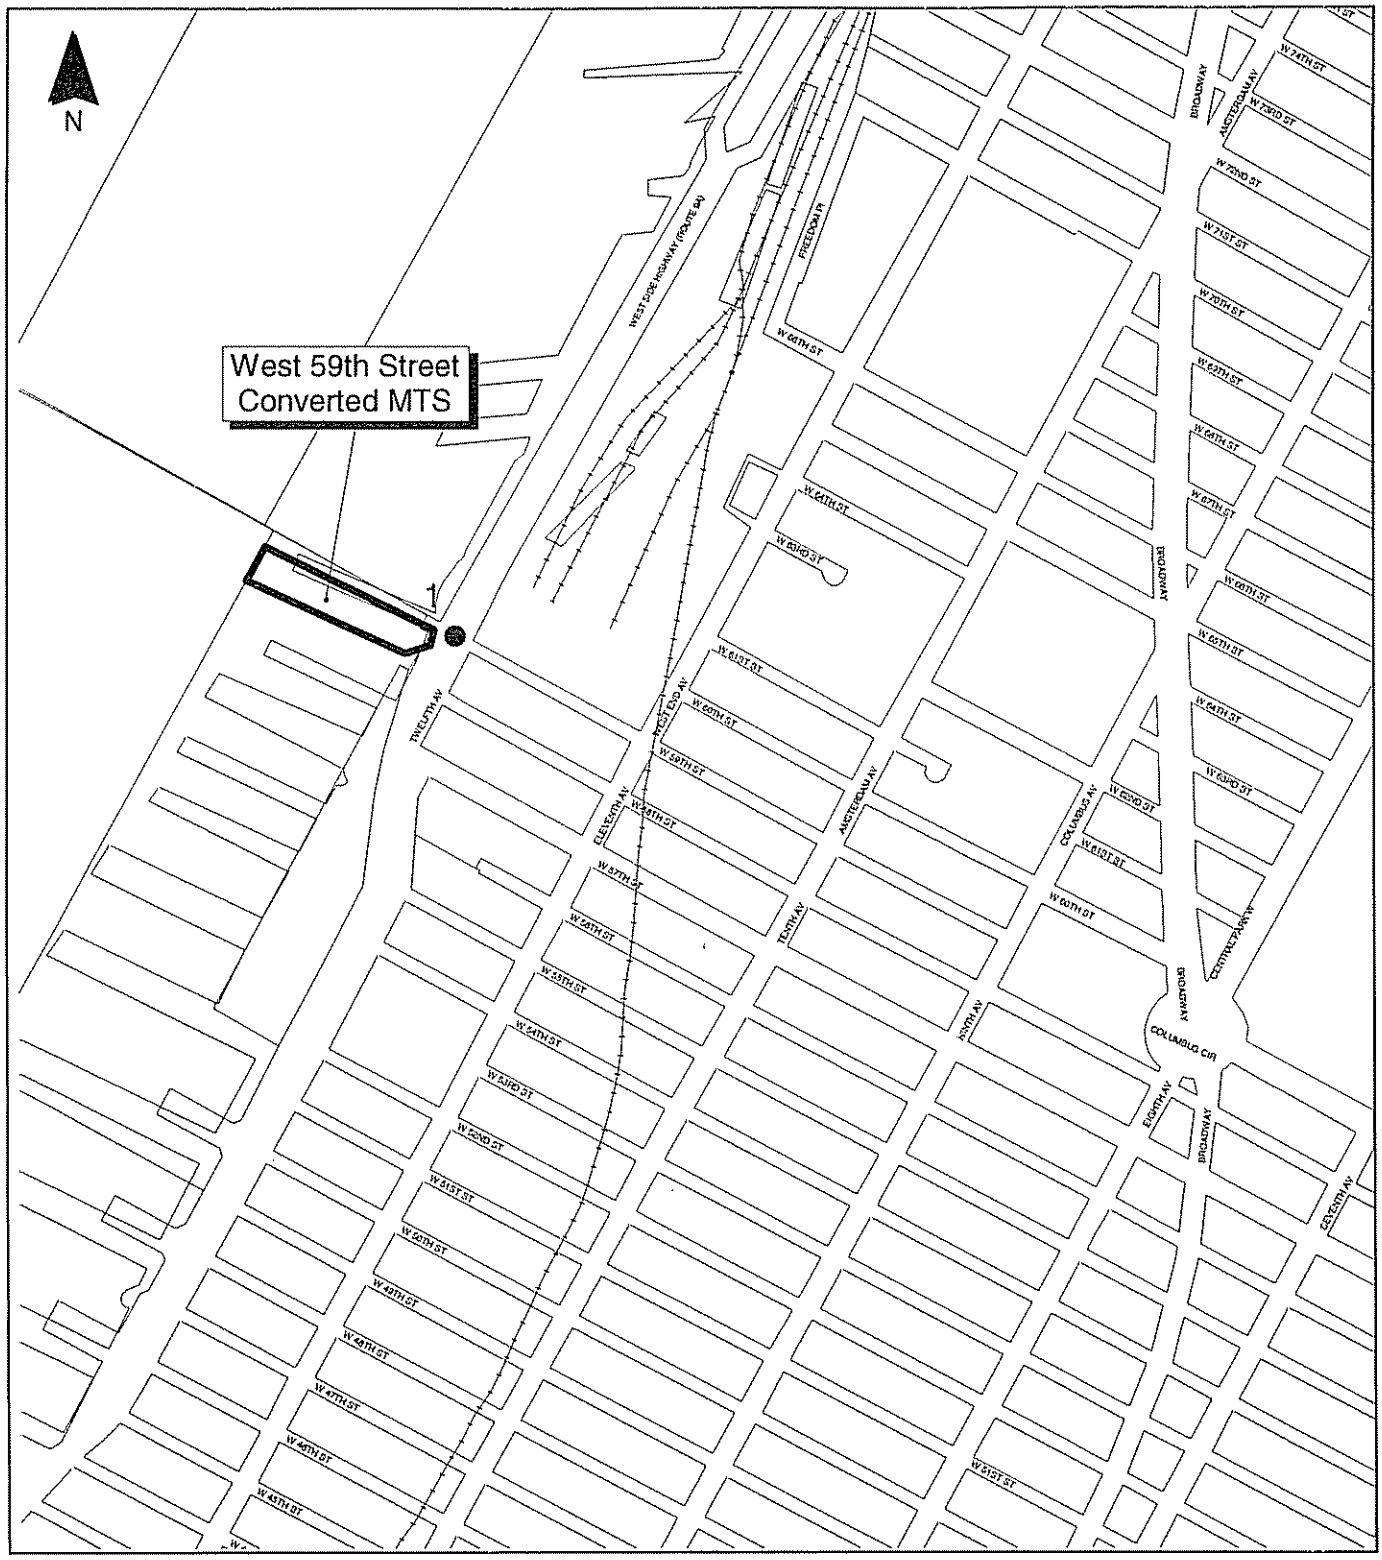
(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts

NA = Not Applicable

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

22.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 22.15-5, are all within (less than) the applicable state and federal ambient air quality standards, STVs (for $PM_{2.5}$) and/or de minimus impact values (for CO). A Tier II analysis of the intersection of Route 9A and West 57th Street was done to determine the off-site annual impacts for $PM_{2.5}$. The results of this Tier II analysis are within the applicable annual STVs for $PM_{2.5}$. The off-site operations of the West 59th Street Converted MTS are not, therefore, considered to be significant.

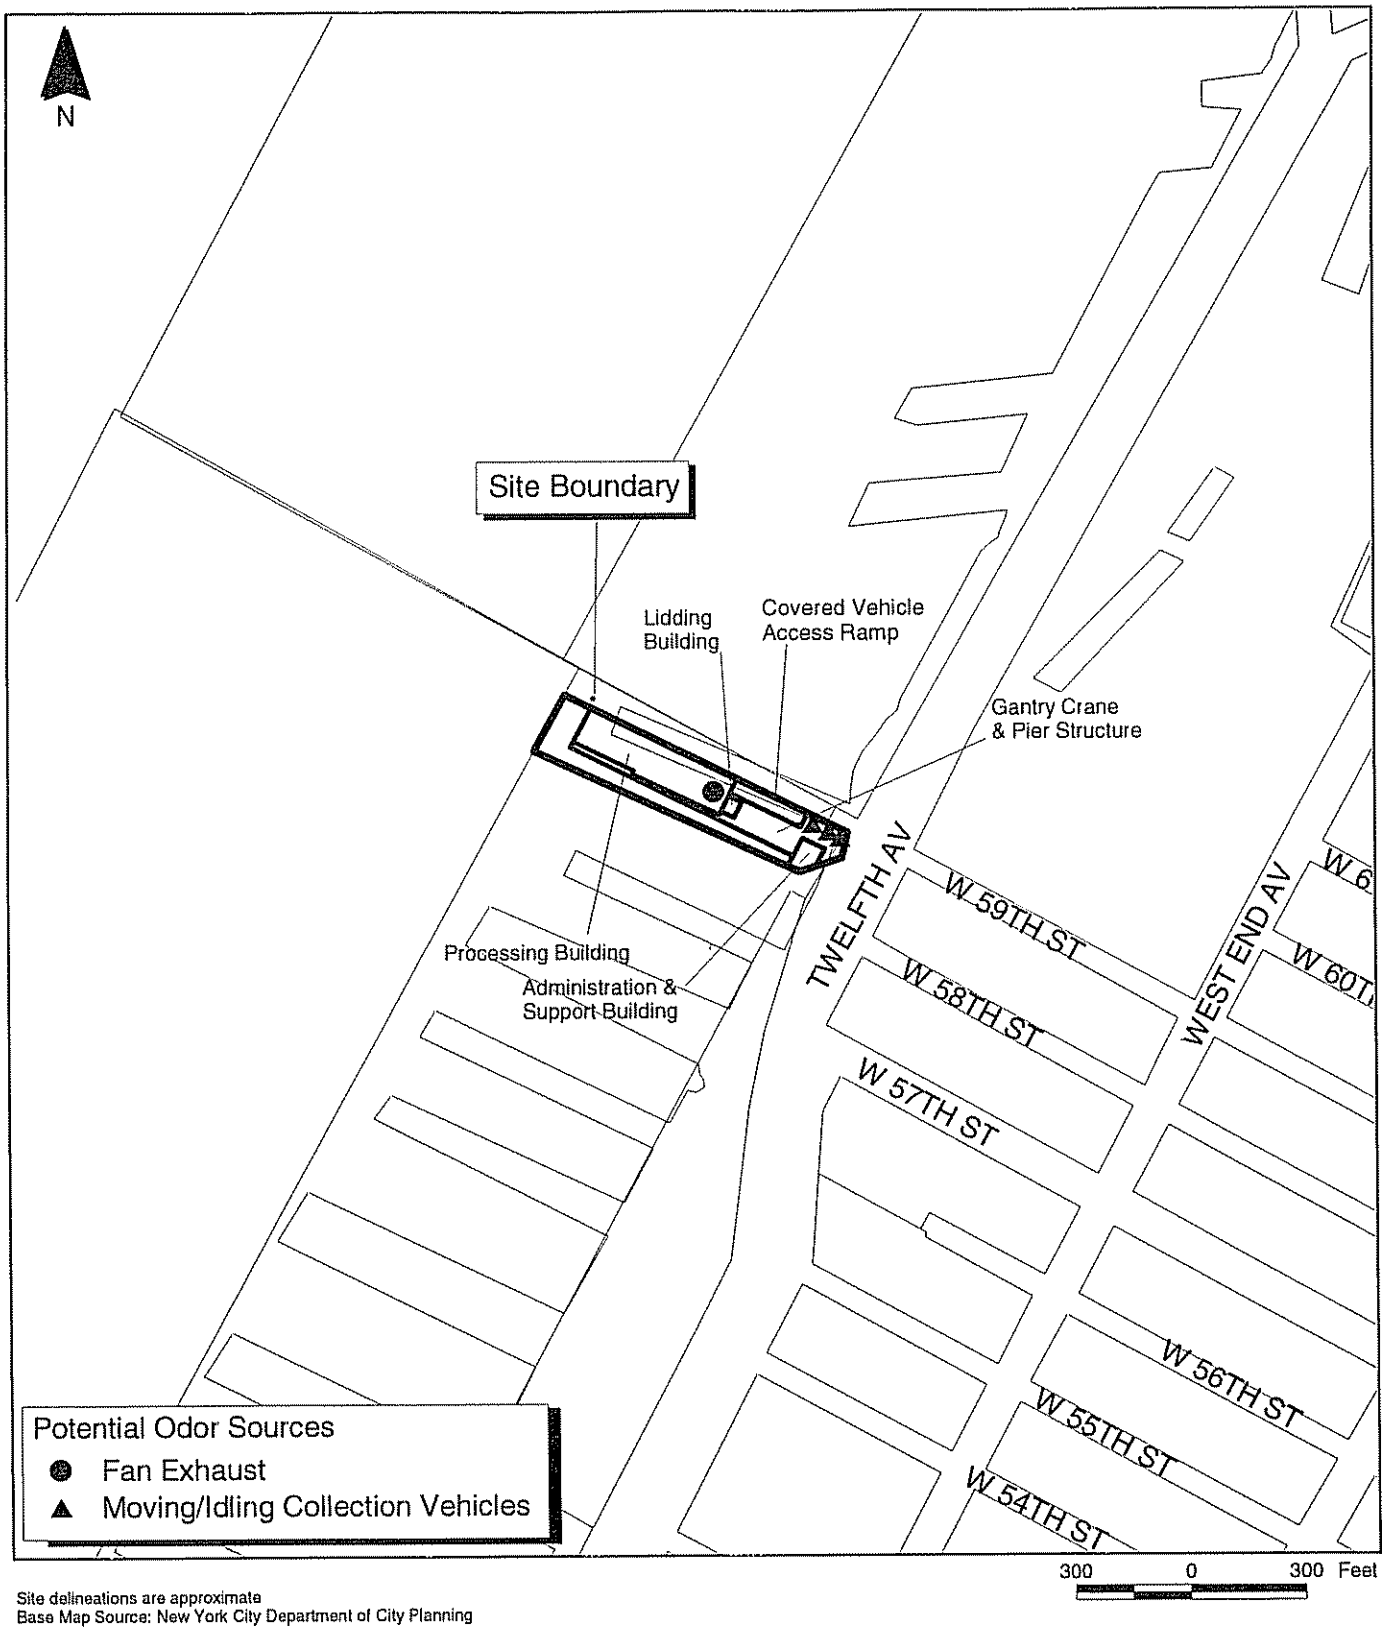
22.16 Odor

22.16.1 Existing Conditions

Paper recycling activities are conducted at the existing MTS. There are no putrescible waste handling operations there, however, and, therefore, there are no existing sources of odor at the site. The study area is within 500 meters (0.3 miles) from the facility boundary. The locations for sensitive receptors in this analysis are the same as those used in the noise analysis. The nearest sensitive receptor is the bike path along the river and the apartment building located on 11th Avenue between 61st Street and 62nd Street, approximately 1,739 feet from the site boundary.

22.16.2 Future No-Build Conditions

No additional odor-producing sources are currently anticipated in the vicinity of the West 59th Street Converted MTS. Thus, Existing Conditions are assumed to be representative of Future No-Build Conditions.



22.16.3 Potential Impacts with the West 59th Street Converted MTS

22.16.3.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the West 59th Street Converted MTS are provided in Table 22.16-1. Figure 22.16-1 shows the locations of these sources within the site.

Table 22.16-1
Odor Sources Included in Odor Analysis

Figure 22.16-1 Potential Odor Sources

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT of SANITATION

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the West 59th Street Converted MTS.

22.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 22.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the West 59th Street Converted MTS at any nearby sensitive receptor is less than 1, so odors from the West 59th Street Converted MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 22.16-2
~~-~~Highest Predicted Odor Concentration(s) from On-Site Sources
West 59th Street Converted MTS

Parameter	Resulting ~~D/T~~ ~~Ratio~~ Odor Units [1]
Estimated Detectable Concentration	5.0

Notes:

[1] Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.

[2] Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.

~~(1) D/T ratio is dimensionless.~~

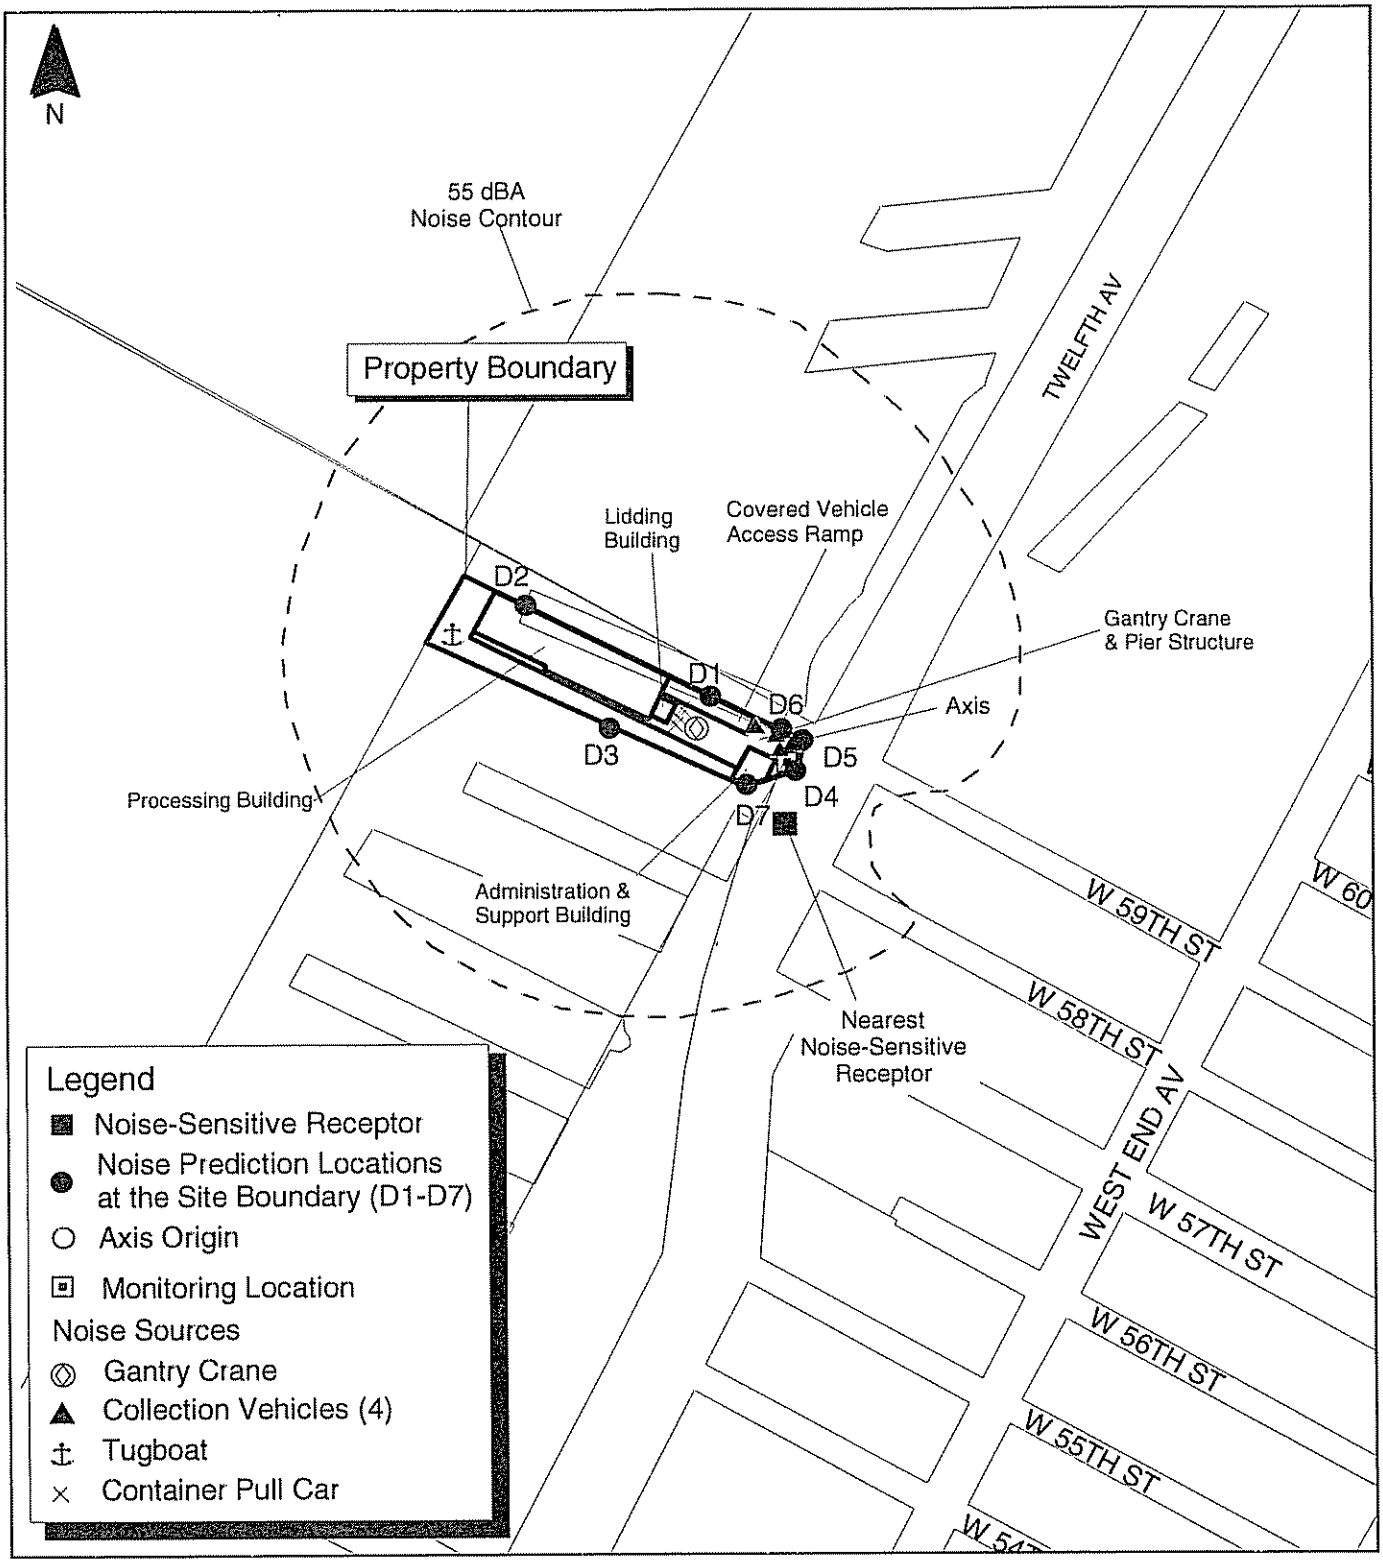
~~(2) Measured from the site boundary.~~

~~(3) Measured from the site property line~~

22.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from West 59th Street Converted MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

22.17.1 Existing Conditions



22.17.1.1 Introduction

Figure 22.17-1 shows the location of the West 59th Street Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is Riverside Park South directly adjacent the West 59th Street Converted MTS property line. Riverside Park South is a shared walkway area and public recreational bicycle path designated as parkland. It passes on the east side of the West 59th Street Converted MTS site. Additional residential areas exist immediately east and north of the path.

22.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptor. Noise monitoring data recorded hourly included: $L_{eq(1)}$, L_{min} and L_{max},[12] and the statistical metrics of L_{10}, L_{50} and L_{90}.[13]

[12] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[13] Terms L_{10}, L_{50} and L_{90} are defined in Section 3.19.2.

Site delineations are approximate.

HDR HydroQual URBITRAN PB EEA Cambridge Environmental Inc

Figure 22.17-1 Noise Sources and Receptors

West 59th Street Converted MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

Table 22.17-1 presents monitored noise levels. As shown, the quietest hours at the monitoring location occurred between 5:00 p.m. to 6:00 p.m. and had an $L_{eq(1)}$ of 66.5 dBA on December 23, 2003. Although the quietest hour is typically a nighttime hour, the traffic conditions on the Henry Hudson Parkway during the evening rush hour, when cars are not moving, reduces the noise level that would normally be expected next to a highway. Activities and events that contribute to the on-site noise levels are as follows:

- Recycling activities at the existing West 59th Street MTS;
- Traffic from the Henry Hudson Parkway; and
- Marine activity on the Henry Hudson River.

22.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of noise from the existing traffic and other background noise. A screening analysis was conducted to determine if noise monitoring would be required along the 59th Street Converted MTS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, no off-site noise analysis was required. Therefore, no noise monitoring data were collected for off-site noise levels.

22.17.2 Future No-Build Conditions

22.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

22.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 22.17-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime for locations where there is a possible impact based on the first-level screening.

Table 22.17-1
Existing Hourly (Monitored) Noise Levels On Site[1]

6:00-7:00 a.m.	68.9	65.1	68.7	70.6	58.1	80.5
7:00-8:00 a.m.	70.3	67.8	69.8	71.8	63.1	79.0
8:00-9:00 a.m.	69.8	66.2	68.7	71.2	61.1	84.8
9:00-10:00 a.m.	69.6	65.4	68.2	70.9	59.0	87.0
10:00-11:00 a.m.	73.3	67.2	70.3	75.4	60.3	99.0

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest noise-sensitive receptor to identify the quietest background hour.

Table 22.17-2
Off-Site Noise Traffic Volume
West 59th Street Converted MTS

Location	Hour Beginning	Existing Traffic Volume (1) (Vehicles / Hour)	Future No-Build Traffic Volume (2) (Vehicles / Hour)
12th Avenue between West 58th & W 59th Streets	11:00 a.m.	94	95
West 59th Street between 10th & 11th Avenues	2:00 a.m.	68	69
West 59th Street between 10th & 11th Avenues	11:00 a.m.	375	381

Notes:
(1) Existing Traffic Volumes are based on ATR data.
(2) Future No-Build Traffic Volumes are based on CEQR annual traffic growth rates.

22.17.3 Potential Impacts with the West 59th Street Converted MTS

22.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the West 59th Street Converted MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 22.17-3. Spectral noise levels used in the Performance Standards Noise Code analysis are shown in Table 22.17-4. The number and types of equipment assumed for this analysis were based on the West 59th Street Converted MTS's peak design capacity. Shown earlier, Figure 22.17-1 indicates the West 59th Street Converted MTS layout, the locations of the points along the facility boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 22.17-3
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
West 59th Street Converted MTS

Equipment Name (quantity) [1]	Reference Sound Pressure Noise Level at 50 feet (dBA) [2]

Hz = Hertz

K = Thousand

22.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the West 59th Street Converted MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 61 meters (199 feet) from the property boundary in the direction of the nearest noise-sensitive receptor, which is directly abutting the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA, (i.e., the point off site where noises generated on site attenuate to 55 dBA), is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (see Figure 22.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on noise monitoring provided in Table 22.17-1 above. A detailed noise analysis was performed to calculate the West 59th Street Converted MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The difference between this combined noise level and the existing noise level at the noise-sensitive receptor represents the predicted incremental change in noise level from the West 59th Converted MTS. Since the quietest hour occurs during the daytime, the CEQR threshold is 65 dBA. However, since the background noise level is greater than 62 dBA, an impact would be caused if the predicted incremental change is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor. Therefore, there is a predicted impact that would be caused by the West 59th Converted MTS on-site operations based on this conservative analysis.

On-site queuing collection vehicles were further analyzed to refine the calculated noise levels from the West 59th Street Converted MTS facility truck ramp to the Riverside Park South receptor. Individual, position-specific utilization factors were assigned to each inbound collection vehicle position on the inbound side of the ramp, and to one collection vehicle position on the outbound scale based on the processing time at the West 59th Street Converted MTS. The utilization factor for each truck was estimated based on the peak hour of inbound collection vehicles, totaling 8 trucks and conservatively assuming these utilization factors would occur for 24 hours. The assumption was made that each inbound truck would be queuing on-site for approximately two minutes before proceeding one truck length further up the ramp towards the facility.

Table 22.17-5 below shows the results of the CEQR analysis with the refined queuing analysis at the Riverside Park South. The table includes the existing noise level at the noise-sensitive receptors, the West 59th Street Converted MTS-related noise levels and the combined noise level. The table also provides the difference between this combined noise level and the existing noise level at the sensitive receptors. This difference represents the predicted incremental change in noise level from the West 59th Street Converted MTS. Because this incremental change is less than the CEQR threshold of 3 dBA during nighttime hours, or during daytime hours when the daytime background noise level is greater than 62 dBA, for the Riverside Park South receptor analyzed, there is no predicted impact that would be caused by the West 59th Street Converted MTS on-site operations.

22.17.3.3 Performance Standards for Zoning Code Analysis

Overall noise predictions were calculated at the locations of the points representative of the West 59th Street Converted MTS boundary (D1, etc.) to determine the total noise level for each octave band from indoor and outdoor sources, not including DSNY and other agency collection vehicles and tugboats, in accordance with the New York City Zoning Code Performance Standards for Manufacturing Districts (assuming tugboats are transportation facilities) (see Table 22.17-6). ~~Based on this analysis, no exceedances to the Performance Standards are predicted.~~

The NYC Zoning Resolution Performance Standards for Noise (Article IV: Manufacturing District Regulations, Section 42-21) requires that a lower standard (Maximum Permitted Sound Pressure Levels identified in 42-213 lowered by 6 dB) be met at any point at the manufacturing district boundary that adjoins a residential district. Two locations analyzed that are residentially zoned, though use of this property is recreational (not residential), are points on the promenade between the Henry Hudson Parkway and the Hudson River to the north of the entrance ramp to the existing MTS. (The closest actual residence to this point is across the Henry Hudson Parkway, over 1,150 feet away on West End Avenue). Background noise levels at the point on the promenade are between 7.1 dB and 39.7 dB higher that the required standard, adjusted for residential zoning. At these levels, the theoretical exceedance at the boundary cannot be perceived and, therefore, no impact is predicted.

Table 22.17-5
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor with Refined On-Site Queuing Collection Vehicle Utilization Factor
West 59th Street Converted MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/ feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
Riverside Park South	Directly abutting	65.4	~~61.0~~ 60.2	~~66.8~~ 66.6	~~1.4~~ 1.2	No

Notes:
(1) Twenty-minute noise level readings measured at the closest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.
(2) Existing noise levels measured on February 10, 2004 at 5:00 p.m.
(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.
(4) According to CEQR, an increase of 3 dBA or more, when the daytime existing noise level is greater than 62 dBA, is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the West 59th Street Converted MTS with the quietest background noise levels that occur during facility operation. The quietest hour of background noise levels occurred during the daytime hours for the nearest noise-sensitive receptor; therefore, only daytime impact criteria are discussed in this analysis for this noise-sensitive receptor.

Bold = Exceedance

22.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the West 59th Street Converted MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. The overall noise predictions were based on the refined queuing analysis. ~~This is~~is The results are shown in Table 22.17-7. Based on this analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 22.17-7
Current Noise Code Analysis
West 59th Street Converted MTS

Location at Plant Boundary(1)	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	~~61.6~~ 56.2
D2	~~51.3~~ 47.6
D3	~~63.0~~ 52.5
D4	~~64.6~~ 65.3
D5	~~68.2~~ 69.3
D6	69.7
D7	62.6

Note:
(1) D1 through D7 are points representative of the West 59th Street Converted MTS boundary that are used in all noise analyses.

analysis was required. Results of the second-level screening for the hour expected to receive the largest change in noise levels (when the difference between traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 22.17-8.

Because the screening results presented above showed that the PCEs would not double on a roadway due to DSNY and other agency collection vehicles coming to or going from the West 59th Street Converted MTS, a detailed off-site noise analysis was not required.

22.17.3.6 Combined On-Site and Off-Site Noise Levels

An ~~off~~-on-site noise analysis was performed for the West 59th Street Converted MTS. The results of the ~~on~~off-site screening analysis showed that PCEs would not double on a roadway due to DSNY and other agency collection vehicles. ~~noise-sensitive receptors were not located within the 55-dBA contour line (see Figure 4.17-1); therefore~~Therefore, ~~on~~off-site noise monitoring and an ~~on~~off-site noise analysis were not required. Since an ~~on~~off-site analysis was not required, a combined noise analysis was not performed.

Table 22.17-8
Off-Site Noise Screening Results
West 59th Street Converted MTS

Location	Hour Beginning	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicle PCEs[1]	Future Build PCEs[1][2]	Possible Impact[3]
12th Avenue between Westr 58th and West 59th Streets	11:00 a.m.	1,523	10	0	470	1993	No
West 59th Street between 10th and 11th Avenues	2:00 a.m.	528	3	0	141	669	No
West 59th Street between 10th and 11th Avenues	11:00 a.m.	1,736	17	0	799	2,535	No

Notes:
(1) Total PCEs are rounded to the nearest whole number.
(2) Future Build PCEs include West 59th Street Converted MTS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47, and employee vehicles are converted to PCEs using a factor of 1.
(3) There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

22.18 Commercial Waste to the West 59th Street Converted MTS

22.18.1 Existing Conditions

No commercial waste is delivered to the West 59th Street MTS site under Existing Conditions. Commercial waste generated in Manhattan is taken directly out of the City to remote disposal locations.

22.18.2 Future No-Build Conditions

Under Future No-Build Conditions, no commercial waste would be delivered to the West 59th Street Converted MTS; therefore, Future No-Build Conditions are the same as Existing Conditions.

22.18.3 Potential Impacts of Sending Commercial Waste to the West 59th Street Converted MTS

The complete analysis of potential impacts of sending commercial waste to the Converted MTSs is presented in Volume III of the March 2004 Commercial Waste Management Study, which is included as Appendix D to this FDEIS.

22.18.3.1 On-Site Air Quality, Odor and Noise

Under Future Build Conditions, the West 59th Street Converted MTS was evaluated for on-site air quality, odor and noise impacts at its maximum design capacity of approximately 2,145 tpd (see Sections 22.15, 22.16 and 22.17). Results showed no unmitigatible adverse on-site air quality, odor or noise impacts. Although the peak hourly arrival rates of collection vehicles are not sustained over a 24-hour period, the analysis of on-site impacts conservatively modeled these peak hour conditions to predict the potential for on-site noise and odor impacts, and air quality impacts for short-term (1-hour, 3-hour, 8-hour and 24-hour) averaging periods. Because the analysis of short-term averaging periods was based on facility operations at the design capacity, no additional evaluation of on-site noise was required.

An evaluation of potential on-site air quality impacts for pollutants compared to annual average standards was modeled assuming commercial waste was processed at the Converted MTS. Based on these analyses, the potential processing of these quantities of the City's commercial putrescible waste would not cause any significantly adverse air quality impacts attributable to on-site operations. Likewise, odors from on-site operations of the Converted MTS with the addition of commercial waste at levels discussed in the Commercial Waste Management Study were also analyzed and results showed no unmitigatible significant adverse odor impacts.

See Appendix D for the revised tables to the Commercial Waste Management Study that contain the results of the on-site air quality and odor analyses.

22.18.3.2 Off-Site Traffic, Air Quality and Noise

Potential off-site traffic, air quality and noise impacts of deliveries of DSNY-managed Waste to the West 59th Street Converted MTS were evaluated in Sections 22.14, 22.15 and 22.17 based on temporal distributions of DSNY and other agency collection vehicles identified in Section 22.14.

The greatest number of DSNY and other agency collection vehicles analyzed for traffic impacts during all three periods (AM, midday and PM peak hours) was 21 (inbound trip ends) per hour, which occurred during the AM peak. These 21 DSNY and other agency collection vehicles are also more than the 12 peak hour DSNY and other agency collection vehicle and commercial waste hauling vehicle inbound trip ends that can be processed per hour at the West 59th Street Converted MTS during the 8:00 p.m. to 8:00 a.m. shift. In addition, the intersection LOS is lower (i.e., poorer) and the background volumes of traffic are higher during the AM peak than the 8:00 p.m. to 8:00 a.m. hours, so the AM peak analysis represents worst-case conditions. As reported above, there were no unmitigatible significant adverse environmental impacts from the 21 DSNY and other collection agency vehicles at the West 59th Street Converted MTS. Therefore, the addition of the 12 DSNY and other agency collection vehicles and commercial waste hauling vehicles at the West 59th Street Converted MTS per hour during the 8:00 p.m. to 8:00 a.m. shift — during a period with a better LOS and lower background traffic volumes — would also have no unmitigatible significant adverse traffic impacts.

Likewise, the 21 inbound DSNY and other agency collection vehicles analyzed for off-site air quality impacts during the AM peak hour was the highest number of collection vehicles analyzed for all three periods (AM, midday and PM peak hours). For off-site air quality modeling, a Tier I analysis assumed conservatively that the 21 inbound DSNY and other agency collection vehicles would travel through the analyzed intersections each hour over a 24 hour period. Results showed there would be no unmitigatible significant adverse environmental impacts at several analyzed intersections. Consequently, because the 12 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that can travel through these intersections per hour during the 8:00 p.m. to 8:00 a.m. shift would be fewer than the number of such vehicles analyzed for the AM peak over a 24-hour period, there would be no significant adverse off-site air quality impacts.

For the intersection of Route 9A and West 57th Street, a Tier II analysis was required. The estimated actual hourly distribution over 24 hours included the estimated 21 inbound DSNY and other agency collection vehicles and commercial waste hauling vehicles that could potentially be processed at the West 59th Street Converted MTS, and no unmitigatible significant adverse environmental impacts were identified.

Evaluating the potential for off-site noise impacts required the use of a second-level noise screening analysis. The results of this analysis indicate that the potential number of commercial waste hauling vehicles that could be routed to the West 59th Street Converted MTS during various hours within the 8:00 p.m. to 8:00 a.m. period must be limited to less than the available excess capacity to avoid causing potential impacts at noise-sensitive receptors on the approach routes these vehicles would take to the Converted MTS. The amount of available capacity that can be used to process commercial waste during the hours of 8:00 p.m. to 8:00 a.m., without causing any significant adverse noise impacts, is 956 tons (or 91 commercial waste hauling vehicles, assuming an average of 11 tons per truck) over this 12-hour period.

CHAPTER 22A ENVIRONMENTAL REVIEW – 215 VARICK AVENUE SITE (NEW CHAPTER)

22a.1 Introduction

The 215 Varick Avenue Transfer Station is a potential Alternative site that has been added after publication of the DEIS. Should the Alternative become a part of the Proposed Action, a detailed environmental review will be required and submitted in a supplemental environmental review to this FEIS.

22a.2 Land Use, Zoning, and Public Policy

See Section 22a.1 for a description of the analysis required.

22a.3 Socioeconomic Conditions

See Section 22a.1 for a description of the analysis required.

22a.4 Community Facilities and Services

See Section 22a.1 for a description of the analysis required.

22a.5 Open Space

See Section 22a.1 for a description of the analysis required.

22a.6 Cultural Resources

See Section 22a.1 for a description of the analysis required.

22a.7 Urban Design, Visual Resources, and Shadows

See Section 22a.1 for a description of the analysis required.

22a.8 Neighborhood Character

See Section 22a.1 for a description of the analysis required.

22a.9 Natural Resources

See Section 22a.1 for a description of the analysis required.

22a.10 Hazardous Materials

See Section 22a.1 for a description of the analysis required.

22a.11 Water Quality

See Section 22a.1 for a description of the analysis required.

22a.12 Waterfront Revitalization Program

See Section 22a.1 for a description of the analysis required.

22a.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

See Section 22a.1 for a description of the analysis required.

22a.14 Traffic, Parking, Transit, and Pedestrians

CHAPTER 23 ENVIRONMENTAL REVIEW: EXISTING SOUTH BRONX MTS

23.1 Introduction

The results of the environmental analyses of the Existing South Bronx MTS are presented in the following sections:

23.2 Land Use, Zoning, and Public Policy
23.3 Socioeconomic Conditions
23.4 Community Facilities and Services
23.5 Open Space
23.6 Cultural Resources
23.7 Urban Design, Visual Resources, and Shadows
23.8 Neighborhood Character
23.9 Natural Resources
23.10 Hazardous Materials
23.11 Water Quality
23.12 Waterfront Revitalization Program
23.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
23.14 Traffic, Parking, Transit, and Pedestrians
23.15 Air Quality
23.16 Odor
23.17 Noise

Section 2.4.5 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

23.2 Land Use, Zoning, and Public Policy

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

23.3 Socioeconomic Conditions

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Socioeconomic Conditions section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

23.4 Community Facilities and Services

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Community Facilities and Services section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

23.5 Open Space

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Open Space section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

23.6 Cultural Resources

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Cultural Resources section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

23.7 Urban Design, Visual Resources, and Shadows

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

23.8 Neighborhood Character

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Neighborhood Character section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

23.9 Natural Resources

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Natural Resources section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information of the review of this facility in this category.

23.10 Hazardous Materials

The Existing South Bronx MTS is located at the site of the South Bronx Converted MTS. The analysis of the Hazardous Materials section of the South Bronx Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

23.11 Water Quality

The Existing South Bronx MTS has a smaller footprint than the South Bronx Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the South Bronx Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing South Bronx MTS.

23.12 Waterfront Revitalization Program

The Existing South Bronx MTS has a smaller footprint than the South Bronx Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts for the South Bronx Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing South Bronx MTS.

23.13 Infrastructure. Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing South Bronx MTS would be equal to or less than the staffing levels of the South Bronx Converted MTS. Therefore, the analyses performed for the South Bronx Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing South Bronx MTS.

23.14 Traffic, Parking, Transit, and Pedestrians

The Existing South Bronx MTS may receive the same amount of DSNY-managed and potential commercial waste as the South Bronx Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the South Bronx Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing South Bronx MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

23.15 Air Quality

The Existing South Bronx MTS would have less on-site emission-generating equipment, and the sources located farther from the property line receptors, than the South Bronx Converted MTS. Since there are no unmitigatible significant adverse environmental air quality impacts from the South Bronx Converted MTS, there will be no unmitigatible significant adverse environmental air quality impacts from the Existing South Bronx ~~Street~~ MTS.

23.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing South Bronx MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing South Bronx MTS operating at 4,800 tpd.

Table 23.16-1
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing South Bronx MTS

Parameter	Resulting Odor Unit [1]
Estimated Detectable Concentration	5.0
Highest Result Type of Receptor Location of Receptor[2]	1.02 Fence Line Receptor Site Boundary
Closest Sensitive Receptor Result [2] Type of Receptor Distance to Receptor [3]	0.16 Prison Barge 340 Feet

Notes:
[1] Odor Unit is defined as concentration that an average person in a laboratory setting could just barely detect.
[2] Sensitive receptors in this analysis are the same as sensitive receptors in the noise analysis.
~~[1] D/T ratio is dimensionless.~~
~~[2] Measured from the site boundary.~~
~~[3] Measured from the site property line.~~

Table 23.16-2
Odor Sources Included in Odor Analysis
Existing South Bronx MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving Vehicles[1]	21
Barge	2

Notes:
[1] This is the number of collection vehicle inbound and outbound from the MTS.

23.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing South Bronx MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

23.17.1 Existing Conditions

23.17.1.1 Introduction

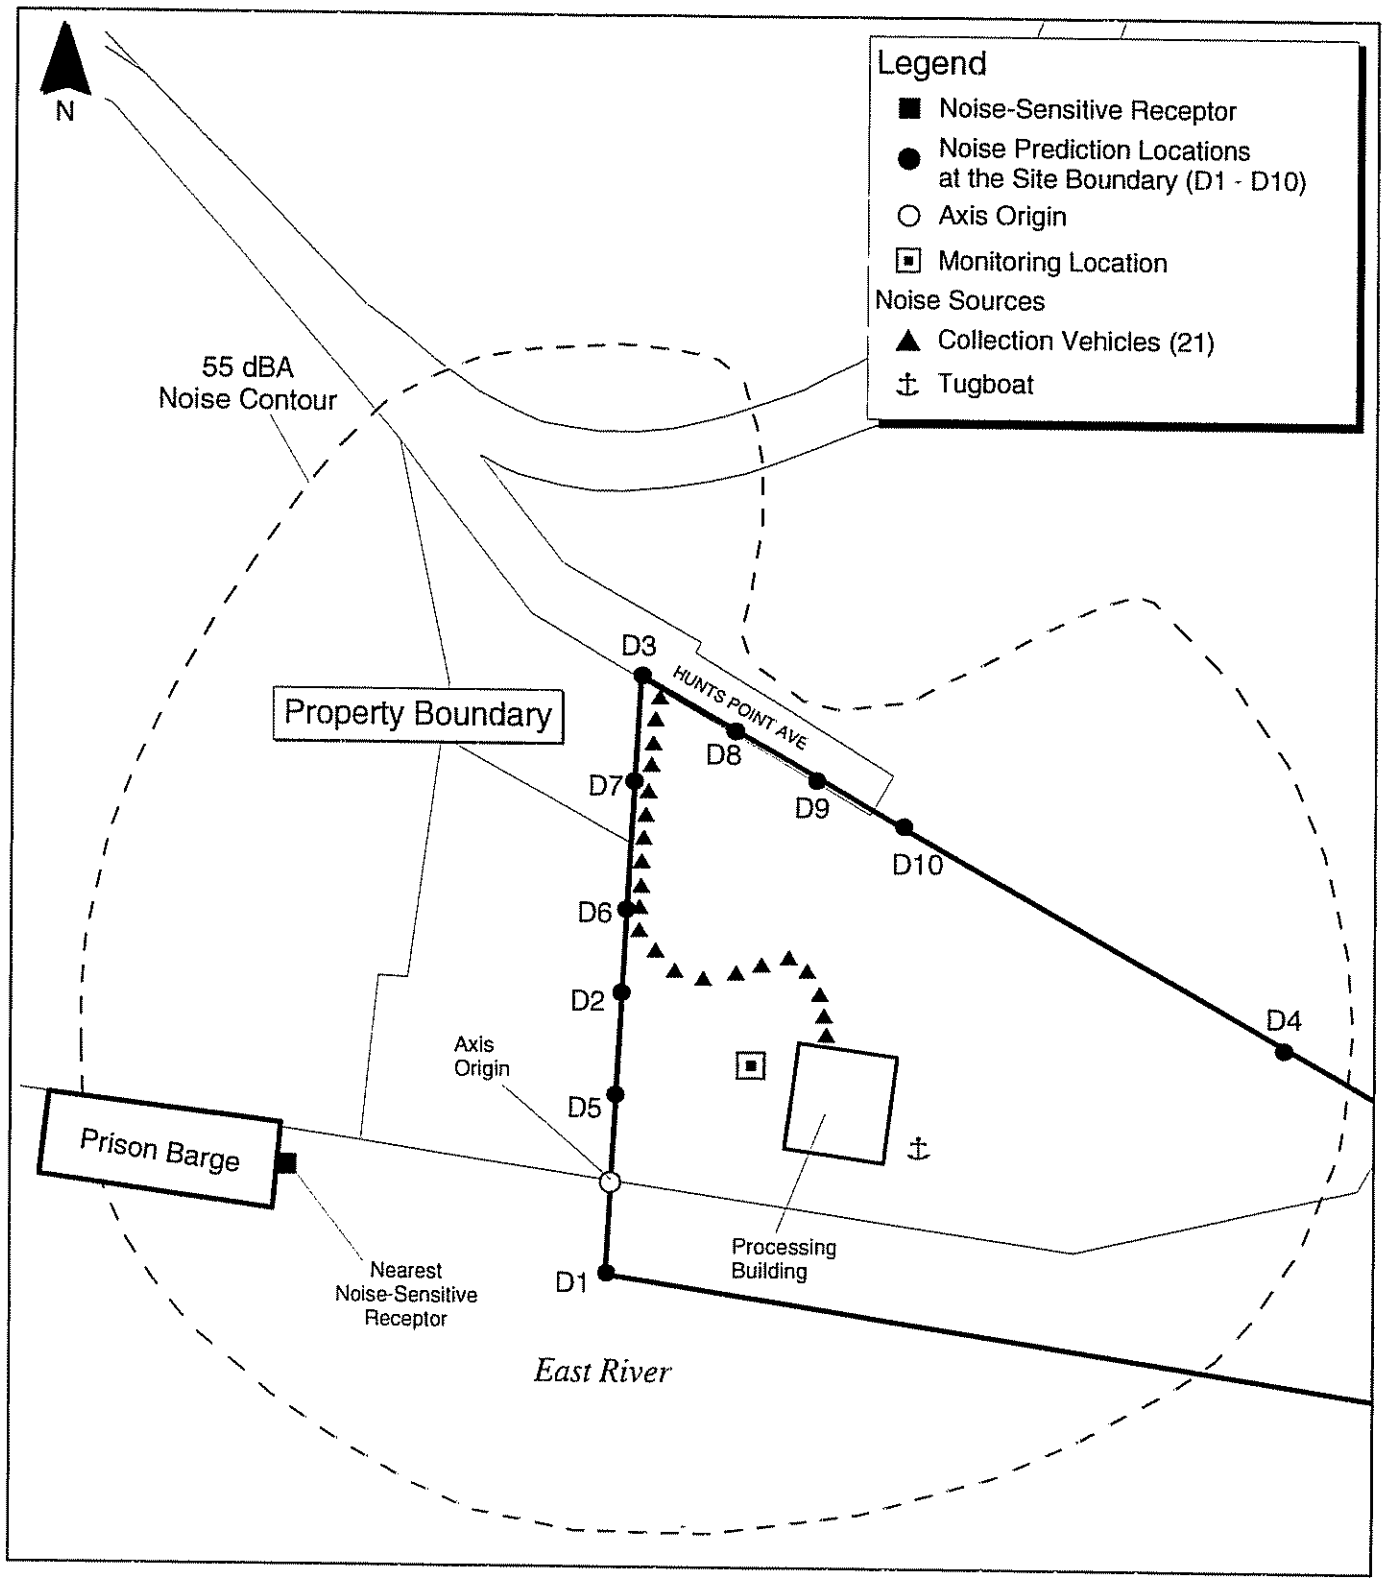
Figure 23.17-1 shows the location of the Existing South Bronx Converted MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 19.17.1.1 for further information.

23.17.1.2 On-Site Noise Levels

See Section 19.17.1.2.

23.17.1.3 Off-Site Noise Levels

See Section 19.17.1.3.



23.17.2 Future No-Build Conditions

23.17.2.1 On-Site Noise Levels

See Section 19.17.2.1.

23.17.2.2 Off-Site Noise Levels

See Section 19.17.2.2.

23.17.3 Potential Impacts with the Existing South Bronx MTS

23.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing South Bronx MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 23.17-1. The number and types of equipment assumed for this analysis were based on the Existing South Bronx MTS's peak design capacity. Shown earlier, Figure 23.17-1 indicates the Existing South Bronx MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

23.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing South Bronx MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 238 meters (781 feet) from the property boundary in the direction of the nearest noise-sensitive receptor, which is approximately 197 meters (645 feet) from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. Since the background noise level at the receptor is 54.0 dBA, which is less than 55 dBA, the contour of the predicted facility L_{eq} equivalent to the background noise level is also shown in Figure 23.17-1. The results of the screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (see Figure 23.17-1). Therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitivereceptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Table 23.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing South Bronx MTS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Moving/Queuing Collection Vehicle (7)	~~73~~79.0
Outdoor	
Moving/Queuing Collection Vehicle (21)	67
Oceangoing Tugboat (1)	73

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 19.17-1. Table 23.17-2 below identifies the existing background noise level during the quietest hour. The table shows the distance from the Existing South Bronx MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, Existing South Bronx MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptor. This difference represents the predicted incremental change in noise level from the Existing South Bronx MTS. Because this incremental change is greater than the CEQR threshold of 5 dBA at the nearest noise-sensitive receptor, since the existing daytime noise level is 60 dBA or less, there is a predicted impact that would be caused by the Existing South Bronx MTS on-site operations.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the Nnew SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 23.17-2
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
Existing South Bronx MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
Prison Barge	197 / 645	53.5	62.0	62.6	9.1	Yes

Notes:
(1) Twenty-minute noise level readings measured at the nearest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.
(2) Existing noise levels measured on May 7, 2003 at 3:00 p.m.
(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.
(4) According to CEQR, if the existing noise level is less than 60 dBA, an increase over 5 dBA during the daytime is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the Existi South Bronx MTS with the quietest background noise levels that occur during facility operation. The quietest hour of background noise levels occurred during the daytime hours for the noise-sensitive receptor; therefore, only daytime impact criteria are discussed in this analysis for this noise-sensitive receptor.

23.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

23.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Existing South Bronx MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 23.17-3. Based on this analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 23.17-3
Current Noise Code Analysis
Existing South Bronx MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	63.9
D2	**71.6**
D3	69.0
D4	62.0
D5	**70.5**
D6	**73.9**
D7	**73.2**
D8	**73.5**
D9	67.7
D10	66.2

Notes:
D1 through D10 are points representative of the Existing South Bronx MTS boundary that are used in all noise analysis.
Bold = Exceedance

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the Nnew SWMP, a supplementary refined analysis will be performed.

23.17.3.6 Off-Site Noise Levels

An off-site noise screening was performed in Section 19.17 for the Existing South Bronx MTS which did not require an off-site noise analysis; the trucks routed to the Existing South Bronx MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis was required for the Existing South Bronx MTS.

23.17.3.7 Combined On-Site and Off-Site Noise Levels

An on-site noise analysis was performed for the Existing South Bronx MTS. As a result of the off-site screening analysis, which is described above in 19.17, no off-site noise analysis was required. Since an off-site analysis was not required, a combined noise analysis was not performed.

This page intentionally left blank.

CHAPTER 24 ENVIRONMENTAL REVIEW: EXISTING SOUTHWEST BROOKLYN MTS

24.1 Introduction

The results of the environmental analyses of the Existing Southwest Brooklyn MTS are presented in the following sections:

24.2 Land Use, Zoning, and Public Policy
24.3 Socioeconomic Conditions
24.4 Community Facilities and Services
24.5 Open Space
24.6 Cultural Resources
24.7 Urban Design, Visual Resources, and Shadows
24.8 Neighborhood Character
24.9 Natural Resources
24.10 Hazardous Materials
24.11 Water Quality
24.12 Waterfront Revitalization Program
24.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
24.14 Traffic, Parking, Transit, and Pedestrians
24.15 Air Quality
24.16 Odor
24.17 Noise

Section 2.4.6 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

24.2 Land Use, Zoning, and Public Policy

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

24.3 Socioeconomic Conditions

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Socioeconomic Conditions section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.4 Community Facilities and Services

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Community Facilities and Services section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.5 Open Space

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Open Space section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.6 Cultural Resources

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Cultural Resources section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.7 Urban Design, Visual Resources, and Shadows

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

24.8 Neighborhood Character

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Neighborhood Character section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.9 Natural Resources

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Natural Resources section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.10 Hazardous Materials

The Existing Southwest Brooklyn MTS is located at the site of the Southwest Brooklyn Converted MTS. The analysis of the Hazardous Materials section of the Southwest Brooklyn Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

24.11 Water Quality

The Existing Southwest Brooklyn MTS has a smaller footprint than the Southwest Brooklyn Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the Southwest Brooklyn Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing Southwest Brooklyn MTS.

24.12 Waterfront Revitalization Program

The Existing Southwest Brooklyn MTS has a smaller footprint than the Southwest Brooklyn Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the Southwest Brooklyn Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing Southwest Brooklyn MTS.

24.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing Southwest Brooklyn MTS would be equal to or less than the staffing levels of the Southwest Brooklyn Converted MTS. Therefore, the analyses performed for the Southwest Brooklyn Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing Southwest Brooklyn MTS.

24.14 Traffic, Parking, Transit, and Pedestrians

The Existing Southwest Brooklyn MTS may receive the same amount of DSNY-managed and potential commercial waste as the Southwest Brooklyn Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the Southwest Brooklyn Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing Southwest Brooklyn MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

24.15 Air Quality

The Existing Southwest Brooklyn MTS would have less on-site emission-generating equipment, but the sources located closer to the property line receptors, than the Southwest Brooklyn Converted MTS. This section presents the results of the air quality analysis for the Existing Southwest Brooklyn MTS operating at 4,800 tpd.

24.15.1 Potential Impacts with the Existing Southwest Brooklyn MTS

24.15.1.1 On-Site Analysis

24.15.1.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 24.15-1.

24.15.1.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 24.15-2. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from Existing Southwest Brooklyn MTS-generated vehicles at any of the receptor locations considered, which are also presented in Table 24.15-2, are below the STVs. Based on the results presented in Table 24.15-2, operations at the Existing Southwest Brooklyn MTS would not significantly impact air quality in the area.

Table 24.15-1
Emission Sources Considered for On-Site Air Quality Analysis[1]
Existing Southwest Brooklyn MTS

Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Moving/Queuing Collection Vehicles	36	20
Space Heaters	10	4
Boiler	1	1
Outside Processing Building		
Moving Street Sweepers	0	0
Moving Collection Vehicles	69	20
Queuing Collection Vehicles[2]	33	3
Oceangoing Tugboats	1	1

Notes:
(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.
(2) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 6. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (33), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

24.15.1.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 24.15-3. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by USEPA as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Existing Southwest Brooklyn MTS are not considered to be significant.

Table 24.15-2
Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions
Existing Southwest Brooklyn MTS

Pollutant	Averaging Time Period	Maximum Impacts from On-Site Emission Sources [1]	Background Pollutant Concentrations [2]	Highest Estimated On-Site Pollutant Concentrations	NAAQS[3]	STV[4]
Carbon Monoxide (CO), $\mu g/m^3$	1-hour[6]	914	3,781	4,695	40,000	NA
	8-hour[6]	403	2,635	3,038	10,000	NA
Nitrogen Dioxide (NO_2), $\mu g/m^3$	Annual	18	56	74	100	NA
Particulate Matter (PM_{10}), $\mu g/m^3$	24-hour[7]	19	~~91~~90	~~110~~109	150	NA
	Annual	2	~~27~~20	~~29~~22	50	NA
Particulate Matter ($PM_{2.5}$), $\mu g/m^3$	24-hour	3.5	NA	NA	NA	5
	Annual Neighborhood Average	0.02[5]	NA	NA	NA	0.1
Sulfur Dioxide (SO_2), $\mu g/m^3$	3-hour[6]	155	~~152~~186	~~307~~341	1,300	NA
	24-hour[6]	16	~~94~~107	~~110~~123	365	NA
	Annual	2	~~24~~18	~~26~~20	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~memorandum dated February 18, 2005.

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is quite conservative.

NA = Not Applicable

Notes to Table 24.15-3:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGCs) established by NYSDEC.

(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGCs) established by NYSDEC

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.

(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

NA = Not Applicable

24.15.1.2 Off-Site Analysis

An off-site air quality analysis was performed for the Southwest Brooklyn Converted MTS. The trucks routed to the Existing Southwest Brooklyn MTS would be equivalent to or less than this analysis. Therefore, no additional off-site air quality analysis is required for the Existing Southwest Brooklyn MTS.

24.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing Southwest Brooklyn MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing Southwest Brooklyn MTS operating at 4,800 tpd.

Table 24.16-1
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing Southwest Brooklyn MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	1.27
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.97
Type of Receptor	Rehabilitation Center
Distance to Receptor[3]	780 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
(3) Measured from the site property line.

Table 24.16-2
Existing Southwest Brooklyn MTS
Odor Sources Included in Odor Analysis

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Barge	2
Queuing Collection Vehicles[1]	33

Notes:
(1) This is the number of collection vehicle inbound and outbound from the MTS.

24.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing Southwest Brooklyn MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

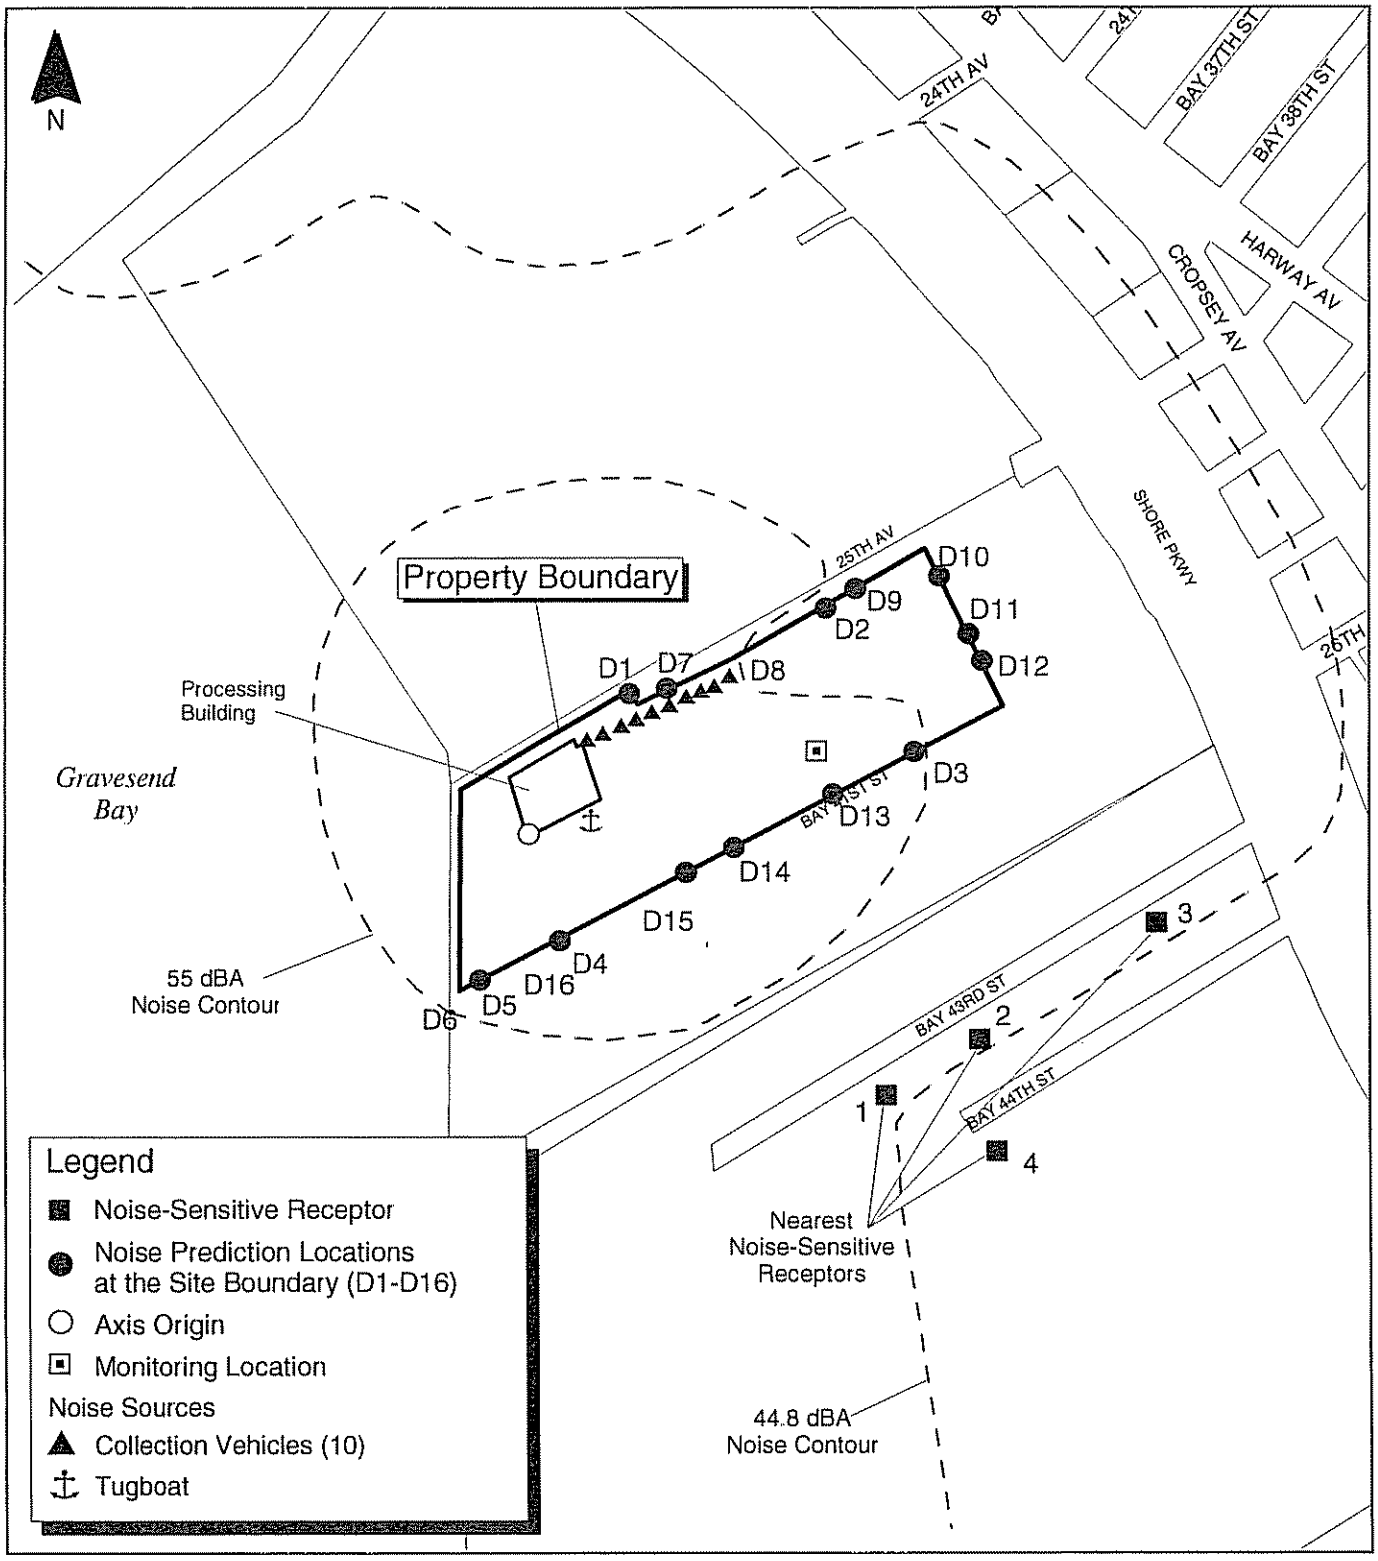
24.17.1 Existing Conditions

24.17.1.1 Introduction

Figure 24.17-1 shows the location of the Existing Southwest Brooklyn MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 5.17.1.1 for further information.

24.17.1.2 On-Site Noise Levels

See Section 5.17.1.2.



24.17.1.3 Off-Site Noise Levels

See Section 5.17.1.3.

24.17.2 Future No-Build Conditions

24.17.2.1 On-Site Noise Levels

See Section 5.17.2.1.

Site delineations are approximate.

See Section 5.17.2.2.

24.17.3 Potential Impacts with the Existing Southwest Brooklyn MTS

24.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing Southwest Brooklyn MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 24.17-1. The number and types of equipment assumed for this analysis were based on the Existing Southwest Brooklyn MTS's peak design capacity. Shown earlier, Figure 24.17-1 indicates the Existing Southwest Brooklyn MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 24.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing Southwest Brooklyn MTS

Equipment Name (quantity) [1]	**Reference Sound Pressure Noise Level at 50 feet (dBA)**[2]
Indoor	
Moving/Queuing Collection Vehicle (8)	~~73~~79.0
Outdoor	
Moving/Queuing Collection Vehicle -(10)	67
Oceangoing Tugboat (1)	73

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

24.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing Southwest Brooklyn MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 72 meters (237 feet) from the property boundary in the direction of the rehabilitation center, which is approximately 277 meters (910 feet) from the property boundary, approximately 66 meters (217 feet) from the property boundary in the direction of the residential house, which is approximately 239 meters (785 feet) from the property boundary, directly abutting the property boundary in the direction of the school which is approximately 228 meters (749 feet) from the property boundary and approximately 76 meters (250 feet) from the baseball field which is approximately 340 meters (1,114 feet) from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. Since the background noise level at the receptor is 44.8 dBA, which is less than 55 dBA, the contour of the predicted facility L_{eq} equivalent to the background noise level is also shown in Figure 24.17-1. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line. However, they are located within the contour based on the background noise level (see Figure 24.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hour based on monitoring data provided in Table 5.17-1. Table 24.17-2 below identifies the existing background noise level during the quietest hour. The table shows the distance from the Existing Southwest Brooklyn MTS to the noise-sensitive receptor, Existing Southwest Brooklyn MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptor. The difference represents the predicted incremental change in noise level from the Existing

Table 24.17-2
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
Existing Southwest Brooklyn MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/ feet)	Existing Noise Levels During Quietest Hour (dBA)[1]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[4]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[5] (yes or no)
Rehabilitation Center [2]	277 / 910	44.8	56.1	56.4	11.6	Yes
Residential House [2]	239 / 785	44.8	56.1	56.4	11.6	Yes
Public School [3]	228 / 749	50.5	55.8	56.9	6.4	Yes
Baseball Field [3]	340 / 1114	50.5	54.6	56.0	5.5	Yes

Notes:

[1] Twenty-minute noise level readings measured at the closest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

[2] Existing noise levels measured on February 10, 2004 at 2:00 a.m.

[3] Existing noise levels measured on February 10, 2004 at 1:00 p.m.. This was the quietest daytime hour. The quietest nighttime hour was not used since the Baseball Field and Public School are assumed to be closed during nighttime hours.

[4] Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.

[5] According to CEQR, an increase of 3 dBA or more at nighttime is considered an impact. In addition, if the daytime background noise level is 62 dBA or more, an increase of 3 dBA or more is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the Existing Southwest Brooklyn MTS with the quietest background noise levels that occur during facility operation.

Southwest Brooklyn MTS. Because this incremental change is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor, there is a predicted impact that would be caused by the Existing Southwest Brooklyn MTS on-site operations.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the Nnew SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

24.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

24.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Existing Southwest Brooklyn MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 24.17-3. Based on this analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the Nnew SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 24.17-3
Current Noise Code Analysis
Existing Southwest Brooklyn MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	**70.5**
D2	63.1
D3	55.7
D4	60.4
D5	57.4
D6	57.4
D7	**72.4**
D8	67.0
D9	61.4
D10	59.3
D11	54.6
D12	53.7
D13	61.8
D14	62.7
D15	61.8
D16	59.4

Notes:
D1 through D16 are points representative of the Existing Southwest Brooklyn MTS boundary that are used in all noise analysis.
Bold= exceedence

24.17.3.6 Off-Site Noise Analysis

An off-site noise analysis was performed in Section 5.17 for the Southwest Brooklyn Converted MTS; the trucks routed to the Existing Southwest Brooklyn MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis was required for the Existing Southwest Brooklyn MTS.

24.17.3.7 Combined On-Site and Off-Site Noise Levels

An on-site noise analysis was performed for the Existing Southwest Brooklyn MTS. As a result of the off-site screening analysis, which is described above in 5.17, no off-site noise analysis was required. Since an off-site analysis was not required, a combined noise analysis was not performed.

CHAPTER 25 ENVIRONMENTAL REVIEW: EXISTING GREENPOINT MTS

25.1 Introduction

The results of the environmental analyses of the Existing Greenpoint MTS are presented in the following sections:

25.2 Land Use, Zoning, and Public Policy
25.3 Socioeconomic Conditions
25.4 Community Facilities and Services
25.5 Open Space
25.6 Cultural Resources
25.7 Urban Design, Visual Resources, and Shadows
25.8 Neighborhood Character
25.9 Natural Resources
25.10 Hazardous Materials
25.11 Water Quality
25.12 Waterfront Revitalization Program
25.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
25.14 Traffic, Parking, Transit, and Pedestrians
25.15 Air Quality
25.16 Odor
25.17 Noise

Section 2.4.7 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

25.2 Land Use, Zoning, and Public Policy

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

25.3 Socioeconomic Conditions

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Socioeconomic Conditions section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.4 Community Facilities and Services

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Community Facilities and Services section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.5 Open Space

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Open Space section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.6 Cultural Resources

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Cultural Resources section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.7 Urban Design, Visual Resources, and Shadows

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

25.8 Neighborhood Character

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Neighborhood Character section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.9 Natural Resources

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Natural Resources section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.10 Hazardous Materials

The Existing Greenpoint MTS is located at the site of the Greenpoint Converted MTS. The analysis of the Hazardous Materials section of the Greenpoint Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

25.11 Water Quality

The Existing Greenpoint MTS has a smaller footprint than the Greenpoint Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the Greenpoint Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing Greenpoint MTS.

25.12 Waterfront Revitalization

The Existing Greenpoint MTS has a smaller footprint than the Greenpoint Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the Greenpoint Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing Greenpoint MTS.

25.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing Greenpoint MTS would be equal to or less than the staffing levels of the Greenpoint Converted MTS. Therefore, the analyses performed for the Greenpoint Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing Greenpoint MTS.

25.14 Traffic and Transportation

The Existing Greenpoint MTS may receive the same amount of DSNY-managed and potential commercial waste as the Greenpoint Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the Greenpoint Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing Greenpoint MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

25.15 Air Quality

The Existing Greenpoint MTS would have less on-site emission-generating equipment, and the sources located farther from the property line receptors, than the Greenpoint Converted MTS. Since there are no unmitigatible significant adverse environmental air quality impacts from the Greenpoint Converted MTS, there will be no unmitigatible significant adverse environmental air quality impacts from the Existing Greenpoint MTS.

25.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing Greenpoint MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing Greenpoint MTS operating at 4,800 tpd.

25.16.1 Potential Impacts with the Existing Greenpoint MTS

25.16.1.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Existing Greenpoint MTS are provided in Table 25.16-1.

Table 25.16-1
Odor Sources Included in Odor Analysis
Existing Greenpoint MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving Vehicles[1]	9
Barge	2

Notes:
(1) This is the number of collection vehicle inbound and outbound from the MTS.

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Existing Greenpoint MTS.

25.16.1.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 25.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Existing Greenpoint MTS at any nearby sensitive receptor is less than 1, so odors from the Existing Greenpoint MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 25.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing Greenpoint MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	1.43
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.06
Type of Receptor	Apartment Building
Distance to Receptor[3]	1,188 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
(3) Measured from the site property line.

25.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing Greenpoint MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

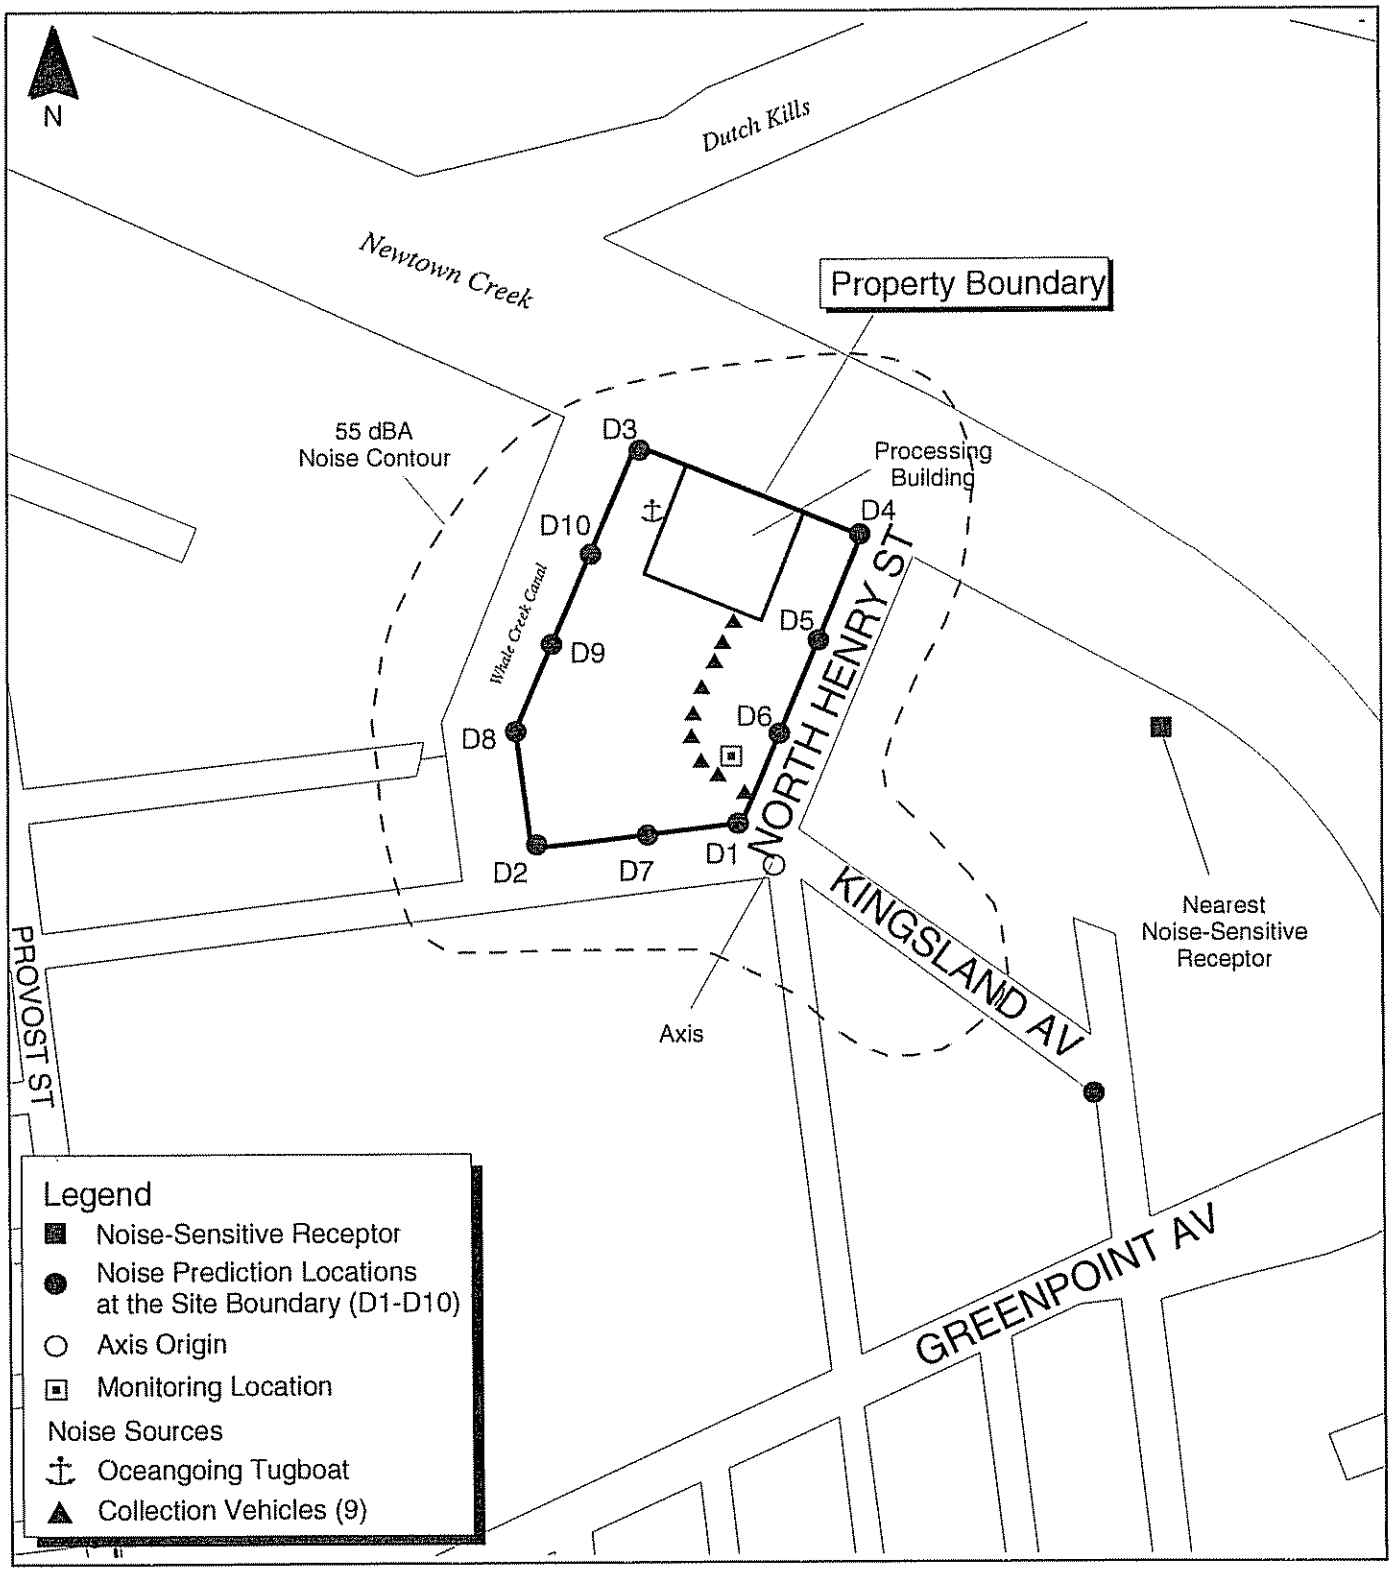
25.17.1 Existing Conditions

25.17.1.1 Introduction

Figure 25.17-1 shows the location of the Existing Greenpoint MTS, the surrounding area and points that represent the property boundary (D1, etc.) for all noise analyses. See Section 20.17.1.1 for further information.

25.17.1.2 On-Site Noise Levels

See Section 20.17.1.2.



25.17.1.3 Off-Site Noise Levels

See Section 20.17.1.3.

25.17.2 Future No-Build Conditions

25.17.2.1 On-Site Noise Levels

See Section 20.17.2.1.

Site delineations are approximate

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

25.17.2.2 Off-Site Noise Levels

See Section 20.17.2.2.

25.17.3 Potential Impacts with the Existing Greenpoint MTS

25.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing Greenpoint MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 25.17-1. The number and types of equipment assumed for this analysis were based on the Existing Greenpoint MTS's peak design capacity. Shown earlier, Figure 25.17-1 indicates the Existing Greenpoint MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

25.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing Greenpoint MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 51 meters (167 feet) from the property boundary in the direction of the nearest noise-sensitive receptor, which is 761 meters (2,498 feet) from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (see Figure 25.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was not required.

Table 25.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing Greenpoint MTS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Moving/Queuing Collection Vehicle (7)	~~73~~79.0
Outdoor	
Moving/Queuing Collection Vehicle (9)	67
Oceangoing Tugboat (1)	73

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

25.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

25.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Existing Greenpoint MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 25.17-2. Based on this analysis, the total L_{eq} does ~~not~~ exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the New SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 25.17-2
Current Noise Code Analysis
Existing Greenpoint MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	65.7
D2	56.9
D3	62.9
D4	63.2

D8	63.7
D9	66.0
D10	69.2

Notes:
D1 through D10 are points representative of the Existing Greenpoint MTS boundary that are used in all noise analysis.
Bold= exceedence

25.17.3.5 Off-Site Noise Levels

An off-site noise analysis was performed in Section 20.17 for the Greenpoint Converted MTS; the trucks routed to the Existing Greenpoint MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis was required for the Existing Greenpoint MTS.

23.17.3.7 Combined On-Site and Off-Site Noise Levels

As a result of both the on- and off-site screening analyses performed for the Existing Greenpoint MTS, neither an on- or off-site noise analyses were required; therefore, a combined noise analysis was not performed.

This page intentionally left blank.

CHAPTER 26 ENVIRONMENTAL REVIEW: EXISTING HAMILTON AVENUE MTS

26.1 Introduction

The results of the environmental analyses of the Existing Hamilton Avenue MTS are presented in the following sections:

26.2 Land Use, Zoning, and Public Policy
26.3 Socioeconomic Conditions
26.4 Community Facilities and Services
26.5 Open Space
26.6 Cultural Resources
26.7 Urban Design, Visual Resources, and Shadows
26.8 Neighborhood Character
26.9 Natural Resources
26.10 Hazardous Materials
26.11 Water Quality
26.12 Waterfront Revitalization Program
26.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
26.14 Traffic, Parking, Transit, and Pedestrians
26.15 Air Quality
26.16 Odor
26.17 Noise

Section 2.4.8 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

26.2 Land Use, Zoning, and Public Policy

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

26.3 Socioeconomic Conditions

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Socioeconomic Conditions section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.4 Community Facilities and Services

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Community Facilities and Services section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.5 Open Space

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Open Space section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.6 Cultural Resources

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Cultural Resources section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.7 Urban Design, Visual Resources, and Shadows

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

26.8 Neighborhood Character

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Neighborhood Character section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.9 Natural Resources

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Natural Resources section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.10 Hazardous Materials

The Existing Hamilton Avenue MTS is located at the site of the Hamilton Avenue Converted MTS. The analysis of the Hazardous Materials section of the Hamilton Avenue Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

26.11 Water Quality

The Existing Hamilton Avenue MTS has a smaller footprint than the Hamilton Avenue Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the Hamilton Avenue Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing Hamilton Avenue MTS.

26.12 Waterfront Revitalization Program

The Existing Hamilton Avenue MTS has a smaller footprint than the Hamilton Avenue Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the Hamilton Avenue Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing Hamilton Avenue MTS.

26.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing Hamilton Avenue MTS would be equal to or less than the staffing levels of the Hamilton Avenue Converted MTS. Therefore, the analyses performed for the Hamilton Avenue Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing Hamilton Avenue MTS.

26.14 Traffic, Parking, Transit, and Pedestrians

The Existing Hamilton Avenue MTS may receive the same amount of DSNY-managed and potential commercial waste as the Hamilton Avenue Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the Hamilton Avenue Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing Hamilton Avenue MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

26.15 Air Quality

The Existing Hamilton Avenue MTS would have less on-site emission-generating equipment, and the sources located farther from the property line receptors, than the Hamilton Avenue Converted MTS. Since there are no unmitigatible significant adverse environmental air quality impacts from the Hamilton Avenue Converted MTS, there will be no unmitigatible significant adverse environmental air quality impacts from the Existing Hamilton Avenue MTS.

26.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing Hamilton Avenue MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing Hamilton Avenue MTS operating at 4,800 tpd.

26.16.1 Potential Impacts with the Existing Hamilton Avenue MTS

26.16.1.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Existing Hamilton Avenue MTS are provided in Table 26.16-1.

Table 26.16-1
Odor Sources Included in Odor Analysis
Existing Hamilton Avenue MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving Vehicles[1]	13
Barge	2

Notes:
(1) This is the number of collection vehicle inbound and outbound from the MTS.

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Existing Hamilton Avenue MTS.

26.16.1.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 26.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Existing Hamilton Avenue MTS at any nearby sensitive receptor is less than 1, so odors from the Existing Hamilton Avenue MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 26.16-2

Existing Hamilton Avenue MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	~~1.54~~1.88
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.17
Type of Receptor	Apartment Buildings
Distance to Receptor[3]	372 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
(3) Measured from the site property line.

26.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing Hamilton Avenue MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

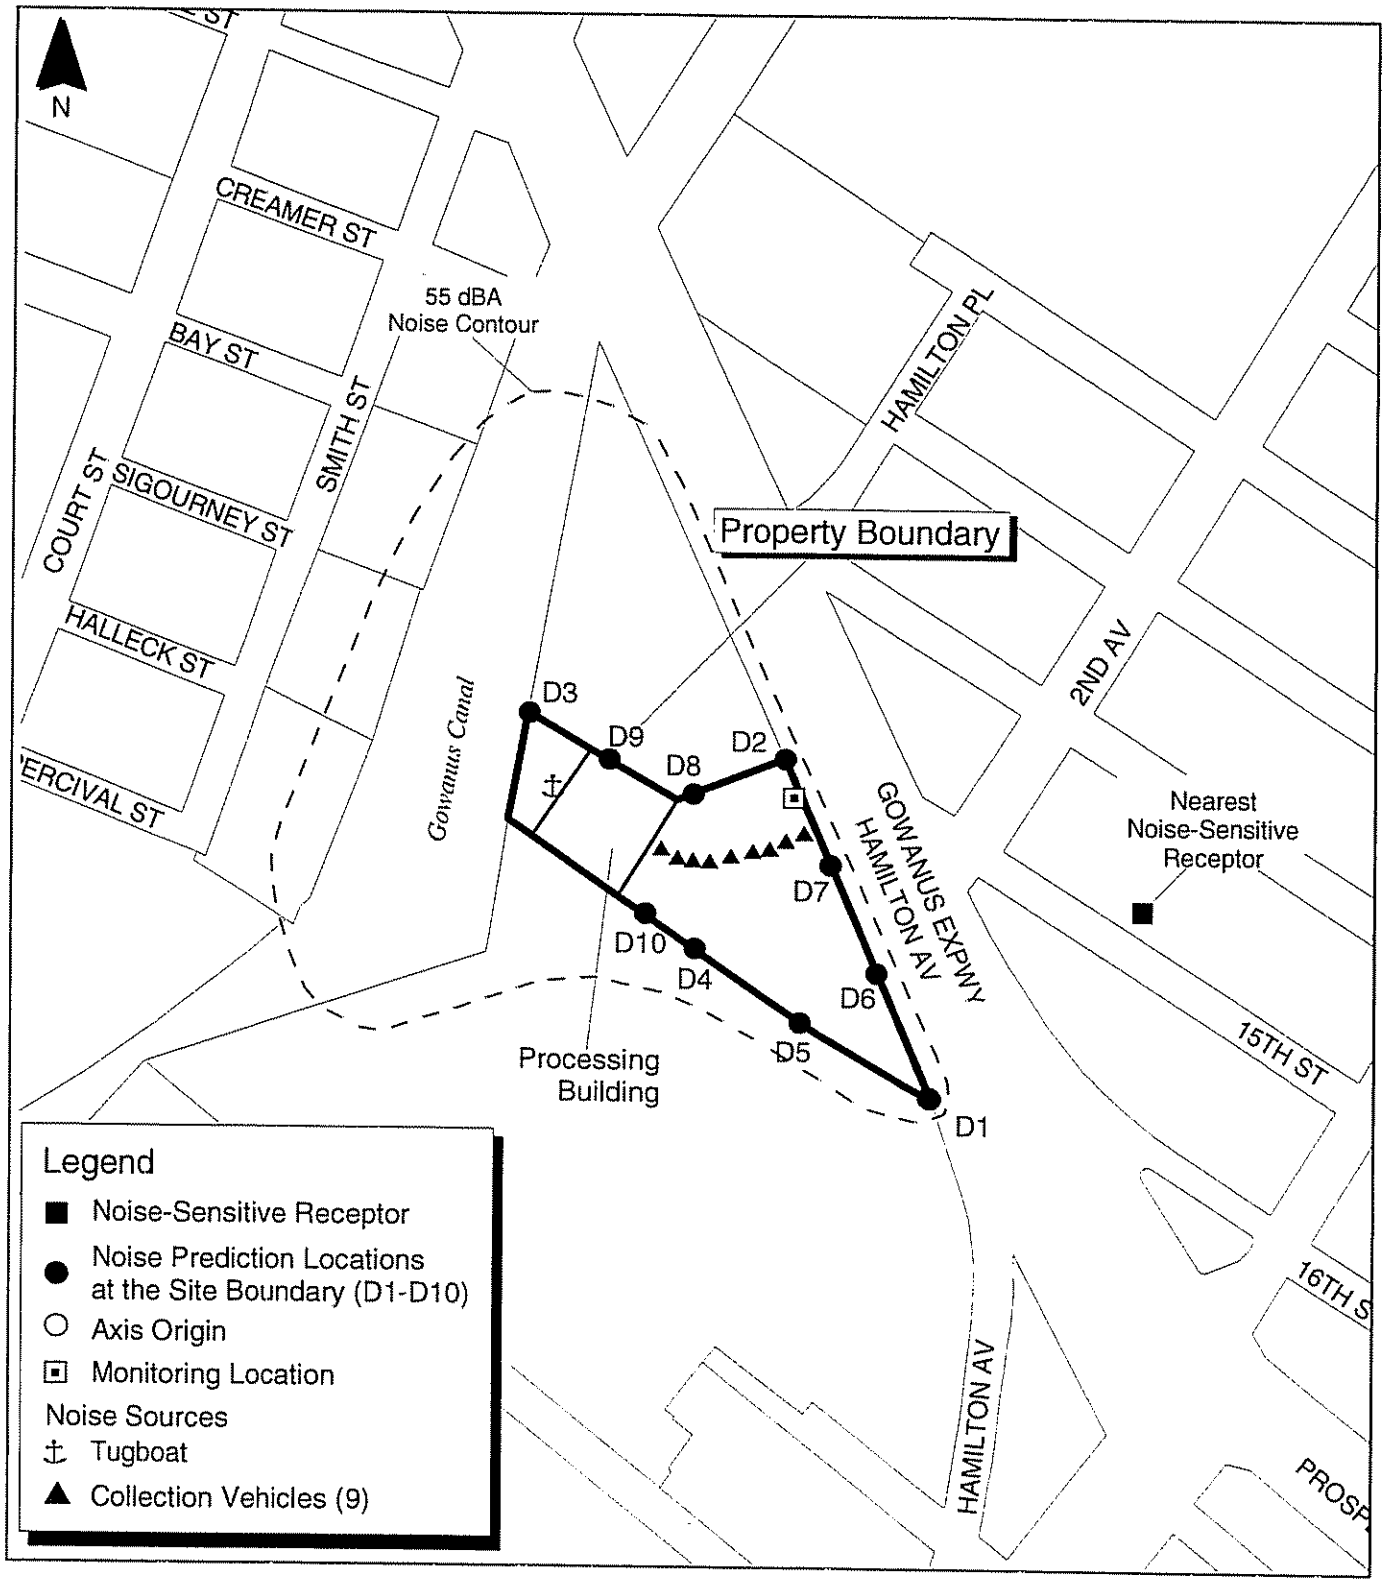
26.17.1 Existing Conditions

26.17.1.1 Introduction

Figure 26.17-1 shows the location of the Existing Hamilton Avenue MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 4.17.1.1 for further information.

26.17.1.2 On-Site Noise Levels

See Section 4.17.1.2.



26.17.1.3 Off-Site Noise Levels

See Section 4.17.1.3.

26.17.2 Future No-Build Conditions

26.17.2.1 On-Site Noise Levels

See Section 4.17.2.1.

DEPARTMENT OF SANITATION

26.17.2.2 Off-Site Noise Levels

See Section 4.17.2.2.

26.17.3 Potential Impacts with the Existing Hamilton Avenue MTS

26.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing Hamilton Avenue MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 26.17-1. The number and types of equipment assumed for this analysis were based on the Existing Hamilton Avenue MTS's peak design capacity. Shown earlier, Figure 26.17-1 indicates the Existing Hamilton Avenue MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

26.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing Hamilton Avenue MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 22 meters (72 feet) from the property boundary in the direction of the nearest noise-sensitive receptor, which is approximately 136 meters (447 feet) from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line; therefore, on-site noise monitoring and an on-site noise analysis were not required.

Table 26.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing Hamilton Avenue MTS

Equipment Name (quantity)[1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Moving/Queuing Collection Vehicle (6)	79
Outdoor	
Moving/Queuing Collection Vehicle (10)	67
Oceangoing Tugboat (1)	73

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

26.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

26.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc) representative of the Existing Hamilton Avenue MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 26.17-2. Based on this analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the ~~N~~new SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 26.17-2
Current Noise Code Analysis
Existing Hamilton Avenue MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	60.6
D2	68.3
D3	68.1
D4	66.1
D5	64.9
D6	**71.4**
D7	**70.3**
D8	67.6
D9	68.1
D10	63.4

Note:
Bold = Exceedance
D1 through D10 are points representative of the Existing Hamilton Avenue MTS boundary that are used in all noise analysis.

26.17.3.6 Off-Site Noise Levels

An off-site noise analysis was performed in Section 4.17 for the Hamilton Avenue Converted MTS; the trucks routed to the Existing Hamilton Avenue MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis was required for the Existing Hamilton Avenue MTS.

26.17.3.7 Combined On-Site and Off-Site Noise Levels

As a result of both the on- and off-site screening analyses performed for the Existing Hamilton Avenue MTS, neither the on- or the off-site noise analyses were required; therefore, a combined noise analysis was not performed.

CHAPTER 27 ENVIRONMENTAL REVIEW: EXISTING WEST 135TH STREET MTS

27.1 Introduction

The results of the environmental analyses of the Existing West 135th Street MTS are presented in the following sections:

27.2 Land Use, Zoning, and Public Policy
27.3 Socioeconomic Conditions
27.4 Community Facilities and Services
27.5 Open Space
27.6 Cultural Resources
27.7 Urban Design, Visual Resources, and Shadows
27.8 Neighborhood Character
27.9 Natural Resources
27.10 Hazardous Materials
27.11 Water Quality
27.12 Waterfront Revitalization Program
27.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
27.14 Traffic, Parking, Transit, and Pedestrians
27.15 Air Quality
27.16 Odor
27.17 Noise

Section 2.4.9 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

27.2 Land Use, Zoning, and Public Policy

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

27.3 Socioeconomic Conditions

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Socioeconomic Conditions section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.4 Community Facilities and Services

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Community Facilities and Services section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.5 Open Space

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Open Space section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.6 Cultural Resources

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Cultural Resources section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.7 Urban Design, Visual Resources, and Shadows

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

27.8 Neighborhood Character

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Neighborhood Character section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.9 Natural Resources

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Natural Resources section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.10 Hazardous Materials

The Existing West 135th Street MTS is located at the site of the West 135th Street Converted MTS. The analysis of the Hazardous Materials section of the West 135th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

27.11 Water Quality

The Existing West 135th Street MTS has a smaller footprint than the West 135th Street Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the West 135th Street Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing West 135th Street MTS.

27.12 Waterfront Revitalization Program

The Existing West 135th Street MTS has a smaller footprint than the West 135th Street Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the West 135th Street Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing West 135th Street MTS.

27.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing West 135th Street MTS would be equal to or less than the staffing levels of the West 135th Street Converted MTS. Therefore the analyses performed for the West 135th Street Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing West 135th Street MTS.

27.14 Traffic, Parking, Transit, and Pedestrians

The Existing West 135th Street MTS may receive the same amount of DSNY-managed and potential commercial waste as the West 135th Street Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the West 135th Street Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing West 135th Street MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

27.15 Air Quality

The Existing West 135th Street MTS would have less on-site emission-generating equipment, and the sources located farther from the property line receptors, than the West 135th Street Converted MTS. Since there are no unmitigatible significant adverse environmental air quality impacts from the West 135th Street Converted MTS, there will be no unmitigatible significant adverse environmental air quality impacts from the Existing West 135th Street MTS.

27.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing West 135th Street MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing West 135th Street MTS operating at 4,800 tpd.

27.16.1 Potential Impacts with the Existing West 135th Street MTS

27.16.1.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Existing West 135th Street MTS are provided in Table 27.16-1.

Table 27.16-1
Odor Sources Included in Odor Analysis
Existing West 135th Street MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving Vehicles[1]	46
Barge	2

Notes:
(1) This is the number of collection vehicle sources inbound and outbound from the MTS. The actual number of vehicles is 10.

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Existing West 135th Street MTS.

27.16.1.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 27.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Existing West 135th Street MTS at any nearby sensitive receptor is less than 1, so odors from the Existing West 135th Street MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 27.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing West 135th Street MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	1.37
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.40
Type of Receptor	Riverbank State Park
Distance to Receptor(3)	60 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
(3) Measured from the site property line.

27.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing West 135th Street MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

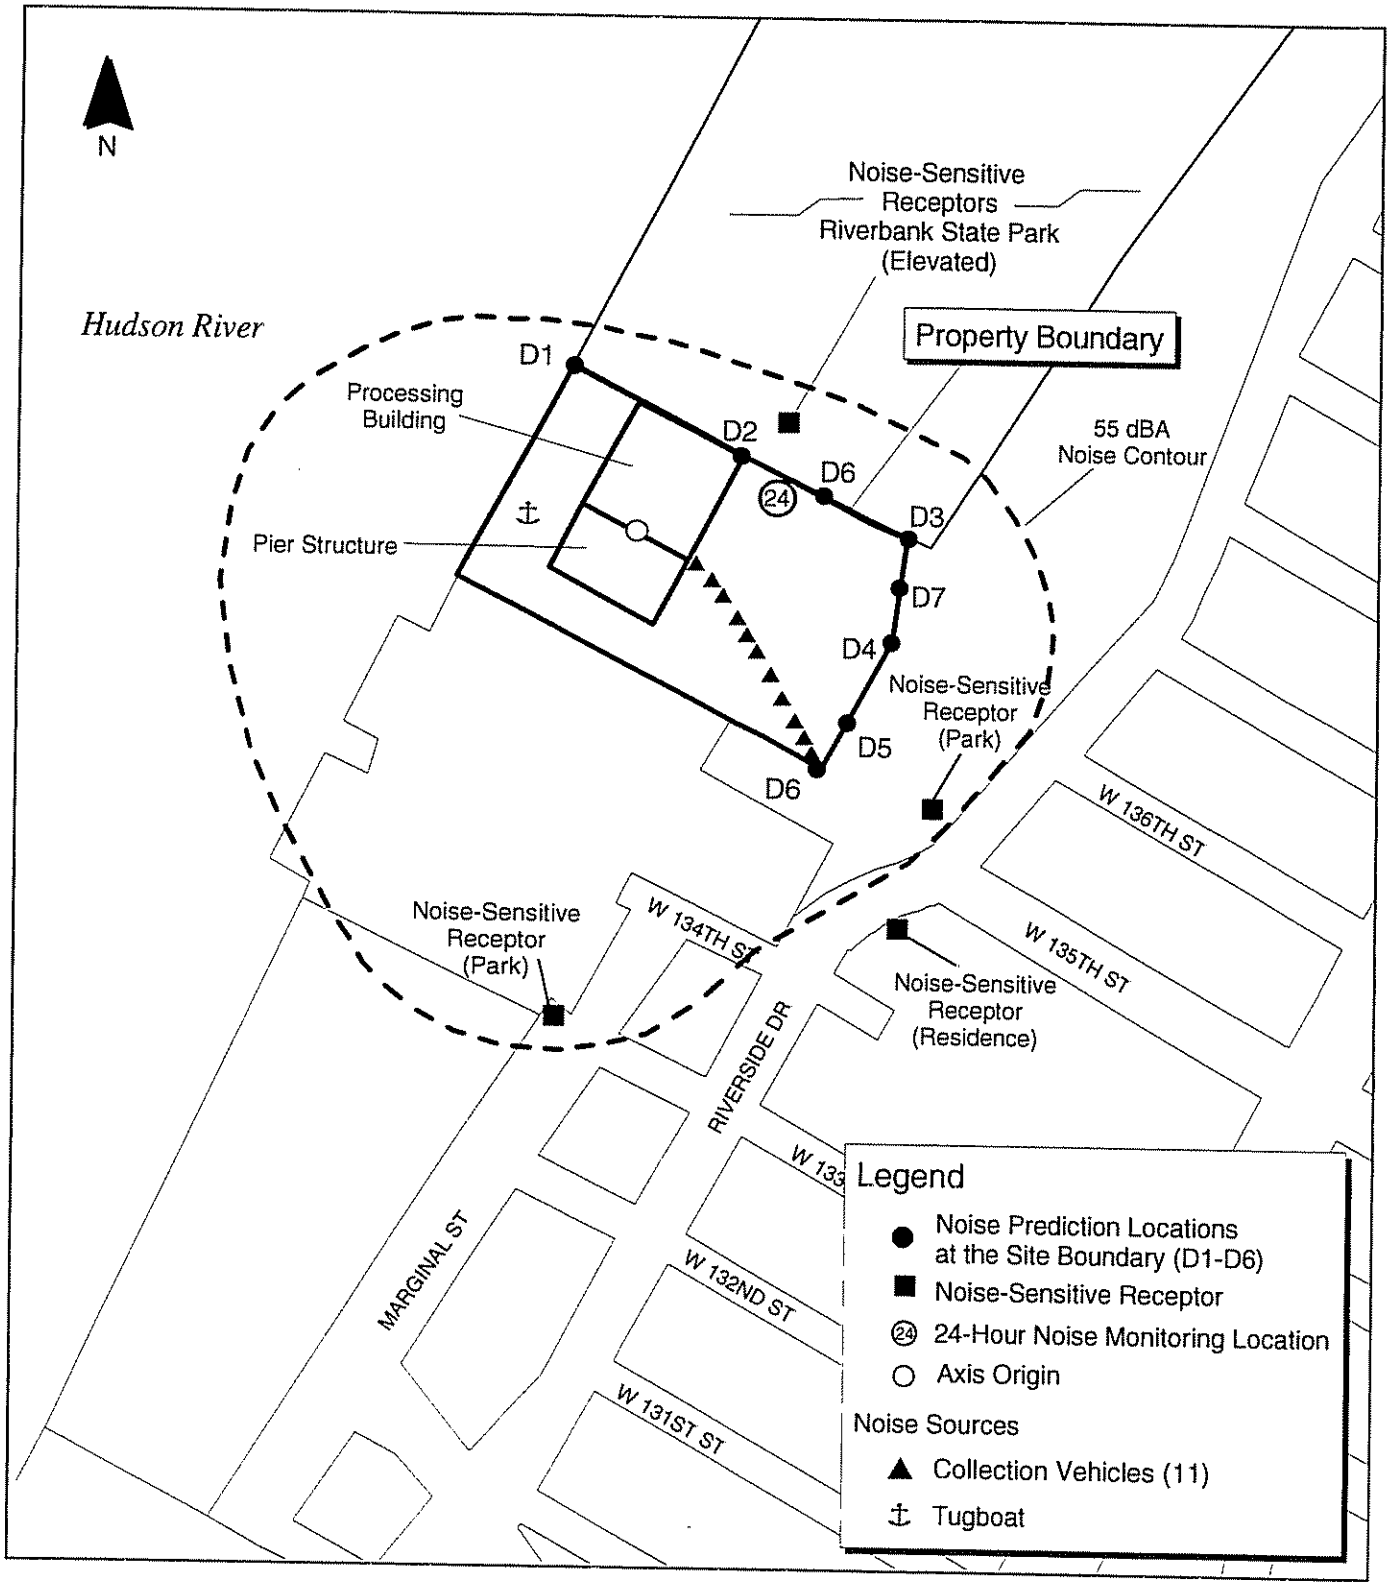
27.17.1 Existing Conditions

27.17.1.1 Introduction

Figure 27.17-1 shows the location of the Existing West 135th Street MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 21.17.1.1 for further information.

27.17.1.2 On-Site Noise Levels

See Section 21.17.1.2.



27.17.1.3 Off-Site Noise Levels

See Section 21.17.1.3.

27.17.2 Future No-Build Conditions

27.17.2.1 On-Site Noise Levels

See Section 21.17.2.1.

27.17.3 Potential Impacts with the Existing West 135th Street MTS

27.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing West 135th Street MTS and its reference noise levels, used in the CEQR and Current Noise Code analysis, are shown in Table 27.17-1. The number and types of equipment assumed for this analysis were based on the Existing West 135th Street MTS's peak design capacity. Shown earlier, Figure 27.17-1 indicates the Existing West 135th Street MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 27.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing West 135th Street MTS

Equipment Name (quantity)[1]	**Reference Sound Pressure Noise Level at 50 feet (dBA)**[2]
Indoor	
Moving/Queuing Collection Vehicle (7)	~~73~~79.0
Outdoor	
Moving/Queuing Collection Vehicle (10)	67
Oceangoing Tugboat (1)	73

Note:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

27.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing West 135th Street MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 61 meters (200 feet) from the property boundary in the direction of Riverbank State Park, which is approximately 27 meters (90 feet) away from the property boundary. The 55 dBA contour line is approximately 76 meters (250 feet) from the property boundary in the direction of Riverside Ramparts, which is approximately 67 meters (220 feet) away from the property boundary. Similarly, the 55 dBA contour line is approximately 69 meters (225 feet) from the property boundary in the direction of the apartment building on Riverside Drive, which is approximately 99 meters (325 feet) away from the property boundary. The 55 dBA contour line is approximately 213 meters (700 feet) from the property boundary in the direction of Harlem Piers Park, which is approximately 183 meters (600 feet) away from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55.dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1discusses this concept in greater detail. The results of the screening analysis show that three of the four noise-sensitive receptors are located within the 55 dBA contour line (see Figure 27.17-1). Therefore, an on-site noise analysis, including noise monitoring at the Riverbank State Park, Riverside Ramparts and Harlem Piers Park noise-sensitive receptors, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptors during the quietest hour based on monitoring data provided in Table 21.17-1. Table 27.17-2 below identifies the existing background noise level during the quietest hour. The table shows the distance from the Existing West 135th Street MTS to the noise-sensitive receptors, the monitored existing background noise level at the noise-sensitive receptors, Existing West 135th Street MTS-related predicted noise levels at the noise-sensitive receptors, and the predicted noise levels with both facility noise and

Table 27.17-2
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
Existing West 135th Street MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/ feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
Riverbank State Park	27 / 90	64.2	66.0	68.1	3.9	Yes
Riverside Ramparts Park	67/220	62.4	58.2	63.8	1.4	No
Riverside Drive Apartment	119/389	59.3	56.0	61.0	1.7	No
Harlem Piers Park	183 / 600	62.2	58.8	63.8	1.6	No

Notes:

(1) Twenty-minute noise level readings measured at the nearest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

(2) Existing noise levels at the proposed Harlem Piers Park were measured July 16, 2004 at 10:15 a.m. Existing noise levels at Riverside Ramparts were measured at August 18, 2004 at 10:40 a.m. Existing noise levels at Riverbank State Park were measured on April 16, 2003 at 2:45 p.m. Existing noise levels at Riverside Drive Apartment were measured on May 9, 2003 at 2:30 a.m.

(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.

(4) According to CEQR, an increase of 3 dBA during the daytime if the existing noise level is greater than 62 dBA is considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the Existing West 135th Street MTS with the quietest background noise levels that occur during its operation. Only an analysis during the quietest daytime noise levels was performed, since the parks are not expected to be opened during the nighttime hours.

background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptors. This difference represents the predicted incremental change in noise level from the Existing West 135th Street MTS. Because this incremental change is less than the CEQR threshold of 3 dBA, since the existing background noise level is 62 dBA or greater at all of the noise-sensitive receptors analyzed, there is ~~no~~ a predicted impact that would be caused by the Existing West 135th Street MTS on-site operations at the Riverbank State Park

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the New SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

27.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

27.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Existing West 135th Street MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 27.17-3. Based on this analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the New SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 27.17-3
Current Noise Code Analysis
Existing West 135th Street MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	61.1
D2	65.1
D3	65.1
D4	**70.2**
D5	**72.7**
D6	**75.1**
D7	65.2
D8	67.6

Notes:
D1 through D8 are points representative of the Existing West 135th Street MTS boundary that are used in all noise analysis.
Bold= exceedence

27.17.3.6 Off-Site Noise Levels

An off-site noise analysis was performed in Section 21.17 for the West 135th Street Converted MTS. The trucks routed to the Existing West 135th Street MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis is required for the Existing West 135th Street MTS.

27.17.3.7 Combined On-Site and Off-Site Noise Levels

An on-site and off-site noise analysis was performed for the Existing West 135th Street MTS. Since the potential impacts of these analyses can affect the same noise-sensitive receptor, a screening analysis must be conducted to determine if a combined noise analysis would be required for the operations at the Existing West 135th Street MTS.

If this facility is chosen to be part of the New SWMP, a supplementary refined on-site noise analysis will be performed, including a combined noise analysis.

CHAPTER 28 ENVIRONMENTAL REVIEW: EXISTING WEST 59TH STREET MTS

28.1 Introduction

The results of the environmental analyses of the Existing West 59th Street MTS are presented in the following sections:

28.2 Land Use, Zoning, and Public Policy
28.3 Socioeconomic Conditions
28.4 Community Facilities and Services
28.5 Open Space
28.6 Cultural Resources
28.7 Urban Design, Visual Resources, and Shadows
28.8 Neighborhood Character
28.9 Natural Resources
28.10 Hazardous Materials
28.11 Water Quality
28.12 Waterfront Revitalization Program
28.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
28.14 Traffic, Parking, Transit, and Pedestrians
28.15 Air Quality
28.16 Odor
28.17 Noise

Section 2.4.10 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

28.2 Land Use, Zoning, and Public Policy

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

28.3 Socioeconomic Conditions

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Socioeconomic Conditions section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.4 Community Facilities and Services

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Community Facilities and Services section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.5 Open Space

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Open Space section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.6 Cultural Resources

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Cultural Resources section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.7 Urban Design, Visual Resources, and Shadows

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

28.8 Neighborhood Character

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Neighborhood Character section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.9 Natural Resources

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Natural Resources section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.10 Hazardous Materials

The Existing West 59th Street MTS is located at the site of the West 59th Street Converted MTS. The analysis of the Hazardous Materials section of the West 59th Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

28.11 Water Quality

The Existing West 59th Street MTS has a smaller footprint than the West 59th Street Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the West 59th Street Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing West 59th Street MTS.

28.12 Waterfront Revitalization Program

The Existing West 59th Street MTS has a smaller footprint than the West 59th Street Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the West 59th Street Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing West 59th Street MTS.

28.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing West 59th Street MTS would be equal to or less than the staffing levels of the West 59th Street Converted MTS. Therefore, the analyses performed for the West 59th Street Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing West 59th Street MTS.

28.14 Traffic, Parking, Transit, and Pedestrians

The Existing West 59th Street MTS may receive the same amount of DSNY-managed and potential commercial waste as the West 59th Street Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the West 59th Street Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing West 59th Street MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

28.15 Air Quality

The Existing West 59th Street MTS would have less on-site emission-generating equipment, and the sources located farther from the property line receptors, than the West 59th Street Converted MTS. Since there are no unmitigatible significant adverse environmental air quality impacts from the West 59th Street Converted MTS, there will be no unmitigatible significant adverse environmental air quality impacts from the Existing West 59th Street MTS.

28.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing West 59th Street MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing West 59th Street MTS operating at 4,800 tpd.

28.16.1 Potential Impacts with the Existing West 59th Street MTS

28.16.1.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Existing West 59th Street MTS are provided in Table 28.16-1.

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% percent and 99% percent of odorous compounds. For purposes of modeling odor dispersion, a 90% percent reduction of odorous emissions was conservatively assumed for the Existing West 59th Street MTS.

Table 28.16-1
Odor Sources Included in Odor Analysis
Existing West 59th Street MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving Vehicles[1]	1
Barge	4

Notes:
(1) This is the number of collection vehicle inbound and outbound from the MTS.

28.16.1.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 28.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Existing West 59th Street MTS at any nearby sensitive receptor is less than 1, so odors from the Existing West 59th Street MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 28.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing West 59th Street MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	1.54
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.2
Type of Receptor	Apartment Buildings
Distance to Receptor[3]	1,739 Feet

Notes:

(1) D/T ratio is dimensionless.

(2) Measured from the site boundary.

(3) Measured from the site property line.

28.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing West 59th Street MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

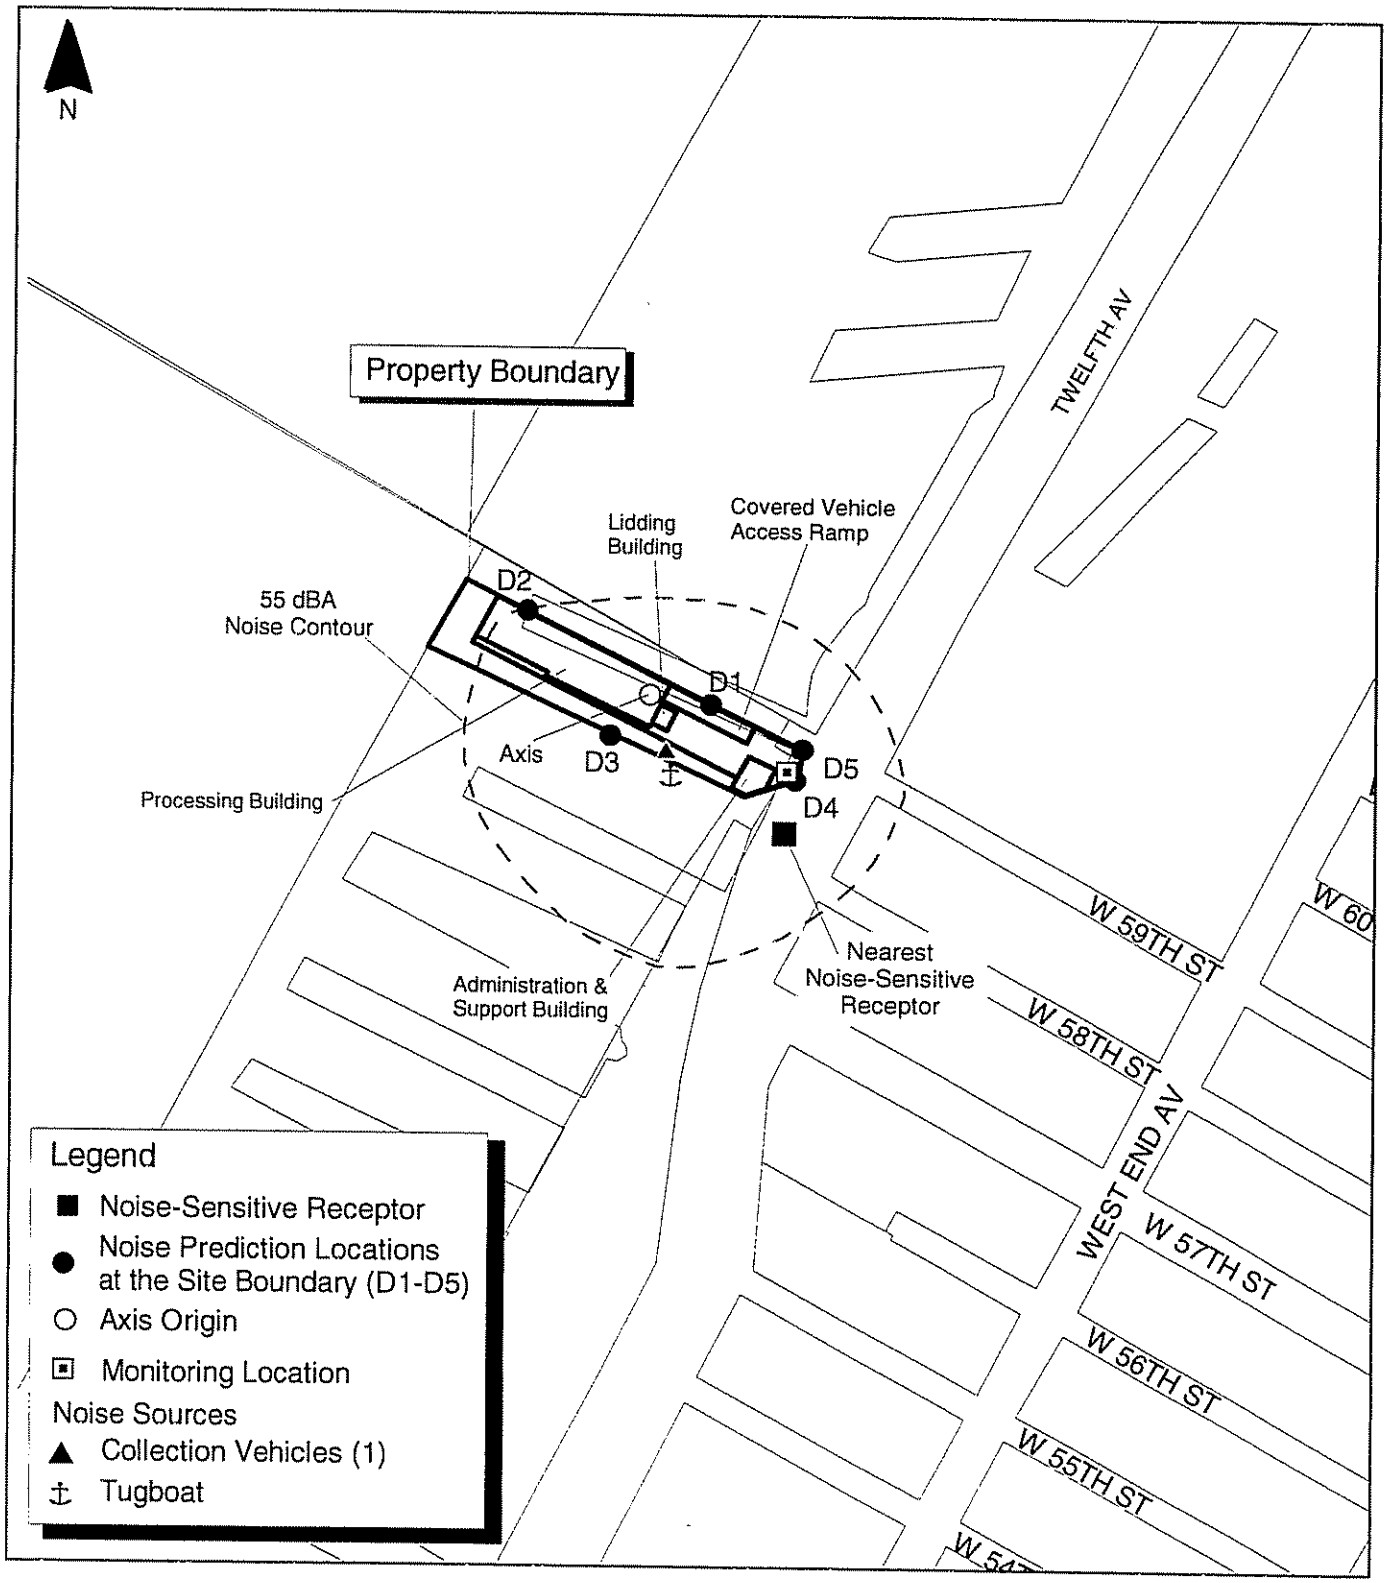
28.17.1 Existing Conditions

28.17.1.1 Introduction

Figure 28.17-1 shows the location of the Existing West 59th Street MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 22.17.1.1 for further information.

28.17.1.2 On-Site Noise Levels

See Section 22.17.1.2.



28.17.1.3 Off-Site Noise Levels

See Section 22.17.1.3.

28.17.2 Future No-Build Conditions

28.17.2.1 On-Site Noise Levels

See Section 22.17.2.1.

DEPARTMENT OF SANITATION

28.17.2.2 Off-Site Noise Levels

See Section 22.17.2.2.

28.17.3 Potential Impacts with the Existing West 59th Street MTS

28.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing West 59th Street MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 28.17-1. The number and types of equipment assumed for this analysis were based on the Existing West 59th Street MTS's peak design capacity. Shown earlier, Figure 28.17-1 indicates the Existing West 59th Street MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 28.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing West 59th Street MTS

Equipment Name (quantity) [1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Moving /Queuing Collection Vehicle (13)	79.0
Outdoor	
Moving Queuing Collection Vehicle (1)	67
Oceangoing Tugboat (1)	73

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

28.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing West 59th Street MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 77 meters (253 feet) from the property boundary in the

direction of the nearest noise-sensitive receptor, which is directly abutting the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA, (i.e., the point off site where noises generated on site attenuate to 55 dBA), is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are located within the 55 dBA contour line (see Figure 28.17-1). Therefore, an on-site analysis, including noise monitoring at the nearest sensitive receptor, was required to determine if an impact is predicted under Section R of 2001 CEQR Technical Manual.

Noise monitoring was conducted at the noise-sensitive receptor during the quietest hours based on monitoring data provided in Table 22.17-1. Table 28.17-2 below identifies the existing background noise level during the quietest hour. The table shows the distance from the Existing West 59th Street MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, Existing West 59th Street MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between this combined noise level and the existing noise level at the noise-sensitive receptor. This difference represents the predicted incremental change in noise level from the Existing West 59th Street MTS. Since the quietest hour occurs during the daytime, the CEQR threshold is 65 dBA. However, since the background noise level is greater than 62 dBA, an impact would be caused if the predicted incremental change is greater than the CEQR threshold of 3 dBA at the nearest noise-sensitive receptor. Based on this, there is no predicted impact that would be caused by the Existing West 59th Street MTS on-site operations.

28.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

Table 28.17-2
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
Existing West 59th Street MTS

Noise-Sensitive Receptor	Distance from Facility (meters / feet)	Existing Noise Level During Quietest Hour (dBA) [1][2]	Predicted Facility Noise Level at Noise-Sensitive Receptor (dBA) [3]	Combined Facility and Background Noise Level at Noise-Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact [4] (yes or no)
Riverside Park South	Directly abutting property boundary	65.4	60.9	65.4	1.3	No

Notes:
(1) Twenty minute noise level reading measured at the nearest noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.
(2) Existing noise levels measured on February 10, 2003 at 5:00 p.m.
(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.
(4) According to CEQR, an increase of 3 dBA or more when the daytime existing noise level is 62 dBA or greater is considered an impact. The impact compares the loudest noise emissions from daily operations at the Existing West 59th Street MTS with the quietest background noise levels that occur during facility operation. The quietest hour of background noise levels occurred during the daytime hours for the noise-sensitive receptor; therefore, only daytime impact criteria are discussed in this analysis for the noise-sensitive receptor.

28.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Existing West 59th Street MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 28.17-3. Based on this analysis, the total L_{eq} does not exceed the current Noise Code Standard of 70 dBA at the property boundary.

Table 28.17-3
Current Noise Code Analysis
Existing West 59th Street MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	53.0
D2	40.4
D3	51.1
D4	59.8
D5	55.1
D6	66.2
D7	64.8
D8	64.2

Notes:
D1 through D8 are points representative of the Existing West 59th Street MTS boundary that are used in all noise analysis.
Bold= exceedence

28.17.3.5 Off-Site Noise Analysis

An off-site noise analysis was performed in Section 22.17 for the West 59th Street Converted MTS; the trucks routed to the Existing West 59th Street MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis was required for the Existing West 59th Street MTS.

28.17.3.7 Combined On-Site and Off-Site Noise Levels

As a result of the on- and off-site screening analyses performed for the Existing West 59th Street MTS, neither an on- or off-site noise analyses were required; therefore, a combined noise analysis was not performed.

CHAPTER 29 ENVIRONMENTAL REVIEW: EXISTING EAST 91ST STREET MTS

29.1 Introduction

The results of the environmental analyses of the Existing East 91st Street MTS are presented in the following sections:

29.2 Land Use, Zoning, and Public Policy
29.3 Socioeconomic Conditions
29.4 Community Facilities and Services
29.5 Open Space
29.6 Cultural Resources
29.7 Urban Design, Visual Resources, and Shadows
29.8 Neighborhood Character
29.9 Natural Resources
29.10 Hazardous Materials
29.11 Water Quality
29.12 Waterfront Revitalization Program
29.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
29.14 Traffic, Parking, Transit, and Pedestrians
29.15 Air Quality
29.16 Odor
29.17 Noise

Section 2.4.11 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

29.2 Land Use, Zoning, and Public Policy

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

29.3 Socioeconomic Conditions

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Socioeconomic Conditions section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.4 Community Facilities and Services

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Community Facilities and Services section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.5 Open Space

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Open Space section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.6 Cultural Resources

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Cultural Resources section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.7 Urban Design, Visual Resources, and Shadows

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

29.8 Neighborhood Character

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Neighborhood Character section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.9 Natural Resources

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Natural Resources section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.10 Hazardous Materials

The Existing East 91st Street MTS is located at the site of the East 91st Street Converted MTS. The analysis of the Hazardous Materials section of the East 91st Street Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

29.11 Water Quality

The Existing East 91st Street MTS has a smaller footprint than the East 91st Street Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the East 91st Street Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing East 91st Street MTS.

29.12 Waterfront Revitalization Program

The Existing East 91st Street MTS has a smaller footprint than the East 91st Street Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the East 91st Street Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing East 91st Street MTS.

29.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing East 91st Street MTS would be equal to or less than the staffing levels of the East 91st Street Converted MTS. Therefore, the analyses performed for the East 91st Street Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing East 91st Street MTS.

29.14 Traffic, Parking, Transit, and Pedestrians

The Existing East 91st Street MTS may receive the same amount of DSNY-managed and potential commercial waste as the East 91st Street Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the East 91st Street Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing East 91st Street MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

29.15 Air Quality

The Existing East 91st Street MTS would have less on-site emission-generating equipment, and the sources located farther from the property line receptors, than the East 91st Street Converted MTS. Since there are no unmitigatible significant adverse environmental air quality impacts from the East 91st Street Converted MTS, there will be no unmitigatible significant adverse environmental air quality impacts from the Existing East 91st Street MTS.

29.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing East 91st Street MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing East 91st Street MTS operating at 4,800 tpd.

29.16.1 Potential Impacts with the Existing East 91st Street MTS

29.16.1.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Existing East 91st Street MTS are provided in Table 29.16-1.

Table 29.16-1
Odor Sources Included in Odor Analysis
Existing East 91st Street MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Moving Vehicles(1)	14
Barge	2

Notes:
(1) This is the number of collection vehicle inbound and outbound from the MTS.

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% percent and 99% percent of odorous compounds. For purposes of modeling odor dispersion, a 90% percent reduction of odorous emissions was conservatively assumed for the Existing East 91st Street MTS.

29.16.1.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 29.16-2. The predicted odor unit OU values at sensitive receptor locations are compared to an OU odor unit of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted odor unit OU associated with the Existing East 91st Street MTS at any nearby sensitive receptor is less than 1, so odors from the Existing East 91st Street MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 29.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing East 91st Street MTS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	2.55
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.46
Type of Receptor	Apartment Building
Distance to Receptor(3)	360 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
(3) Measured from the site property line.

29.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing East 91st Street MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

29.17.1 Existing Conditions

29.17.1.1 Introduction

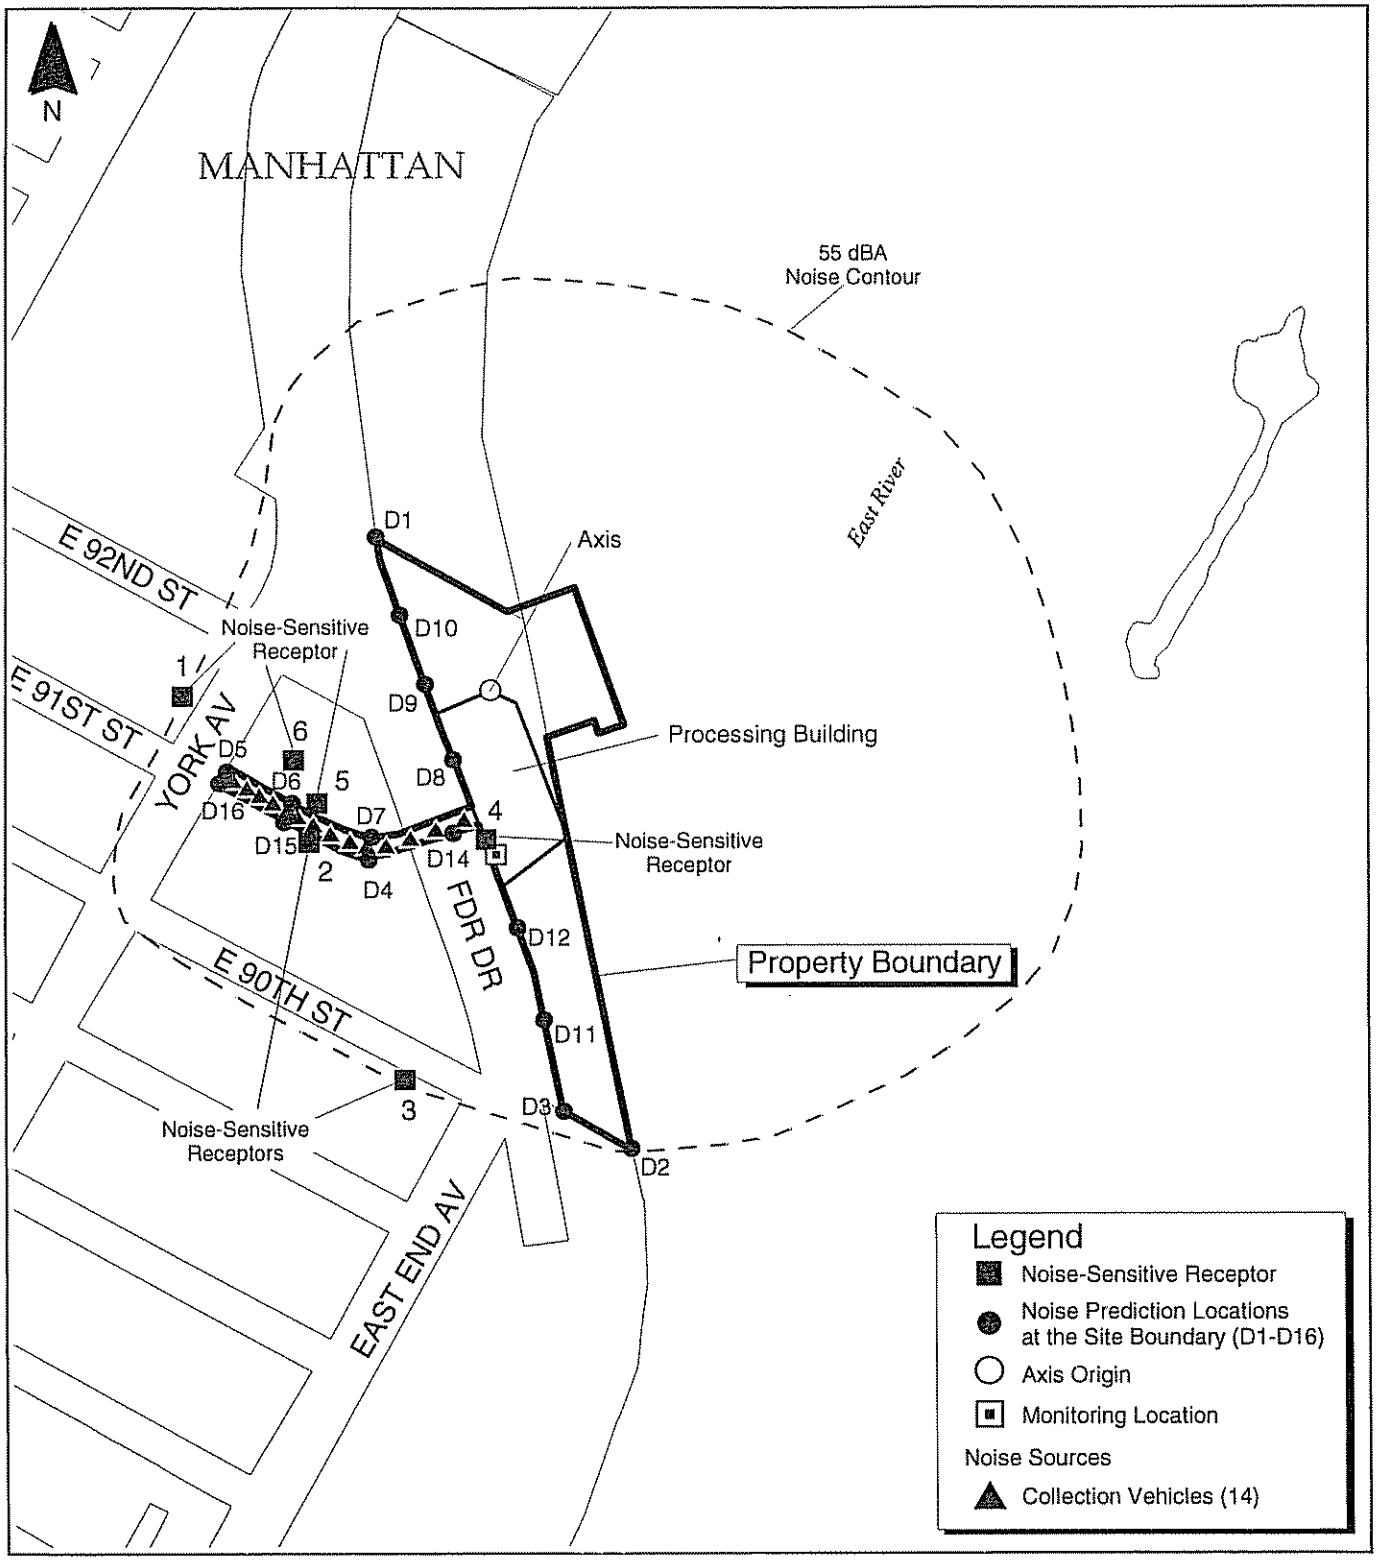
Figure 29.17-1 shows the location of the Existing East 91st Street MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 6.7.1.1 for further information.

29.17.1.2 On-Site Noise Levels

See Section 6.17.1.2.

29.17.1.3 Off-Site Noise Levels

See Section 6.17.1.3.



29.17.2 Future No-Build Conditions

29.17.2.1 On-Site Noise Levels

See Section 6.17.2.1.

29.17.2.2 Off-Site Noise Levels

See Section 6.17.2.2.

Site delineations and study area boundaries are approximate.

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

29.17.3 Potential Impacts with the Existing East 91st Street MTS

29.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing East 91st —Street MTS, and its reference noise levels, which were used in the CEQR and Noise Code analysis, are shown in Table 29.17-1. The number and types of equipment assumed for this analysis were based on the facility's peak design capacity. Shown earlier, Figure 29.17-1 indicates the Existing East 91st Street MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and predicted the 55 dBA contour line.

Table 29.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing East 91st Street MTS

Equipment Name (quantity) [1]	Reference Sound Pressure Noise Level at 50 feet (dBA)[2]
Indoor	
Moving/Queuing Collection Vehicle (7)	~~73~~79.0
Outdoor	
Moving/Queuing Collection Vehicle (14)	67
Oceangoing Tugboat (1)	73

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

29.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing East 91st Street MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 50 meters (164 feet) from the property boundary in the direction of the York Avenue Apartment Building, which is approximately 40 meters (131 feet) from the property boundary; approximately 114 meters (373 feet) from the property boundary in the direction of the Asphalt Green Recreational Field, which is directly abutting the property boundary; approximately 136 meters (446 feet) from the property boundary in the direction of

the East 90th Street Apartment Building, which is approximately 114 meters (375 feet) from the property boundary; approximately 160 meters (523 feet) from the property boundary in the direction of the Bobby Wagner Walk, which is directly abutting the property boundary; approximately 107 meters (353 feet) from the property boundary in the direction of Asphalt Green, which is directly abutting the property boundary; and approximately 144 meters (473 feet) from the property boundary in the direction of the Asphalt Green Playground, which is directly abutting the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that receptors are located within the 55 dBA contour line (see Figure 29.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was required to determine if an impact is predicted under Section R of the 2001 CEQR Technical Manual.

Noise monitoring was conducted at the receptor during the quietest hour based on monitoring data provided in Table 6.17-1. Table 29.17-2 identifies the existing background noise level during the quietest hour. The table shows the distance from the Existing East 91st Street MTS to the noise-sensitive receptor, the monitored existing background noise level at the noise-sensitive receptor, Existing East 91st Street MTS-related predicted noise levels at the noise-sensitive receptor, and the predicted noise levels with both facility noise and background noise combined. The table also provides the difference between the combined noise level and the existing noise level at the noise-sensitive receptor. The difference represents the predicted incremental change in noise level from the Existing East 91st Street MTS. Because this incremental change is greater than the CEQR threshold of 3 dBA during the nighttime hours or during the daytime hours when the daytime background noise level is greater than 62 dBA at the nearest noise-sensitive receptor, there is a predicted impact that would be caused by the Existing East 91st Street MTS on-site operations.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the Nnew SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

Table 29.17-2
CEQR Analysis
Existing and Predicted Noise Levels (L_{eq}) at the Nearest Noise-Sensitive Receptor
Existing East 91st Street MTS

Noise-Sensitive Receptor ID	Distance from Facility (meters/feet)	Existing Noise Levels During Quietest Hour (dBA)[1][2]	Predicted Facility Noise Level at Sensitive Receptor (dBA)[3]	Combined Facility and Background Noise Level at the Sensitive Receptor (dBA)	Increase over Existing Noise Levels (dBA)	Impact[4] (yes or no)
York Avenue Apartment Building-	40 / 131	~~63.6~~63.4	~~65.1~~65.2	67.4	~~3.8~~4.0	Yes
Asphalt Green Recreational Field[5]	Directly abutting truck ramp	~~69.0~~71.1	~~74.0~~76.5	~~75.2~~77.6	~~6.2~~6.5	Yes
East 90th Street Apartment Building	114 / 375	~~64.5~~63.4	~~63.8~~64.0	~~67.2~~66.7	~~2.7~~3.3	~~No~~Yes
Bobby Wagner Walk	Directly abutting property boundary	68.0	~~68.6~~75.4	~~71.3~~76.1	~~3.3~~8.1	Yes
Asphalt Green Building[5]	Directly abutting truck ramp	71.1	76.1	77.3	6.2	Yes
Asphalt Green Playground[5]	Directly abutting truck ramp	69.0	71.7	73.6	4.6	Yes

Notes:

(1) Twenty-minute noise level readings measured at the noise-sensitive receptor during the quietest hour determined from the 24-hour noise level readings.

(2) Existing noise levels measured on ~~July 22, 2003~~August 10, 2004 at 3:00 a.m. at the York Avenue Apartment Building; ~~July 7, 2004~~September 1, 2004 at 5:00 p.m. for the Asphalt Green Recreational Field and ~~Playground~~Building; ~~January 30, 2003~~ August 10, 2004 at ~~5~~3:00 ~~p~~a.m. for the East 90th Street apartment building; July 8, 2004 at 5:00 p.m. at the Bobby Wagner Walk; and ~~September 1st~~July 7, 2004 at 5:00 p.m. for the Asphalt Green Playground.

(3) Predicted noise level calculations at noise-sensitive receptor include on-site and off-site shielding from structures.

(4) According to CEQR, an increase over 65 dBA at daytime is considered an impact. However, if the existing noise level at the receptor during the daytime is 62 dBA or greater or if the analysis is for a nighttime hour, an increase over 3 dBA would be considered an impact. The impact analysis compares the loudest noise emissions from daily operations at the Existing East 91st Street MTS with the quietest background noise levels that occur during facility operation

(5) This noise-sensitive receptor was assumed to only be in use during daytime hours. Therefore, noise monitoring and noise analysis were only performed for the quietest daytime hour.

29.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

29.17.3.4 NYC Noise Code Analysis-Current

Overall noise predictions were calculated at the locations of the points along the facility boundary to determine the total L_{eq} from all indoor and outdoor sources. This is shown in Table 29.17-3. Based on this analysis, the total L_{eq} does exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the Nnew SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

29.17.3.5 Off-Site Noise Analysis

An off-site noise analysis was performed in Section 6.17 for the East 91st Street Converted MTS. The trucks routed to the Existing East 91st Street MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis is required for the Existing East 91st Street MTS.

29.17.3.6 Combined On-Site and Off-Site Noise Levels

An on-site and off-site noise analysis was performed for the Existing East 91st Street MTS. Since the potential impacts of these analyses can affect the same noise-sensitive receptor, a screening analysis must be conducted to determine if a combined noise analysis would be required for the operations at the East 91st Street Converted MTS.

If this facility is chosen to be part of the New SWMP, a supplementary refined on-site noise analysis will be performed, including a combined noise analysis.

Table 29.17-3
Current Noise Code Analysis
Existing East 91st Street MTS

Location at Plant Boundary	Total L_{eq} Contribution at Plant Boundary (dBA)
D1	61.9
D2	60.4
D3	61.5
D4	**77.2**
D5	**73.0**

CHAPTER 30 ENVIRONMENTAL REVIEW: EXISTING NORTH SHORE MTS

30.1 Introduction

The results of the environmental analyses of the Existing North Shore MTS are presented in the following sections:

30.2 Land Use, Zoning, and Public Policy
30.3 Socioeconomic Conditions
30.4 Community Facilities and Services
30.5 Open Space
30.6 Cultural Resources
30.7 Urban Design, Visual Resources, and Shadows
30.8 Neighborhood Character
30.9 Natural Resources
30.10 Hazardous Materials
30.11 Water Quality
30.12 Waterfront Revitalization Program
30.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
30.14 Traffic, Parking, Transit, and Pedestrians
30.15 Air Quality
30.16 Odor
30.17 Noise

Section 2.4.12 provides a summary description of the site and important characteristics of the facility design. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

30.2 Land Use, Zoning, and Public Policy

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analyses of the Land Use, Zoning, and Public Policy section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

30.3 Socioeconomic Conditions

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Socioeconomic Conditions section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.4 Community Facilities and Services

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Community Facilities and Services section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.5 Open Space

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Open Space section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.6 Cultural Resources

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Cultural Resources section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.7 Urban Design, Visual Resources, and Shadows

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analyses of the Urban Design, Visual Resources, and Shadows section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in these respective categories.

30.8 Neighborhood Character

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Neighborhood Character section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.9 Natural Resources

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Natural Resources section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.10 Hazardous Materials

The Existing North Shore MTS is located at the site of the North Shore Converted MTS. The analysis of the Hazardous Materials section of the North Shore Converted MTS chapter in this FDEIS provides the necessary information for the review of this facility in this category.

30.11 Water Quality

The Existing North Shore MTS has a smaller footprint than the North Shore Converted MTS. Since there are no unmitigatible significant adverse environmental water quality impacts from the North Shore Converted MTS, there will be no unmitigatible significant adverse environmental water quality impacts from the Existing North Shore MTS.

30.12 Waterfront Revitalization Program

The Existing North Shore MTS has a smaller footprint than the North Shore Converted MTS. Since there are no unmitigatible significant adverse environmental WRP impacts from the North Shore Converted MTS, there will be no unmitigatible significant adverse environmental WRP impacts from the Existing North Shore MTS.

30.13 Infrastructure, Solid Waste and Sanitation Services, and Energy

It is assumed that the staffing levels of the Existing North Shore MTS would be equal to or less than the staffing levels of the North Shore Converted MTS. Therefore the analyses performed for the North Shore Converted MTS to assess impacts to water supply, sanitary sewage, and solid waste would also apply to the assessment of these utilities for the Existing North Shore MTS.

30.14 Traffic, Parking, Transit, and Pedestrians

The Existing North Shore MTS may receive the same amount of DSNY-managed and potential commercial waste as the North Shore Converted MTS. See the Traffic, Parking, Transit, and Pedestrians section of the North Shore Converted MTS chapter in this FDEIS. If the amount of waste delivered to the Existing North Shore MTS is less than or equal to that analyzed, there will be no unmitigatible significant adverse environmental impacts.

30.15 Air Quality

The Existing North Shore MTS would have less on-site emission-generating equipment, but the sources located closer to the property line receptors, than the North Shore Converted MTS. This section presents the results of the air quality analysis for the Existing North Shore MTS operating at 4,800 tpd.

30.15.1 Potential Impacts with the Existing North Shore MTS

30.15.1.1 On-Site Analysis

30.15.1.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 30.15-1.

Table 30.15-1
Emission Sources Considered for On-Site Air Quality Analysis[1]
Existing North Shore MTS

Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During 24-hour and Annual Average Hour
Within Processing Building		
Moving/Queuing Collection Vehicles	37	20
Space Heaters	10	4
Boiler	1	1
Outside Processing Building		
Moving Collection Vehicles	50	20
Queuing Collection Vehicles[2]	13	3
Oceangoing Tugboats	1	1

Notes:
(1) Emission factors used and emission rates estimated for each of these sources are included in technical backup provided to the NYCDEP.
(2) Peak 8-hour and 3-hour average number of queuing collection vehicles outside building is 5. Theoretically, the 3-hour value should be no less than one-third of the peak 1-hour value (13), but for this analysis, the 3-hour and 8-hour values are more realistic estimates of actual peak queuing activity, while the 1-hour peak is simply a conservative assumption based on the maximum available physical queuing space on the entrance road/ramp.

30.15.1.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any of the receptor locations considered are presented in Table 30.15-2. These values are below the national and state ambient air quality standards for the appropriate averaging time periods. In addition, the highest estimated changes in 24-hour and annual $PM_{2.5}$ concentrations from project-generated vehicles at any of the receptor locations considered, which are also presented in Table 30.15-2, are below the STVs. The Existing North Shore MTS would not, therefore, significantly impact air quality in the area.

30.15.1.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 30.15-3. The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by NYSDEC as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Existing North Shore MTS are not considered to be significant.

30.15.1.2 Off-Site Analysis

An off-site air quality analysis was performed for the North Shore Converted MTS. The trucks routed to the Existing North Shore MTS would be equivalent to or less than this analysis. Therefore, no additional off-site air quality analysis is required for the Existing North Shore MTS.

Table 30.15-2
Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emissions
Existing North Shore MTS

Pollutant	Averaging Time Period	Maximum Impacts from On-Site Emission Sources[1]	Background Pollutant Concentrations [2]	Highest Estimated On-Site Pollutant Concentrations	NAAQS[3]	STV[4]
Carbon Monoxide (CO), $\mu g/m^3$	1-hour[6]	782	3,781	4,563	40,000	NA
	8-hour[6]	221	2,635	2,856	10,000	NA
Nitrogen Dioxide (NO_2), $\mu g/m^3$	Annual	10	56	66	100	NA
Particulate Matter (PM_{10}), $\mu g/m^3$	24-hour[7]	19	90	109	150	NA
	Annual	5	20	25	50	NA
Particulate Matter ($PM_{2.5}$), $\mu g/m^3$	24-hour	2	NA	NA	NA	5
	Annual Neighborhood Average	0.02[5]	NA	NA	NA	0.1
Sulfur Dioxide (SO_2), $\mu g/m^3$	3-hour[6]	86	186	272	1,300	NA
	24-hour[6]	7	107	114	365	NA
	Annual	1	18	19	80	NA

Notes:

(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.

(2) Background concentrations were obtained from the NYCDEP on ~~April 18, 2003~~ memorandum dated February 18, 2005.

(3) NAAQS = National Ambient Air Quality Standard.

(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.

(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.

(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.

(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is quite conservative.

NA = Not Applicable.

Table 30.15-3
Highest Estimated Non-Cancer Hazard Index and Cancer Risk of Toxic Air Pollutants from On-Site Emissions
Existing North Shore MTS

No.	Toxic Air Pollutants	Acute Non-Cancer Risk			Chronic Non-Cancer Risk			Cancer Risk		
		Highest Estimated Short-Term (1-hr) Pollutant Conc.[1] ($\mu g/m^3$)	Short-Term (1-hr) Guideline Conc. (SGCs) [2] ($\mu g/m^3$)	Acute Non-Cancer Hazard Index[3]	Highest Estimated Long-Term (Annual) Pollutant Conc.[4] ($\mu g/m^3$)	Long-Term (Annual) Guideline Conc. 30.16 Odor

In addition to the odors from waste processing operations in the building that will be controlled through an odor neutralizing system, the Existing North Shore MTS would have full and empty barges moored and queued outdoors during operations. This section presents the results of the odor analysis for the Existing North Shore MTS operating at 4,800 tpd.

30.16.1 Potential Impacts with the Existing North Shore MTS

30.16.1.1 Odor Source Types and Locations Considered in the Analysis

The anticipated number and types of odor sources that would be associated with waste processing operations at peak design capacity at the Existing North Shore MTS are provided in Table 30.16-1.

Table 30.16-1
Odor Sources Included in Odor Analysis
Existing North Shore MTS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Barge	2
Queuing Collection Vehicles[1]	41

Notes:
(1) This is the number of collection vehicle sources inbound and outbound from the MTS. The actual number of vehicles is 13.

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Existing North Shore MTS.

30.16.1.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 30.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the Existing North Shore MTS at any nearby sensitive receptor is less than 1, so odors from the Existing North Shore MTS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 30.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
Existing North Shore MTS

Parameter	**Resulting Odor Unit[1]**
Estimated Detectable Concentration	5.0
Highest Result	1.56
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.18
Type of Receptor	Residential House
Distance to Receptor[3]	280 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
(3) Measured from the site property line.

30.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from Existing North Shore MTS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for both on-site and off-site sources, and, for on-site sources only, the Performance Standards of the New York City Zoning Code for Manufacturing Districts and the Current New York City Noise Code. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies used in this analysis.

30.17.1 Existing Conditions

30.17.1.1 Introduction

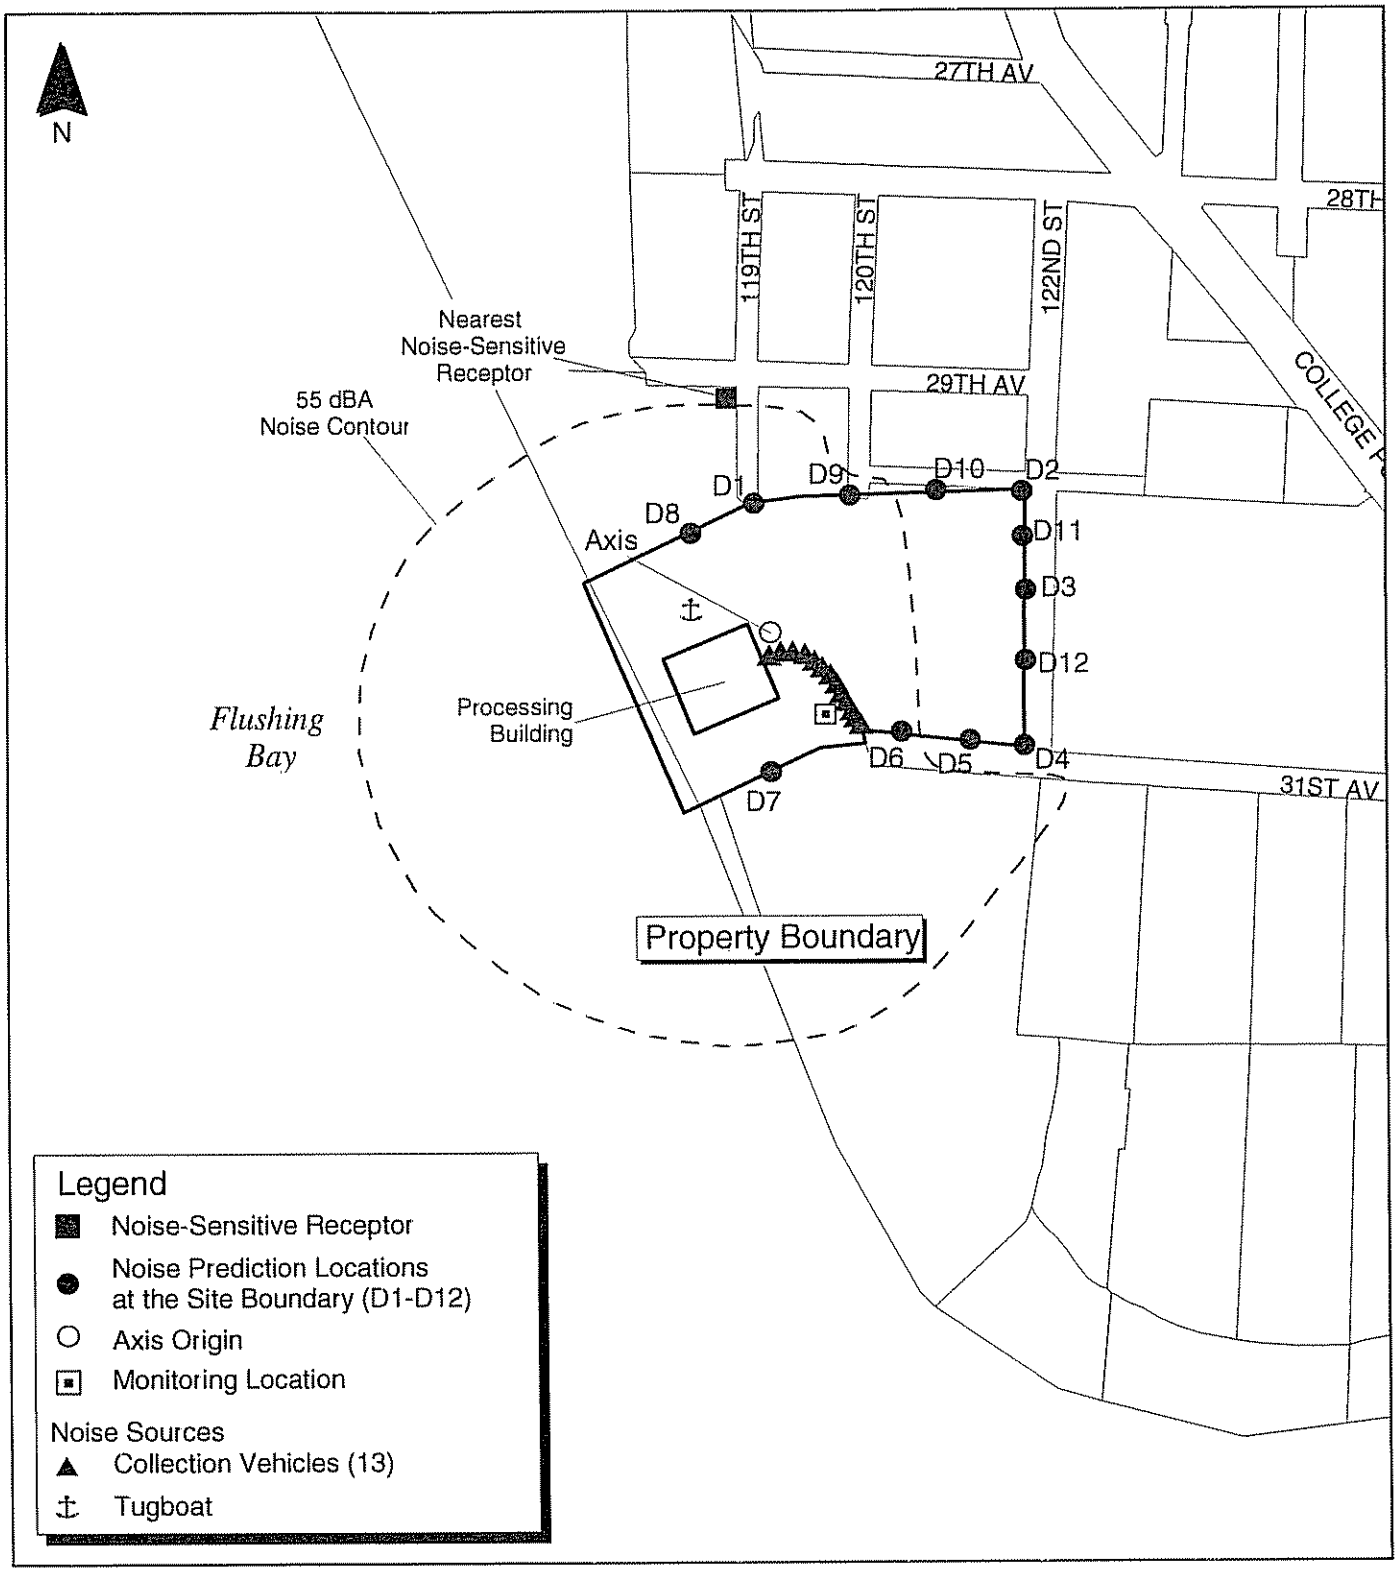
Figure 30.17-1 shows the location of the Existing North Shore MTS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. See Section 7.17.1.1 for further information.

30.17.1.2 On-Site Noise Levels

See Section 7.17.1.2.

30.17.1.3 Off-Site Noise Levels

See Section 7.17.1.3.



30.17.2 Future No-Build Conditions

30.17.2.1 On-Site Noise Levels

See Section 7.17.2.1.

30.17.2.2 Off-Site Noise Levels

See Section 7.17.2.2.

Existing North Shore MTS

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

30.17.3 Potential Impacts with the Existing North Shore MTS

30.17.3.1 On-Site Noise Levels

Equipment assumed to be operating at the Existing North Shore MTS and its reference noise levels used in the CEQR and Current Noise Code analysis are shown in Table 30.17-1. The number and types of equipment assumed for this analysis were based on the Existing North Shore MTS's peak design capacity. Shown earlier, Figure 30.17-1 indicates the Existing North Shore MTS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 30.17-1
Equipment Modeled in the Noise Analysis and Reference Noise Levels (L_{eq})
Existing North Shore MTS

Equipment Name (quantity) (1)	Reference Sound Pressure Noise Level at 50 feet (dBA)(2)
Indoor	
Moving/Queuing Collection Vehicle (7)	~~73~~79
Outdoor	
Moving/Queuing Collection Vehicle (13)	67
Oceangoing Tugboat (1)	73

Notes:
(1) Instantaneous maximum number of pieces of equipment on site at any given time.
(2) Noise level representative of each piece of equipment.

30.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the Existing North Shore MTS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is approximately 88 meters (290 feet) from the property boundary in the direction of the nearest noise-sensitive receptor, which is approximately 92 meters (301 feet) from the property boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on-site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this

concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (see Figure 30.17-1). Therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was not required.

30.17.3.3 Performance Standards for Zoning Code Analysis

Performance Standards do not apply to the Existing MTS analyses since the only on-site equipment are DSNY and other agency collection vehicles and tugboats, which are not to be included in the analyses per the Zoning Code (assuming tugboats are transportation facilities).

30.17.3.4 NYC Noise Code Analysis – Current

Overall noise predictions were calculated at the locations of the points (D1, etc.) representative of the Existing North Shore MTS boundary to determine the total L_{eq} from all indoor and outdoor sources for comparison to the current Noise Code. This is shown in Table 30.17-3. Based on this analysis, the total L_{eq} does ~~not~~ exceed the current Noise Code Standard of 70 dBA at the property boundary.

The data presented in this section is for the analysis to date. If this facility is chosen to be part of the New SWMP, a supplementary refined analysis, including refining utilization factors for equipment, will be performed.

30.17.3.5 Off-Site Noise Analysis

An off-site noise analysis was performed in Section 7.17 for the North Shore Converted MTS; the trucks routed to the Existing North Shore MTS would be equivalent to or less than this analysis. Therefore, no additional off-site noise analysis was required for the Existing North Shore MTS.

30.17.3.6 Combined On-Site and Off-Site Noise Levels

As a result of both the on- and off-site screening analyses performed for the Existing North Shore MTS, neither an on- or off-site noise analyses were required; therefore, a combined noise analysis was not performed.

Table 30.17-3

CHAPTER 31 MESEROLE STREET TRUCK TO RAIL TS

31.1 Introduction

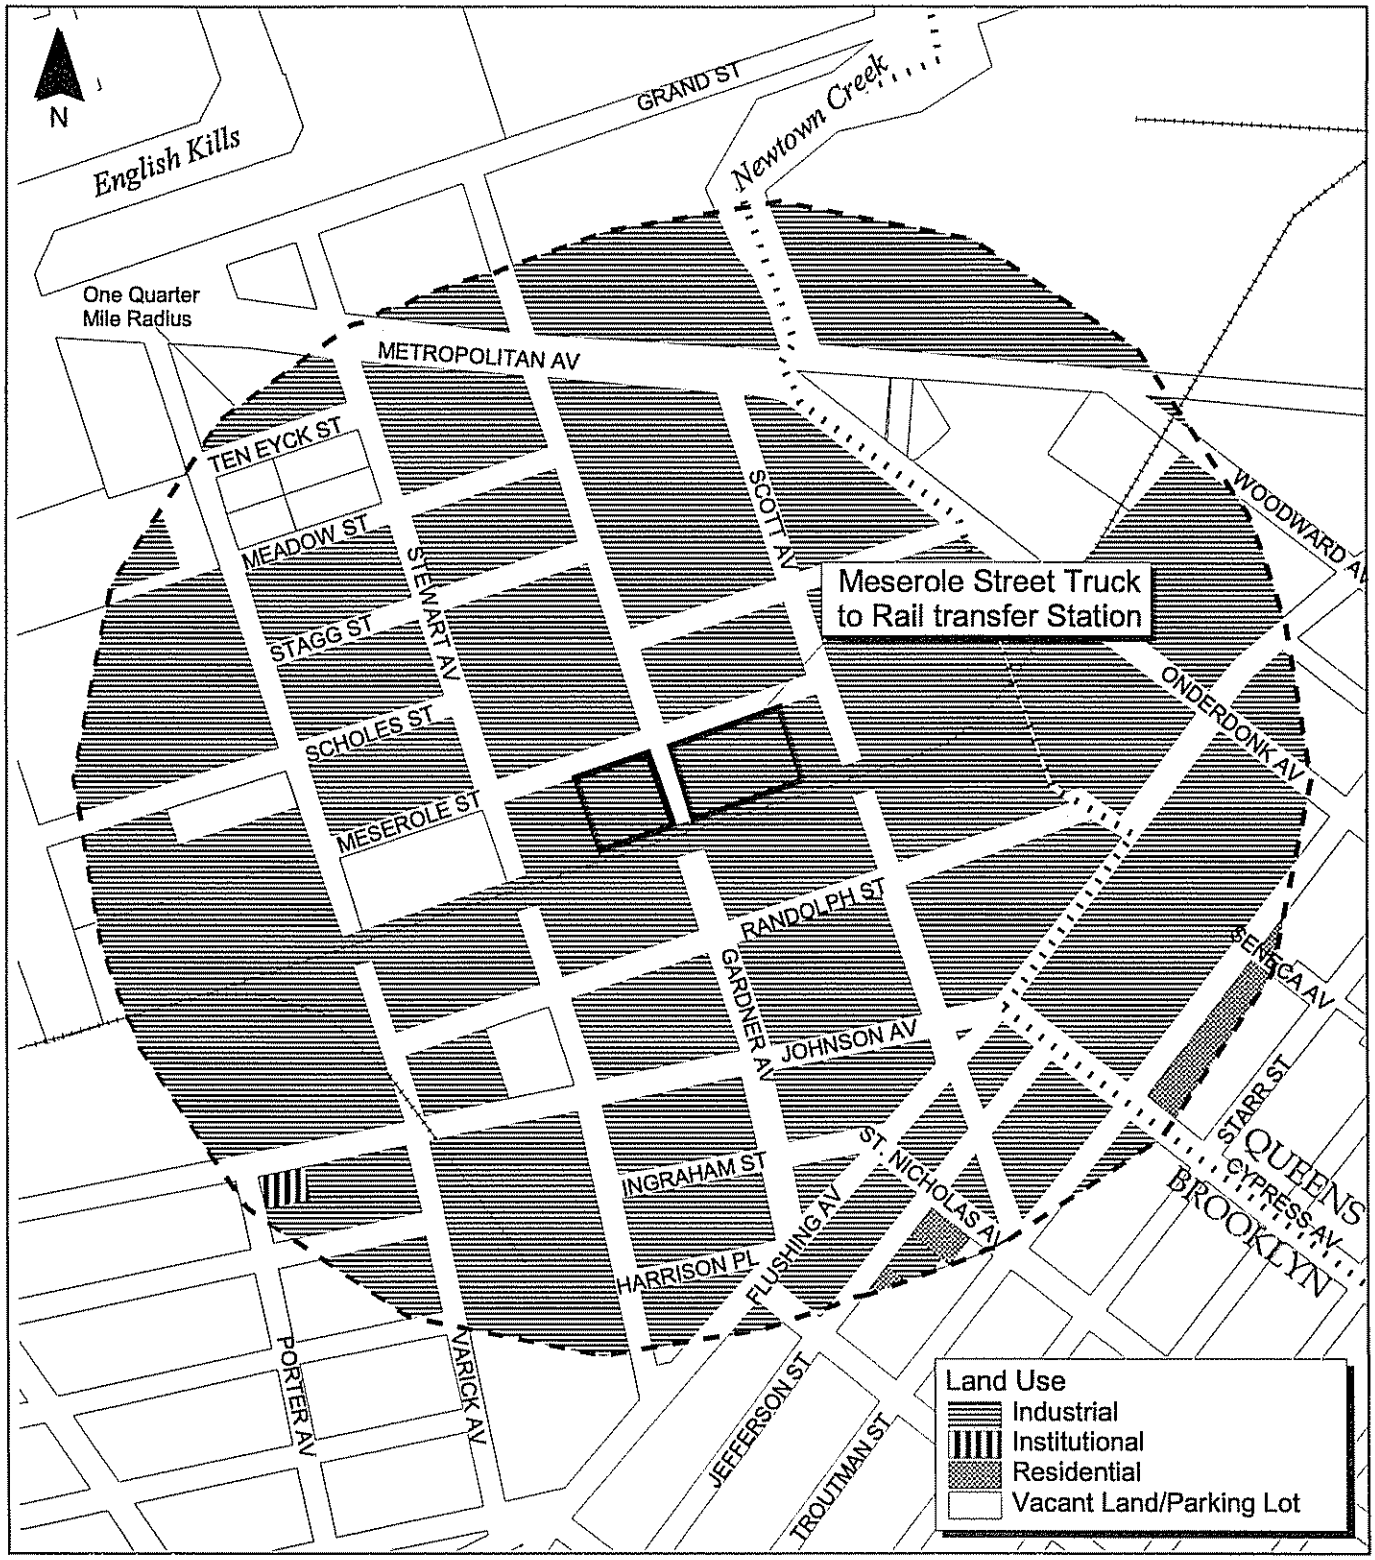
The results of the environmental analyses of the Meserole Street Truck to Rail TS are presented in the following sections:

31.2 Land Use, Zoning, and Public Policy
31.3 Socioeconomic Conditions
31.4 Community Facilities and Services
31.5 Open Space
31.6 Cultural Resources
31.7 Urban Design, Visual Resources, and Shadows
31.8 Neighborhood Character
31.9 Natural Resources
31.10 Hazardous Materials
31.11 Water Quality
31.12 Waterfront Revitalization Program
31.13 Infrastructure, Solid Waste and Sanitation Services, and Energy
31.14 Traffic, Parking, Transit, and Pedestrians
31.15 Air Quality
31.16 Odor
31.17 Noise

Section 2.4.13 provides a summary description of the site and important characteristics of the two Alternative facility designs. A detailed discussion of the methodologies that were applied in conducting each analysis is provided in Chapter 3. Supplemental information on the site or the study area is provided in the following sections when appropriate to the analysis.

31.2 Land Use, Zoning, and Public Policy

31.2.1 Existing Conditions



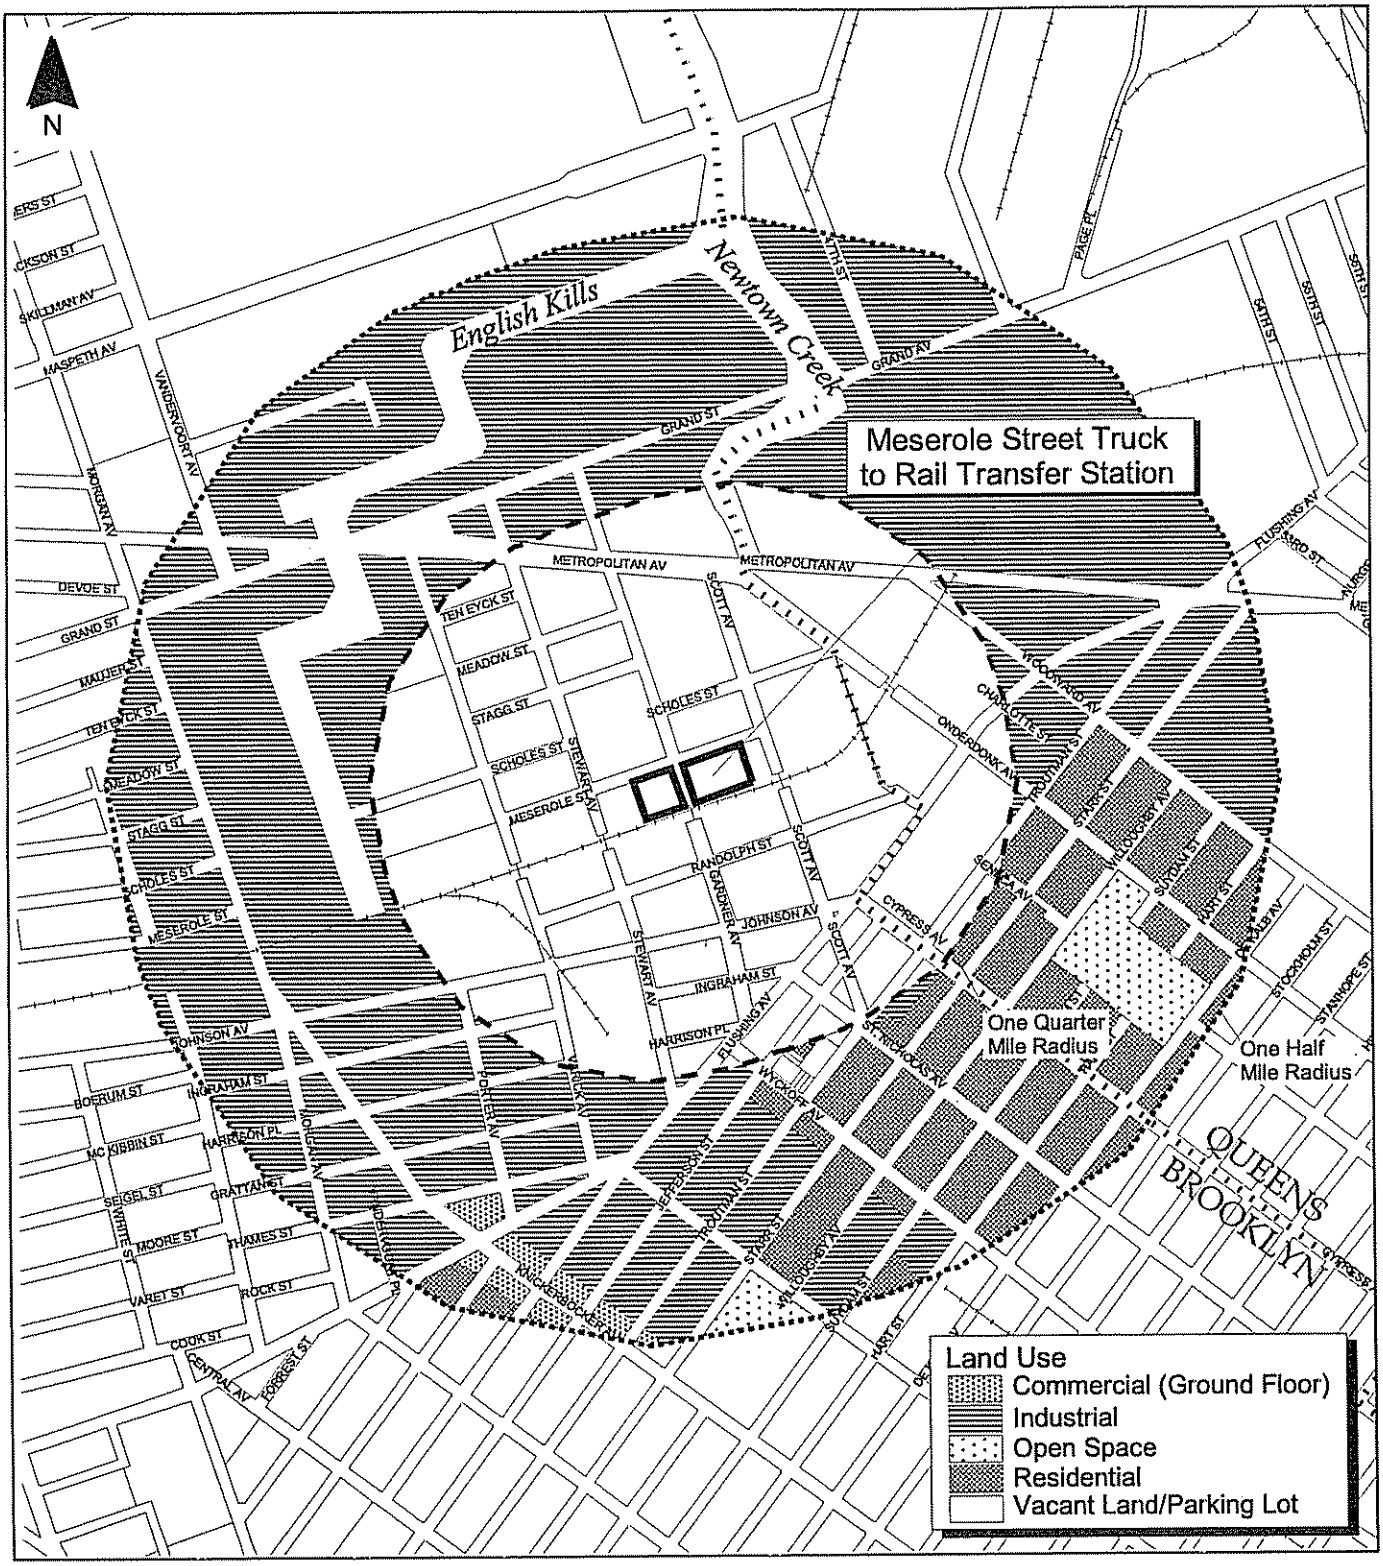
31.2.1.1 Definition of the Study Area

For the land use, zoning, and public policy analyses, the primary study area is defined as the area within ¼-mile of the site (Figure 31.2-1). The secondary study area is defined as the area between ¼-mile and ½-mile of the site (Figure 31.2-2). Section 3.4 describes the methodology employed in these analyses and Section 2.4.13 provides information on existing land uses and operations on the site.

31.2.1.2 Land Use Patterns

31.2.1.2.1 General Context

The Meserole Street Truck to Rail TS site is located in Community District 1 near the Brooklyn/Queens border, in the predominantly industrial section of East Williamsburg, Brooklyn. It is largely surrounded by canals and railroad tracks: English Kills on the west, Newtown Creek on the east and LIRR tracks to the east and south, thus making it directly accessible on land only from the north. The site consists of two parcels on either side of Gardner Avenue. 568 Meserole Street contains the Meserole Street (paper) Recycling Facility on the southeast corner of Gardner Avenue and Meserole Street, and the Filco Carting Company's truck parking lot occupies most of the lot at 111 Gardner Avenue, on the southwest corner of Gardner Avenue.



Site delineations and study area boundaries are approximate.

Figure 31.2-2 Land Use in the Secondary Study Area

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

31.2.1.2.2 Land Uses in the Primary Study Area

The Meserole Street Truck to Rail TS site is situated just west of the Brooklyn/Queens border which separates East Williamsburg, Brooklyn to the west and Maspeth, Queens to the east. The primary study area is characterized by several private waste transfer stations (including BFI Waste Systems facilities on Scholes Street and Gardner Avenue, and Waste Management of New York facilities on Stewart Avenue and Varick Avenue) as well as a DSNY parking lot on Meserole Street, a new CD 1 and 4 garage under construction on Varick Avenue and an existing garage on Johnson Avenue.

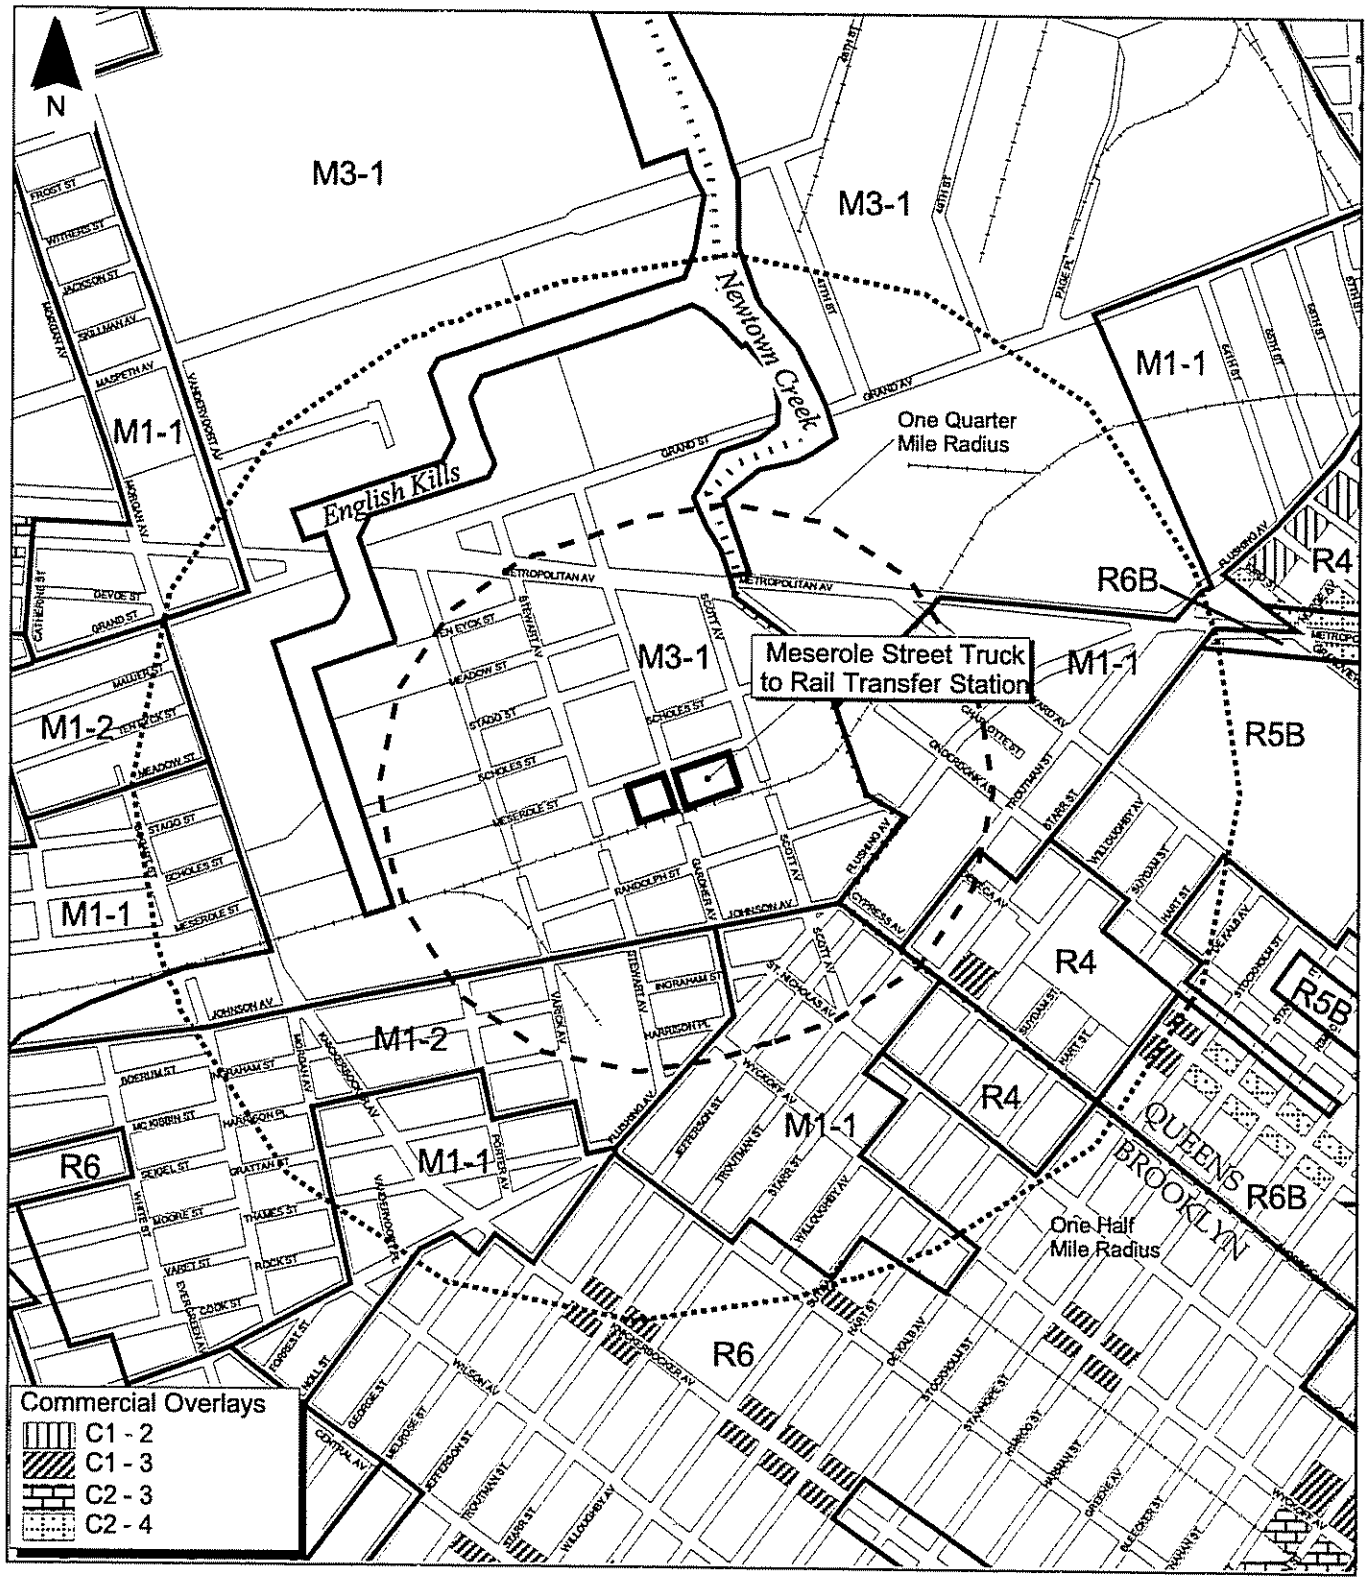
The English Kills canal runs along the eastern border of the primary study area, is approximately 200 feet wide and connects with Newtown Creek at the Brooklyn/Queens boundary. The LIRR tracks bisect the ½-mile study area east to west and pass immediately south of the site between Meserole and Randolph Streets. The NY&A operates freight trains on these tracks, with a terminal nearby, in Bushwick (to the west).

North and south of the existing site are scrap metal yards and plastic manufacturing facilities, window and door manufacturing facilities, lumber yards and hydraulic equipment leasing companies. Development surrounding the site is primarily low density with open parking lots and low-scale masonry buildings ranging from two to four stories in height.

The area surrounding the Meserole Street site includes some vacant land to the north on Gardner and Stewart Avenues, as well as lots undergoing construction. Some sites have been rehabilitated to accommodate new industrial loft space and community facilities such as a Peter Jay Sharp Center for Opportunity on Porter Street (89-111). The other community facilities include a fire station on Morgan Avenue and a daycare center on Knickerbocker Street. The area is also characterized by abundant parking lots and garage facilities, some of which are leased by DSNY for trucks and other equipment storage.

31.2.1.2.3 Land Uses in the Secondary Study Area

Within ½-mile of the site there is a mix of residential, industrial and some commercial uses. Industrial uses in the secondary area tend to be lighter than those found in the primary study area. These uses include printers, auto salvage and repair shops and food product manufacture and distribution companies. The residential area closest to the site is Bushwick, which is characterized by three- and four-story apartment buildings along Willoughby and Starr Streets to the southeast as well as single-family homes and townhouses ½-mile south of the site, and in Ridgewood (Queens), ½-mile east of the site.



The secondary area contains a major city park: Maria Hernandez Park, located ½-mile south of the site. Another open space, the five-acre Grover Cleveland High School Athletic Field about 1/3-mile to the southeast, provides recreational opportunities to neighborhood residents, as well as students of the school.

Local commercial and retail activities are primarily concentrated along the western border of the secondary study area along Knickerbocker and Morgan Avenues. These corridors are characterized by ground floor retail uses and upper floor residences. Flushing and Jefferson Avenues serves as local retail streets as well as hubs of wholesale activity. Bakery and restaurant suppliers, plumbing and electrical equipment manufacturers, and window and door products manufacturers, are all found on these mixed-use streets.

31.2.1.3 Zoning On and Near the Site

31.2.1.3.1 Zoning Within the Primary Study Area

The project site is located within an M3-1 zoning district (see Figure 31.2-3 and Table 3.4-1 Zoning District Characteristics). This M3-1 zone extends from beyond the northern boundary of the primary study area to Johnson Avenue in the south. M1-2 and M1-1 zoning districts comprise the remainder of the primary study area to the south in Brooklyn and east, into Queens. The M1 zones act as a buffer between the residential and the heavier manufacturing districts and feature both residential and light manufacturing (e.g., distribution) activities.

Site delineations and study area boundaries are approximate

500 0 500 Feet

HDR HydroQual URBITRAN DD EEA Cambridge Environmental Inc

Figure 31.2-3 Zoning

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

31.2.1.3.2 Zoning Within the Secondary Study Area

Zoning in the secondary area is largely comprised of M3-1 districts in the north and M1-1 and M1-2 districts in the south and east. In addition, there are R4 zoning districts covering Ridgewood (Queens and Brooklyn) and a small portion of a large R6 district in Bushwick which both permit residential development such as single-family homes and apartment buildings. Knickerbocker Avenue is mapped R6 with a commercial overlay of C1-3 which permits ground floor retail uses.

31.2.1.4 Plans and Policies

The project site lies within the City Coastal Zone, the East Williamsburg In-Place Industrial Park and the North Brooklyn Empire Zone. Since it is situated within the Coastal Zone, it is subject to the WRP. The Plan for the Brooklyn Waterfront recommends a restriction of public access within the Newtown Creek environs for Reach 13, since it is an important industrial area that should be retained.

The site is located within the East Williamsburg In-Place Industrial Park, which is now a 650-acre manufacturing district covering 150 City blocks in northern Brooklyn. The EWVIDC, a local development corporation, provides comprehensive business services and helps local firms access public incentive programs. The EWVIDC administers the North Brooklyn Empire Zone (a New York State designation) which offers tax and financial incentives to attract and retain businesses in the area.

The FY 2004 CDNS for CD 1 does not provide physical planning recommendations that may be relevant specifically to the site or the primary and secondary study areas.

31.2.2 Future No-Build Conditions

No major development changes are expected to result in the immediate project area by the Future No-Build year. The large DSNY Varick Avenue Garage (serving CDs 1 and 4) at 137-165 Varick Street is currently under construction a few blocks northwest of the site and due to be completed at the end of 2004.

The larger Greenpoint-Williamsburg neighborhood, north and west of the site (beyond the secondary study area), is expecting more mixed development as a result of the MX-1 rezoning (NYCDCP). This rezoning would introduce changes such as the conversion of manufacturing lofts to residential use. Long-term projects for the area include the Bushwick Creek Inlet Development, the Greenpoint Terminal Market and the Sludge Tank Adaptive Reuse Project, though the Build years for these projects are 2012 and 2013.

31.2.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

31.2.3.1 Land Use and Zoning

The potential land use impacts of the proposed Meserole Street Truck to Rail TS facility would be equivalent to the existing industrial recycling operations that occur at the site. While improvements would be made to the site, and the capacity of the facility increased, existing and proposed land uses in the area would not be significantly affected since land use would not change. Existing buildings on the two parcels will be demolished to accommodate new site construction. However, no significant adverse land use or zoning impacts are anticipated.

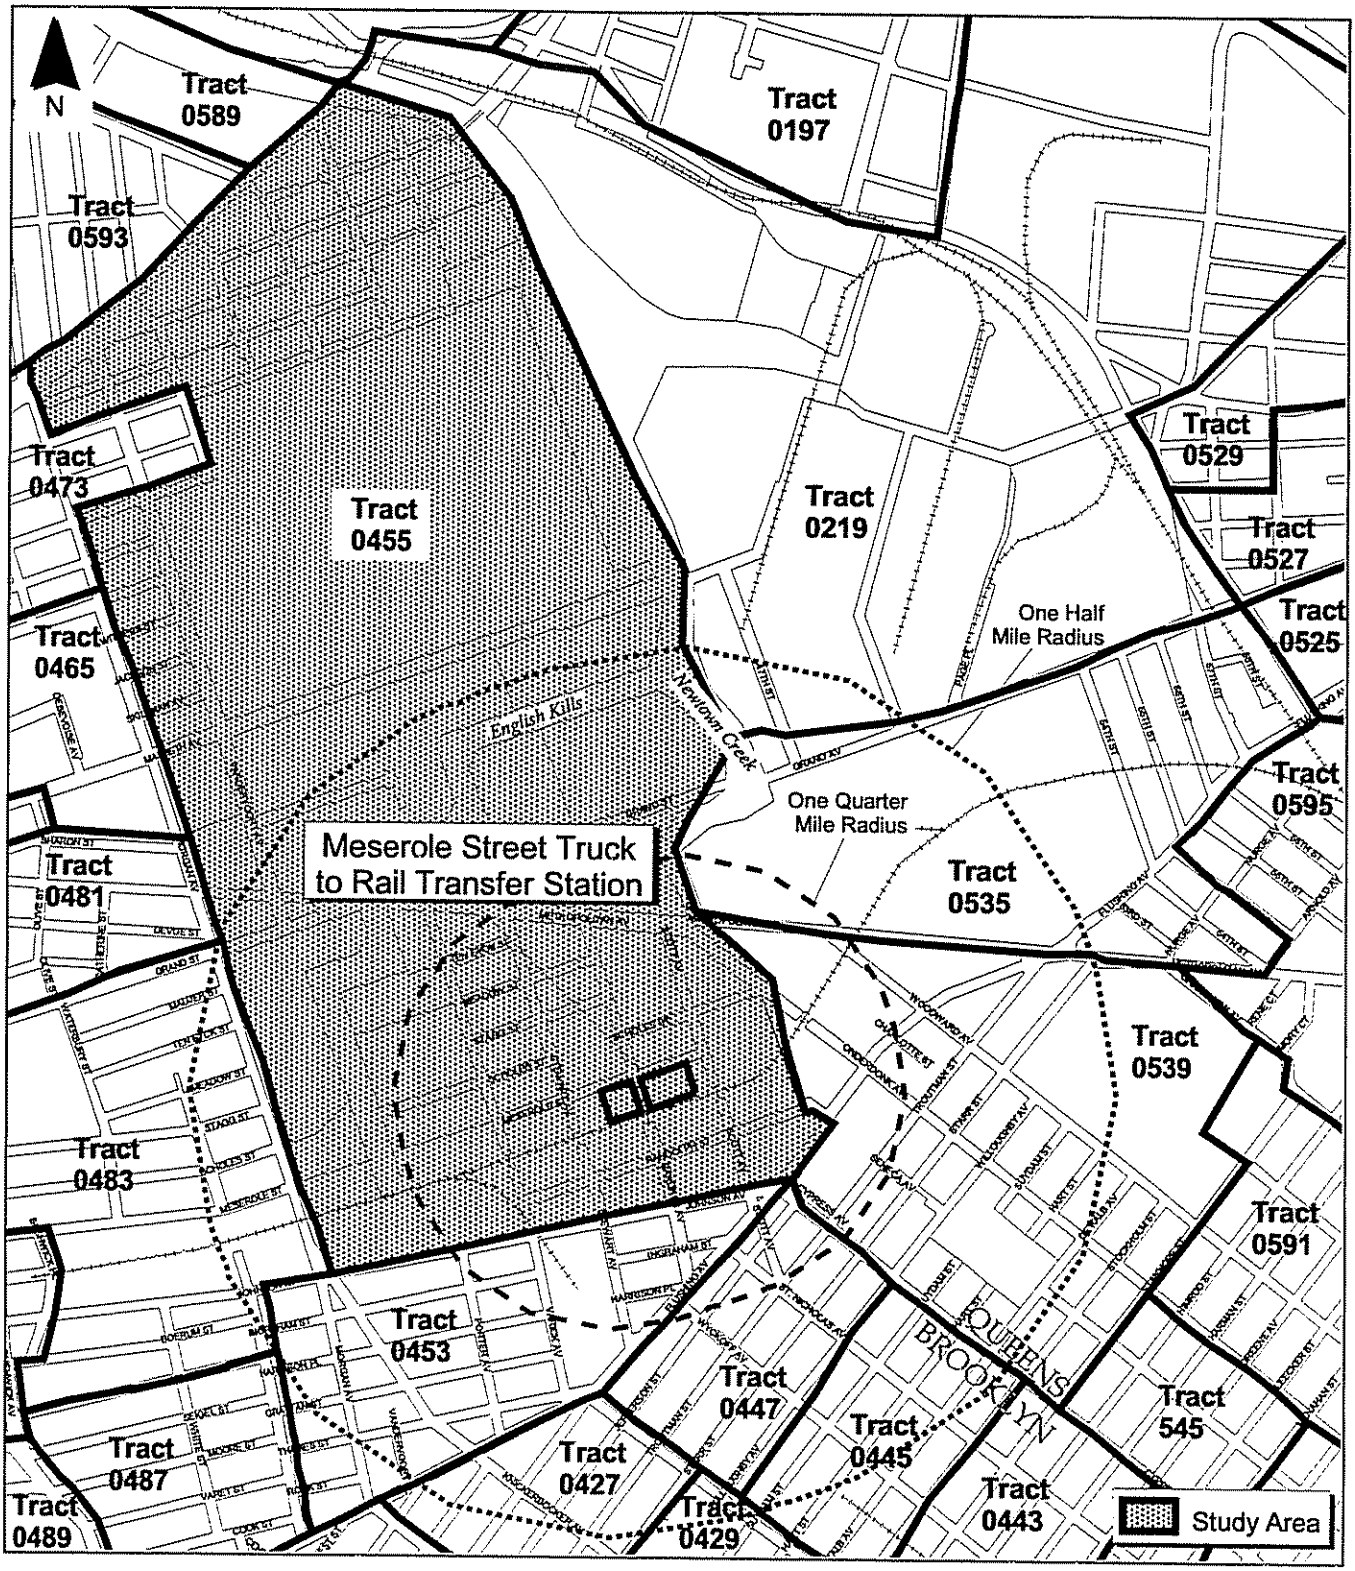
31.2.3.1 Consistency with Public Plans and Policies

The waste transfer station at 568 Meserole Street and 111 Gardener Avenue would be consistent with the stated objectives of the pertinent plans and policies affecting the site and environs.

31.2.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.2.3.

31.3 Socioeconomic Conditions



31.3.1 Existing Conditions

31.3.1.1 Definition of the Study Areas

Two study areas were used for the analysis of socioeconomic conditions: (1) a demographic study area based roughly on census tracts within ¼-mile of the site; and (2) a study area related to economic activity that generally covers a larger area that extends ½-mile from the site. (Refer to Section 3.5 for a more detailed description of study area delineation.) In this case, the demographic study area consists only of Census Tract 455 (Figure 31.3-1). This large tract surrounds the English Kills and the area west of Newtown Creek. It encompasses predominantly industrial areas on around the site along the northern border of Brooklyn.

31.3.1.2 Demographic Characteristics

The 2000 Census of the study area reported a population of only 103 individuals and 6 families, none of whom reside on or adjacent to the proposed site. Because the area is so lightly populated, socioeconomic data (comparing 1990 and 2000 Census data for the study area, borough and City) are provided in Appendix B.

Site delineations and study area boundaries are approximate

HDR | URBITRAN | EEA | Hydroqual | DD | Cambridge Environmental Inc

Figure 31.3-1 Census Tracts
Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

31.3.1.3 Economic Conditions

Current forecasts indicate that about 68,787 employees worked in Brooklyn CD 1 in 2005, which was about 9.4% of the borough's total employment.[1]

31.3.2 Future No-Build Conditions

31.3.2.1 Demographic Characteristics

Regional projections indicate that the population of Brooklyn CD 1 will remain about the same as current conditions.[2]

31.3.2.2 Economic Conditions

Regional projections indicate that employment in Brooklyn CD 1 will remain about 9.4% of the borough total.[3]

31.3.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

The Meserole Street Truck to Rail TS would be compatible with its industrial surroundings and not be expected to have a significant adverse impact on socioeconomic conditions within the study area.

31.3.3.1 Residential Impacts

Because the site would be far removed from the nearest residential concentrations (approximate ½-mile to the east and south of the site), it is not expected to significantly affect residential populations in the general area. Analyses of traffic, air quality and noise indicate that there would be no significant project-related impacts at these locations (see Sections 31.14, 31.15 and 31.17). Therefore, the Meserole Street Truck to Rail TS is not expected to result in indirect displacement of residents.

---

[1] Based on New York Metropolitan Transportation Council, Population and Employment Forecasts, approved 7-17-03.
[2] Ibid.
[3] Ibid.

31.3.3.2 Direct Business and Institutional Impacts

No direct displacement of businesses or institutions would occur as a result of the Meserole Street Truck to Rail TS.

31.3.3.3 Indirect Business and Institutional Impacts

The site would continue to operate as a recycling facility under Future No-Build Conditions, and so the Meserole Street Truck to Rail TS would be compatible with its industrial surroundings. The adjacent industrial uses are not expected to experience significant adverse effects related to air quality or odor as a result of the operations of the transfer facility. While noise levels will increase on the site, they are not expected to affect the surrounding industrial operations of businesses in the study area.

Increased truck volumes on designated truck routes in the area resulting from the Meserole Street Truck to Rail TS would not be expected to result in indirect displacement of existing businesses or institutional uses, as these routes are already heavily used by trucks (some serving the existing operations) and have an industrial character.

31.3.3.4 Employment Impacts

The Meserole Street Truck to Rail TS would be expected to generate approximately 37 new jobs associated with its new operation and maintenance (crane operators, mechanics, supervisors) and transportation operations (drivers, dispatchers). In addition to direct positive employment impacts, the new workers would generate a minor amount of indirect economic benefits through local spending.

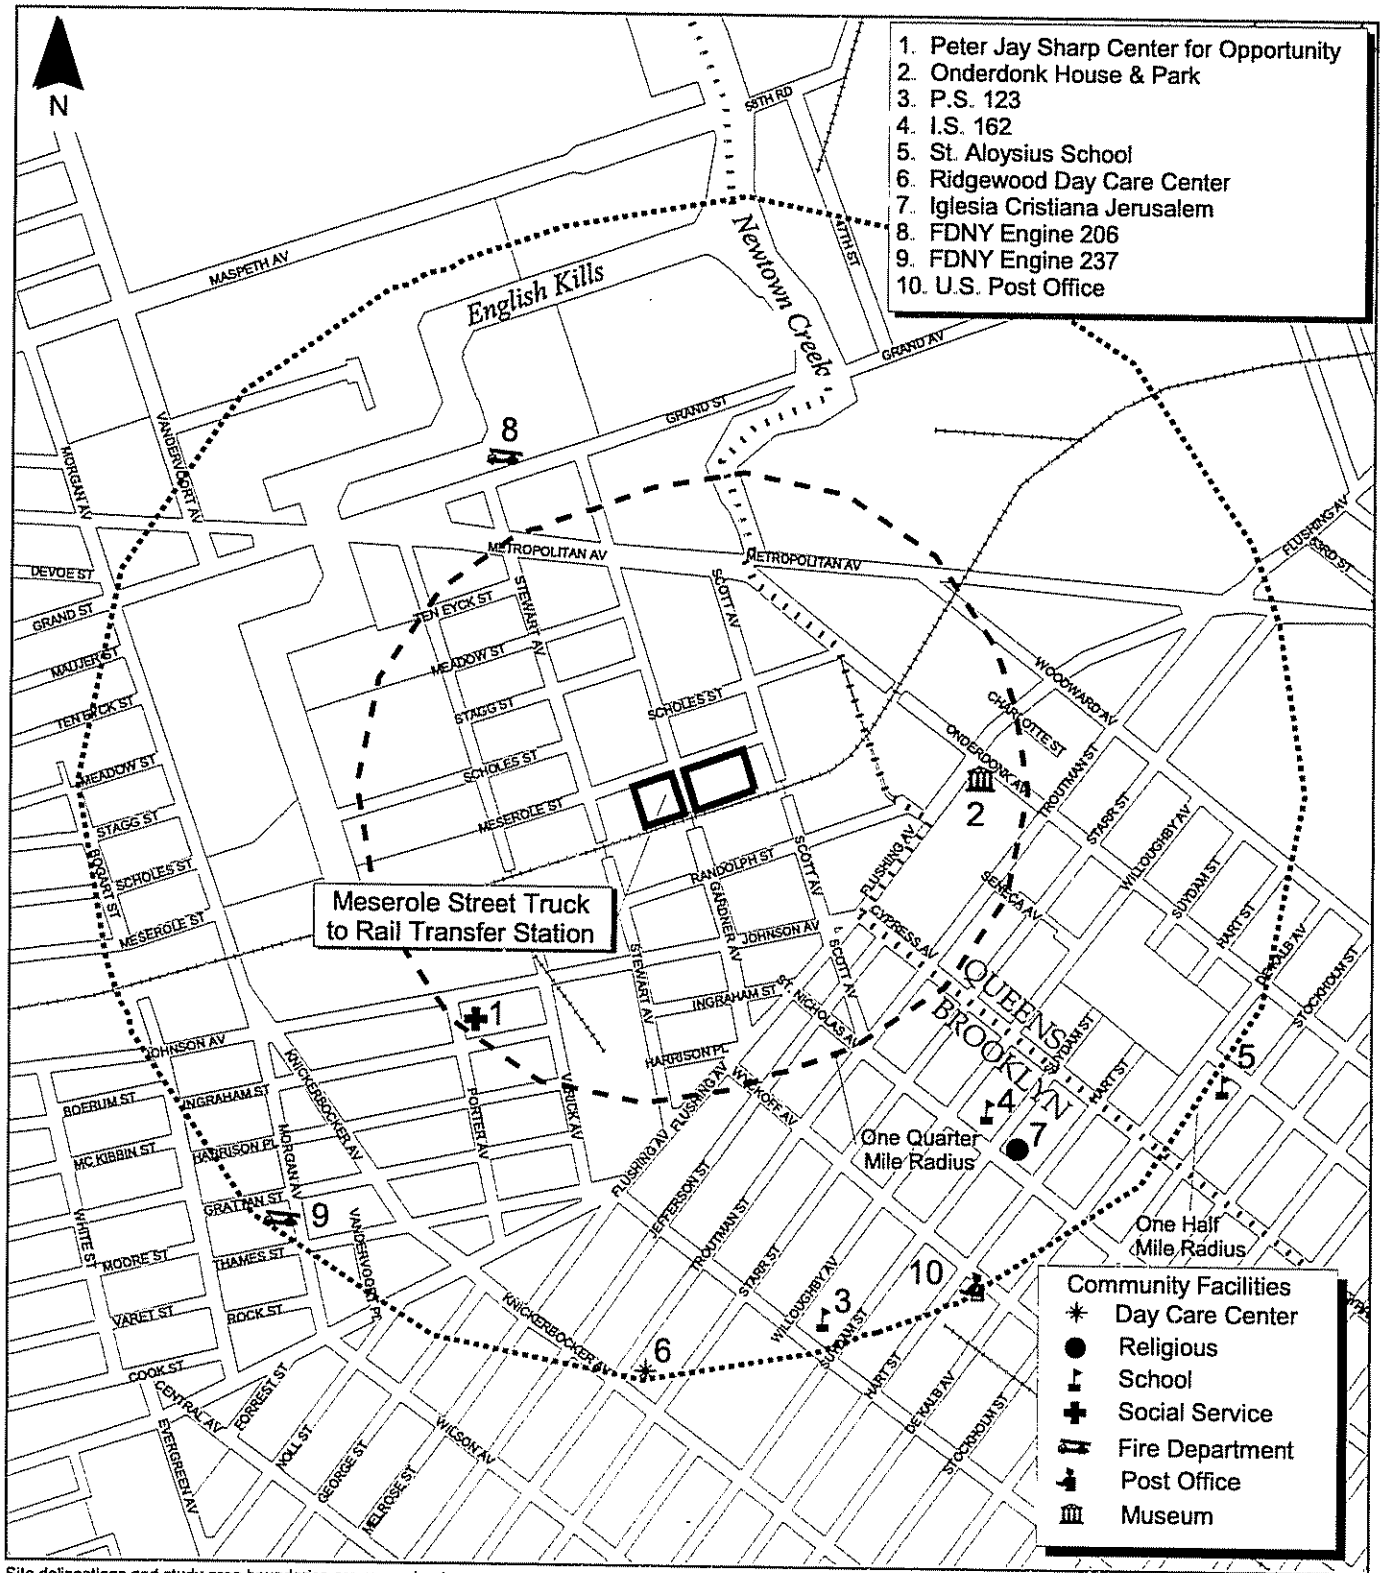
31.3.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.3.3.

31.4 Community Facilities and Services

31.4.1 Existing Conditions

31.4.1.1 Definition of the Study Areas



The primary study area is defined as the area within ¼-mile of the site. The secondary study area is defined as the area between ¼-mile and ½-mile of the site.

31.4.1.2 Summary of Community Facilities and Services

There are two community facilities within the primary study area: the Peter Jay Sharp Center for Opportunity (a homeless shelter and training center) and the Onderdonk House and Park (a local historical museum). Eight others are located within the secondary study area. The community facilities are listed in Table 31.4-1 and shown on Figure 31.4-1.

Table 31.4-1

500 0 500 Feet

Figure 31.4-1 Community Facilitites and Services
Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

31.4.2 Future No-Build Conditions

There are no known changes planned for the community facilities and services within the primary and secondary study areas by the Future No-Build year. Therefore, anticipated Future No-Build Conditions are expected to be fundamentally the same as Existing Conditions regarding availability of facilities and services and their capacity or adequacy of delivery.

31.4.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

The Meserole Street Truck to Rail TS would create no significant new demand on services or community facilities, and would not displace facilities or disrupt services. No significant adverse impacts to service delivery are expected. The FDNY states that it would have no problem supporting the new facility (see Appendix A).

31.4.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.4.3.

31.5 Open Space

31.5.1 Existing Conditions

31.5.1.1 Definition of the Study Area

The study area for open space is defined as being the area within a ½-mile radius of the site.

31.5.1.2 Summary of Open Space in the Study Area

There are five public parks and open spaces within the study area. They are listed in Table 31.5-1 and shown on Figure 31.5-1.

The study area's major recreational facility, Maria Hernandez Park, is located in Bushwick.

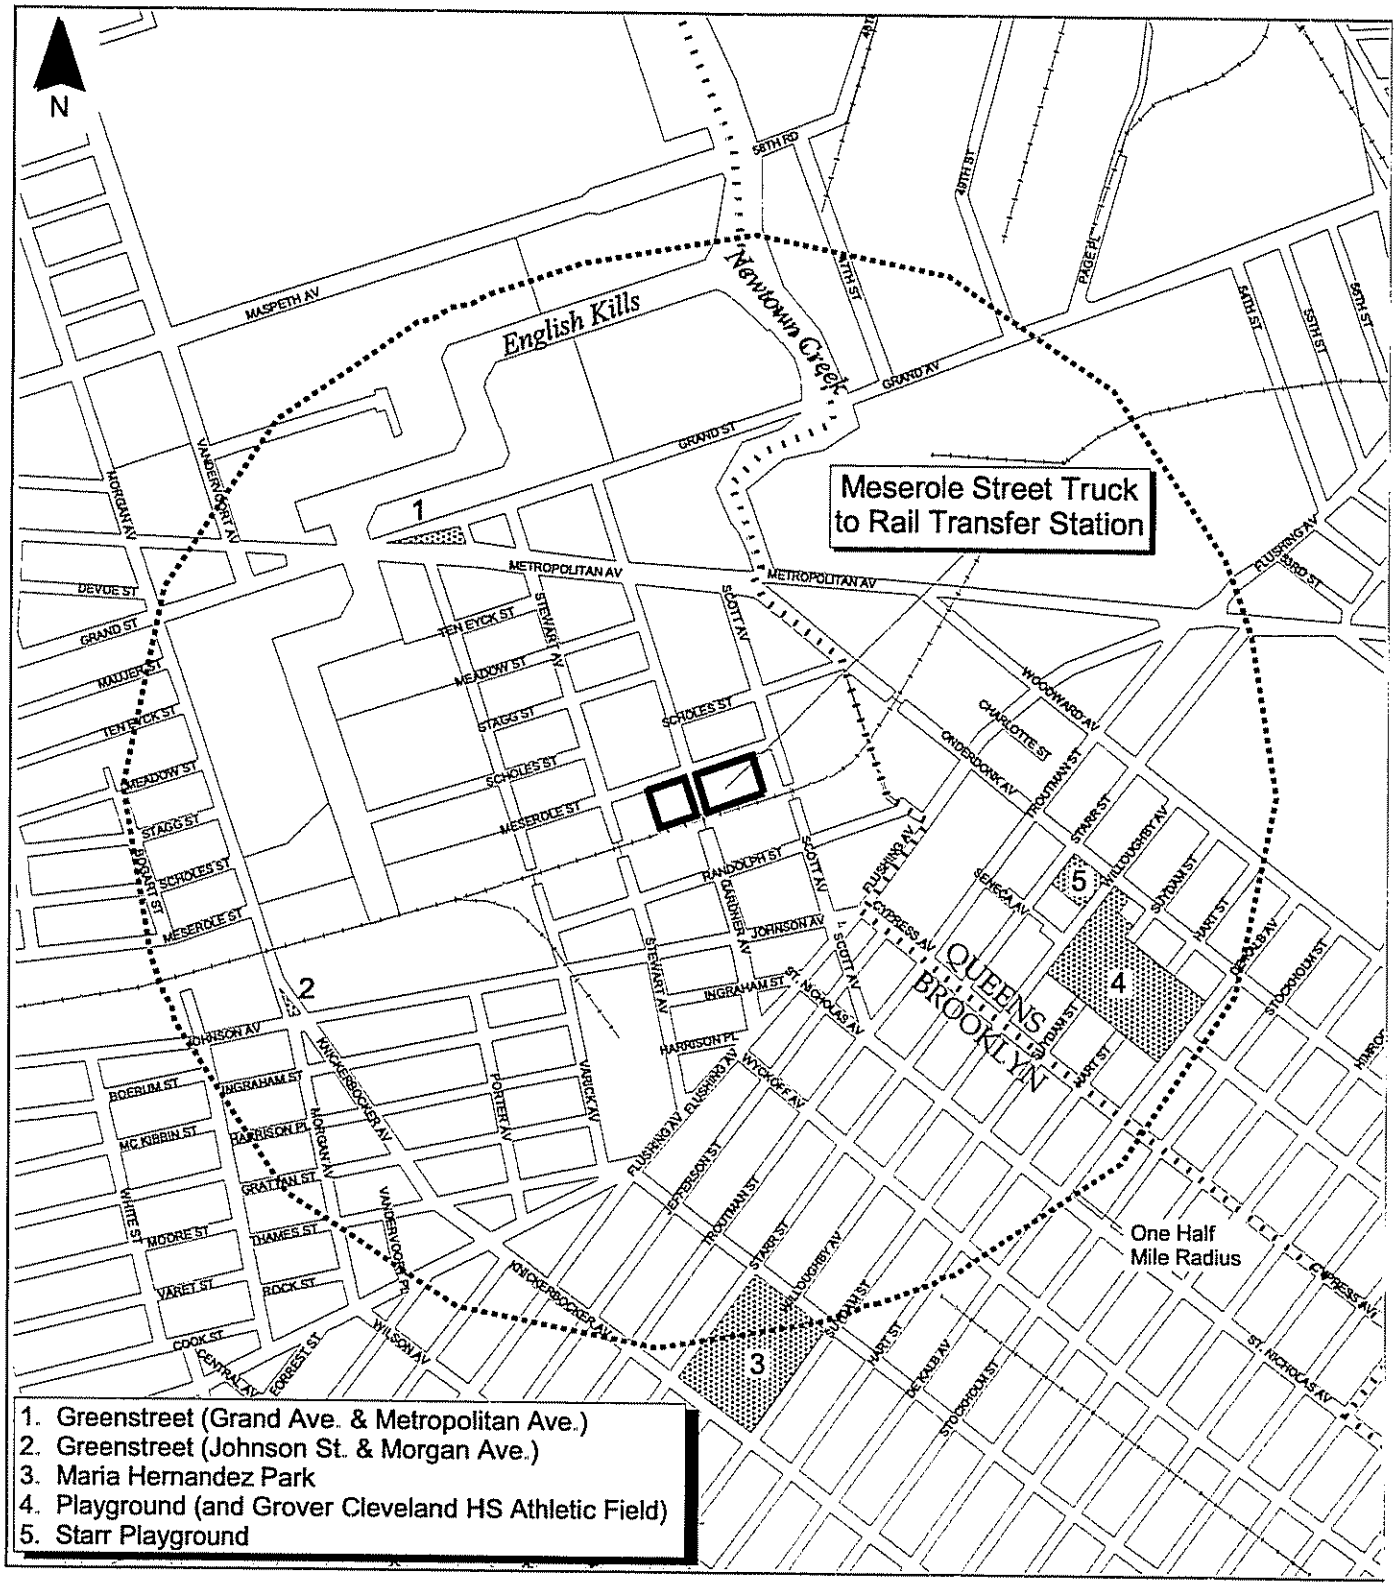
Maria Hernandez Park (formerly Bushwick Park) is a large City park – nearly seven acres – located ¼-mile south of the site. This community park recently underwent significant reconstruction to provide additional courts, game tables, paths, benches and other infrastructural improvements, as well as public performance space, ornamental gates, etc.

Though not NYCDPR property or jurisdiction, the five-acre Grover Cleveland High School Athletic Field was also recently reconstructed to provide passive and active recreational space for the neighborhood, including new play equipment for young children.

Table 31.5-1
Public Parks and Open Spaces

Name	Address	Acreage
Greenstreet	Grand Avenue and Metropolitan Avenue	--
Greenstreet	Johnson Street and Morgan Street	--
Maria Hernandez Park (formerly Bushwick Park)	Bounded by Knickerbocker Avenue, Starr Street, Irving Avenue and Suydam Street	6.87
Playground (a.k.a. Grover Cleveland High School Athletic Field)	210 Onderdonk Avenue	5.1
Starr Playground	Bounded by Starr Street, Onderdonk Avenue, Willoughby Avenue, and Seneca Street	0.9

31.5.2 Future No-Build Conditions



NYCDPR has no new development plans or notable development projects associated with open space resources in the study area. Therefore, Future No-Build Conditions are anticipated to resemble Existing Conditions.

31.5.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

The facility would not directly displace or significantly change demands on nearby parks. Therefore, no impacts to the public open spaces would result from the Meserole Street facility.

31.5.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.5.3.

Site delineations and study area boundaries are approximate

DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

31.6 Cultural Resources

31.6.1 Existing Conditions

31.6.1.1 Definition of the Study Area

The study area for cultural resources is defined as the area within ½-mile of the site and includes portions of four historic neighborhoods, all clustered along Newton Creek: East Williamsburg and Bushwick in Brooklyn, and Maspeth and Ridgewood in Queens.

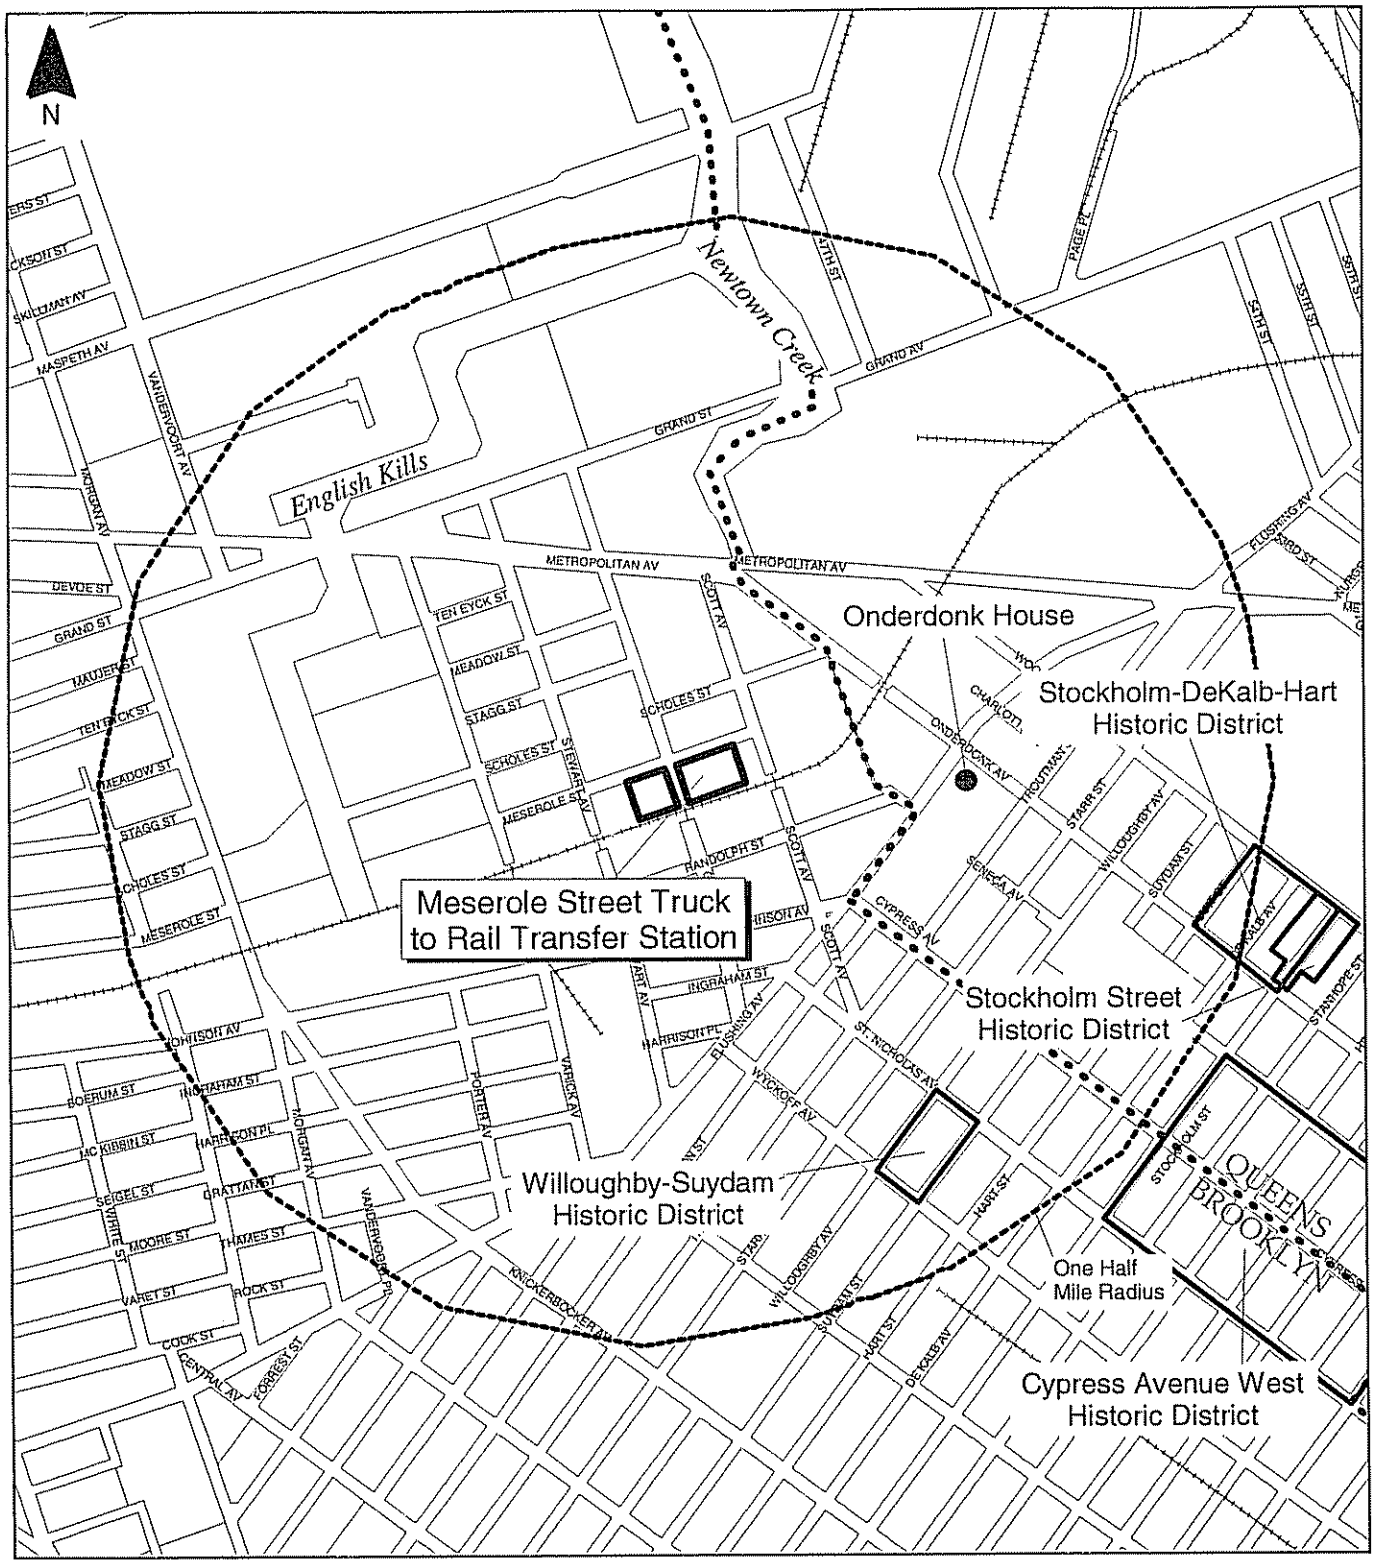
31.6.1.2 Development History of the Area

East Williamsburg in Brooklyn was established as an independent village in 1664 and remained a small farming community until the opening of the Erie Canal in 1825. Williamsburg became an independent city in 1827 and joined the city of Brooklyn in 1854. During the Civil War, The Monitor, the world's first ironclad warship, was built at the Brooklyn Navy Yard in Williamsburg. It remains an industrial neighborhood along the waterfront with an expanding residential population further inland.

Bushwick in the southern portion of the study area was one of six original towns in Brooklyn during Dutch rule in the 17th century. It was an established farming community well into the 19th century. With a large influx of German immigrants in the mid 1800s, many breweries were established; between 1850 and 1880 there were at least 11 breweries located in the neighborhood. Bushwick became part of Brooklyn, along with Williamsburg, in 1854. Housing development and associated residential population surged after the opening of the elevated railroad to Manhattan in 1888. The area's demographics changed over the decades with the improved access and available housing supply. As with many other neighborhoods in the outer boroughs, Bushwick declined in the 1960s and 1970s, and has recently experienced some revitalization of its housing stock.

The Ridgewood neighborhood of Queens was originally developed as part of Newtown, the first of Queens' three original towns, established in 1642. Following the protracted economic depression of the mid-1870s, Ridgewood boomed as a residential community after the Brooklyn City Railroad built its car barns there in 1881. The coming of the Myrtle Avenue Elevated in 1888 furthered this process, attracting great numbers of people from other parts of the City.

Maspeth is a large neighborhood in west central Queens, named for the Mespat Indians who lived there, near the headwaters of Newtown Creek. Though it was initially settled by Europeans in 1642, it remained sparsely developed until the mid-19th century. Heavy industrial uses lined Newtown Creek (in the study area) and that section of Maspeth remains industrial, though there are many vacant sites where fertilizer plants, lumber yards and linoleum plants once stood.



31.6.1.3 Cultural Resources on the Site

According to SHPO and LPC, there are no historic structures or areas of archaeological importance on the site.

31.6.1.4 Historic Resources Within the Study Area

Within or just beyond the study area, there are three early-20th-century historic districts and one individual property that are listed on the S/NR. The property and a large portion of one of the districts are also designated by the LPC. (See Figure 31.6-1.)

The Vander Ende-Onderdonk House (a.k.a., The Adrian and Anne Wyckoff Onderdonk House), located nearly ¼-mile east of the site, is a City landmark and is listed on the S/NR. It is the oldest Dutch-American fieldstone house in the City and houses the Greater Ridgewood Historical Society. The stone part of the house was built around 1709 and parts of the older frame date as far back as 1655. It served as a locus of 17th- and 18th-century Dutch and Huguenot settlement, and played a role in the boundary settlement between Kings and Queens Counties.

HDR HydroQual URBITRAN PB EEA Cambridge Environmental Inc

Figure 31.6-1 Cultural Resources

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

The three historic districts within (or just beyond) the study area are all intact groupings of late-19th-century/early-20th-century working class rowhouse and tenement housing. They are all in the bisected neighborhood of Ridgewood, which spans the Queens and Brooklyn border.

The Willoughby-Suydam Historic District covers 1½ blocks composed of 50 three-story brick tenements built between 1904 and 1906. Located more than ¼-mile southeast of the site, the district reflects the earliest phase of working class tenement housing constructed in Ridgewood, distinct from the rest of the Brooklyn Ridgewood community, which was developed with large industrial buildings at the time of construction. The district is listed on the S/NR.

The Stockholm-DeKalb-Hart Historic District covers 2½ blocks at the edge of the study area, east of the site. The two-story brick structures, designed in Romanesque and Renaissance Revival styles, are "an intact and cohesive neighborhood containing distinctive examples of working-class row houses constructed during Ridgewood's major period of development," between 1905 and 1921.[4] (The central portion of this district is also designated by LPC as the Stockholm Street Historic District.)

Located just beyond the study area boundary, further southeast of the site, the Cypress Avenue West Historic District is a 16-block district that stretches between Queens and Brooklyn. It serves as "an intact example of low-scale, working-class housing built at the turn of the twentieth century by German immigrants."[5] This district also contains two-story Romanesque and Renaissance Revival brick houses and other public buildings that were built between 1888 and 1906.

31.6.2 Future No-Build Conditions

There are no additional elements of potential architectural or archaeological significance slated for review; therefore, anticipated Future No-Build Conditions are assumed to be the same as Existing Conditions.

---

[4] The New York State/National Register, Number 92NR00293, page 4.
[5] The New York State/National Register, Number 90NR01600, page 4.

31.6.3 Potential Impact with the TransRiver Marketing Company, L.P. Truck to Rail TS

The SHPO and ~~NYC~~LPC have determined that there are no elements of architectural or archaeological significance within the site.

31.6.4 Potential Impact with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.6.3.

31.7 Urban Design, Visual Resources, and Shadows

31.7.1 Existing Conditions

31.7.1.1 Definition of the Study Area

The urban design and visual quality study area is the same as the neighborhood character study area (Figure 31.8-1). The site has been developed in a manner consistent with the urban design of the adjacent properties and visual quality of the overall study area. It is a non-sensitive industrial area, in terms of urban design and visual quality assessment. There are no sensitive-view corridors, publicly accessible open areas or points of waterfront access – areas that would likely experience visual quality impacts from the proposed transfer facility development.

31.7.1.2 Description of the Site

The existing transfer station comprises most of the on-site development. Both lots are surrounded by walls of about 8 to 12 feet in height, of cinder block or corrugated-metal fencing to block views into the site. While the gates are open, however, the trucks and containers are clearly visible from the street. Bales stacked on site are also visible from the streets where the stacks are several feet taller than the enclosing walls and fencing at the boundary. Where the interiors of the sites are visible from the street, however, they appear generally well organized. 111 Gardner Avenue features a two-story operations building and 586 Meserole Street contains a smaller wood-frame office building that seems to have once been a house. There is no formal landscaping on or adjacent to the site, but the perimeter walls are well maintained and free of graffiti.

31.7.1.3 Urban Design and Visual Resources of the Study Area

There are no sensitive-view corridors or important visual resources within the study area. The site is visually compatible with its industrial surroundings, which include several other waste transfer stations, recycling facilities and truck parking lots. Most industrial buildings in the area are two or three stories tall, with truck bays, and many with accompanying off-street parking. There is also on-street parking throughout the study area, but there is little daytime pedestrian activity. Vacant lots are adjacent to many of the buildings, though they tend to be maintained, some planted in grass. Although there is no formal and consistent landscaping for the public area, there are small strips of lawn along many of the area sidewalks, and there are mature trees throughout the study area. The area is generally tidy; the low-scale buildings, numerous parking lots and other unbuilt lots give the area an open quality. (See Figures 31.7-1 through 31.7-4.)

31.7.2 Future No-Build Conditions

There are no plans for development that would change the general street grid and development pattern throughout the area. Therefore, the urban design and visual resources of the area under Future No-Build Conditions are anticipated to resemble Existing Conditions.

31.7.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

While improvements would be made to the site, the industrial use would generally remain unchanged, and physical changes would be limited to the site. Although existing buildings on the two parcels will be demolished to accommodate new site construction, the improvements will likely produce a processing building, outdoor truck parking and container storage similar to the functional structures and open lot operations currently on the site. No significant adverse impacts to the urban design and visual quality of the area are anticipated.

31.7.4 Potential Impact with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.7.3.

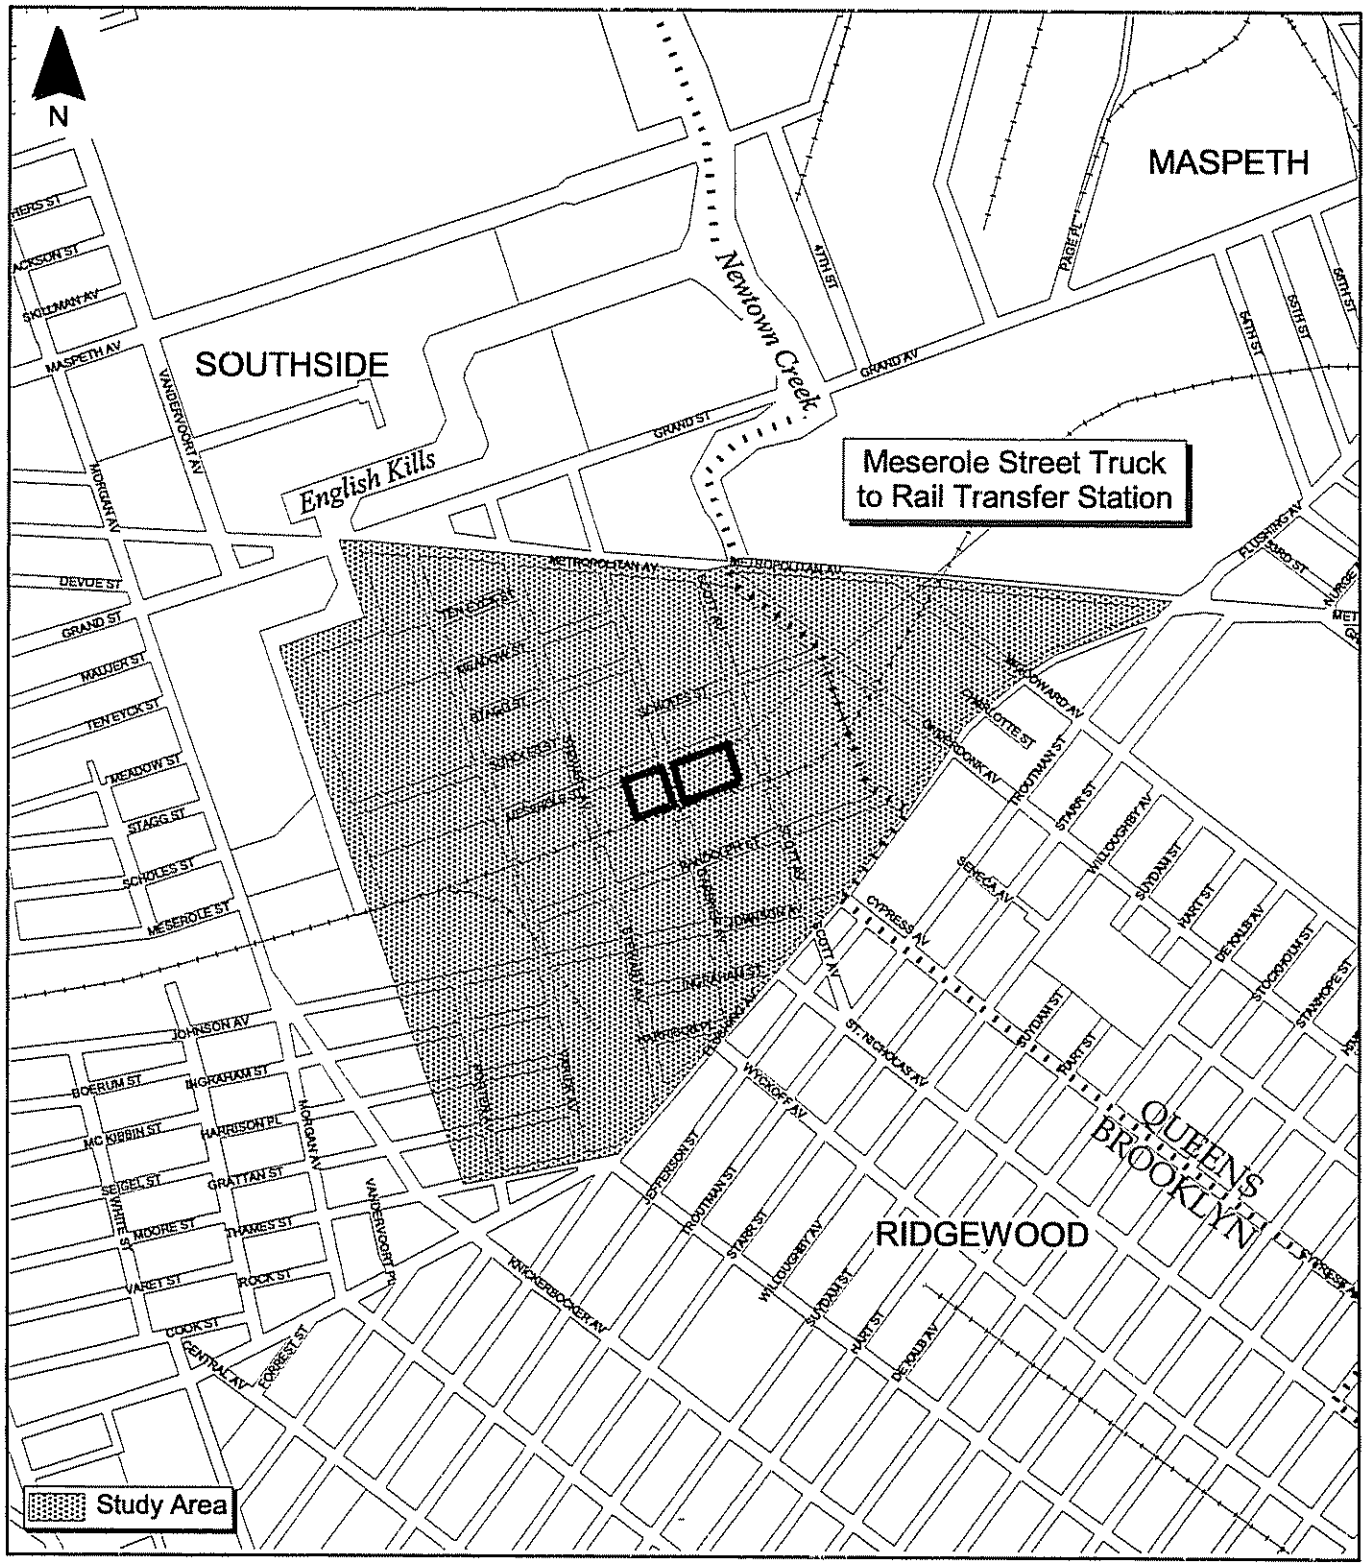
31.8 Neighborhood Character

31.8.1 Existing Conditions

31.8.1.1 Definition of the Study Area

The neighborhood character study area and site is defined by predominantly industrial land use and visual quality. The study area is defined by physical landscape elements that distinctly mark the edge of a specific neighborhood character, visually insulate the site and study area or physically obstruct pedestrian and vehicular access to it from outlying areas.



With these criteria, the study area is bounded by the English Kills to the west, LIRR tracks to the south, Newtown Creek to the east and Metropolitan Avenue to the north (Figure 31.8-1).

31.8.1.2 Description of Neighborhood Character

The study area is characterized by industrial uses, including several waste transfer and recycling operations. Consistent with a heavily industrial area, there are no sensitive visual resources or unique features, and while there are sidewalks and the area is generally tidy, with a few trees and some grass, there is little pedestrian activity. This is largely the result of there being no commercial or residential uses within the study area, heavy truck traffic through the area and limited pedestrian access into the study area.

31.8.2 Future No-Build Conditions

Future development plans in the vicinity of the site are beyond the study area and would not be expected to alter neighborhood character in their surroundings, particularly as they are industrial developments. The site will continue to operate as a recycling facility, and Future No-Build Conditions would generally resemble Existing Conditions.

Site delineations are approximate.

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

31.8.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

No change to the industrial neighborhood character would be expected because the Meserole Street Truck to Rail TS operation would be similar to Future No-Build Conditions. Technical analyses for the new facility predict no unmitigatible impacts associated with traffic, air, odor or noise. Therefore, no impacts to neighborhood character are predicted.

31.8.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.8.3.

31.9 Natural Resources

31.9.1 Existing Conditions

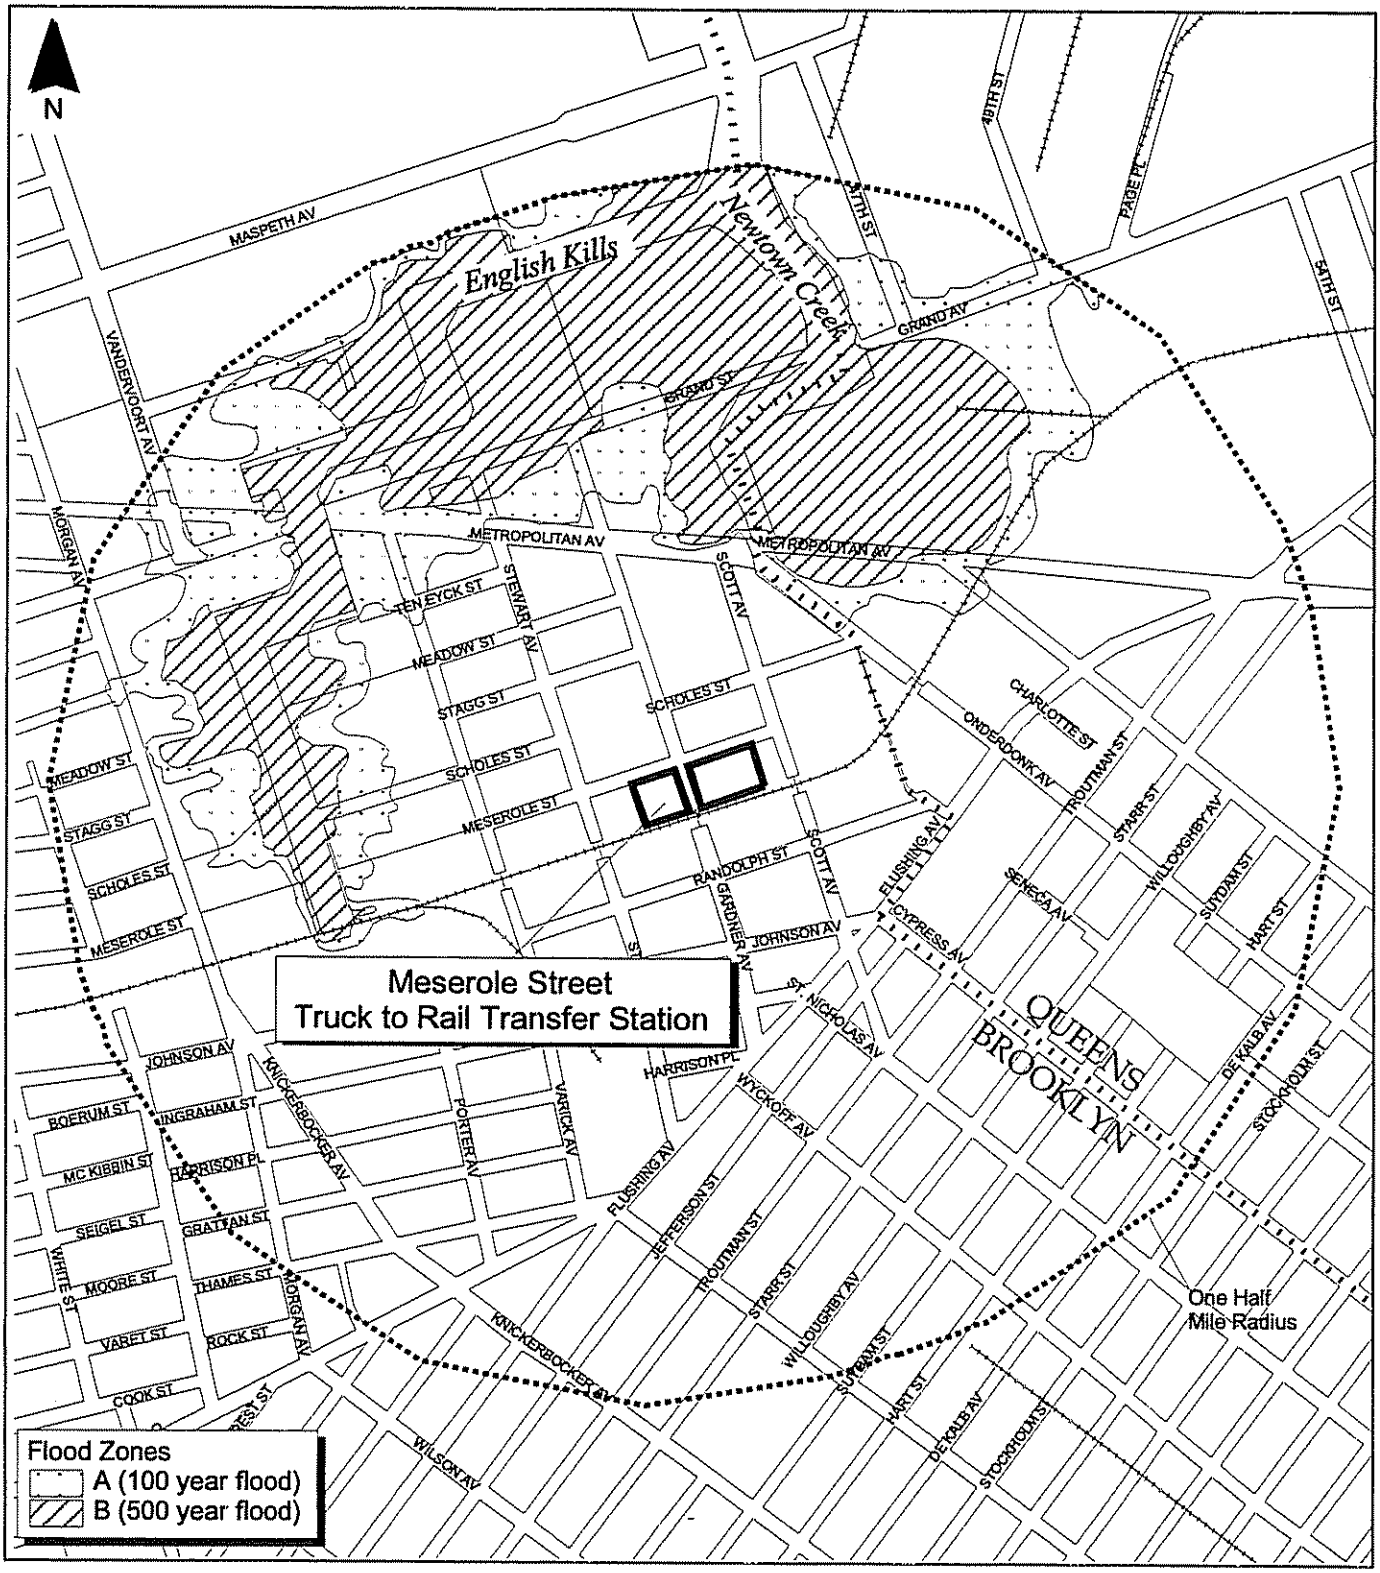
Existing Conditions include stressed terrestrial communities that are typical of this area of Brooklyn. Conditions associated with the presence of natural resources, including endangered species and habitats, were investigated within the defined study area to identify potential impacts that might arise if the Meserole Street Truck to Rail TS were developed.

31.9.1.1 Definition of Study Area

The study area includes the sites located at 568 Meserole Street and 111 Gardner Avenue. The 568 Meserole Street site is located on the southeast corner of Meserole Street and Gardner Avenue. The 111 Gardner Street site is located directly across Gardner Street, on the southwest corner of the intersection (Figure 2.4.13-1). Meserole Street Recycling, Inc. is presently on site. The area is zoned M3-1 for heavy manufacturing and is heavily developed. Therefore, the site has very limited terrestrial natural resources. Such resources that do exist are discussed in following sections.

31.9.1.2 Geology

Based on information derived from a review of the Bedrock and Engineering Geologic Maps of New York County by Charles A. Baskerville, 1994, the depth to bedrock is 125 feet below surface soil.[6] The property is paved with asphalt, covered with gravel and broken concrete, and has several buildings.



[6] Baskerville, C. A., 1994. Bedrock and Engineering Geologic Maps of New York County and Parts of Kings and Queens Counties, New York and Parts of Bergen and Hudson Counties, New Jersey.

31.9.1.3 Floodplains

The proposed Meserole Street Truck to Rail TS is located within a zone of minimal flooding (Figure 31.9-1). No intertidal wetlands exist in the study area. Newtown Creek and English Kills, which are NYSDEC-designated littoral zones, are to the northeast and west of the study area (Figure 31.9-2). The end of Newtown Creek falls just within a ¼-mile radius of the site and English Kills falls just outside the ¼-mile radius. The site is located within the City's WRP boundaries and is a designated SMIA.

31.9.1.4 Ecosystems

The site is essentially fully developed with buildings and paved lots, leaving little terrestrial natural resources to be impacted. The transfer station facility was devoid of vegetation; however, there was vegetation documented along the railroad tracks located immediately south of the facility. The species observed were non-native weed species, including: poor man's peppergrass (*Lepidium virginicum*), yellow nutsedge (*Cyperus esculentus*), lady's thumb (*Polygonum persicaria*), common mugwort (*Artemisia vulgaris*), redroot pigweed (*Amaranthus retroflexus*), common sow thistle (*Sonchus oleraceus*), crabgrass (*Digitaria sanguinalis*), green foxtail (*Setaria viridis*), common ragweed (*Ambrosia artemisiifolia*), Japanese knotweed (*Polygonum cuspidatum*), lamb's quarters (*Chenopodium album*), brome (*Bromus* sp.), daisy fleabane (*Erigeron annuus*), tree-of-heaven (*Ailanthus altissima*), black cherry (*Prunus serotina*), black medic (*Medicago lupulina*), horseweed (Conyza canadensis) and thistle (*Cirsium* sp.). Any construction along the railroad would impact the above-mentioned vegetation, but none of the species are threatened or endangered and all are considered to be invasive weed species.

Site delineations and study area boundaries are approximate.

Figure 31.9-2 Wetlands

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

THE CITY OF NEW YORK DEPARTMENT OF SANITATION

According to the USF&WS, except for occasional transients, there are no federally listed or proposed endangered or threatened species, or any "critical habitats" present on the site. According to the NYSDEC, there are no records of rare or state-listed animals or plants, significant natural communities or other significant habitats, on or in the immediate vicinity of the site.

31.9.2 Future No-Build Conditions

If the Meserole Street Truck to Rail TS were not developed, the study area would remain as is. The limited terrestrial natural resources will remain and the study area will continue to be an ecologically unproductive and stressed urban area.

31.9.3 Potential Impacts with TransRiver Marketing Company, L.P. TS

31.9.3.1 Geology

The geology of the study area would not be impacted as a result of the Meserole Street Truck to Rail TS.

31.9.3.2 Floodplains

Potential development of the Meserole Street Truck to Rail TS would have no effect on the elevation of the site. The potential development does not include any provisions for raising any portions of the site over this level. The facility would be constructed within the zone of minimal flooding and within the SMIA. The proposed activity, however, does not "substantially hinder" the area and therefore complies with New York State's CMP as expressed in the City's approved local WRP.

31.9.3.3 Ecosystems

The Meserole Street facility is covered with buildings and paved lots, which have precluded any opportunity for natural resources to establish themselves and, as such, native species of vegetation have probably been absent from the site since its original construction. Vegetation observed on the site was opportunistic weeds and plants, none of which were rare, endangered or particularly important from an ecological perspective. Implementation of the new facility would not have any significant impact on the few areas of vegetation present on the site. The few opportunistic, invasive, weed species on the property are located along the railroad tracks. Any construction or alteration of the property will not impact the vegetative community, as only weeds are present. There may be a loss of the vegetative communities along the railroad tracks with increased usage, but the species present along the tracks are also opportunistic species that do not have a significant community value.

31.9.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

31.9.4.1 Geology

Impacts for this Alternative are assumed to be the same as described in Section 31.9.3.1.

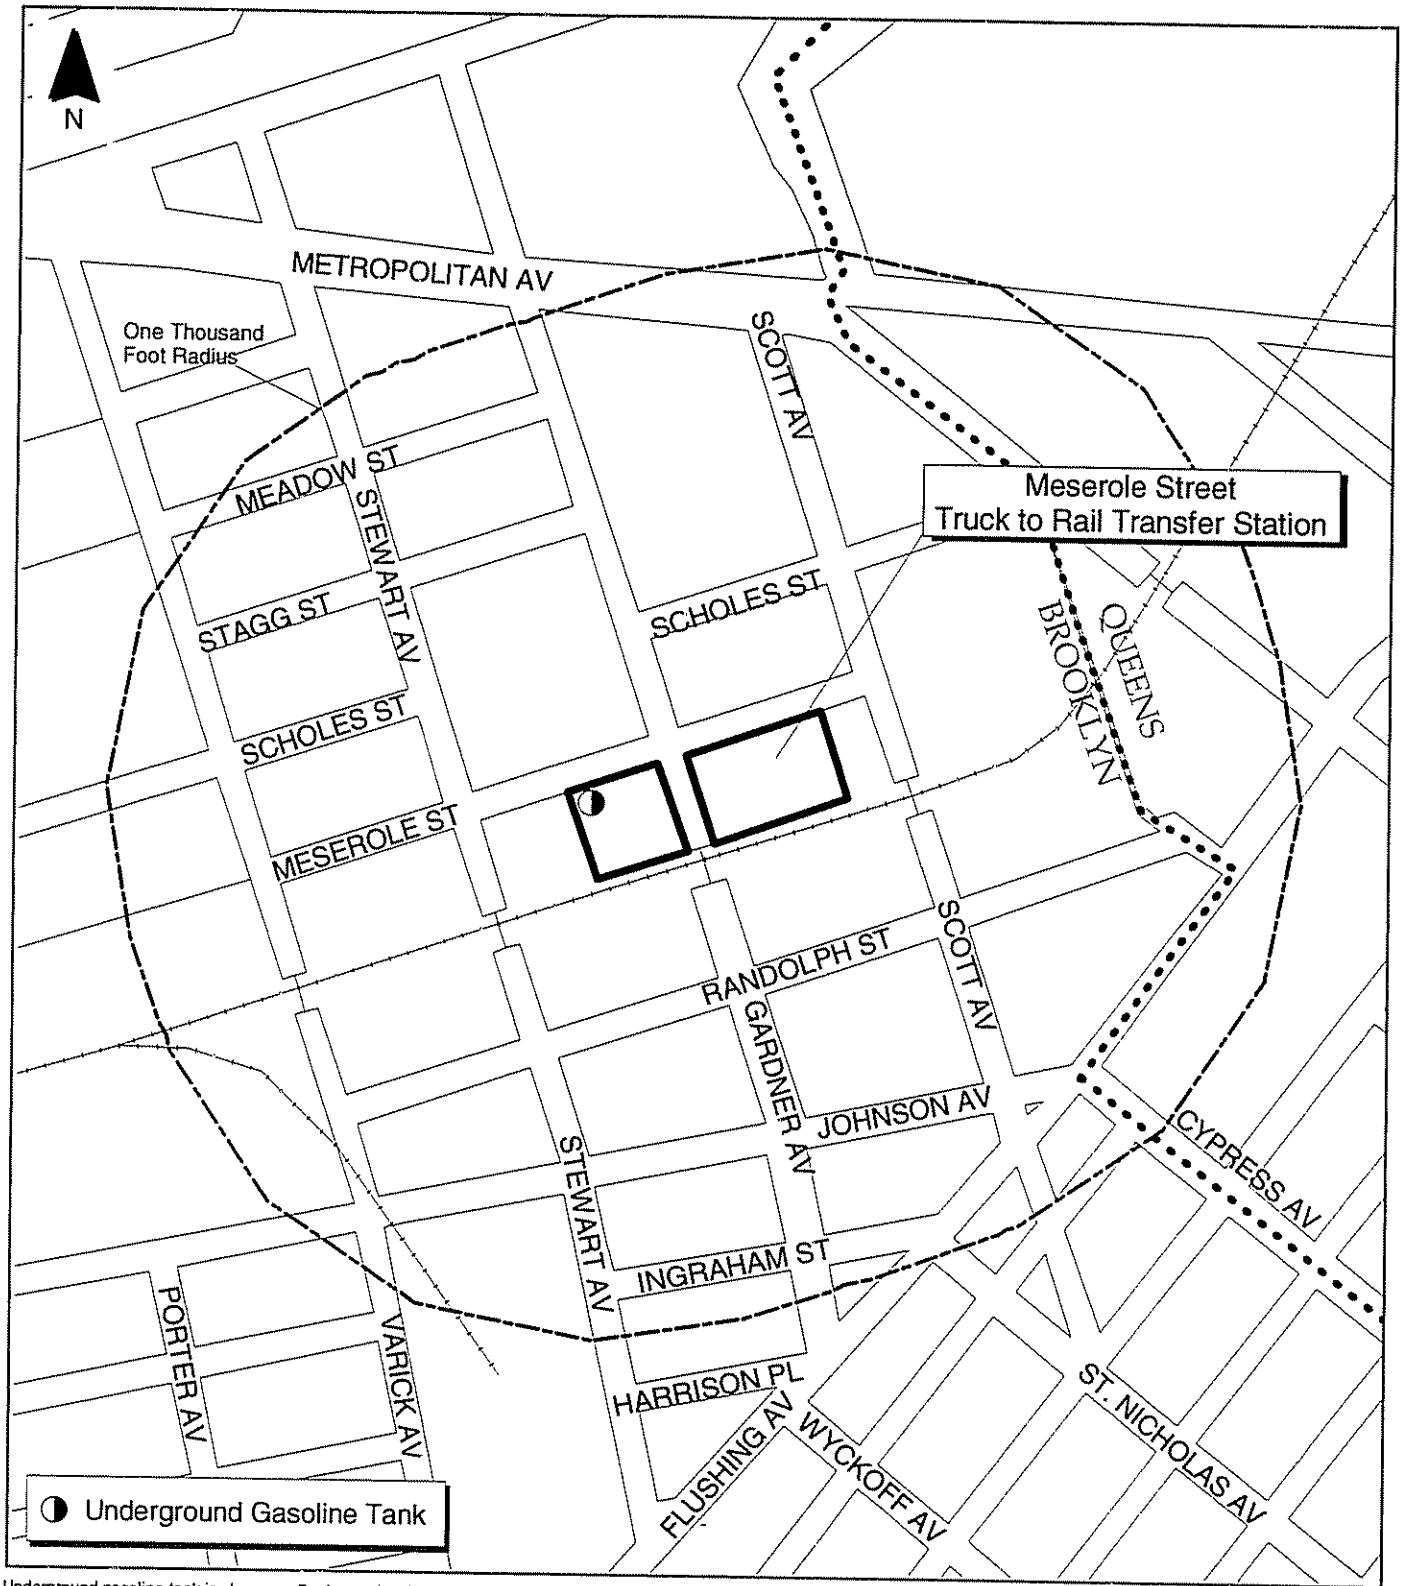
31.9.4.2 Floodplains

Impacts for this Alternative are assumed to be the same as described in Section 31.9.3.2.

31.9.4.3 Ecosystems

Impacts for this Alternative are assumed to be the same as described in Section 31.9.3.3.

31.10 Hazardous Materials



31.10.1 Existing Conditions

Existing Conditions associated with the presence or suspected presence of hazardous materials in soils, groundwater, and building components/equipment were assessed within the defined study area. The Hazardous Materials Assessment was performed in accordance with the guidelines for a preliminary assessment presented in the 2001 CEQR Technical Manual, and is consistent with the requirements for a Phase I ESA established by the ASTM (ASTM E-1527-00). The assessment was performed in July and August of 2004. It included a historic land use review, regulatory agency database review, reconnaissance of the study area and surrounding area, and surface and subsurface drainage evaluation.

The historical land use review included an assessment of Sanborn fire insurance maps and information contained within City Building Department database records for the study area. Standard federal and state environmental databases were assessed for records of sites within the study area that had evidence of hazardous waste activity or spills. A Freedom of Information Law request was submitted to the NYCDEP to solicit records pertaining to toxic or hazardous materials activities within the study area. A pedestrian reconnaissance of accessible interior and exterior areas within the study area was conducted in July 2004. During the reconnaissance, visual evidence was sought of hazardous materials handling or storage, including the presence of tanks, drums, transformers, and unusual stains and odors.

31.10.1.1 Definition of Study Area

The study area includes the existing site and its neighboring properties within an approximate 1,000-foot radius. (See Figure 31.10-1.) The existing site consists of two separate parcels: (1) 568 Meserole Street (Block 2978, Lot 1); and (2) 111 Gardner Avenue (Block 2977, Lots 14, 15 and 16).

Underground gasoline tank is shown on Sanborn atlas, but was not located during site visit

HDR URBITRAN EEA Cambridge Environmental Inc

Figure 31.10-1 Hazardous Materials Sites
Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

31.10.1.2 Delineation of Area of Concern

Areas of concern are defined as parts of the soil, groundwater and building components/equipment within the study area where the presence or likely presence of hazardous materials exist and implementation (i.e., development and construction) of the Meserole Street Truck to Rail TS could lead to possible increased exposure of people or the environment to those materials. The areas of concern within the study area identified during the assessment include:

- Previous Occupants and Uses – Historical Sanborn atlases and regulatory database records indicated former occupants and uses of the existing site included a liquid bleach manufacturer and a chemical distributor (111 Gardner Avenue site), and an iron frame works facility and lumberyards (568 Meserole Street site). Former building occupant, Alfred Chemical Corp. listed at 111 Gardner Avenue, was identified within the following regulatory databases: NYSDEC CBS Facility, Spill Log, and TRI Facilities; USEPA and NYSDEC RCRA Hazardous Waste Generator; and USEPA Civil & Administrative Enforcement Docket. Any improper releases of chemicals stored or used by these former on-site businesses, especially those occurring on then-unpaved property areas or within paved areas with drains, could have resulted in potential subsurface contamination at the existing site. It should be noted that exterior portions of the existing site, not covered by on-site buildings and structures, were either paved with asphalt and concrete, or covered with gravel and broken concrete. No visual evidence of stained soil or stressed vegetation was observed on the existing site during the site assessment.

- Underground Storage Tanks (USTs) - Historical Sanborn atlases (i.e., 1951, 1977, 1981 and 1991) depicted an outdoor buried gasoline tank on the northwest corner of the 111 Gardner Avenue site. In addition, City Building Department database records indicated a gasoline tank was installed circa 1904 at the 111 Gardner Avenue site, and oil burner applications were filed in 1954, 1956 and 1957 for the 111 Gardner Avenue site. It is unknown if the storage tanks associated with the installation of on-site oil-fired heating systems were located above ground and/or below ground. No fill ports or vent lines, normally associated with the presence of USTs, were noted at the 111 Gardner Avenue site. It should be noted that natural gas-fired systems presently supply heat within the 111 Gardner Avenue building.

- Past and Present Adjacent and Neighboring Uses – Review of historical Sanborn atlases and regulatory agency databases, as well as pedestrian reconnaissance of neighboring properties, indicated the study area is located within a neighborhood that has historically been developed for and occupied by a variety of manufacturing and industrial uses. Manufacturing and industrial operations typically involve the storage and use of toxic or hazardous materials, and generation of toxic or hazardous wastes.

Based upon this information, it is considered likely that some level of groundwater degradation exists within the study area.

31.10.2 Future No-Build Conditions

Under Future No-Build Conditions, the study area would remain as is. Contamination may exist within the study area from previous historic use, suspected USTs, and/or from documented and undocumented hazardous material releases at adjacent or neighboring properties.

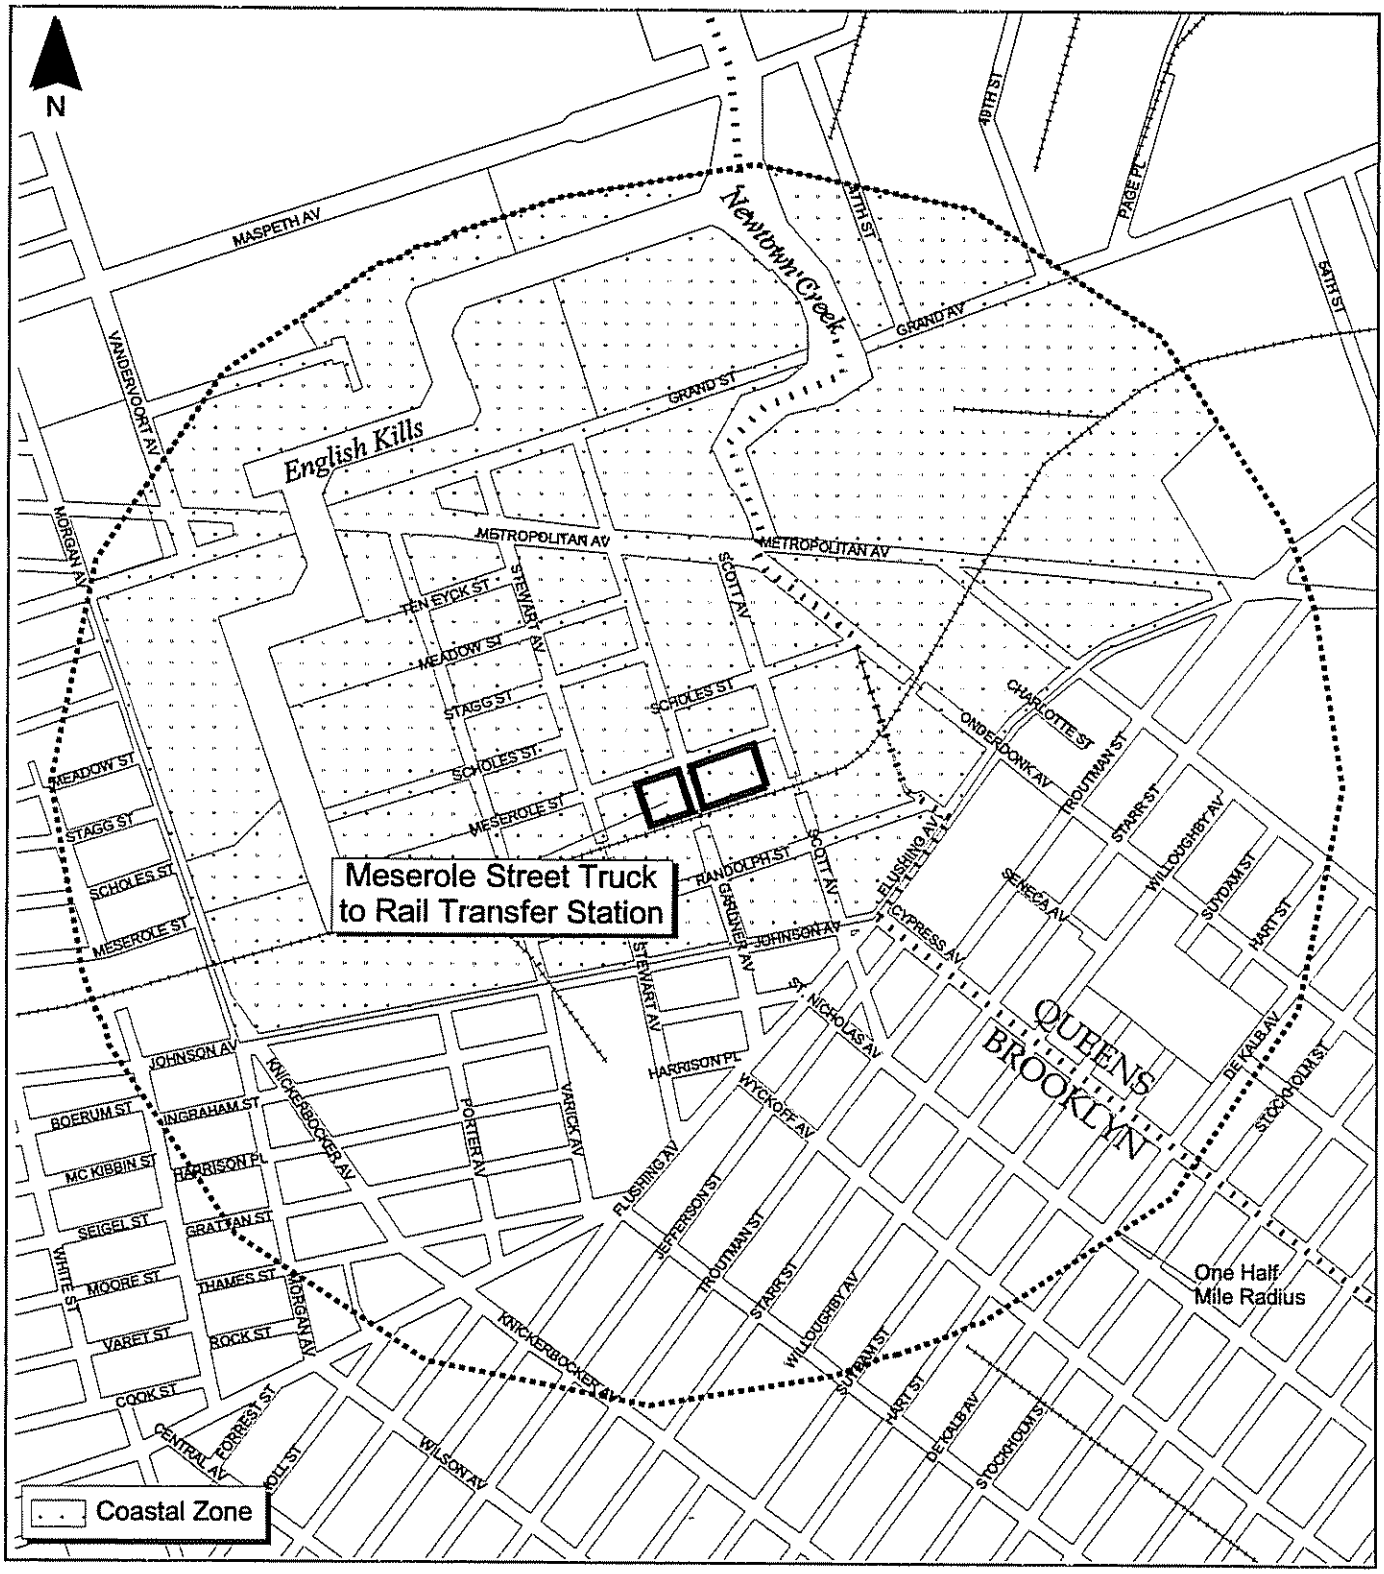
31.10.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

Based on the land use history of the study area and the possible presence of on-site USTs, contamination may exist within the study area where the new construction of the Meserole Street Truck to Rail TS would occur. If the Meserole Street Truck to Rail TS project was to be implemented, a soil and groundwater Phase II sampling protocol would be developed for review and approval by NYCDEP (NYSDEC may be involved in the decisions to test and remediate the study area depending on the actual events and levels of contamination encountered). If elevated levels of contamination are encountered, remediation of said contamination would be performed in a manner that is consistent with the levels of contamination discovered to ensure that no significant impact to on-site and off-site occupants occurs. Since construction and excavation may increase the exposure to contaminants by dermal contact, ingestion or inhalation, the necessary and appropriate health and safety measures would be implemented to mitigate and minimize any exposure risk to workers and the general public.

31.10.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

Impacts for this Alternative are assumed to be the same as described in Section 31.10.3.

31.11 Water Quality



The Meserole Street Truck to Rail TS is not located near or adjacent to surface waters and would have no potential to impact water quality. Therefore, no analysis was required.

31.12 Waterfront Revitalization Program

31.12.1 Introduction

The Federal Coastal Zone Management Act of 1972 established coastal zone management programs to preserve, protect, develop and restore the coastal zone of the U.S. Due to its proximity to the waterfront of English Kills and Newtown Creek, the proposed Meserole Street Truck to Rail TS would be located within the City's coastal zone boundary (Figure 31.12-1). The site is located within a designated SMIA and Reach 13/Newtown Creek as indicated within the "New York City Comprehensive Waterfront Plan" and the "Plan for the Brooklyn Waterfront." The proposed Meserole Street Truck to Rail TS is, therefore, subject to review under the 10 primary policies and the 32 subpolicies identified within "The New Waterfront Revitalization Program" that address the waterfront's important natural, recreational, industrial, commercial, ecological, cultural, aesthetic and energy resources.

The Meserole Street Truck to Rail TS was reviewed to determine its general consistency with each of these policies and subpolicies. This review identified several subpolicies that were not applicable. These included subpolicies 1.1, 1.2, 2.2, 3.1, 4.4, 6.2, 6.3 and 8.5. All policies and subpolicies, including those identified as not applicable, are listed in Table 3.14-1. In instances where a component of the proposed Meserole Street Truck to Rail TS required clarification or was inconsistent with a specific policy or subpolicy, further discussion is provided below. A description of waste handling operations that would occur at the proposed site is provided in Section 2.4.13.

Site delineations and study area boundaries are approximate.

31.12.2 Consistency Assessment for TransRiver Marketing Company, L.P. TS

Policy 1: Support and facilitate commercial and residential redevelopment in areas well-suited to such development.

1.3 Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

A review of available information indicates that there are sufficient public services and facilities to support the new Meserole Street Truck to Rail TS. As part of the proposed facility, connections from the new facility to existing utilities in the vicinity (e.g., sewer and electrical connections, etc.) would be established.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

2.1 Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The proposed Meserole Street Truck to Rail TS would be located within the boundaries of the NYCDCP-designated Newtown Creek SMIA. The proposed facility would serve as a truck-to-rail facility where MSW would be delivered, processed and containerized, then transported via rail lines to the American Ref-Fuel Company's waste-to-energy facility located in Niagara Falls, New York. The proposed facility would occupy two adjacent sites and would require demolition and construction activities in order to operate as a truck-to-rail transfer station. Development of the proposed facility would include the removal of existing buildings; development of a new 200-foot-by-200-foot building that would contain a tipping floor, rail line loading dock and weighing scales; and an additional building that would consist of the truck queuing area and container storage area. In addition, existing rail connections would need to be extended and

two new rail spurs constructed. The Meserole Street Truck to Rail TS would be consistent with existing land uses in the immediate vicinity of the site and would be compatible with surrounding uses. Therefore, the proposed facility would be consistent with this subpolicy.

2.3 *Provide infrastructure improvements necessary to support working waterfront uses.*

The proposed Alternative would not be considered a waterfront use as it is not located at the waterfront. The action would involve the development of a truck-to-rail facility. The proposed facility would allow for rail transport of compacted containerized solid waste to a licensed out-of-City disposal facility. The proposed development would involve the demolition of existing buildings and subsequent development of a new 200-foot-by-200-foot building that would contain a tipping floor, rail loading dock and weighing scales, and an additional building which would include a truck queuing area and container storage area. In addition, existing rail connections would be extended and two new rail spurs constructed. Once development activities are completed, the facility would provide a site where MSW could be received, processed and containerized, then transported by rail to a licensed disposal facility. The Proposed Action would involve the demolition and redevelopment of existing buildings. It would not result in a need for significant infrastructure improvements and would, therefore, be consistent with this subpolicy.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

3.2 *Minimize conflicts between recreational, commercial, and ocean-going freight vessels.*

The Meserole Street Truck to Rail TS would not be a waterfront use and would not be located in an area that would cause conflicts with recreational, commercial or ocean-going vessels. This subpolicy would not, therefore, be applicable.

3.3 *Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.*

The proposed facility would not be a waterfront use. The proposed Meserole Street Truck to Rail TS would serve as a truck-to-rail facility where MSW would be delivered, processed and containerized, then transported via rail lines to an out-of-City disposal facility. No impacts on the aquatic environment and surrounding land and water uses would result from the development of the facility. This subpolicy would not be applicable.

Policy 4: Protect and restore the quality and function of ecological systems within the New York coastal area.

4.1 *Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.*

Based upon a review of SNWAs, as described in "The New Waterfront Revitalization Program," as well as Recognized Ecological Complexes, the Meserole Street Truck to Rail TS would not be within a designated area. SCFWH information maintained by the New York State Department of State indicates that the Meserole Street Truck to Rail TS would also not be located within an SCFWH.

Development of the Meserole Street Truck to Rail TS would involve the demolition of existing structures and subsequent development of a new facility. The proposed facility would not be located on the waterfront, nor would it be a water-dependent use. The Proposed Action would not be anticipated to

significantly impact natural resources in the vicinity of the site. The Meserole Street Truck to Rail TS would, therefore, be consistent with this subpolicy.

4.2 *Protect and restore tidal and freshwater wetlands.*

A review of NYSDEC tidal and freshwater wetland maps was conducted in order to determine the presence of wetlands within the project site. No tidal or freshwater wetlands exist on the site. The proposed Meserole Street Truck to Rail TS would be a land-based facility. No impacts to wetlands would occur as a result of the Proposed Action. This subpolicy would not, therefore, be applicable.

4.3 *Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.*

A review of the NYSDEC NHP database indicates there are no vulnerable plant, fish and wildlife species or rare ecological communities on site or in the immediate vicinity of the proposed site.

Development of the proposed facility would involve the demolition of existing structures and the subsequent development of a new facility that would operate as a truck-to-rail TS. As stated in Section 31.9, modifications to the site would result in little, if any, adverse ecological impacts or loss of habitat for rare or endangered species due to the previous and ongoing industrial activities at and in the vicinity of the site. Sanitary and process wastewaters would be routed to on-site treatment systems and then discharged to the municipal sewer system. Management of stormwater runoff from the Meserole Street Truck to Rail TS and the storage of any petroleum products would be conducted in accordance with applicable federal, state and local regulations. The Meserole Street Truck to Rail TS would also not introduce hazardous wastes or other pollutants into the

environment that could adversely impact fish and wildlife resources within the coastal area.

Policy 5: Protect and improve water quality in the New York City coastal area.

5.1 Manage direct or indirect discharges to waterbodies.

The Meserole Street Truck to Rail TS would be developed in accordance with applicable federal, state and local regulations. Consistent with this subpolicy, the solid waste processing areas would be cleaned on a regular basis. All sanitary and process wastewaters (e.g., floor washdown waters, etc.) would be conveyed to an on-site disposal treatment system and then discharged to the municipal sewer system. Stormwater runoff from the Meserole Street Truck to Rail TS would be managed in accordance with applicable regulations. The proposed facility would be consistent with this subpolicy.

5.2 Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

During the development and operation of the Meserole Street Truck to Rail TS, BMPs would be used to the extent possible to minimize any nonpoint discharges. Construction and operation of the proposed facility would comply with applicable federal, state and local requirements for the management of stormwater runoff and erosion. All handling and containerization of solid waste would be performed inside the processing building, limiting the risk for the introduction of hazardous wastes or other pollutants into the environment. Control methods would be implemented at the facility to minimize or eliminate the potential for litter to escape into the surrounding environment. The Proposed Action would be consistent with this subpolicy.

5.3 *Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.*

The proposed facility would be not be situated on a navigable water or within a natural area. Development of the proposed facility would involve demolition of existing buildings and subsequent construction of a new, land-based facility. There would be no excavation or placement of fill within any watercourse or wetlands associated with the proposed facility. Therefore, this subpolicy would not be applicable.

5.4 *Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.*

The proposed development of the Meserole Street Truck to Rail TS would have no impact on the quality or quantity of surface or ground waters. In addition, the facility would not be located on a surface water. No surface or ground waters in the vicinity of the site constitute a primary or sole source aquifer or water supply. The Meserole Street Truck to Rail TS would be consistent with this subpolicy.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

6.1 *Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.*

The proposed Meserole Street Truck to Rail TS would not be a waterfront facility. In addition, based upon a review of the FEMA National Flood Insurance Program maps, the Meserole Street Truck to Rail TS would not be located within a designated floodplain. This subpolicy would not, therefore, be applicable.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

7.1 Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

The proposed Meserole Street facility would involve the management and processing of solid waste through a truck-to-rail system. Waste would be transported in sealed containers via rail to an out-of-City disposal facility. All waste handling operations would occur inside an enclosed processing building, which would minimize the escape of litter into the surrounding environment. Solid waste would generally be containerized within 24 hours of arriving at the facility. All solid waste handling operations would be conducted in accordance with the NYSDEC Part 360 regulations (6 NYCRR Parts 360-1 and 360-11) for solid waste transfer stations, which would be incorporated by reference into the permit to construct and operate the proposed facility.

Contingency plans would be put in place to address the potential receipt of unauthorized waste and/or other situations that could disrupt the operation of the facility. Litter control methods would also be implemented at the facility to minimize or eliminate the potential for litter entering the environment. The proposed Meserole Street Truck to Rail TS would not result in adverse impacts and would be operated in a manner to ensure that there would be no impact to surface and ground waters, significant fish and wildlife habitats, recreational areas and scenic resources. The proposed facility would be consistent with this subpolicy.

7.2 Prevent and remediate discharge of petroleum products.

See response to Subpolicy 7.1.

7.3 *Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.*

See response to Subpolicy 7.1.

Policy 8: Provide public access to and along New York City's coastal waters.

8.1 *Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.*

The proposed Meserole Street Truck to Rail TS would not be located on the waterfront and, therefore, would not affect existing access to the waterfront. This subpolicy would not be applicable.

8.2 *Incorporate public access into new public and private development where compatible with proposed land use and coastal location.*

The proposed Meserole Street Truck to Rail TS would not be a waterfront facility, and public access would generally not be compatible with the principal use of the site or the surrounding areas. Therefore, this subpolicy would not be applicable.

8.3 *Provide visual access to coastal lands, waters and open space where physically practical.*

The Meserole Street Truck to Rail TS would be compatible with surrounding uses. It would involve the development of a new facility on an existing industrial site. As discussed in Section 31.7, existing visual access to coastal lands, waters and open space is minimal due to the highly industrial nature of the surrounding vicinity. Therefore, no impacts to visual access would be anticipated. See also response to Subpolicy 9.1.

8.4 Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

No mapped parklands or open space areas have been identified at or within the immediate vicinity of the proposed site. Therefore, this subpolicy is not applicable.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

9.1 Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The proposed Meserole Street Truck to Rail TS would not result in significant impact upon visual quality, as noted in Section 31.7. Based on the information discussed in that section, the proposed facility would be consistent with this subpolicy.

9.2 Protect scenic values associated with natural resources.

The proposed facility would involve the removal of existing buildings and the subsequent development of a new facility. The existing facility provides no scenic values associated with natural resources, and the Proposed Action would pose no additional impacts to scenic values associated with natural resources. It would, therefore, be consistent with this subpolicy.

Policy 10: Protect, preserve and enhance resources significant to the historical, archaeological and cultural legacy of the New York City coastal area.

10.1 Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

No adverse effects on cultural resources would result from the development of the Meserole Street Truck to Rail TS, as stated in Section 31.6. Based on the information presented in that section, the proposed facility would be consistent with this subpolicy.

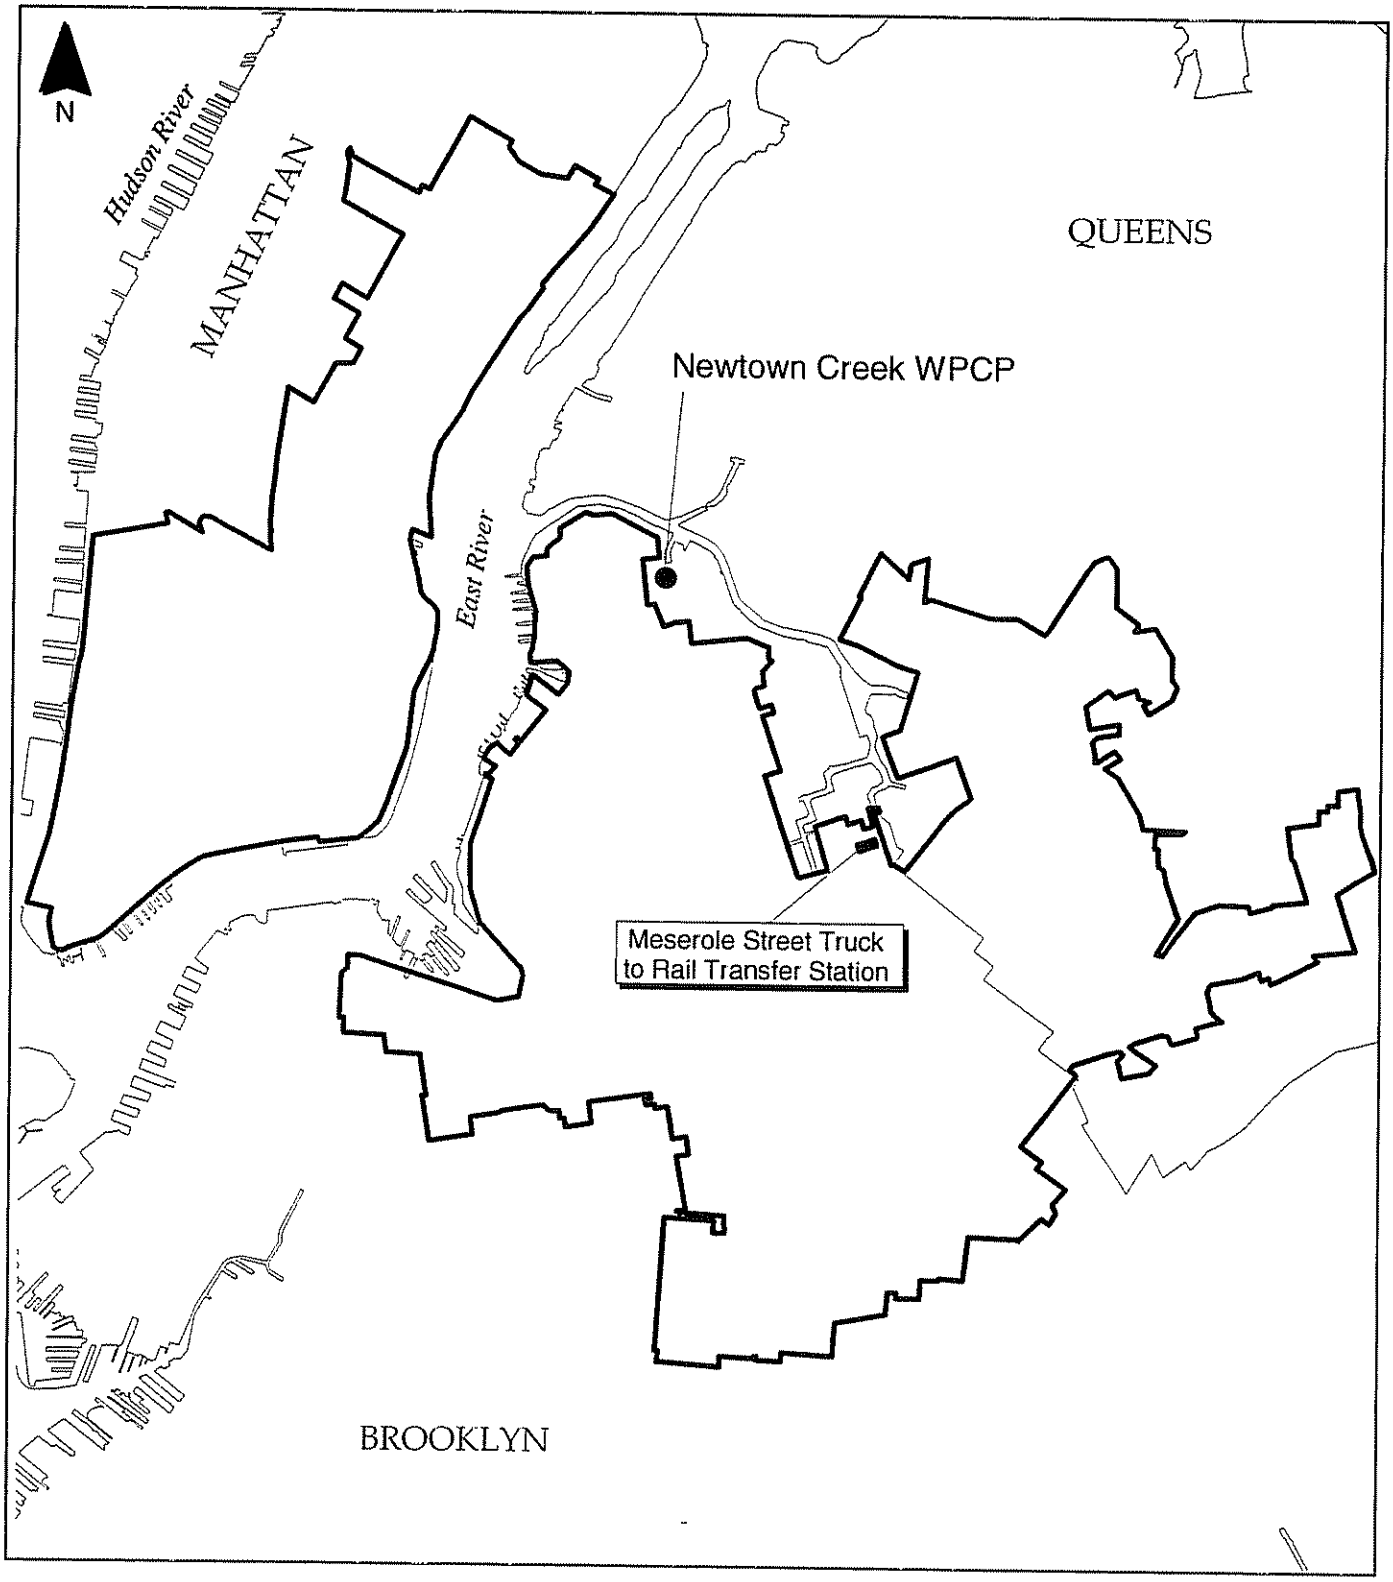
10.2 Protect and preserve archaeological resources and artifacts.

No archaeologically significant resources are located at the site or in the study area. This subpolicy, therefore, is not applicable.

31.12.3 Consistency Assessment for IESI NY Corporation TS

Assessment for this Alternative is assumed to be the same as described in Section 31.12.2.

31.13 Infrastructure, Solid Waste and Sanitation Services, and Energy



31.13.1 Existing Conditions

31.13.1.1 Water Supply

Potable water is supplied to the vicinity of the Meserole Street Truck to Rail TS site from the Delaware and Catskill reservoir systems through the City's municipal water distribution system. An 8-inch-diameter water supply line exists along Meserole Street and a 12-inch line exists along Gardner Avenue, based on a review of the NYCDEP water distribution maps. Water pressure throughout the City system is generally maintained at about 20 psi, which is the minimum pressure acceptable for uninterrupted service (2001 CEQR Technical Manual).

31.13.1.2 Sanitary Sewage and Stormwater

A review of NYCDEP I&I maps shows that the site is served by the Newtown Creek WPCP, which serves portions of Manhattan, Queens and Brooklyn. The WPCP drainage area is illustrated in Figure 31.13-1. From July 2002 through June 2003, the WPCP treated an average of 216 mgd of wastewater under dry weather flow conditions and an average flow of 238 mgd, which includes the sanitary and stormwater flows received by the WPCP during wet weather (Table 31.13-1). The maximum dry weather flow during this period was 239 mgd in August 2002 and the maximum average flow was 259 mgd during June 2003. Effluent from the plant is discharged to the East River and is regulated by NYSDEC under the SPDES. The current SPDES permit limit for flow to the Newtown Creek WPCP is 310 mgd. As the Meserole Street Truck to Rail TS is currently not staffed and no operations take place at the site, no water is used by personnel or process operations.

Site delineations are approximate

August	239	256
September	229	253
October	224	255
November	208	238
December	213	228
January 2003	212	223
February	204	224
March	218	240
April	207	228
May	201	219
June	218	259
Average Effluent	**216**	**238**

Note:
(1)_-Average flow includes the sanitary and stormwater flows received by the plant during wet weather.

Based on a review of the I&I maps and information provided by the NYCDEP, Brooklyn Water and Sewer Permits, the area in proximity to the Meserole Street Truck to Rail TS is served by two branches of a 10-inch-diameter sanitary sewer that flow east and west along Meserole Street to a 24-inch sanitary sewer on Gardner Avenue. The 24-inch line flows south to a 36-inch interceptor on Randolph Avenue, which conveys sanitary flow to the west and north along Varick, Johnson, Knickerbocker, Morgan and Lombardy Avenues and Monitor and Russell Streets, to the Newtown Creek WPCP.

Stormwater sewers in the vicinity of the site include a 12-inch-diameter line that conveys stormwater to the west along Meserole Street from the intersection with Scott Avenue. The storm sewer increases in diameter to a 42-inch line at the intersection of Meserole Street and Gardner Avenue and connects to a 48-inch storm sewer at the intersection of Meserole Street and Stewart Avenue, which conveys flow to the north along Stewart Avenue. The 48-inch line connects to a 54-inch storm sewer that flows west along Scholes Street, which increases to a 60-inch-diameter line at the Varick Avenue intersection before reaching the outfall at Scholes Street and English Kills. A 36-inch stormwater sewer also exists along Gardner Avenue and flows north to a connection with the 42-inch storm sewer on Meserole Street.

31.13.1.3 Solid Waste

Commercial and industrial wastes generated in the City are collected by private companies. Residential solid waste is collected and managed by DSNY. As the site is not currently staffed and no operations take place, no solid waste is generated at the site.

31.13.1.4 Energy

Based on a review of applicable service plates, Consolidated Edison maintains electric lines along Gardner Avenue and Meserole Street.

Keyspan maintains gas lines in the vicinity of the site, including a 6-inch-diameter line along Meserole Street and a 6-inch line north of Meserole Street along Gardner Avenue.

The Meserole Street Truck to Rail TS site currently utilizes a negligible amount of gas and electricity due to the absence of staff and a lack of operations.

31.13.2 Future No-Build Conditions

The Meserole Street Truck to Rail TS site would continue without operations. Potable water use, process and sanitary wastewater generation, solid waste generation and energy use would remain at or near the Existing Conditions levels for the site. Wastewater flows to the Newtown Creek WPCP would continue to increase and would be projected to be 240.4 mgd in 2006.

31.13.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS

31.13.3.1 Water Supply

The Meserole Street Truck to Rail TS site would have up to 37 employees working three shifts per day. They would require approximately 925 gallons of potable water per day plus an additional 1,800 gpd for truck and tipping floor washdown and dust control. It was assumed that this facility would use approximately the same amount of water for truck and tipping floor washdown and dust control as the Converted MTSs. The combined total usage of 2,725 gpd of potable water would represent an increase of 2,725 gpd above current consumption levels.

The Meserole Street Truck to Rail TS site would have no impact on the existing system's ability to supply water reliably. According to NYCDEP, the water pressure in the area is about 45 psi. Under worst-case conditions, the increased usage would not have significant impacts on water pressure in the system.

31.13.3.2 Sanitary Sewage

Based on the estimated water usage of 2,725 gpd for the Meserole Street Truck to Rail TS site, the small quantities of wastewater sent to the Newtown Creek WPCP would not significantly impact the sewage flow rate or the ability of the Newtown Creek WPCP to meet its SPDES permit limits. The projected wastewater flows at the WPCP would be anticipated to be approximately 240.4 mgd in 2006, which would be well below the permitted capacity of 310 mgd. In addition, the new wastewater flows due to the proposed action would not result in a significant increase in CSOs.

31.13.3.3 Solid Waste

Solid waste transfer station facility use is not cited under the solid waste generation rates provided in the 2001 CEQR Technical Manual, so rates for a commercial office building (1.3 lbs/day per employee) were used as a basis for a conservative estimate of waste generation. For an estimated 37 facility employees per day, 289 pounds of solid waste would be generated per week (48 lbs/day) and would represent an incremental increase of approximately 289 pounds per week (48 lbs/day) above current waste generation levels. This volume would be managed at the Meserole Street Truck to Rail TS site and would not significantly impact the system.

31.13.3.4 Energy

Detailed energy requirements for the Meserole Street Truck to Rail TS site were not available at the time of this analysis. Therefore, it was assumed that energy requirements of the Meserole Street Truck to Rail TS site would be similar to the energy requirements of a Converted MTS. Based on this assumption, the Meserole Street Truck to Rail TS site would require approximately 5.51E+10 BTU/year of electricity to operate the facility and natural gas facility heating would be used with an estimated demand of 1.34E+08 BTU/year.

Consolidated Edison has been notified of the power requirements of the Greenpoint Converted MTS and has stated that all demands generated by the facility could be met without an impact on the power requirements of the surrounding community and without the need for additional power generation capacity. Based on this statement, it is assumed that Consolidated Edison would also be able to meet all power demands without impacts of the Meserole Street Truck to Rail TS site, which is located in close proximity to the location of the Greenpoint Converted MTS.

Consolidated Edison was also notified of the natural gas requirements of the Greenpoint Converted MTS and has stated that the facility could be supplied with natural gas with no adverse impacts on the utility. Based on this statement, it is assumed that Consolidated Edison would also be able to meet all natural gas demands without impacts of the Meserole Street Truck to Rail TS site, which is located in close proximity to the location of the Greenpoint Converted MTS.

31.13.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

31.13.4.1 Water Supply

Impacts for this Alternative are assumed to be the same as described in Section 31.13.3.1.

31.13.4.2 Sanitary Sewage

Impacts for this Alternative are assumed to be the same as described in Section 31.13.3.2.

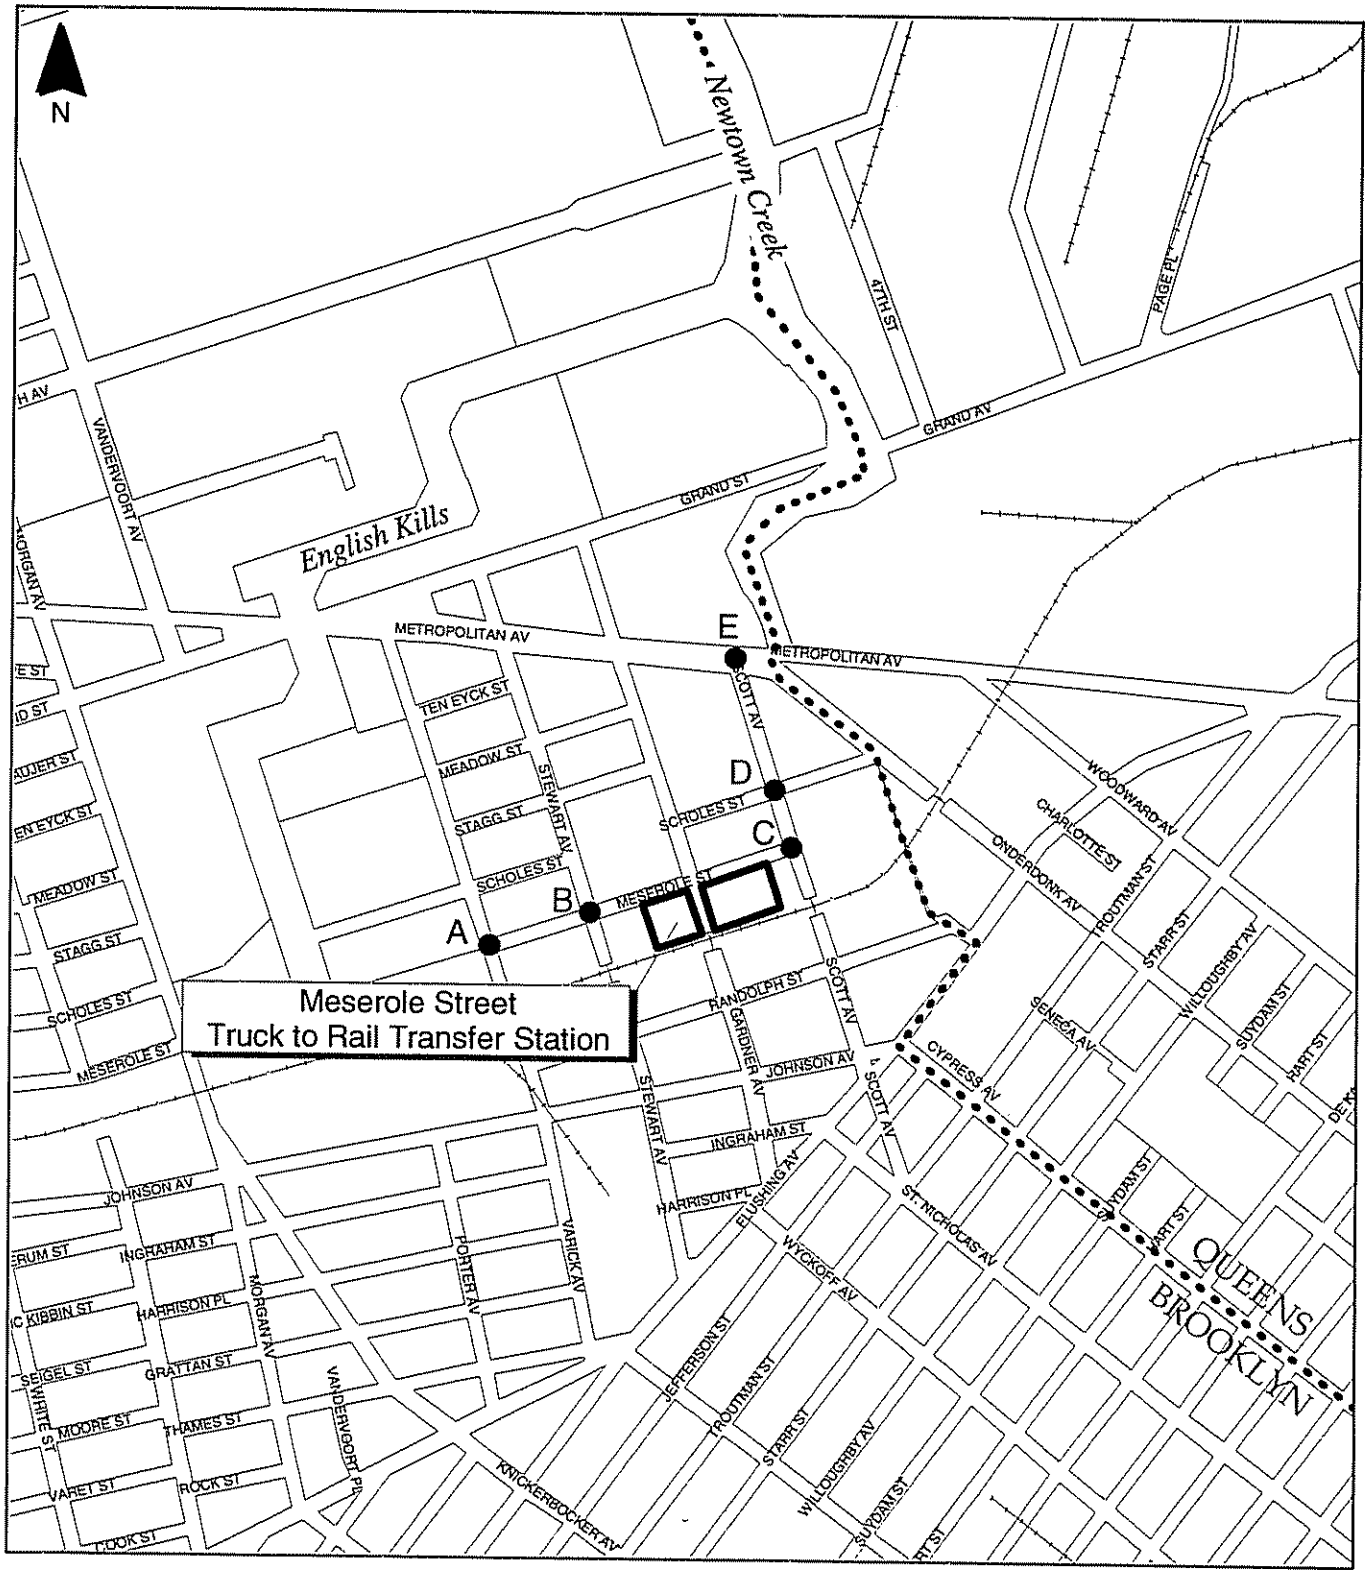
31.13.4.3 Solid Waste

Impacts for this Alternative are assumed to be the same as described in Section 31.13.3.3.

31.13.4.4 Energy

Impacts for this Alternative are assumed to be the same as described in Section 31.13.3.4.

31.14 Traffic, Parking, Transit, and Pedestrians



31.14.1 Existing Conditions

The Meserole Street Truck to Rail TS would receive waste from DSNY and other agency collection vehicles. Therefore, pursuant to CEQR guidelines, a traffic analysis was performed on the projected net increase in collection vehicles in the study area (which is defined below) and on other site-generated traffic. (See Section 3.16 for a discussion of CEQR analysis thresholds.)

31.14.1.1 Definition of Study Area

The traffic analysis study area is broad and includes the East Williamsburg neighborhood of Brooklyn. It includes the area bounded by Grand Street on the north, Flushing Avenue on the south, the dividing line between Kings County and Queens County on the east (which approximately follows Onderdonk Avenue in the area), and Varick Avenue and Vandervoort Avenue on the west. The traffic study area is predominantly light industrial in nature. There are no CEQR-defined areas of concern located within the study area. Figure 31.14-1 shows the locations of the intersections selected for analysis (locations A through E). Intersections analyzed were selected using the procedures defined in Section 3.16.

The analysis of collection vehicle routing to the site included highway access points more than ½-mile away in conjunction with local truck routes. Eastbound collection vehicles would approach the site along Flushing Avenue, Grand Street and Metropolitan Avenue and turn northbound or southbound onto Varick Avenue. Collection vehicles would then turn onto Meserole Street to access the facility. Northbound and southbound collection vehicles could travel along the BQE or local designated truck routes to Flushing Avenue, Grand Street or Metropolitan Avenue and then follow the same routes as eastbound collection vehicles. Westbound DSNY collection and other City agency vehicles are not expected to deliver DSNY-managed Waste to this facility.

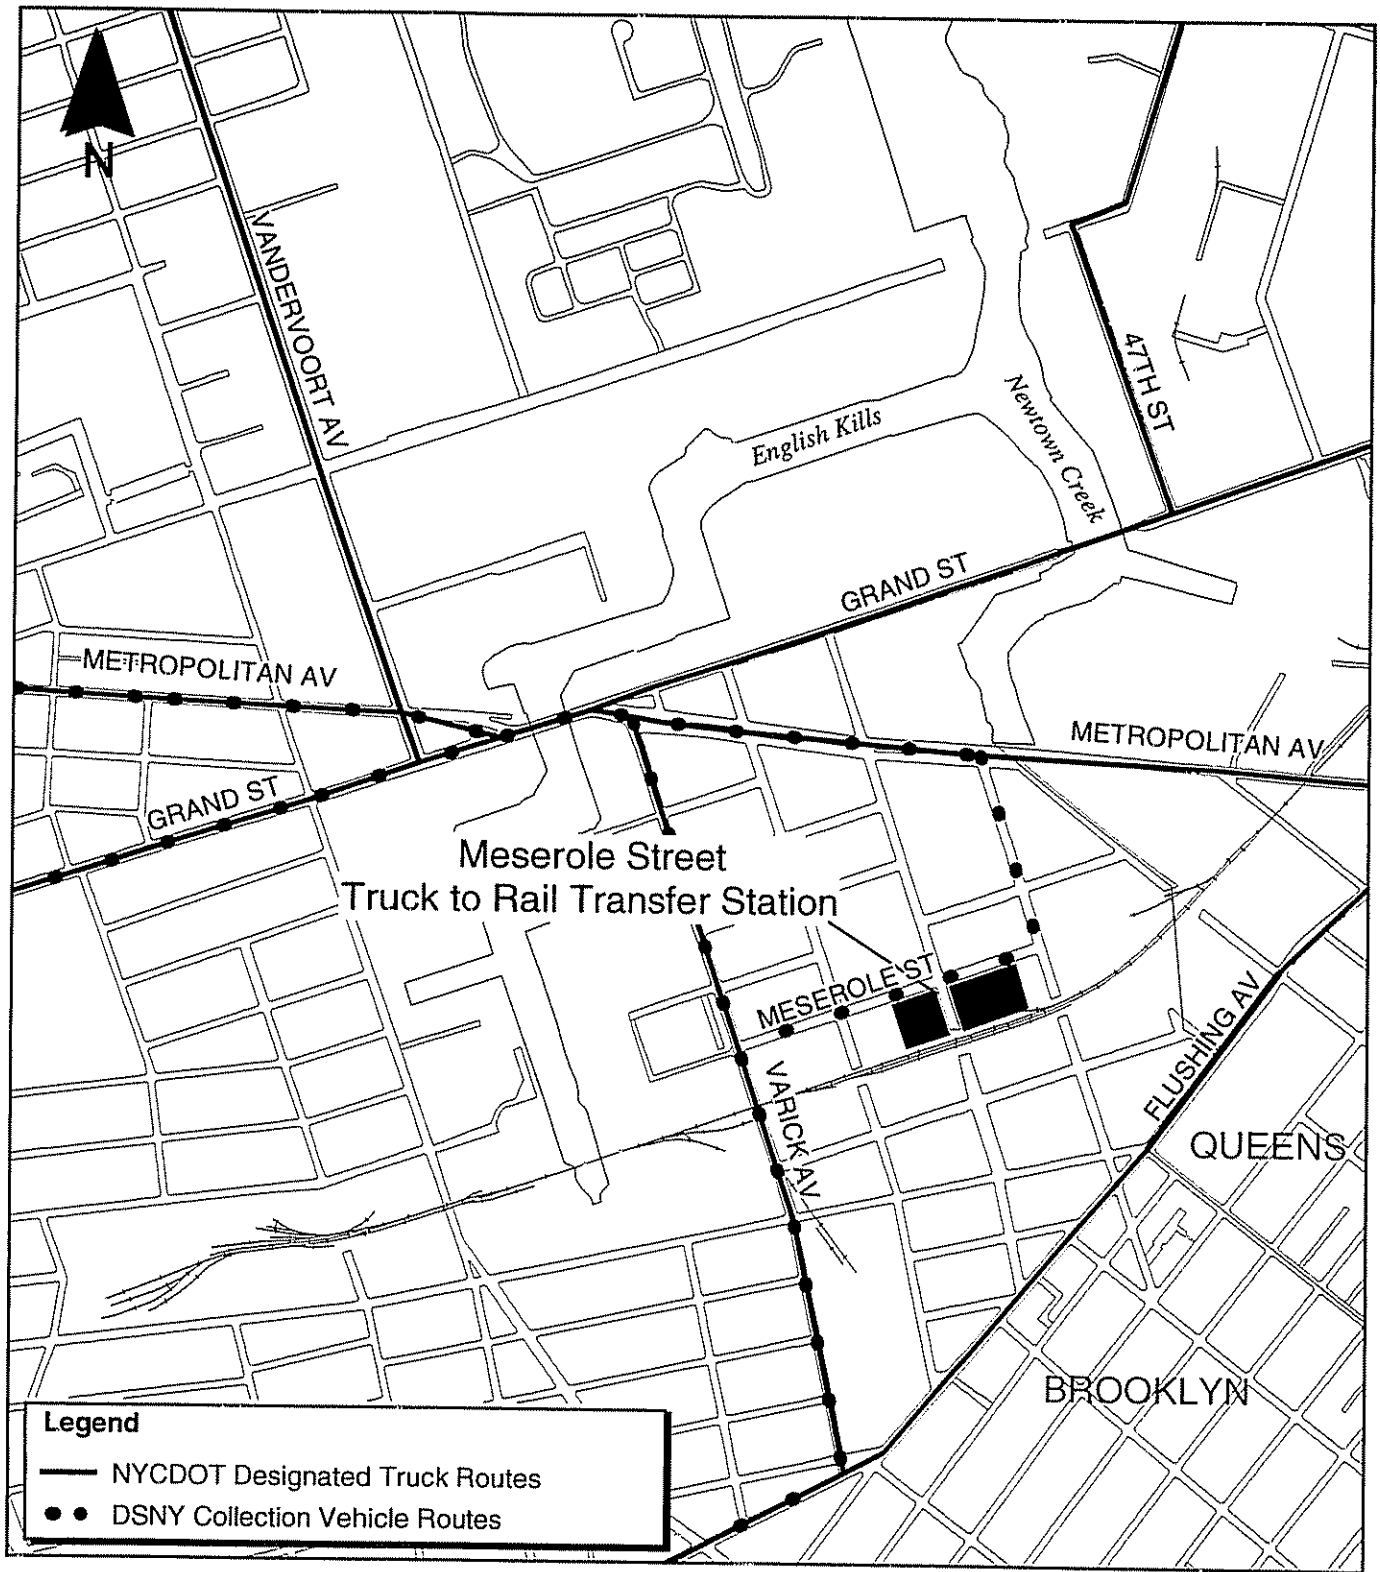
THE CITY OF NEW YORK DEPARTMENT OF SANITATION



31.14.1.2 Surface Network

One major highway, the predominantly north-south BQE, services the traffic analysis study area. Flushing Avenue, Grand Street and Metropolitan Avenue are local truck routes that provide access from east and west of the site. Varick Avenue is a local truck route that provides access from north and south of the site. A map showing all major truck routes and local truck routes in Brooklyn is provided in Section 3.16 (Figures 3.16-3 and 3.16-5).

Flushing Avenue, Grand Street and Metropolitan Avenue are principal arterials that provide access to the BQE to the west of the facility. Varick Avenue is a collector road for local traffic and provides access for local and industrial traffic between Metropolitan Avenue and Flushing Avenue.

DSNY and other agency collection vehicles approaching the Meserole Street Truck to Rail TS from the south on the BQE would exit at Grand Street and travel east towards the facility. Other vehicles approaching the facility from the south would follow a designated truck route to Flushing Avenue and proceed east to Varick Avenue. DSNY and other agency collection vehicles traveling to the facility from the north would approach the area using local truck routes to Metropolitan Avenue and then proceed east towards the facility. Vehicles traveling east on Metropolitan Avenue and Grand Street merge onto the same street when crossing English Kills and then turn south onto Varick Avenue.. All inbound DSNY and other agency collection vehicles converge at the intersection of Varick Avenue and Meserole Street and turn east onto Meserole Street. Collection vehicles gain access to the facility from Meserole Street between Stewart Avenue and Gardener Avenue.

Exiting vehicles all turn east onto Meserole Street between Gardener Avenue and Scott Avenue, then north onto Scott Avenue. DSNY and other agency vehicles then would turn west onto Metropolitan Avenue and return to their CD of origin. Trucks returning to the south of the facility would turn onto Grand Street from Metropolitan Avenue and proceed to the BQE or a local designated truck route running north-south in the area. Trucks returning to areas north of the facility would follow Metropolitan Avenue to the west to a local designated truck route running north-south in the area. Figure 31.14-2 depicts NYCDOT-designated truck routes near the facility and the future DSNY and other agency collection vehicle routes to the facility.

Site delineations are approximate.

31.14.1.3 Existing Traffic Operations

The five intersections listed below were identified for analysis because they are the most likely to be impacted by the Meserole Street Truck to Rail TS. Diagrams of these intersections are included in technical backup submitted to NYCDOT.

- Meserole Street and Varick Avenue– Unsignalized Intersection (Figure 31.14-1 – location A)
- Meserole Street and Stewart Avenue – Unsignalized Intersection (Figure 31.14-1 – location B)
- Meserole Street and Scott Avenue – Unsignalized Intersection (Figure 31.14-1 – location C)
- Scott Avenue and Scholes Street – Unsignalized Intersection (Figure 31.14-1 – location D)
- Scott Avenue and Metropolitan Avenue – Unsignalized Intersection (Figure 31.14-1 – location E)

Metropolitan Avenue is a principal arterial that provides access to the BQE to the west of the facility. Varick Avenue is a collector road for local traffic and provides access for local and industrial traffic between Metropolitan Avenue and Flushing Avenue. Meserole Street, Stewart Avenue, Scott Avenue and Scholes Street are local streets that are not designated truck routes.

A traffic data collection program that consisted of manual turning movement counts with vehicle classifications and ATR counts was undertaken to define existing weekday traffic operations (see Section 3.16 for a discussion on traffic data collection). Manual turning movement counts were conducted on May 26, 2004, while ATR counts were conducted between May 24 and May 31, 2004. Figures 31.14-3, 31.14-4 and 31.14-5 depict the existing traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. The AM peak generally occurred between 7:30 a.m. and 8:30 a.m., the Facility peak between 10:00 a.m. and 11:00 a.m., and the PM peak between 4:45 p.m. and 5:45 p.m. Table 31.14-1 presents the v/c ratio, delay and LOS for the five intersections during the AM, Facility, and PM peaks.

NB = northbound
SB = southbound
EB = eastbound
WB = westbound
NA = Not Applicable

Existing truck traffic through most of the intersections was relatively high. The percentages of trucks during the morning hours and Facility peak hours ranged between 32% and 61% at the study intersections and decreased to between 15% and 20% during the PM peak hours.

31.14.1.3.1 LOS at Signalized Intersections

No signalized intersections were analyzed.

31.14.1.3.2 LOS at Unsignalized Intersections

Table 31.14-1 shows that the unsignalized intersections generally operated at an LOS of C or better with the following exception. The only lane group with LOS below C was the northbound left-right lane at the intersection of Scott Avenue and Metropolitan Avenue. During the PM peak hour, this approach operated at LOS D with a delay of 29.1 seconds. During the AM and Facility peak hours, this lane group operated at LOS C or better.

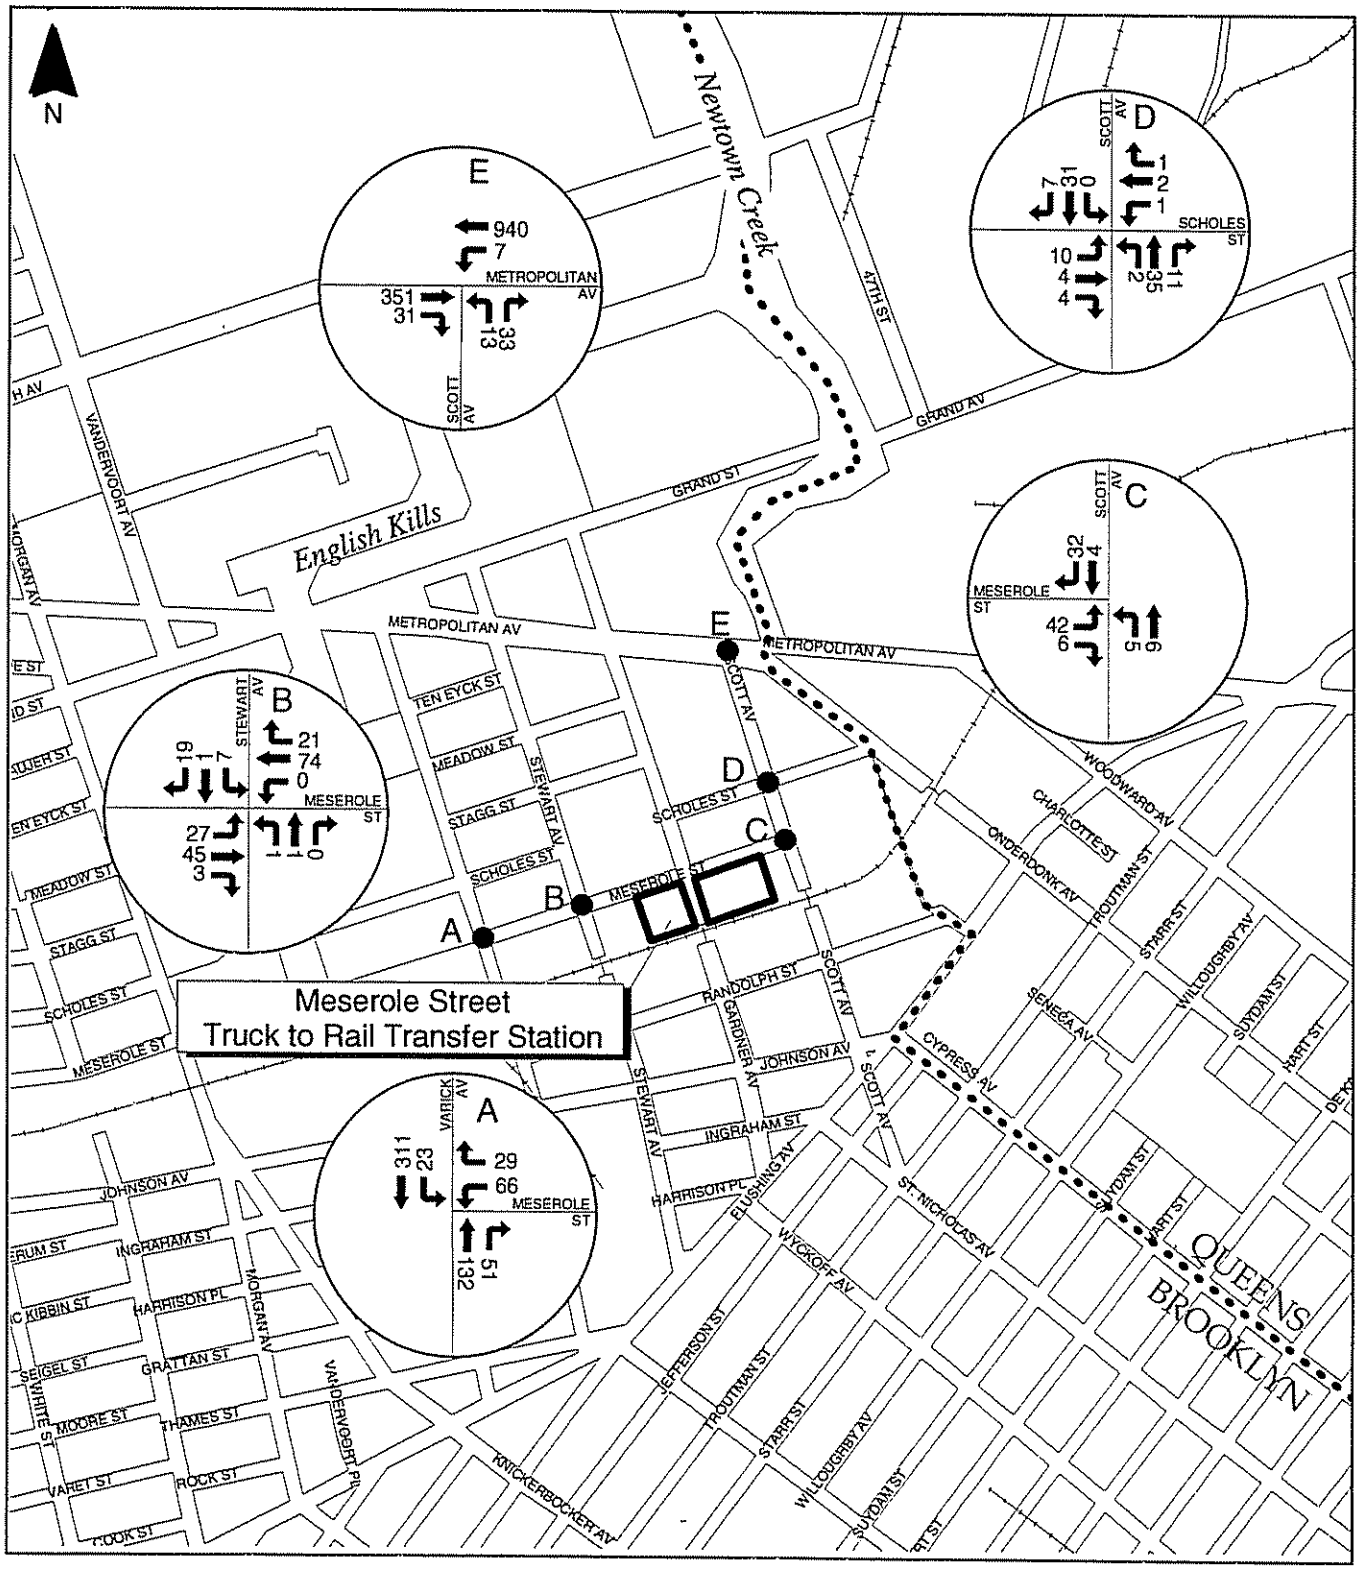
31.14.1.4 Existing DSNY-Related Traffic

The Meserole Street Truck to Rail TS is a facility that will be built in the future if awarded a contract for the long-term export of DSNY-managed Waste. As the facility does not yet exist, no DSNY-related traffic currently travels to or from this facility. Other private transfer stations located in close proximity to the proposed location of the Meserole Street Truck to Rail TS currently accept DSNY-managed Waste. These transfer stations are located at 485 Scott Avenue and 598 Scholes Street, to the east of the proposed facility.

31.14.1.5 Public Transportation

Subway and bus service are provided within the vicinity of the site. The "Jefferson Street" stop on the MTA's "L" subway line is located approximately three-tenths (3/10) of a mile southwest of the site at the Jefferson Street/Wycoff Avenue intersection. The MTA operates several Brooklyn and Queens bus lines that pass through the study area, but the closest bus stop to the facility is located over one mile away, next to the Linden Hill Cemetery by the intersection of Starr Street and Metropolitan Avenue in Queens.

31.14.1.6 Pedestrian Activity



Pedestrian activity is generally low within the study area. Striped crosswalks and pedestrian signals are provided at signalized intersections in the study area. During several field visits, pedestrian activity was minimal and it is not expected to affect the capacity analysis significantly.

31.14.2 Future No-Build Conditions

31.14.2.1 Traffic Conditions

Future No-Build traffic volumes were determined by applying a growth rate of 1% per year to existing traffic volumes in accordance with the 2001 CEQR Technical Manual. Additional traffic generated in the Future No-Build year (2006) generally amounted to less than 25 vehicles per intersection. There are no new developments planned in the study area that would affect Future No-Build traffic volumes in the study area.

Figures 31.14-6, 31.14-7 and 31.14-8 depict the Future No-Build traffic volumes for AM, Facility, and PM peaks at the intersections analyzed. Table 31.14-2 (Future No-Build Conditions) shows the Future No-Build v/c ratio, delay and LOS for the studied intersections. Overall, intersections experienced relatively small increases in delay (less than 5 seconds) and are projected to remain at their Existing Condition LOS.

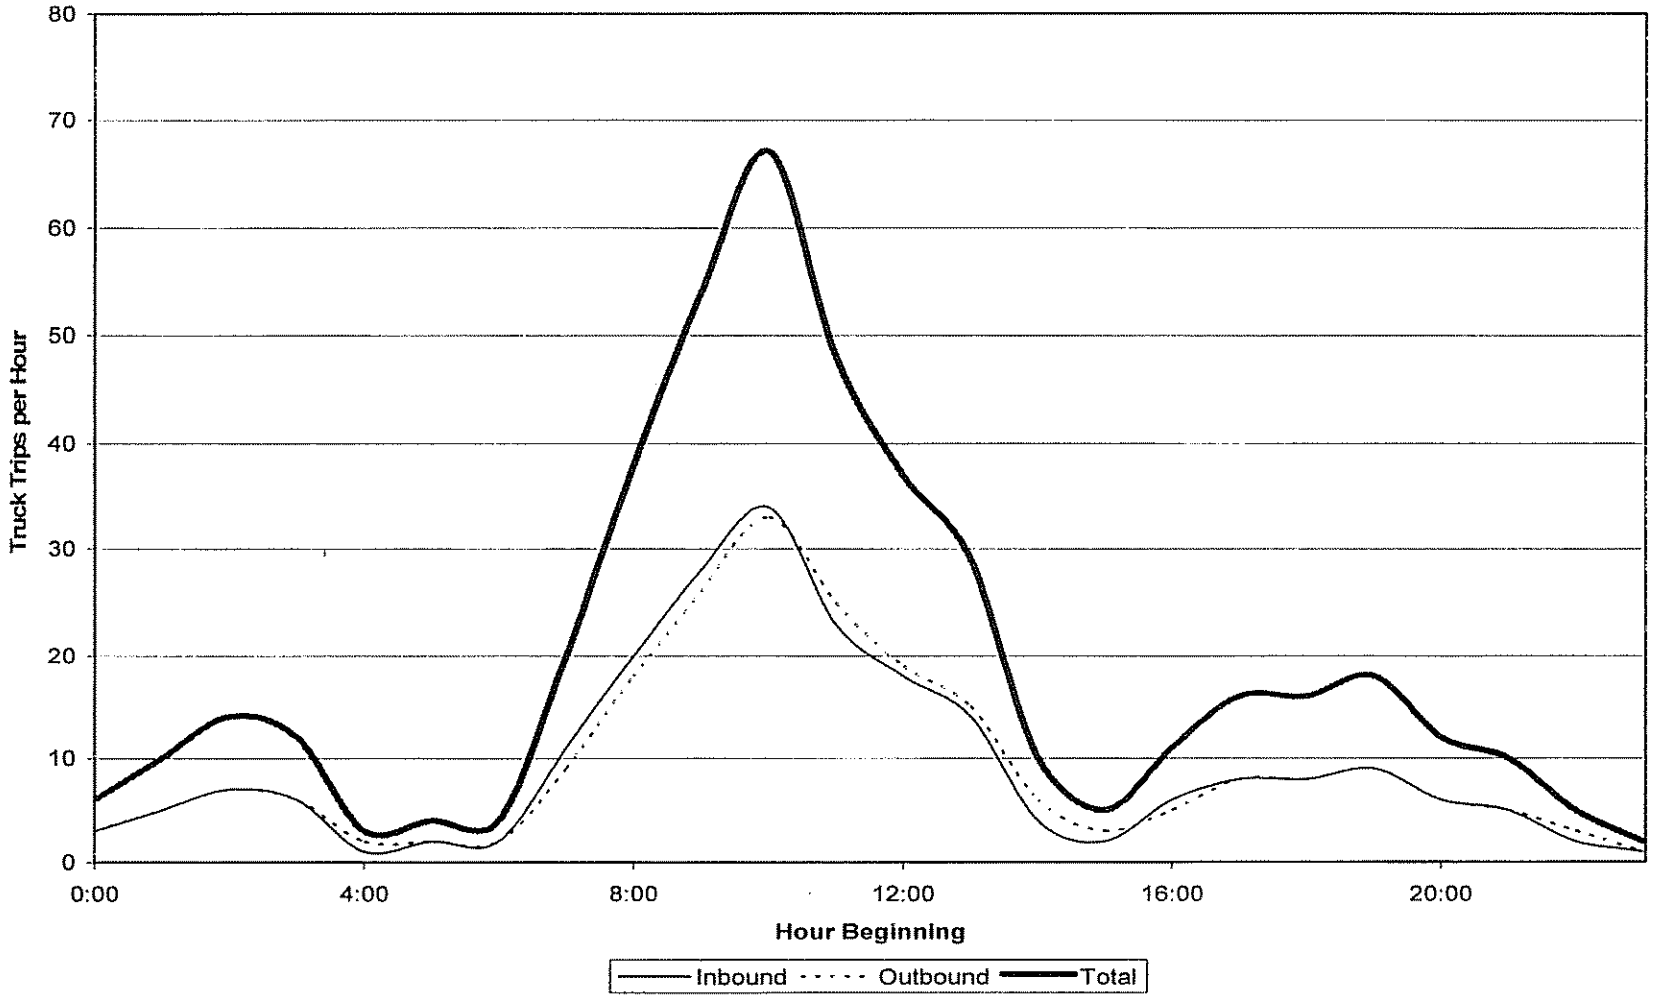
31.14.2.2 Public Transportation

Future No-Build Conditions are expected to remain the same as Existing Conditions.

31.14.2.3 Pedestrian Activity

Future No-Build Conditions are expected to remain the same as Existing Conditions.

31.14.3 Potential Impacts with the TransRiver Marketing Company, L.P. Truck to Rail TS



The Meserole Street Truck to Rail TS would receive waste from Brooklyn CDs 1, 3, 4 and 5 and the AFF. Potential traffic impacts may result from the increase in DSNY and other agency collection vehicle trips to and from the site during all peak hours. Additionally, employee trips to and from the site may result in traffic impacts during the AM peak hour.

31.14.3.1 2006 Future Build Traffic Conditions

2006 Future Build Conditions assume that the Meserole Street Truck to Rail TS would generate 225 net inbound collection vehicles per average peak day. As per NYCDOT Title 34, truck trips to and from the site are restricted to travel along local truck routes directly to the site or the intersection closest to the site if the streets adjacent to the site are not designated truck routes. The proposed collection vehicle truck routes for the Meserole Street Truck to Rail TS are shown in Figure 31.14-2.

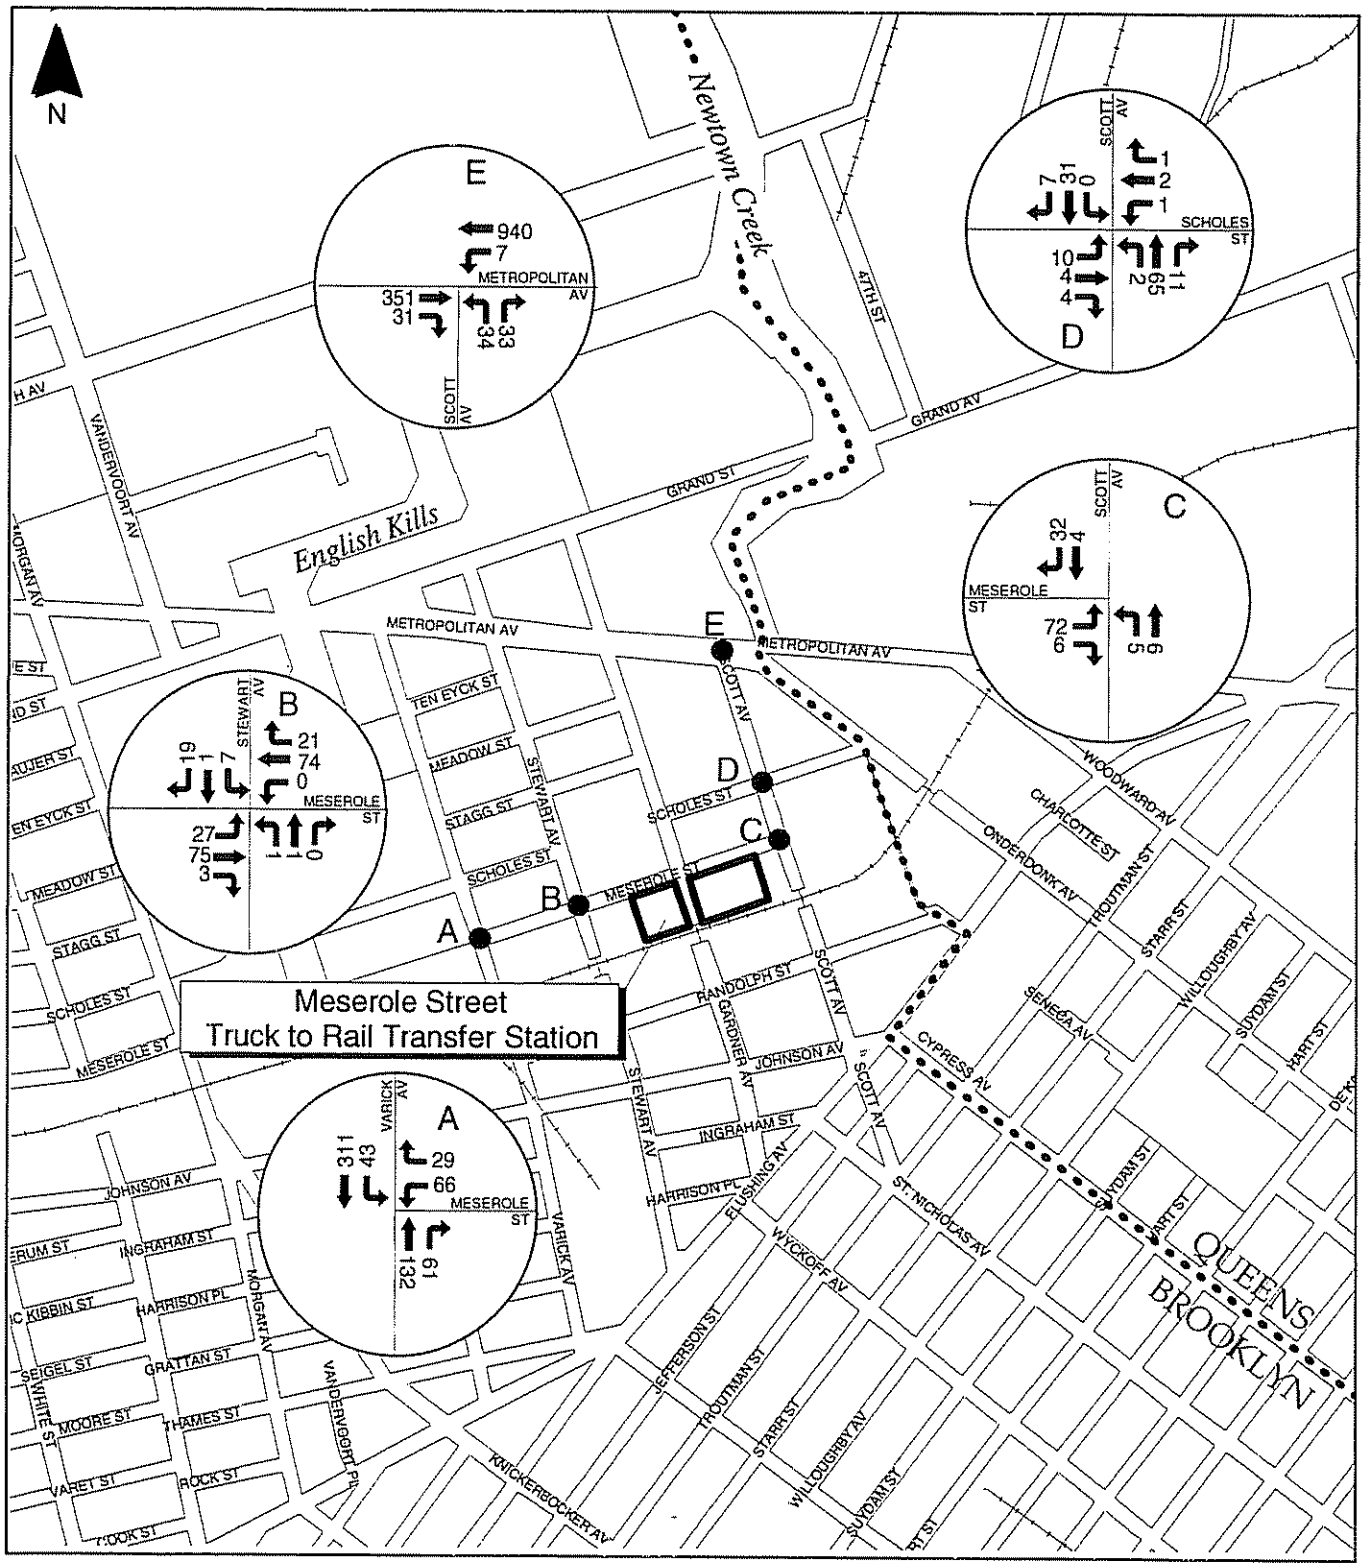


Figure 31.14-9 presents the average peak day temporal distribution of collection vehicles for the Meserole Street Truck to Rail TS. Section 3.16 provides a detailed explanation of DSNY collection and delivery operational shifts (priority, non-priority and relay). As shown, the number of collection vehicles generated by the Meserole Street Truck to Rail TS is expected to vary between approximately 2 to 14 truck trips per hour in the late evening/early morning, 20 to 67 truck trips per hour in the mid-morning/early afternoon, and 5 to 18 truck trips per hour in the late afternoon/early evening. The peak hourly number of collection vehicle truck trips (67) occurs at approximately 10:00 a.m.

Figure 31.14-9
Truck Trips per Hour
Meserole Street Truck to Rail TS

Employee trips generated as a result of the Meserole Street Truck to Rail TS are expected to be about 36 per shift (18 arriving and 18 departing). Employee shifts are projected to run from 8:00 a.m. to 4:00 p.m., 4:00 p.m. to 12:00 a.m., and 12:00 a.m. to 8:00 a.m. Therefore, during shift changes, employees would arrive within approximately 30 minutes before the start of a shift and leave within approximately 30 minutes after the end of a shift. With these projections, employee trips are expected between 7:30 a.m. and 8:30 a.m., 3:30 p.m. and 4:30 p.m., and 11:30 p.m. and 12:30 a.m.

Because only the AM peak (7:30 a.m. to 8:30 a.m.) coincided with a projected employee shift change (7:30 a.m. to 8:30 a.m.), employee trips both to and from the Meserole Street Truck to Rail TS during the shift change (36) were considered as part of the net increase in site-generated traffic. Figures 31.14-10, 31.14-11 and 31.14-12 show the intersections analyzed with the net increase in site-generated traffic added to the Future No-Build traffic levels. Figures 31.14-13, 31.14-14 and 31.14-15 show the intersections analyzed with only the net increase in site-generated traffic. Traffic volumes indicated by a dash (-) are the result of changing the disposal location from the existing commercial vendor facilities to the Meserole Street Truck to Rail TS. These projected net increases were routed through the intersections for each of the three peak hours. The highest net increase in trucks in the ingress or egress direction was 34. The highest net increase at any one intersection was 34 trucks. Both of these net increases occurred at the intersection of Varick Avenue and Meserole Street and at the intersection of Stewart Avenue and Meserole Street.

The need for Saturday analysis was considered. However, a traffic analysis was not performed on the projected net increases on Saturday truck trips because the total net increase in collection vehicles delivering waste on Saturdays would be approximately 75% of the inbound loads delivered during a typical average peak day. Additionally, traffic data indicated that the weekend background traffic volumes were approximately 82% of weekday traffic volumes. Table 31.14-3 illustrates the decrease in weekday background traffic and the decrease in DSNY and other agency collection vehicle traffic on the weekend. No analysis was performed for Sunday because the Meserole Street Truck to Rail TS would not operate on Sundays to receive DSNY-managed Waste. It was, therefore, judged that peak weekday analysis would represent the overall worst-case conditions.

Table 31.14-3

Average Peak Day Trucks/Day	Saturday Trucks/ Day	Weekday average vehicles/Day	Weekend average vehicles/Day
225	169	10,691	8,715

Note:
[1] EB and WB traffic data collected from ATR counts taken on Metropolitan Avenue between Gardener Avenue and Stewart Avenue from June 13 to 20, 2003.

Table 31.14-4 shows the 2006 Future Build v/c ratio, delay time and LOS for the intersections analyzed during the AM, Facility, and PM peak times associated with the Meserole Street Truck to Rail TS. Over an average peak day, the intersections should not experience an extended increase in delay. The one intersection that may experience potentially significant impacts is discussed in Section 31.14.3.2 and summarized in Table 31.14-5.

31.14.3.2 Impacts and Mitigation

One of the five intersections may experience impacts great enough to be considered significant during one of the peak times analyzed; however, 2001 CEQR Technical Manual guidelines require mitigation for significant impacts regardless of the duration, as discussed in Section 3.16. The potential impacts identified and the mitigation measures analyzed are presented below; their effectiveness is summarized in Table 31.14-5.

Metropolitan Avenue/Scott Avenue – During the PM peak hour, a potential impact was identified on the northbound approach when the delay increased from 30.5 seconds to 46.0 seconds. The mitigation measure would be to change the intersection from an unsignalized intersection to a signalized intersection to create ample gaps in through traffic on Metropolitan Avenue to allow northbound vehicles to make a left-turn movement. Under this mitigation measure, all lane groups would have a minimum LOS of B during the PM peak hour. Signalizing the intersection would provide LOS C or better for all lane groups during the AM and Facility peak hours, as well. An alternative mitigation measure to signalizing this intersection would be to send the DSNY-managed collection vehicles exiting the facility on an alternate route to Metropolitan Avenue from the facility. This option would require analysis of additional intersections in the study area which would be addressed in a supplemental EIS, if this facility is selected to receive DSNY-managed Waste as part of the Long Term Export Program.

31.14.3.3 Public Transportation

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

31.14.3.4 Pedestrian Activity

Future Build Conditions are expected to remain the same as Future No-Build Conditions.

31.14.4 Potential Impacts with IESI NY Corporation TS

Impacts for this Alternative are assumed to be the same as described in Section 31.14.3.

31.15 Air Quality

31.15.1 Definition of Study Areas

The study area for the on-site air quality analysis for criteria pollutants (except $PM_{2.5}$) is defined as the area within 500 meters (0.3 miles) of the property line in all directions. The study area for the on-site analysis for $PM_{2.5}$ is defined as the area within 500 meters from the highest impact location of the Meserole Street Transfer Station. The study area for the off-site air quality analysis is defined as the area or intersection listed in Section 31.15.4.2.

31.15.2 Existing Conditions

Applicable air quality data collected at the monitoring station(s) nearest to the study area are shown in Table 31.15-1. These data were compiled by NYSDEC for the latest calendar year for which applicable data are currently available. The monitored levels do not exceed national and state ambient air quality standards.

Table 31.15-1
Representative Ambient Air Quality Data
TransRiver Marketing Company, L.P. TS

Pollutant	Monitor	Averaging Time	Value	NAAQS
CO	Brooklyn	8-Hour	2,634 $\mu g/m^3$	10,000 $\mu g/m^3$
		1-Hour	3,321 $\mu g/m^3$	40,000 $\mu g/m^3$

		24-Hour	57 $\mu g/m^3$	150 $\mu g/m^3$
SO_2	Greenpoint	3-Hour	189 $\mu g/m^3$	1,300 $\mu g/m^3$
		24-Hour	87 $\mu g/m^3$	365 $\mu g/m^3$
		Annual	21 $\mu g/m^3$	80 $\mu g/m^3$

Note:
Source: NYCDEP, April 2003

31.15.3 Future No-Build Conditions

The primarily commercial/industrial nature of the study area is not expected to change by the Future No-Build 2006 analysis year. As such, no changes to air quality levels are anticipated, and Future No-Build Conditions are assumed to be the same as Existing Conditions for all pollutants except CO. CO concentrations are expected to be lowered by increasingly stringent, federally-mandated vehicular emission controls, although any effects may be offset by increases in regional traffic volumes.

31.15.4 Potential Impacts with the TransRiver Marketing Company, L.P. TS

31.15.4.1 On-Site Analysis

31.15.4.1.1 Sources Considered in the Analysis

The sources of emissions and the number of each type of source that are anticipated to be in operation during the peak hour and under daily average conditions are provided in Table 31.15-2. Figure 31.15-1 shows the locations of these sources within the site.

31.15.4.1.2 Results of the Criteria Pollutant Analysis

The highest estimated criteria pollutant concentrations at any one of the receptor sites considered are provided in Table 31.15-3. These values are compared with the applicable standards for the appropriate averaging time periods. Based on the results presented in Table 31.15-3, operations proposed at this facility would not adversely impact air quality in the area. The total predicted concentrations (including appropriate background concentrations) are below the national and state ambient air quality standards.

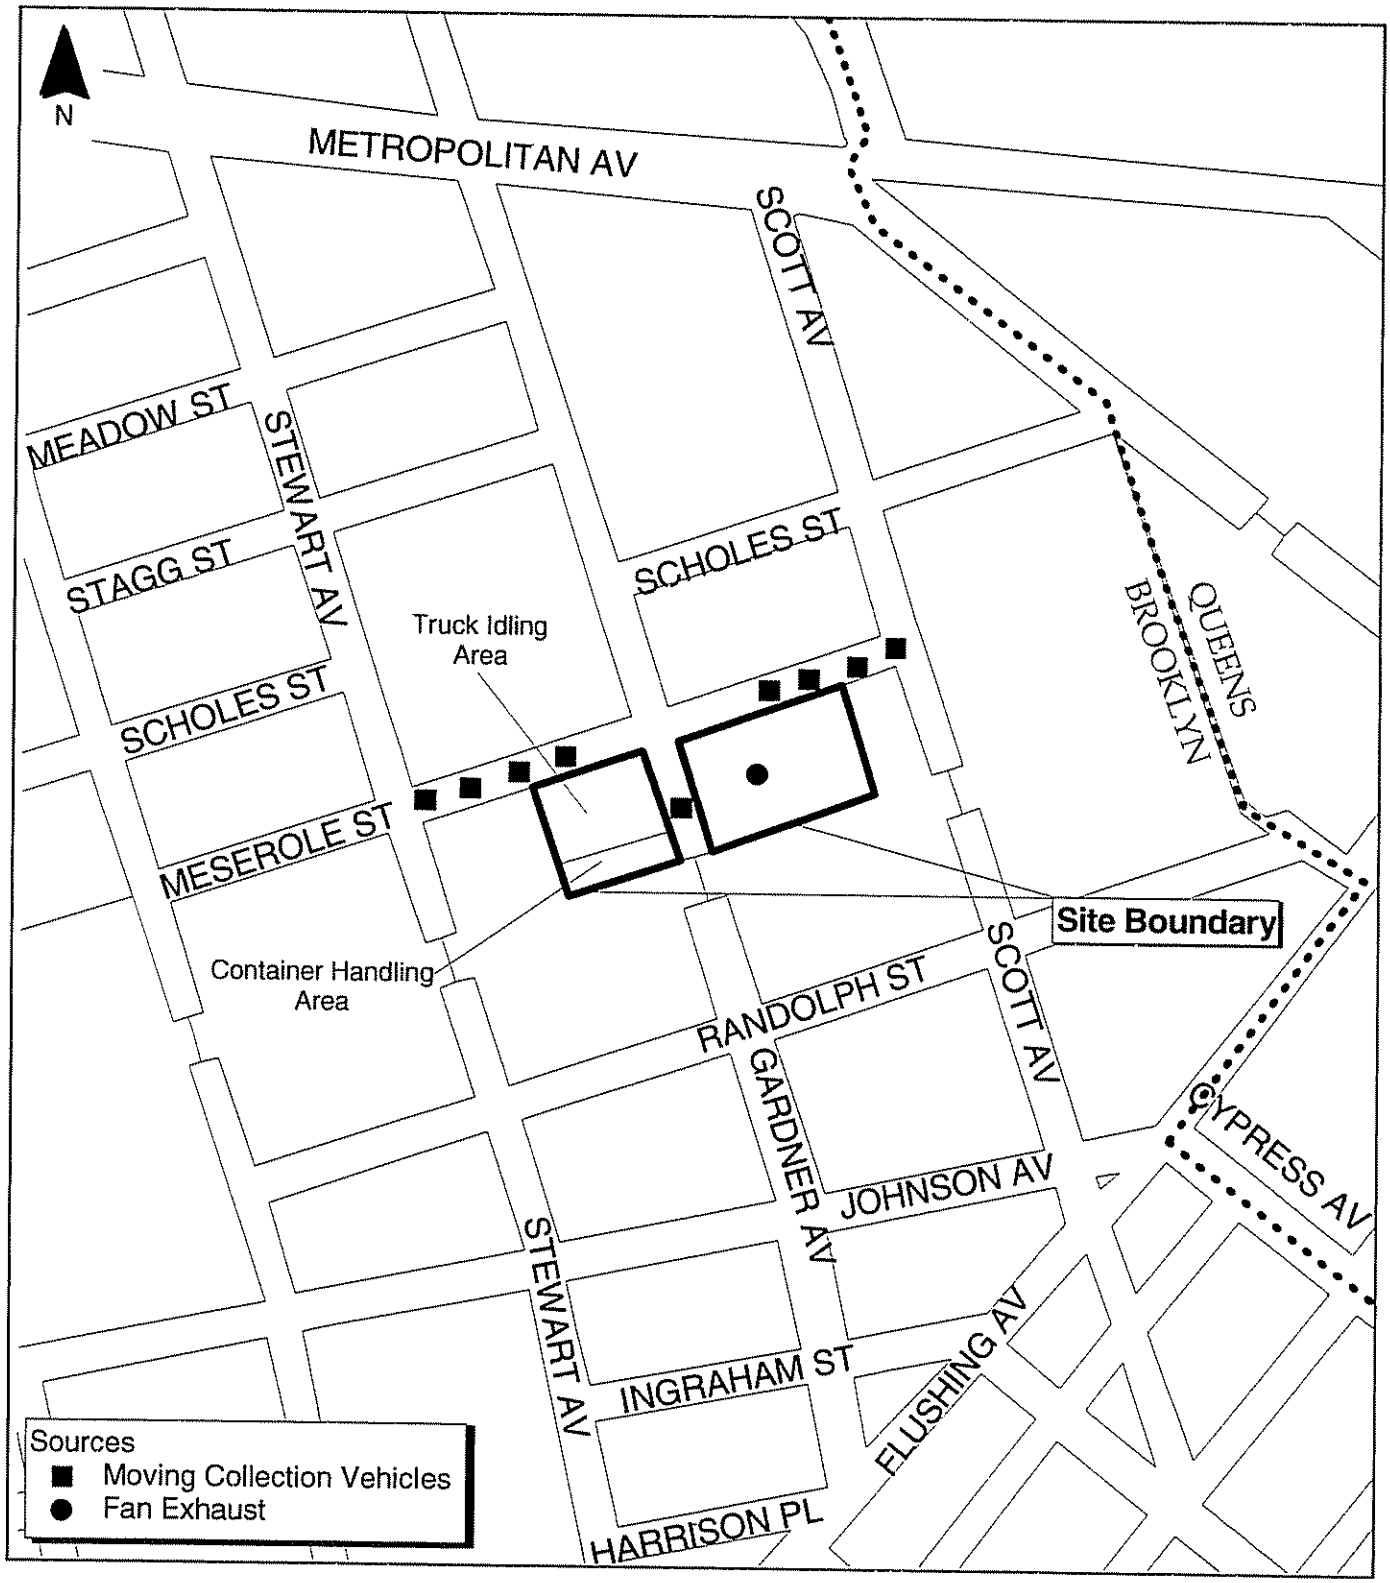

Table 31.15-2
Emission Sources Considered for On-Site Air Quality Analysis[1]
TransRiver Marketing Company, L.P. TS

Type of Emission Source	Maximum Number of Sources Operated During a Single Hour[2]	Number of Sources Operated During Annual Average Hour
Within Processing Building		
Moving/Queuing Collection Vehicles	56	8
Wheel Loaders	2	1
Excavator	2	1
Reachstacker	2	1
Forklift	2	1

	Annual	~~3~~0.9	~~2~~18	~~24~~19	80	NA

Notes:
(1) The highest estimated pollutant concentrations found at any of the off-site receptor locations.
(2) Background concentrations were obtained from the NYCDEP ~~in April 2003~~memorandum dated February 18, 2005..
(3) NAAQS = National Ambient Air Quality Standard.
(4) Screening threshold value (STV) established by the NYCDEP and NYSDEC.
(5) Average $PM_{2.5}$ concentration over 1 km x 1 km "neighborhood-scale" receptor grid.
(6) The standards for these averaging periods allow one exceedance per year, so the use of the overall maximum concentration provides a very conservative comparison with standards.
(7) The 24-hour PM_{10} NAAQS is based on a 99th percentile concentration, which means that the high, 4th high concentration is appropriate for comparison with the standard. Therefore, the use of the overall highest concentration in this comparison is ~~quite~~ very conservative.
NA = Not Applicable

31.15.4.1.3 Results of the Toxic Pollutant Analysis

The results of the toxic pollutant analysis are summarized in Table 31.15-4.[7] The highest estimated non-carcinogenic toxic air pollutant impacts are below the short-term (acute) and long-term (chronic) hazard index thresholds specified in New York State's Air Guide 1. In addition, the highest estimated carcinogenic impacts are less than the one-in-a-million threshold level that is defined by USEPA as being significant. As such, the potential impacts of the toxic pollutant emissions from the on-site operations of the Meserole Street Truck to Rail TS are not considered to be significant.

31.15.4.2 Off-Site Analysis

31.15.4.2.1 Pollutants Considered and Analyses Conducted

Locations potentially affected by DSNY collection and other City agency's collection vehicles were identified using 2001 CEQR Technical Manual guidelines outlined in Section 3.17. Following these guidelines, mobile source analyses were conducted at the following locations for the applicable (i.e., worst-case) time periods:

- The multiple intersections around Meserole Street and Varick Street and Scott Avenue at Scholes Street to determine whether transfer station-generated traffic has the potential to cause exceedances of NYCDEP's 8-hour CO "de minimus" value or a violation of the 8-hour NAAQS;
- The multiple intersections around Meserole Street and Varick Street and Scott Avenue at Scholes Street to determine whether transfer station-generated traffic has the potential to cause exceedances of NYCDEP's and NYSDEC's 24-hour and annual $PM_{2.5}$ STVs; and
- The multiple intersections around Meserole Street and Varick Street and Scott Avenue at Scholes Street to determine whether transfer station-generated traffic has the potential to cause exceedances of the 24-hour and annual PM_{10} NAAQS.

The roadway intersections selected for the mobile source analysis are shown in Figure 31.15-2.

---

[7] These concentrations have been estimated according to the methodology discussed in Section 3.11.2.2.

Notes to Table 31.15-4:

(1) Estimated by multiplying the total 1-hour HCs concentration by the ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(2) Short-term (1-hour) guideline concentrations (SGC) established by NYSDEC.

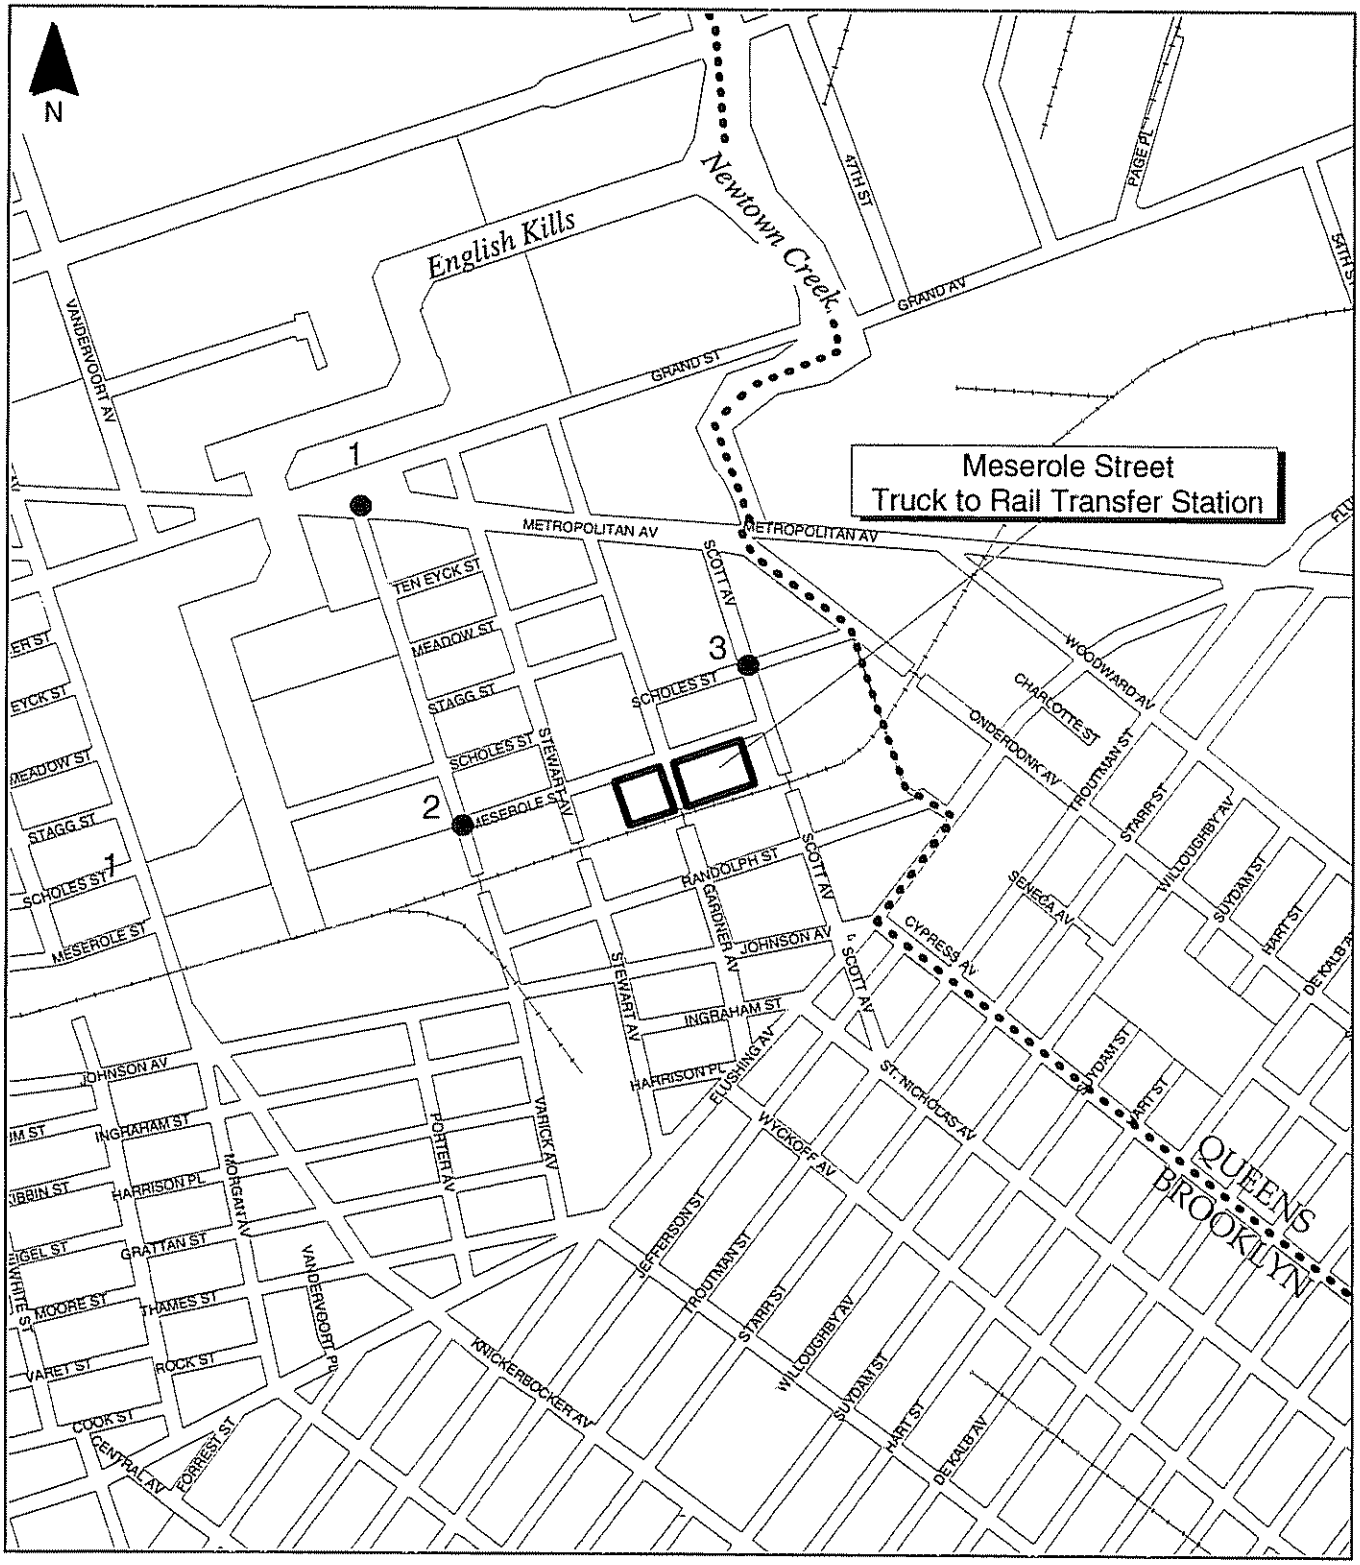
(3) Estimated by dividing the maximum 1-hour concentrations of each pollutant by the SGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(4) Estimated by multiplying the total annual HCs concentration by ratio of the emission factor for that pollutant to the emission factor of the total HCs.

(5) Long-term (annual) guideline concentrations (AGC) established by NYSDEC.

(6) Estimated by dividing the maximum annual concentration of each of the individual pollutants by the AGC value of that pollutant and summing up the resulting values to obtain hazard index for all of the pollutants combined.

(7) Unit risk factors established by USEPA and other governmental agencies for the inhalation of carcinogenic air pollutants.



(8) The maximum cancer risk of each of the individual pollutants was estimated by multiplying the estimated annual concentration of each pollutant by its unit risk factor.

(9) The total incremental cancer risk from all of the pollutants combined was estimated by summing the maximum cancer risk of each of the individual pollutants.

(10) Some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens.

(11) Hazard index and cancer risk thresholds based on NYSDEC "Guidelines for the Control of Toxic Ambient Air Contaminants" dated November 12, 1997. Estimated values below these threshold limits are considered to be insignificant impacts.

31.15.4.2.2 Results of the Off-Site Analysis

Applicable pollutant concentrations estimated near each selected intersection, which are shown in Table 31.15-5, are all within (less than) the applicable state and federal ambient air quality standards and STVs (for $PM_{2.5}$), with the exception of the ~~annual~~ 24-hour PM_{10} NAAQS for the existing conditions. However, it should be noted that the off-site air analyses were performed using a conservative Tier I approach which assumes peak hour conditions for every hour of the day. If a Tier II approach was performed for the annual PM_{10} analyses, the concentrations reported in Table 31.15-5 would decrease by as much as 40%. In addition, a precipitation factor adjustment could be applied to Equation 1 in Section 13.2.1.3 of AP-42 used to determine the PM_{10} emission factors. This factor assumes that annual average emissions are inversely proportional to the frequency of measurable (>0.01 inch) precipitation. Applying the precipitation factor to the off-site annual PM_{10} analyses would decrease the concentrations reported in Table 31.15-5 by as much as 8%, thereby bringing the results below NAAQS. Therefore, the off-site operations of the Meserole Street Truck to Rail TS are not considered to be significant.

31.15.5 Potential Impacts with IESI NY Corporation TS

Impacts with the IESI NY Corporation TS would be essentially the same as those predicted for the TransRiver Marketing Company, L.P. TS if facility designs are similar. A supplemental environmental air quality analysis will be conducted if this facility is part of the proposed Long Term Export Program.

Table 31.15-5

31.16 Odor

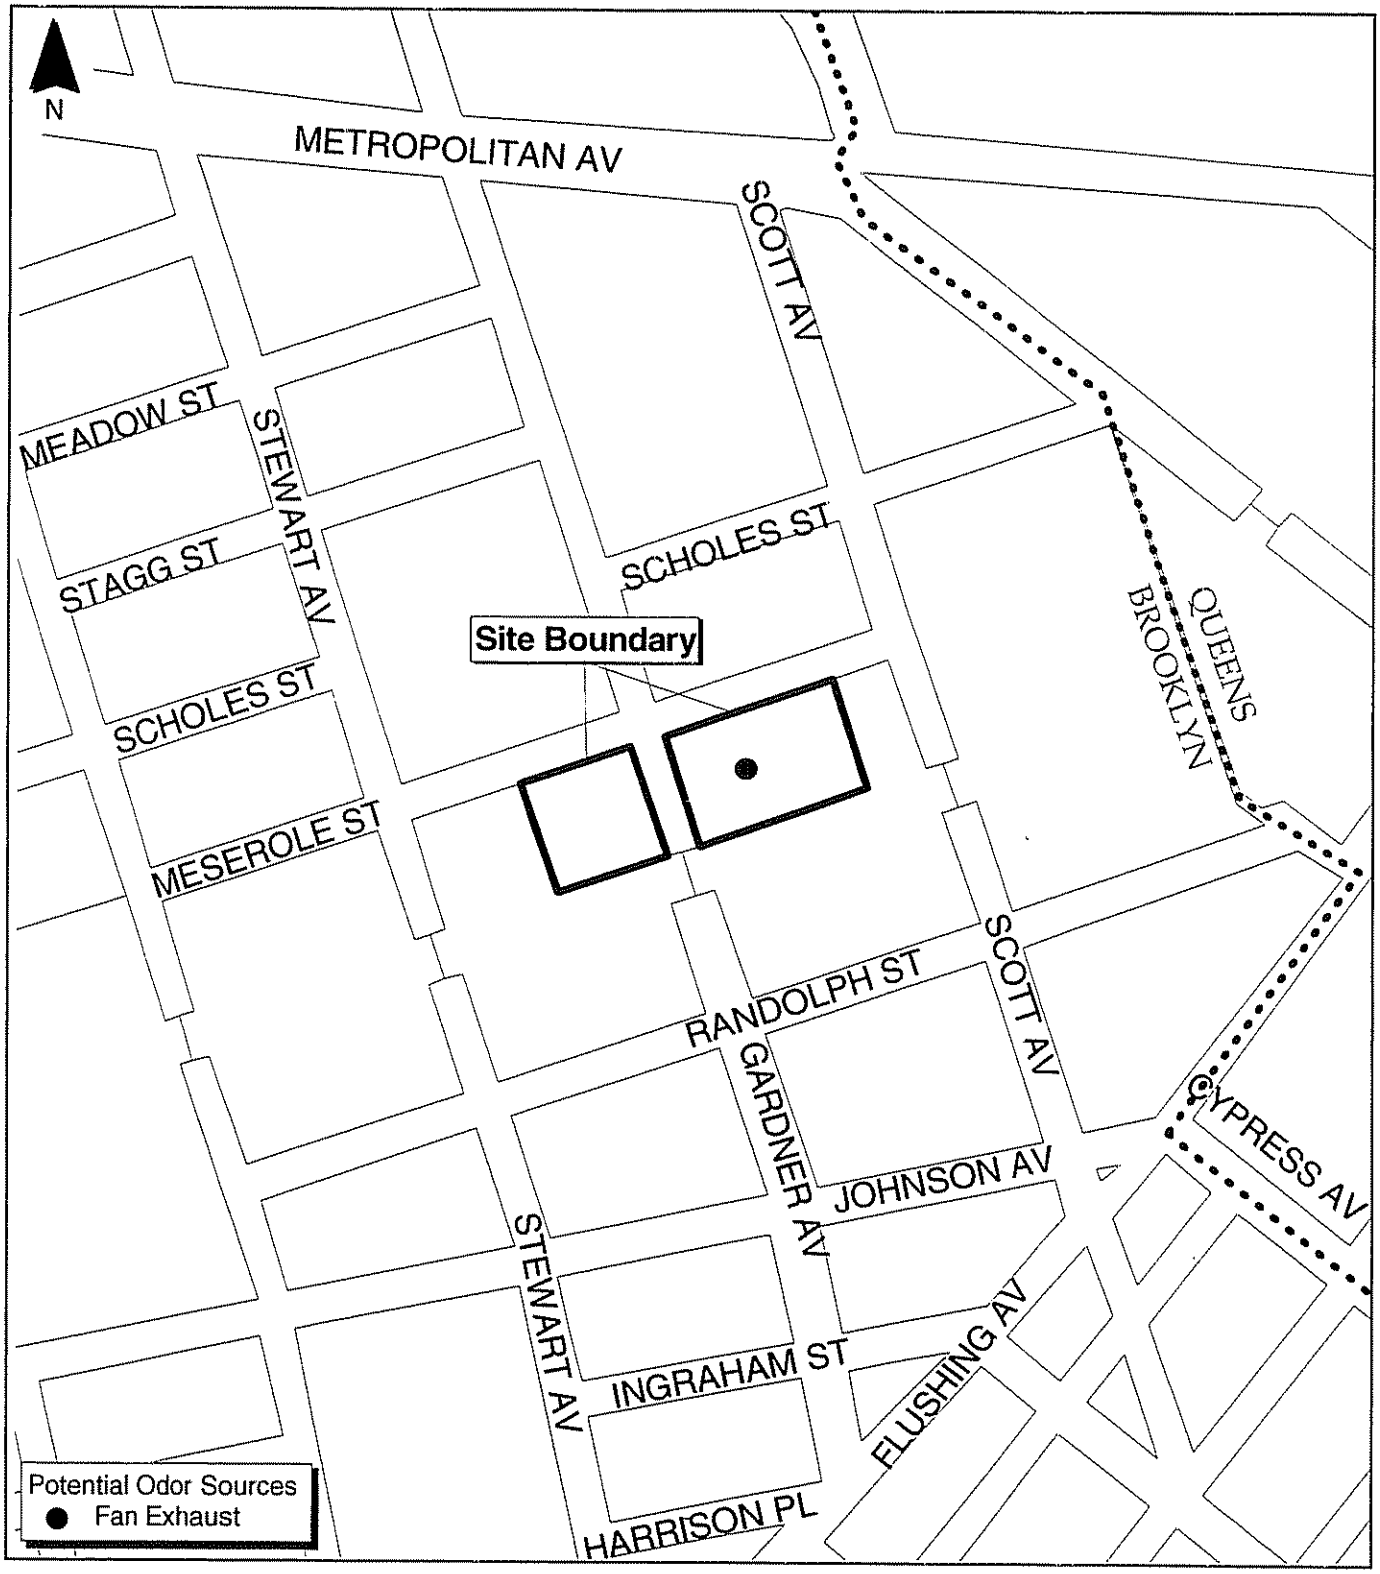
31.16.1 Existing Conditions

To evaluate all potential odors from the proposed Meserole Street Truck to Rail TS, the analysis assumes there are no existing sources of odor on site.

31.16.2 Future No-Build Conditions

Under Future No-Build Conditions, the TransRiver Marketing Company, L.P. TS would not exist. Therefore, odors would remain unchanged.

31.16.3 Potential Impacts with the TransRiver Marketing Company, L.P. TS



31.16.3.1 Odor Source Types and Locations Considered in the Analysis

The number and type of odor sources assumed to be on site with the Meserole Street Truck to Rail TS (while processing waste at proposed capacity for DSNY waste) are provided in Table 31.16-1. Figure 31.16-1 shows the locations of these sources within the project site.

Table 31.16-1
Odor Sources Included in Odor Analysis
Meserole Street Truck to Rail TS

Type of Emission Source	Number of Sources Operated During Peak Design Capacity
Exhaust Fans from Processing Building	1
Queuing Collection Vehicles	56

An odor control system (e.g., scrubber, neutralizing agent misting system injected into the exhaust duct work system, etc.) would be included in the design to control odorous emissions from the processing building. Odor control systems can remove between 90% and 99% of odorous compounds. For purposes of modeling odor dispersion, a 90% reduction of odorous emissions was conservatively assumed for the Meserole Street Truck to Rail TS.

Figure 31.16-1 Potential Odor Sources

Meserole Street Truck to Rail Transfer Station

CITY OF NEW YORK
DEPARTMENT OF SANITATION

31.16.3.2 Results of the Odor Analysis

The highest estimated odor concentrations at any of the receptor sites considered and the concentrations at the closest sensitive receptor are presented in Table 31.16-2. The predicted OU values at sensitive receptor locations are compared to an OU of 5, which represents the level of odor impact that would begin to be detected by an average observer. The highest predicted OU associated with the TransRiver Marketing Company, L.P. TS at any nearby sensitive receptor is less than 1, so odors from the TransRiver Marketing Company, L.P. TS would not be detectable by off-site sensitive receptors and the facility would comply with NYSDEC requirements for effective odor control. Therefore, no significant adverse impacts from odors on receptors are expected to occur as a result of this facility.

Table 31.16-2
Highest Predicted Odor Concentration(s) from On-Site Sources
TransRiver Marketing Company, L.P. TS

Parameter	Resulting Odor Unit[1]
Estimated Detectable Concentration	5.0
Highest Result	1.74
Type of Receptor	Fence Line Receptor
Location of Receptor[2]	Site Boundary
Closest Sensitive Receptor Result	0.22
Type of Receptor	Apartment Building
Distance to Receptor[~~3~~2]	1,188 Feet

Notes:
(1) D/T ratio is dimensionless.
(2) Measured from the site boundary.
~~(3) Measured from the site property line.~~

31.17 Noise

The noise analysis addresses on-site and off-site sources of noise emissions from the Meserole Street Truck to Rail TS-related solid waste management activities. It is based on Section R of the 2001 CEQR Technical Manual for on-site and off-site sources. Section 3.19 provides a general discussion of the relevant regulatory standards and methodologies applied in this analysis.

31.17.1 Existing Conditions

31.17.1.1 Introduction

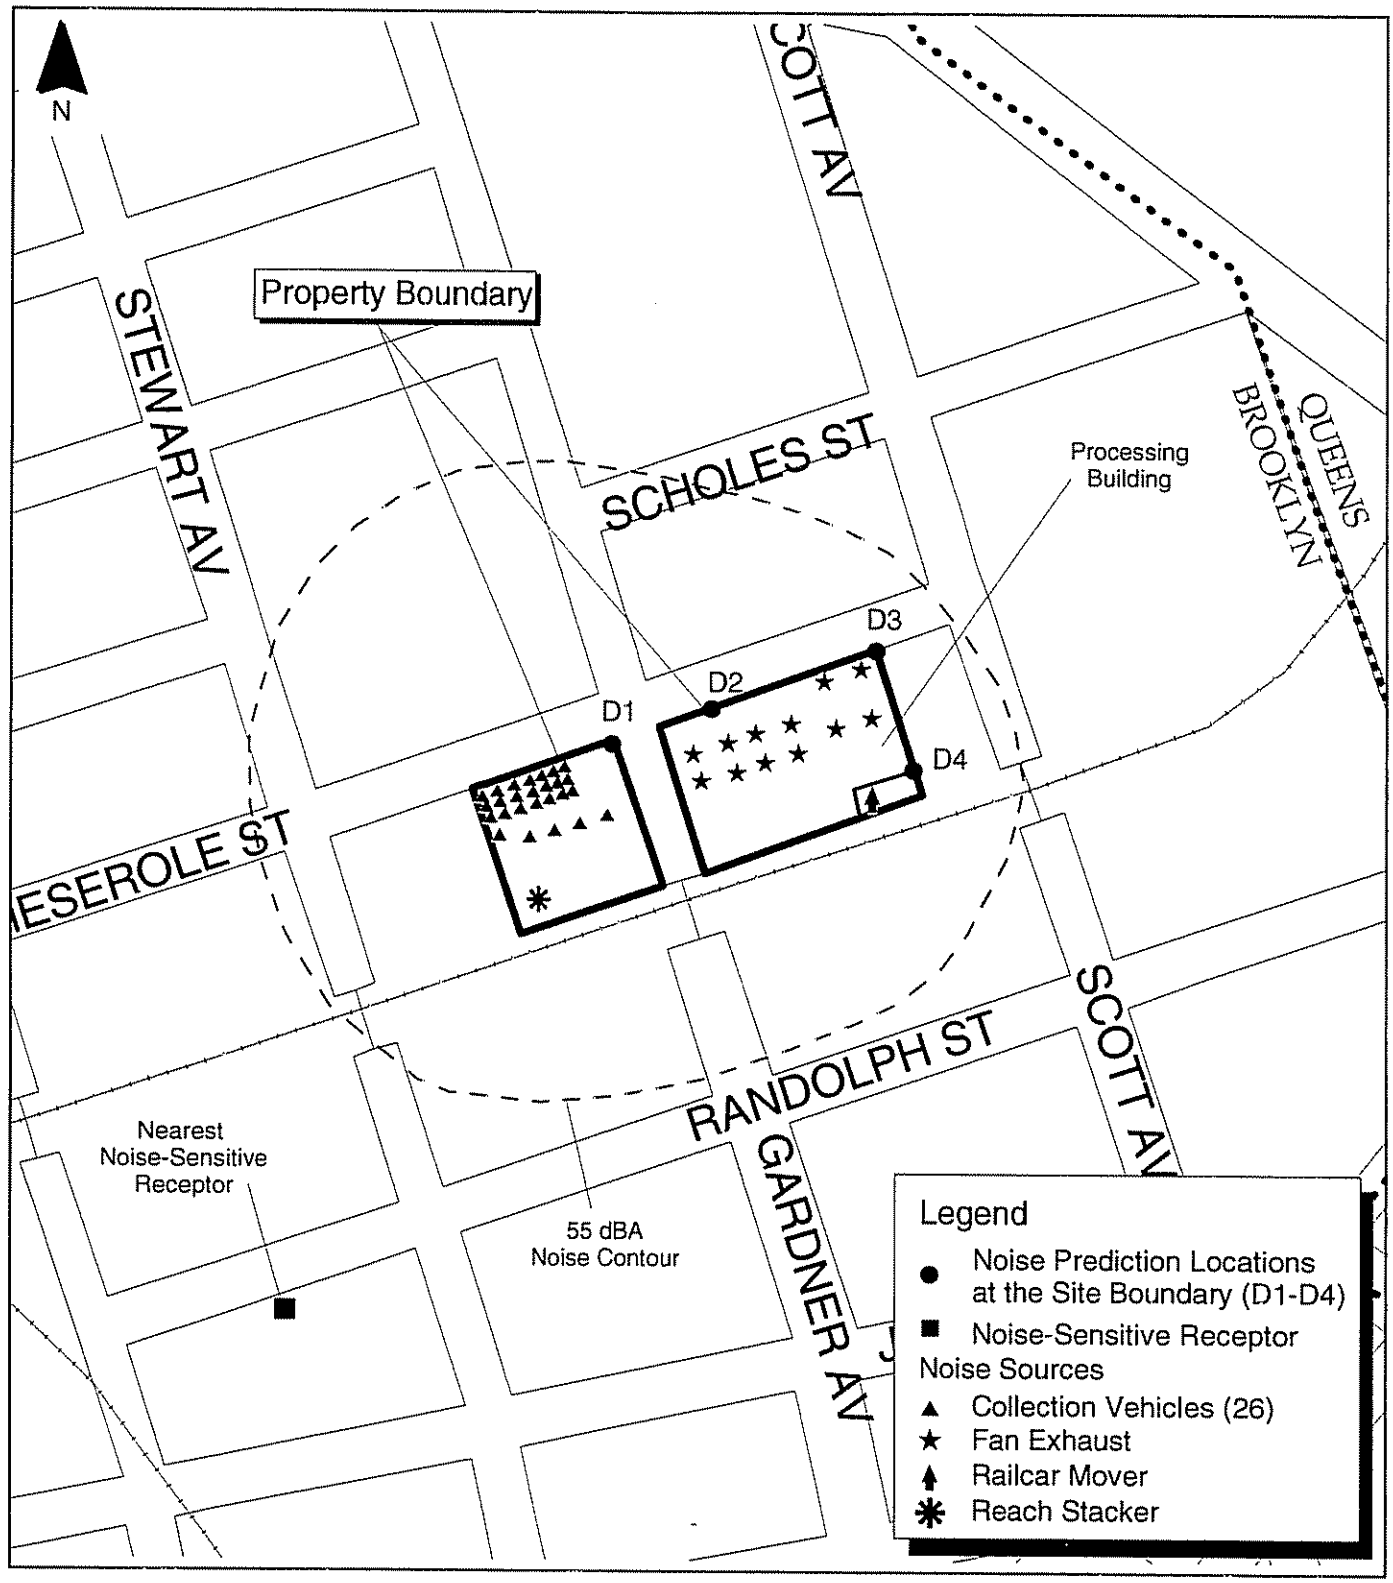

Figure 31.17-1 shows the location of the Meserole Street Truck to Rail TS, the surrounding area and the points that represent the property boundary (D1, etc.) for all noise analyses. The nearest noise-sensitive receptor is an apartment building located on Randolph Street between Stewart Avenue and Varick Avenue, approximately, 172 meters (566 feet) from the property boundary.

31.17.1.2 On-Site Noise Levels

Existing on-site noise levels consist of noise created by the activities and events on and immediately surrounding the site. Existing noise levels were monitored hourly for a 24-hour period at the property line closest to the nearest noise-sensitive receptor. Noise monitoring data recorded hourly included: $L_{eq(1)}$, L_{min} and L_{max},[8] and the statistical metrics of L_5, L_{50} and L_{90}.[9] Table 31.17-1 presents monitored noise levels. As shown, the quietest hour at the monitoring location occurred between 3:00 a.m. and 4:00 a.m. and had an $L_{eq(1)}$ of 59.3 dBA on June 25, 2004. Activities and events that contribute to the on-site noise levels include:

- Transportation of railcars on the adjacent Railroad line; and
- Other noise sources associated with activities in the surrounding industrial areas.

[8] Terms $L_{eq(1)}$, L_{min} and L_{max} are defined in Section 3.19.2.
[9] Terms L_5, L_{50} and L_{90} are defined in Section 3.19.2.

5:00-6:00 a.m.	68.0	59.8	63.6	75.6	58.0	81.6
6:00-7:00 a.m.	65.2	58.3	61.3	69.3	56.7	85.4
7:00-8:00 a.m.	65.7	60.9	63.8	70.2	58.2	82.5
8:00-9:00 a.m.	68.0	62.5	64.6	71.3	60.7	86.4
9:00-10:00 a.m.	67.7	62.0	64.6	72.6	60.3	86.2

Note:
(1) The 24-hour background noise levels were measured at the site boundary nearest to the closest sensitive receptor to identify the quietest background hour.

31.17.1.3 Off-Site Noise Levels

Existing off-site noise levels consist of the noise from existing traffic and other background noise. A screening analysis was conducted to determine if off-site noise monitoring would be required along the Meserole Street Truck to Rail TS-related truck routes due to an increase in traffic caused by DSNY and other agency collection vehicles. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis was not required and, therefore, off-site noise monitoring was not conducted.

31.17.2 Future No-Build Conditions

31.17.2.1 On-Site Noise Levels

No appreciable changes in on-site noise levels are anticipated by 2006; therefore, Future No-Build Conditions are expected to be the same as Existing Conditions.

31.17.2.2 Off-Site Noise Levels

Off-site noise levels for the Future No-Build Conditions in 2006 were calculated using the annual growth rates for traffic volume provided in Section O: Traffic of the 2001 CEQR Technical Manual. Table 31.17-2 presents the existing traffic volume and the Future No-Build traffic volume for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) based on the first-level screening.

Table 31.17-2
Off-Site Noise Traffic Volume
Meserole Street Truck to Rail TS

Location	Hour	Existing Traffic Volume [1] (Vehicles/Hour)	Future No-Build Traffic Volume [2] (Vehicles/Hour)
Metropolitan Avenue between Olive Street and Catherine Street	10:00 a.m.	~~763~~543	~~786~~554
~~Grand~~ Metropolitan Avenue between Olive Street and Catherine Street	2:00 a.m.	~~128~~123	~~132~~125
Flushing Avenue between Vandervoort and Knickerbocker Avenue	2:00 a.m.	156	159

Notes:
[1] Existing traffic volumes are based on ATR data.
[2] Future-No-Build traffic volumes are based on CEQR annual traffic growth rates.

31.17.3 Potential Impacts with the TransRiver Marketing Company L.P. Truck to Rail TS

31.17.3.1 On-Site Noise Levels

Proposed equipment assumed to be operating at the TransRiver Marketing Company L.P. Truck to Rail TS and its reference noise levels used in the CEQR analysis are shown in Table 31.17-3. The number and type of equipment assumed for this analysis were based on the TransRiver Marketing Company L.P. Truck to Rail TS's average design capacity. Shown earlier, Figure 31.17-1 indicates the TransRiver Marketing Company L.P. Truck to Rail TS layout, the locations of the points along its boundary where overall noise predictions were calculated and the predicted 55 dBA contour line.

Table 31.17-3
Equipment Modeled in the Noise Analysis and Reference Noise Level (L_{eq})
TransRiver Marketing Company L.P. Truck to Rail TS

Equipment Name (quantity) [1]	Reference Sound Pressure Noise Level [1,2] at 50 feet (dBA)
Indoor	
Wheel Loader (1)	80.6
Reachstacker (1)	76.2
Excavator 300C (2)	81.0
Fork Lift (21)	68.1
Exhaust Fans (12)	40.8
Moving/Idling Collection Vehicles (11)	~~73~~ 79.0
Outdoor	
Onsite Moving/Queuing Collection Vehicle (26)	67
Offsite Moving/Queuing Collection Vehicle (1)	67
Reachstacker (1)	76.2
Shuttle wagon (1)	76.3
Exhaust Fan (12)	40.8

Note:
[1] Instantaneous maximum number of pieces of equipment on site at any given time.
[2] Noise level representative of each piece of equipment

31.17.3.2 CEQR Analysis

A screening analysis was conducted to determine if a detailed noise analysis would be required for the on-site operations at the TransRiver Marketing Company L.P. Truck to Rail TS. Noise levels from indoor and outdoor sources were combined to determine the location of the 55 dBA contour line. The 55 dBA contour line is 79 meters (260 feet) from the property line in the direction of the nearest noise-sensitive receptor, which is 172 meters (566 feet) from the site boundary. The 55 dBA contour line was selected as a limit for the study area because 55 dBA (i.e., the point off site where noises generated on site attenuate to 55 dBA) is considered an acceptable noise level in an urban environment. Section 3.19.5.1 discusses this concept in greater detail. The results of the screening analysis show that noise-sensitive receptors are not located within the 55 dBA contour line (see Figure 31.17-1); therefore, an on-site noise analysis, including noise monitoring at the nearest noise-sensitive receptor, was not required.

31.17.3.3 Off-Site Noise Levels

A screening analysis was conducted to determine if a detailed off-site noise analysis including noise monitoring would be required along the truck routes serving the TransRiver Marketing Company L.P. Truck to Rail TS. The assumed DSNY and other agency collection vehicle routes are provided in Section 14 of this chapter. As a result of this screening, which is described in Section 3.19.5.2, an off-site noise analysis and off-site noise monitoring was not required. Results of the screening for the hour expected to receive the largest change in noise levels (when the difference between the traffic noise levels and background noise levels is greatest) during the daytime (if any) and nighttime are provided in Table 31.17-4.

31.17.3.4 Combined On-Site and Off-Site Noise Levels

As a result of both the on- and off-site screening analyses performed for the TransRiver Marketing Company L.P. Truck to Rail TS, neither the on- or the off-site noise analyses were required; therefore, a combined noise analysis was not performed.

Table 31.17-4
Off-Site Noise Screening Results
TransRiver Marketing Company L.P. Truck to Rail TS

Location	Hour	Future No-Build PCEs[1]	Collection Vehicles	Employee Vehicles	Total Net DSNY Collection Vehicles PCEs[1][2]	Future Build PCEs[1][2]	Possible Impact[3]
Metropolitan Avenue between Olive Street and Catherine Street	10:00 a.m.	7,085	~~45~~ 56	0	~~2,115~~ 2632	~~9,200~~ 9717	No
Metropolitan Avenue between Olive Street and Catherine Street	2:00 a.m.	1,888	~~10~~ 12	0	~~470~~ 564	~~2,358~~ 2452	No
~~Grand Avenue between Olive Street and Catherine Street~~	~~2:00 a.m.~~	~~247~~	~~3~~	~~0~~	~~141~~	~~388~~	~~No~~
Flushing Avenue between Vandervoort and Knickerbocker Avenue	2:00 a.m.	254	3	0	141	395	No

Notes:
[1] Total PCEs are rounded to the nearest whole numbers.
[2] Future Build PCEs include TransRiver Marketing Company L.P. Truck to Rail TS-related collection vehicles and employee vehicles. Per CEQR, collection vehicles are converted to PCEs using a factor of 47 and employee vehicles are converted using a factor of 1.
[3] There is a possible impact if the Future Build PCEs are double the Future No-Build PCEs or more.

31.17.4 Potential Impacts with the IESI NY Corporation Truck to Rail TS

All potential on-site and off-site impacts with the IESI NY Corporation Truck to Rail TS would be the same as those described above in Section 31.17.3 for the TransRiver Marketing Company L.P. Truck to Rail TS.

CHAPTER 32 CONSTRUCTION IMPACTS

32.1 Introduction

The DSNY is planning to restore and modify solid waste transfer operations at their Converted MTS facilities. The new operations, which will containerize MSW for barge transport, are planned for the City's Converted MTSs and will require varying degrees of over-water and on-shore construction. Construction and operation of the Converted MTSs in the Proposed Plan will have potential short- and long-term impacts on the surrounding marine environment and ambient natural resources. Since construction of the MTSs will be ~~less than 3 years~~approximately 28 to 30 months in duration, a detailed construction related impact analysis was not required (see Section 32.2 for more detail). In this section, two types of impacts will be discussed: potential short-term or construction impacts, and potential long-term or operational impacts.

32.2 Construction Schedule

Preliminary schedules were prepared by DSNY's design consultant for construction of the Converted MTSs and are presented in Appendix N to this FEIS. Based on the schedules, the estimated overall construction duration for the Converted MTSs in the Proposed Plan is approximately 28 to 30 months from Notice to Proceed. At all four of the proposed Converted MTSs, contractor mobilization and environmental abatement of the existing facility (i.e., asbestos and lead based paint remediation) would occur over approximately one and a half months. The estimated demolition period of the over-water existing MTSs at North Shore and East 91st Street, and the Hamilton Avenue existing MTS is approximately five months, during which time dredging will occur over an approximate three to four month period. Demolition of the existing Southwest Brooklyn MTS is not planned at this time. The estimated construction period of the Converted MTSs at North Shore and East 91st Street is approximately 17 to 18 months. After demolition (now underway) of the existing incinerators on the Hamilton Avenue and Southwest Brooklyn sites is completed while dredging occurs over an approximate three to four month duration, the estimated construction period for these upland Converted MTSs is approximately nine (9) to 12 months.

32.3 Construction Activities and Equipment

32.3.1 Construction Activities

The major categories of construction activity at each of the Converted MTSs include:

1. Construction of pile foundations (driving piles and construction of pilecaps and beams) and structural concrete for the deck, walls, elevated slab and columns;
2. Construction of the structural steel portion of the processing building (framing, roofing, siding an punch walls);
3. Construction of the in water king pile wall at the proposed Southwest Brooklyn Converted MTS.
4. Construction of the heating, ventilation and air conditioning (HVAC), odor control and dust suppression systems, and installation of plumbing, fire protection and electrical systems for the facility;
5. Installation of architectural finishes, including windows and doors on the processing building;
6. Installation of the gantry cranes and lidding equipment; and
7. Construction of the ramp, including driving support piers, pier stems and caps, and construction of the road slab and deck.

At the North Shore site, all construction activities will occur in Flushing Bay with the exception of a small portion of the access ramp that extends toward the western end of 31st Avenue where the existing ramp is located. At the Southwest Brooklyn site, construction activities will occur on land adjacent to the existing MTS structure, which will remain in place, with the exception of construction of the in water king pile wall. At the East 91st Street site, construction activities will occur in the East River, with the exception of the access ramp that begins at the foot of 91st Street and York Avenue, bisects the Asphalt Green park property, and crosses the FDR drive. This ramp will be reconstructed over the existing access ramp footprint, and will likely involve some temporary lane closures of the FDR Drive during certain construction periods. A discussion of the short term effects of construction on Asphalt Green Park is contained in Section 32.4. At the Hamilton Avenue site, construction activities will occur both on land and over water in the Gowanus Canal.

32.3.2 Construction Equipment

Although some construction equipment and materials will be brought to the site by truck, most of the construction equipment and materials will likely arrive on barges to take advantage of the waterfront access available at all sites. The barges will likely be staged near the sites during most of the demolition and construction period. Most demolition debris would also be removed on barges that hold large quantities of material and can be towed to a transfer or disposal location in a more efficient manner than using transfer trailers. The types of equipment that may be present during demolition and construction activities include:

- Tugboats
- Barges
- Boats
- Cranes
- Derricks
- Piledrivers
- Construction vehicles (e.g. bulldozers, wheel loaders)
- Hydraulic excavators
- Rock augers/drills
- Concrete delivery trucks
- Concrete Pumps
- Asphalt paving equipment
- Welding machines
- Mechanical dredging equipment
- Scissor lifts/hoists
- Air Compressors
- Pneumatic hammers
- Pneumatic/electric tools

A more detailed discussion on dredging is included in Section 32.5.4.

32.4 Potential Construction Impacts

Potential areas of construction-related impacts from the Proposed Action include:

- Temporarily impeded access to community facilities, parks and open space;
- Short term effects on neighborhood character and natural resources;
- Potential exposure to contaminated materials;
- Disposal of construction debris;
- Temporary street or lane closures; and
- Potential traffic, air quality, vibration, and noise impacts.

Since most of the construction at several sites would be over water, this chapter provides an in-depth description of the potential impacts during construction to the marine environment (which consists of the benthic and epibenthic communities, adult finfish and ichthyoplankton) evaluated during a year long study in 2003. See Section 32.5 for more detail.

The level of construction activity at each site will vary over the course of the construction period because certain activities, such as pile driving and construction-related traffic, will be greater at specific periods of time. DSNY is in the process of preparing final bid documents for construction of the Converted MTSs that are expected to be issued in early 2006, pending required approvals and permits. The bid documents will require the selected contractor(s) to submit a detailed demolition/construction sequencing schedule for DSNY review. The peak periods of both on-site and off-site construction activity cannot be determined until the detailed construction schedules and the means and methods to be employed by the selected contractor(s) are known.

While there will be periods of time when construction activities will cause temporary impacts in the areas listed above, DSNY is committed to minimizing these potential temporary impacts.

For example, among other things, DSNY will require the selected contractor to construct temporary construction fencing around the site, and provide security to restrict access to the site by only authorized personnel for the duration of construction. DSNY will also require the

contractor to submit: (1) a construction waste management plan that identifies the contractor's plan for management of construction debris generated at the site; and (2) air monitoring and dust minimization measures to minimize the potential for the release of particulates during dust-generating activities. As indicated by the Phase II subsurface investigations conducted at the Southwest Brooklyn and Hamilton Avenue sites and described in the Hazardous Materials sections of this FEIS, the potential for contaminated subsurface materials exists at these sites. Therefore, DSNY will require the contractor to submit Health and Safety Plans for its employees, have appropriate safety professionals on site, and submit a site management plan to address the contractor's procedures for excavation, removal and off-site disposal of any potentially encountered contaminated or hazardous materials in accordance with applicable regulations.

DSNY will also require those contractors who are preparing Maintenance and Protection of Traffic (MPT) plans to assure, to the maximum extent practicable, access to community facilities and services, and parks and open space in the vicinity of the Converted MTSs during construction. These MPT Plans will also be reviewed by appropriate state and City agencies, such as NYSDOT and NYCDOT, when the plans include temporary street or lane closures of state or City roads, and DPR in regard to maintaining access to Asphalt Green and the East River Esplanade parks. Any potential traffic, air quality, noise, and pedestrian access impacts of these street or lane closures will be temporary and localized in nature.

Due to the somewhat specialized nature of the over-water and land side construction of the Converted MTSs, the additional traffic generated from construction vehicles and employees traveling to and from the site cannot be estimated at this time. The duration for demolition of the existing MTSs at East 91st Street and North Shore is approximately five (5) to six (6) months, and construction duration of the Converted MTSs at these locations is approximately 17 to 18 months. The construction duration for the upland Southwest Brooklyn and Hamilton Avenue Converted MTSs is estimated to be approximately nine (9) to 12 months, since it is anticipated that construction of pile foundations, structural concrete, and the structural steel building will require less time at the upland sites. During these periods, the peak periods of activity (with the highest number of construction-related vehicles) is likely to be less than nine (9) to 12 months,

so any potential traffic, air quality and noise impacts associated with this construction would be short term. In addition to meeting requirements for applicable state, city and local permits for construction, DSNY will require the contractor to provide noise mitigation strategies, methods, procedures and technology to minimize potential short term noise impacts.

Neighborhood character and visual quality (including river views) near the Converted MTS sites will vary, depending upon the type and duration of demolition/construction activity, but will likely experience some degree of short term adverse impacts as a result.

At the proposed East 91st Street Converted MTS site, the estimated duration for demolition and reconstruction of the access ramp is approximately 11 months. Given that the existing East 91st Street MTS access ramp is adjacent to Asphalt Green (with ballfields to the south and the Aqua Center to the north, east of York Avenue) and crosses over the East River Esplanade, ramp reconstruction would be expected to have short-term effects on these nearby park facilities, even though it would be in the same footprint as the existing ramp. Temporary construction fencing around the construction areas will alter the visual environment, and potentially affect access to small portions of these park facilities while the existing ramp is being demolished and the new one is being built. The estimated duration for demolition of the existing ramp is approximately five (5) months, and for construction of the new ramp is approximately six (6) months (which includes the portion of the ramp over the FDR and the section of ramp passing between the Aqua Center and the park), making these impacts temporary. The ramp work is scheduled to take place towards the end of construction, so that the new ramp is completed at approximately the same time that the proposed Converted MTS is completed. The existing ramp will be used for construction operations until it is demolished.

DSNY is in the process of evaluating specific measures to mitigate these potential impacts at the proposed East 91st Street Converted MTS site. These measures, which will be required in the construction contract documents, could include:

- Requirements that demolition and reconstruction be completed from within the footprint of the existing ramp and from the western most lane of the FDR.
- Isolation of the work area within temporary construction fences and barriers.

- Traffic control provisions and traffic control staff for the York Avenue Transfer Station Ramp intersection.
- Construction of a temporary steel tunnel to maintain the southwest Aqua Center entrance in service.
- Temporary storage structures to compensate for the existing storage space beneath the ramp.
- Facade protection for the Aqua Center.
- Temporary louver filters for the Aqua Center louvers located adjacent to the ramp.
- Strict enforcement of various dust and sedimentation control requirements.
- Soil vibration control and monitoring systems.
- Design of augured shafts for foundations instead of driven piles.
- Stringent post demolition/reconstruction clean up requirements.
- Temporary relocation of Aqua Center utility services.

DSNY is also considering imposing contractual requirements that the work be completed during specific periods of time. DSNY will coordinate these plans with DPR and consult with Asphalt Green to maximize access to these facilities during the various stages of construction activity.

32.52 Construction Impacts to the Marine Environment

Construction impacts to the marine environment result from both the demolition of existing structures and the fabrication of new facilities. Construction impacts are limited temporally to the span of the activities, typically a few years. On a generic basis, these impacts include, but are not limited to, loss of benthic habitat due to dredging, turbidity and siltation from piling removal or installation, loss of encrusting organism habitat from piling removal, and general disruption of existing communities due to human and mechanical activity. Minor water quality impacts, such as localized anoxia, may result if newly exposed reduced sediments draw down dissolved oxygen on contact. It is important to note that extensive sampling of the sediment indicates that the sediments are not "hazardous", although they contain some low levels of contaminants. A list of the potential impacts at the Converted MTSs is presented in Table 32.25-1. The proposed construction plans call for some activity at each of the ~~eight~~ proposed four Converted MTSs in the Proposed Action, but the extent varies, with some sites being totally rebuilt and other sites having relatively minor alterations.

32.52.1 Benthic Communities

Benthic organisms, being immobile (at least in the adult stages), are subject to impacts of construction activities that have the potential for disruption or even obliteration of the populations in the impact zone. The benthic species found at each of the four proposed Converted MTSs are listed in Table 32.25-2. If benthic species diversity is the accepted indicator for overall "health" of the communities around each proposed Converted MTS, it follows that the proposed Converted MTS zones with the highest diversities are likely to be more greatly impacted than those with lower diversities. While species diversity is an accepted indicator, caution must be used in interpreting the data because certain specific monocultures can also be considered highly valuable systems. Nonetheless, lower diversity benthic communities are usually opportunistic species with high abundances and toleration for more degraded environments. The most abundant species observed at thes proposede Converted MTSs were those species tolerant of degraded environments: *Streblospio benedict, Capitella capitata*, polychaetes and oligochaetes. With these caveats in mind, benthic species diversity will be used in this impact analysis to determine probable impacts to the benthic communities.

Table 32.5-1~~25~~ 1
Potential Impacts to Marine Communities at Converted MTSs

Chemical
Heavy metals released from sediment during dredging
Heavy metals and polycyclic aromatic hydrocarbons (PAHs) introduced to sediment and water from treated lumber used in construction
Suspended particles from marine construction and dredging
Anoxia from release of reduced sediments during dredging
Biological
Disrupted communities
Removal of food sources
Minor loss or replacement (< 0.05 acres) of tidal wetland vegetation
Physical
Channel dredging
Dredged material disposal
Dredging and filling
Habitat degradation

The Shannon-Weaver Index for benthic organisms was computed for all four proposed Converted MTSs.[1] This index is used as a measure of community diversity, but also accounts for numbers of individual organisms. Table 32.~~2~~5-3 lists the stations and their respective indices. In a rank of the indices from the highest to the lowest, a high index indicates a high species diversity.

Table 32.5-~~2~~-3
Shannon-Weaver Index and Rank of Benthic Impact at the Proposed Converted MTSs in the Proposed Action

Converted MTS	Shannon-Weaver Index	Rank
Southwest Brooklyn	1.815	High
Hamilton Avenue	1.509	Medium
North Shore	1.487	Medium
East 91st Street	1.116	~~Medium~~Low
Mean (all MTSs)	**~~1.700~~1.482**	

The ranking of high, medium and low are somewhat arbitrary; however, this ranking can be used as a general grouping of the respective proposed four Converted MTS indices to determine impacts. A Shannon-Weaver Index above 1.8 was given a high rank, an index between 1.~~0~~15 and 1.8 was assigned a medium rank (as the mean was 1.48), and an index below 1.~~0~~15 was given a low rank.

At present, the plan is for the degrees of activity and consequent potential for benthic impacts shown in Table 32.~~2~~5-4. The proposed four Converted MTSs that will have construction of new platforms, causing turbidity and siltation, were assigned a high impact rank. Those with minimal or no construction were assigned a low or no impact rank.

[1] New York City Department of Sanitation, March 2004. Marine Biological Studies of the Marine Transfer Stations Operated by the New York City Department of Sanitation. Prepared by EEA, Inc.

Table 32.52-4
Construction Activity and Potential Impacts

Proposed Converted MTS	Construction Activity	Marine Resource Impacts	Degree of Impact
Southwest Brooklyn	Existing platform to remain, king pile wall to be constructed	~~None~~Turbidity, siltation	(~~none~~moderate)
Hamilton Avenue	Existing platform removed	Minimal	(low)
North Shore	New, larger platform	Turbidity, siltation, tidal wetland disturbance	(high)
East 91st Street	New, larger platform	Turbidity, siltation	(high)

If the two above tables are combined, the matrix shown in Table 32.~~2~~5-5 can be constructed. In order to determine the expected impacts, turbidity and siltation received a high rank, while the removal of platforms with no new construction received a low rank. If two high ranks were compared, the expected impact was high. If a high and medium rank were compared, the expected impact was moderate. If the Shannon-Weaver Index or construction activity had a low rank, the expected impact was ranked as minimal or none.

Table 32.52-5
Degree of Expected Benthic Impacts

Proposed Converted MTS	Degree of Expected Impacts
Southwest Brooklyn	~~None~~Moderate
Hamilton Avenue	Minimal
North Shore	Moderate
East 91st Street	Moderate

The needs of the project require that the old platforms be removed and new ones constructed. Southwest Brooklyn is an exception; the existing platform will remain in place. The construction of new platforms will cause turbidity and siltation, which could smother benthic communities. There will also be some turbidity and siltation as a result of the construction of a king pile wall at Southwest Brooklyn, though it will be far less than what would be expected from the construction of new platforms. Impacts will be greatest to the benthic communities at the proposed Converted MTSs that have the most diverse benthic communities. ~~The above ranking of expected benthic impacts from construction appears logical as West 135th Street and South Bronx had the highest Shannon-Weaver indices and significant construction activities. Conversely, Southwest Brooklyn, Greenpoint and Hamilton Avenue ranked low on impacts. No~~ Moderate impacts are expected at the proposed Southwest Brooklyn, North Shore and East 91st Street Converted MTSs. ~~,~~ There ~~as no~~is no over-water platform construction ~~is~~ slated at Southwest Brooklyn, however, there will be some dredging for navigational purposes and construction of a king pile wall, which will cause some short-term impacts to benthic fauna. Both the North Shore and East 91st Street sites will experience moderate impacts to the benthic communities as they will both have new platforms constructed, resulting in turbidity and siltation. The proposed Hamilton Avenue Converted MTS ranked low on impacts. No new over-water construction is planned at Hamilton Avenue ~~and the benthic community at Greenpoint is not very diverse,~~ so the limited construction should not result in drastic impacts.

32.5~~2~~.2 Epibenthic Communities

Examination of the colonization plates revealed that most of the proposed Converted MTSs had extensive macrofaunal communities within a single growing season. Most growth was observed in the spring and summer months. The most abundant species were those that are tolerant of degraded environments, such as the amphipod *Corophium insidiosum*, the polychaete worm, *Polydora sp.* and the tunicate *Molgula manhattensis*. All species found on the colonization arrays at each proposed Converted MTS are listed in Table 32.2~~5~~-6. Removal of the existing structures will temporarily eliminate these communities and cause a localized loss of food sources for fish species (e.g., tautog) that prey on them. At the Hamilton Avenue Converted MTS, this impact will be the most pronounced compared to the others because substrate for

growth will be permanently removed. ~~Greenpoint will also have a loss of macrofauna due to a reduction in platform size.~~ The other Converted MTSs will have as much or more new hard surface available for colonization so this initial habitat loss will not be significant. The epibenthic community is expected to remain at Southwest Brooklyn, as no pier removal ~~or construction~~ is planned at this Converted MTS~~.~~, and the community will colonize the new king pile wall.

It is important to note that colonization was observed during one sampling season and therefore the new structures are expected to be colonized fairly quickly. However, colonization may be delayed if treated lumber is used in construction. Treated lumber prevents marine growth until enough of the treatment has leached out of the lumber to allow a suitable environment for growth. Two widely used treatments for marine construction are creosote and chromated copper arsenate (CCA). Although both are used to deter marine growth, studies have suggested that they do not pose a significant risk to aquatic life.[2] Creosote releases PAHs and CCA releases copper, chromium and arsenic; however, the most leaching occurs with the initial introduction to the water and leaching decreases with time.[3] The leachate from both types of treated lumber is absorbed by the sediment and is either metabolized by microorganisms or becomes biologically unavailable.[4] Because leaching decreases with time, both benthic and epibenthic organisms are expected to recolonize the sediment and reclaim the submerged structures. It must also be noted that many of the benthic and epibenthic organisms found around the proposed Converted MTSs were those tolerant of degraded environments and would generally be the first to be found again.

32.~~2~~.5.3 Adult Finfish

Construction impacts such as turbidity and siltation will be limited spatially to the immediate area of the ~~transfer station~~proposed Converted MTS. These impacts will also be restricted temporally to the time of construction, approximately one to one-and-one-half years. Adult finfish impacts are not expected because motile organisms will avoid construction activities that produce less than optimal environmental conditions. Fish generally display avoidance behavior of areas that have one milligram per liter or more of suspended sediment.[5] Some fish are more tolerant of suspended sediment than others. For example, bottom dwellers, such as flounders, are more tolerant of suspended particles than pelagic species, and clupeids (herring) are most sensitive to suspended sediment as it easily clogs their gills.[6] Table 32.~~2~~4-7 shows the relative sensitivity of the finfish collected at the proposed Converted MTSs to suspended particles in the water column.

The pile-driving activity associated with pier construction may also cause fish to avoid the construction sites. Relative finfish sensitivity to noise is listed in Table 32.~~2~~5-7. Studies on the effects of offshore pile-driving on finfish, which may be more intense than the type used in this project, have indicated that, in general, bottom dwelling fish (flatfish, etc.) are less sensitive to pile-driving than pelagic fish (whose swim bladders are sensitive to pressure changes, which in turn affects the ear).[7] Herring have been documented to show escape responses to pile-driving.[8] Avoidance response of juvenile salmonids to pile-driving activity in harbors has also been documented.[9] Although there were no salmonids at any of the proposed Converted MTSs studied, this study may be extrapolated to suggest that finfish would probably avoid the areas where marine construction is occurring.

Note for Table 32.~~2~~5-7:

(1) This table uses information from European sources to show a relative sensitivity of the fish collected at the MTSs to activities associated with marine construction. Both studies were conducted in Europe and discuss European species. The families of the fish studied were used to determine a general impact on the local finfish families collected at the proposed Converted MTSs.

Table 32.~~2~~4-8 lists the adult finfish species collected at each proposed Converted MTS. It must be noted that only ~~six~~ two of the four proposed Converted ~~eight~~ MTSs in the Proposed Action were sampled for adult finfish due to physical restraints of two of the sites. The two MTSs that were not sampled for adult finfish were East 91st Street and Hamilton Avenue. The flatfishes (flounders) and clupeids were totaled for each proposed Converted MTS. One ~~Four~~ of the ~~six~~four proposed Converted MTSs that were trawled (~~South Bronx,~~ Southwest Brooklyn~~, West 135th Street and West 59th Street~~) had substantially more flatfish than herrings. The finfish communities at the above-mentioned proposed Converted MTSs indicates that there may possibly be a less drastic community shift at ~~those~~ this Converted MTSs during platform modification than at Converted MTSs with a high clupeid population. North Shore ~~and Greenpoint~~ had more herrings surrounding the site ~~Converted MTS~~, and may experience more finfish avoidance behavior that the other proposed Converted MTSs. General avoidance behavior of the finfish that live near the proposed Converted MTSs was observed during the summer months when the dissolved oxygen levels decreased in the water, resulting in the movement of fish away from the affected areas. A similar response would occur if marine construction released anoxic sediment that absorbed the oxygen from the water, causing a temporary drop in dissolved oxygen levels.

32.~~2~~5.4 Ichthyoplankton

Ichthyoplankton are more sensitive to construction impacts than adult finfish. This is due to high mortality experienced in egg and larval stages. The lethal concentration of suspended sediment for finfish eggs and larvae is generally one milligram per liter of water.[10] For demersal fish eggs (those that lay on the substratum), the impacts are similar to those of the benthic invertebrates. These eggs could be smothered by sediment during construction. Pelagic eggs are free-floating and could be carried or swept through an impact zone, but given the current velocities in most of the proposed Converted MTS areas, are unlikely to stay for any extended period. Table 32.~~2~~5-9 indicates

◆ = Unknown.

the time of year and egg type of the more abundant species located in the central part of the Mid-Atlantic Bight.[11] This table may be used as an indicator of those species more at risk to impacts from construction.

Larval forms that have motility (i.e., can swim) will behave like the adult finfish and avoid areas where the environmental conditions are unfavorable. As with the eggs, any that are swept through the construction sites by currents would not be exposed to suspended sediments for extended periods of time due to current velocities in the areas.

Currents may play an important factor in reducing impacts to non-motile finfish eggs and larvae. Most of the proposed Converted MTSs have slated construction that would cause siltation; however, any egg or larvae swept into the construction zone should be swept out of the zone fairly quickly due to strong currents experienced at the proposed Converted MTS sites. The ~~two~~ proposed Hamilton Avenue Converted MTSs ~~that~~ is ~~are~~ on a restricted water bodyies with less strong current regimes., ~~Greenpoint and Hamilton Avenue, are places where~~ eEggs and larvae may have a greater residence time and exposure to suspended sediment., ~~H~~however, thiese proposed Converted MTSs hasve a lesser degree of over-water construction planned than most other proposed Converted MTSs, and had among the lowest concentrations of finfish eggs and larvae, so impacts should be minimal.

The finfish eggs and larvae collected at each of the four proposed Converted MTS are presented in Table ~~32.2~~32.5-10. Winter flounder is the only species collected at the proposed Converted MTSs that lays demersal eggs. Because of its recreational importance and declining numbers, winter flounder is of concern to fisheries biologists and regulatory scientists. Winter flounder eggs were only present and collected at the ~~three of the Converted MTSs – South Bronx,~~ proposed East 91st Street Converted MTS site. ~~and West 59th Street.~~ Winter flounder larvae were collected at all ~~eight~~four of the proposed Converted MTS sites. Construction impacts are expected to be negligible to winter flounder or other ichthyoplankton species.

Although impacts are expected to be minimal, regulatory agencies (USACOE and NYSDEC) will regulate the dredging and construction with environmental safeguards such as environmental buckets for the dredge, silt curtains, and environmental windows (discussed further below) to protect spawning times of striped bass and winter flounder.

There are two basic categories of dredging methods:

- **Mechanical Dredging** – Mechanical dredging uses a clamshell-style bucket to scoop up the sediments. Various types of buckets are available. A conventional bucket is an open top bucket whereas an "Environmental" bucket is an overlapping, sealed clamshell-style bucket. Environmental buckets "grab" the sediments and some water, but seal tightly in order not to let the sediments out into the waterway.
- **Hydraulic Dredging** – Hydraulic dredges work like vacuum cleaners to remove bottom sediments and associated water. The major drawback of hydraulic dredging is that it removes excessive amounts of water that must be transported offsite for disposal. Consequently, hydraulic dredging is generally not suitable or utilized unless the dredged material can be released directly into a disposal area.

In general, the environmental safeguards that may be utilized to protect the environment and may be specified by the regulatory agencies are as follows:

- **Environmental Buckets**

  Resuspension of sediments and any associated contaminants is a concern during the dredging operation. Mechanical dredging using an environmental bucket is suitable to minimize this concern. The environmental bucket is an overlapping, sealed clamshell-style bucket that is used to scoop up the sediments. During its descent, a venting system allows water to pass through the bucket, minimizing sediment resuspension. The bucket is lowered to the bottom, making a cut in the sediments. During closing, the sides overlap, effectively sealing all sediment in the bucket. The bucket is then raised to the surface just above the waterline, where it is allowed to drain water from the vents before releasing the sediments into a receiving container, usually a hopper barge.

- **Silt Curtains**

  These are specifically engineered barriers that float above the water surface and extend to the bottom. Silt curtains, where practical, are used to protect against dispersal of sediments during the dredging operation. Silt curtains, however, are not practical in waters impacted with swift current conditions.

- **Environmental Windows**

  Dredging may not be allowed during certain months of the year to protect the biological organisms. This time period, for example, is generally November 15 through April 15 to protect the Stripped Bass and Winter Flounder during their spawning and earlier growth.

Dredging will be necessary at the Converted MTSs to allow barge access during construction and operation of these facilities. DSNY has carefully considered various dredging methods and has selected to employ mechanical dredging using an environmental bucket.

- The environmental bucket will be equipped with sealing gaskets or overlapping sealed design at the jaws, with a signal light in the control station to verify bucket closure and seal.
- The bucket hoist speed will be limited to approximately 2 ft/second.
- The bucket will be lowered to level of barge gunwales prior to release of load.
- Excessive loss of water, sediment or both from the time the bucket breaks the water surface to the time it crosses the barge gunwale will not be permitted. In

other words, the environmental bucket will be kept in good working order throughout the dredging operation.

In addition to utilizing an Environmental Bucket, DSNY proposes to employ the following safeguards to further protect the environment during the dredging operation:

- No barge overflow or return of untreated water will be allowed.
- Silt curtains will be deployed at those locations, where practical.
- Depending upon stipulations of the Joint Permit issued by the USACOE and NYSDEC, dredging operations may be limited from November 15 through April 15 to protect the Striped Bass and Winter Flounder during their spawning and earlier growth.

Further, DSNY seeks to transport the dredged material offsite for a beneficial use such as its use as a cover material at Fresh Kills or other landfill.

32.56 Operational Impacts

While the construction impacts are limited to the duration of the activities, the operational impacts will persist for the duration of the facilities' life span, a time span measured in decades. For the purpose of this FDEIS section, the major operational impact will be the footprint of the structures over water. While the littoral zone covered by the structures will not be devoid of invertebrate and finfish resources, the coverage will block sunlight and hinder primary production. Each of the four proposed Converted MTSs has differing amounts of existing and proposed coverage; the differences are listed in Table 32.56-1.

Table 32.56-1
Existing and Proposed Platform Coverage at the Proposed~~Each~~ Converted MTSs in the Proposed Action

Proposed Converted MTS	Existing Square Feet	Proposed Square Feet	Difference
Southwest Brooklyn	23,855	23,855	0
Hamilton Avenue	~~34,905~~ 29,450	0	~~(34,905)~~ (29,450)
East 91st Street	~~34,717~~ 35,203	~~78,374~~ 77,815	43,657 42,612
North Shore	~~40,747~~ 40,124	~~87,149~~ 86,283	~~46,402~~ 46,159
Total	**128,632**	**187,953**	**59,321**

Inspection of the above table reveals that the ~~Greenpoint,~~ Hamilton Avenue and Southwest Brooklyn proposed Converted MTSs can be eliminated from the long-term impact discussion since they are either remaining in place or ~~are being replaced with facilities that have substantially smaller footprints.~~their over-water footprint is being removed.

It is safe to say that the impacts of large platforms on the harbor estuary ecology are controversial. Studies conducted by EEA in the late 1980s showed similar finfish and benthic communities in the interpier and underpier environments in two large-scale programs on the Hudson and East Rivers, respectively.[11,12,13] Other studies, primarily by Able *et., al.*, have

shown that caged winter flounder failed to thrive underneath large platforms.[14,15] Able's studies are controversial, however, because the fish were caged, and this may impact the results of the study. Some fish are even known to associate with submerged structures, as it provides shelter and surfaces for food to grow. While the field tests appear to be contradictory for finfish, there is no doubt that fish do indeed inhabit at least the interface of platforms, and the benthic invertebrate communities are virtually identical in the underpier and interpier zones.

From a regulatory perspective, there is acceptance that platforms do not necessarily cause the underpier zones to be devoid of life, but they are still considered to be a taking of marine environmental resources and the procedural, if not environmental, equivalent of fill.

32.~~5~~6.1 Benthic Communities

The studies done by EEA and published in the late 1980s and early 1990s were conclusive regarding the benthic organism communities under large platforms in the Hudson and East Rivers. A comparison involving hundreds of grab samples from the inter and underpier zones indicated there was no statistically significant difference in species composition and abundance.[16,17,18] Based largely upon these published studies, it appears unlikely that the reconstruction, or even enlargement, of the present platforms will materially alter the benthic meiofauna communities over the long term. Benthic communities that may have experienced toxicity due to leachate from treated lumber used to build the piers would quickly be rebuilt as the leaching decreases and the pollution tolerant organisms, that had dominated the benthic communities before construction started, would come back. Those communities displaced by

construction would begin reclaiming the sediment soon after construction was completed.[19,20] The opportunistic species would appear first, followed by longer-lived species.[21,22]

32.~~5~~6.2 Epibenthic Communities

The long-term impact to epibenthic communities will be beneficial. The planned enlargement of the platforms will provide significantly more hard surface for macrofauna and the finfish that use them as a food source. The ~~five~~ two proposed Converted MTSs that will have increased platforms, and therefore increased areas for epibenthic growth once the treated lumber has lost its toxicity, are ~~West 135th Street, West 59th Street,~~ East 91st Street~~, South Bronx~~ and North Shore. Southwest Brooklyn will also have more surface area for epibenthic growth with the addition of the king pile wall. The increase in epibenthic colonizers should lead to an increase in finfish species that feed on these organisms (e.g., cunner and tautog).

32.~~5~~6.3 Adult Finfish

The EEA studies on the East River showed altered finfish communities in the under- and interpier zones. Abundances of fish under South Street Seaport Pier 17, which was used as a model, did show moderately lower numbers under piers and different types of finfish in the two zones.[23] Interpier-underpier studies on the Hudson River also showed slightly different finfish densities for several species beneath piers as opposed to in open water.[24,25] It is possible, even

[23] New York City Public Development Corporation, 1991. East River Landing Aquatic Environmental Study. Final Report. Prepared by EEA, Inc.
[24] New York City Public Development Corporation, 1988. Hudson River Center Aquatic Environmental Study. Draft Interim Report. Prepared by EEA, Inc.
[25] Stoecker, Roy R., J. Collura and P.J. Fallon., 1992. Aquatic Studies at the Hudson River Center Site pp. 407-427 In: Estuarine Research in the 1980s. The Hudson River Environmental Society Seventh Symposium on Hudson River Ecology (C. Lavett Smith ed.). State University of New York Press. Albany.

likely, that construction of larger platforms at the proposed East 91st Street Converted MTS site~~and South Bronx~~, located on the East River, and possibly the proposed North Shore Converted MTS, located in Flushing Bay off the East River, will cause population declines and shifts in finfish species composition underneath these platforms. ~~Interpier underpier studies on the Hudson River also showed slightly different finfish densities for several species beneath piers as opposed to in open water.[26,27] Using this study as a model, there is a possibility of a shift in the finfish communities at the West 59th and West 135th Street Converted MTSs with the expansion of piers.~~ Conversely, the proposed Hamilton Avenue Converted MTSs that have a reduction in pier coverage~~, Greenpoint and Hamilton Avenue,~~ may ~~also~~ see a small shift in local finfish communities. Because finfish for the most part are transient, these shifts cannot be quantified absent a future monitoring program. Regardless, a conservative approach would be to allow for some reduction, measurable or not, in local fish stocks due to construction of the enlarged platforms.

The present plan is to construct ~~120,264~~ 59,321 square feet (approximately ~~2.8~~1.36 acres) of new platforms in the harbor estuary should full build-out be accomplished. Based upon existing data and previous studies, the proposed Converted MTSs which will experience a net gain in pier coverage will be the most likely finfish impact receptors.

32.~~5~~6.4 Ichthyoplankton

Aside from the possible population shifts at the proposed Converted MTSs with increased pier structures, there is little likelihood that the ~~enlarged~~ proposed Converted MTSs would have any significant or even measurable impacts on ichthyoplankton communities.

32.67 Overview of Marine Environmental Impacts

Construction, or short-term impacts resulting from the project, will be limited both spatially and temporally. The greatest impacts will be temporary destruction of benthic and epibenthic communities and avoidance by finfish due to suspended particles and food source reduction. While they may not be amenable to avoidance or reduction, these impacts will be limited and will not last beyond one seasonal cycle for invertebrates. Temporary ~~C~~construction impacts on finfish will not be quantifiable. Further discussions of the details of the impacts and their significance are provided in section 9 of Chapters 4 thru 31.

Full build-out of the project will result in an additional ~~2.8~~1.36 acres of new platform in the harbor marine environment. From a regulatory (not environmental review) perspective, this impact may be significant due to the timeframe of the project – decades. If the judgment of the agencies is a finding of significant negative impact, then mitigation programs may need to be devised, assuming that no landside alternative is possible.

CHAPTER 33 PUBLIC HEALTH EVALUATION

33.1 Introduction

The potential impacts of the Proposed Plan Facilities on public health are evaluated in this chapter. The chief public health concerns are (1) potential health effects (including asthma) of air pollutants released by the Proposed Plan Facilities; (2) effects of noise related to the Proposed Plan Facilities; (3) effects of odors related to the Proposed Plan Facilities; and (4) the potential for vermin (such as rats and insects) to infest areas near Proposed Plan Facility sites.

33.2 Air Pollution

33.2.1 Air Pollutants of Concern

Project-related air pollutants of two kinds have been directly assessed in this FDEIS. One set of pollutants, called criteria pollutants, includes compounds for which NAAQS have been established by the USEPA: CO, NO_2, SO_2 and PM. Two overlapping categories of PM are often measured or modeled in environmental health science, namely fine PM ($PM_{2.5}$) and coarse PM (PM_{10}). Much of the PM associated with the Proposed Plan Facilities would be in the form of diesel particulate matter (DPM). Airborne concentrations of the other set of pollutants, termed hazardous air pollutants (HAPs), are not limited nationally. The HAPs evaluated in this FDEIS include benzene, formaldehyde, 1,3-butadience, benzo(a)pyrene and other chemicals emitted from diesel fuel and/or exhaust.

33.2.2 Health Effects of Air Pollutants of Concern

33.2.2.1 Carbon Monoxide

CO is a colorless, odorless gas released during combustion of many substances, including gasoline, diesel fuel and home heating oil. CO is deadly at high concentrations in air; hence, the need for CO detectors in homes where malfunctioning furnaces or boilers may cause a build up of the gas. At lower concentrations, CO causes fatigue and confusion. CO exerts toxicity by binding to the blood's hemoglobin, thereby creating carboxyhemoglobin (COHb) and displacing oxygen. COHb is a very stable molecule and, thus, the body's tissues become starved for oxygen when COHb levels accumulate. For example, a COHb concentration of 65% or more may be lethal, a concentration of 30% may cause severe headache and a concentration of 10% may cause slight headache and fatigue.[1] USEPA's review of CO toxicity at ambient concentrations determined that the most sensitive effects of exposure are on the cardiovascular system in persons with pre-existing heart disease, namely a quicker onset of angina and

[1] Clayton, G. and Clayton, F., editors. *Patty's Industrial Hygiene and Toxicology, fourth edition, Volume II*. John Wiley and Sons: New York, NY. 1994.

electrocardiogram (EKG) changes.[2] The NAAQS for CO (9 ppm for an 8-hour average and 35 ppm for a 1-hour average) are set to keep COHb levels in the blood low enough to reduce the risk of these cardiovascular effects. The City is in attainment for the CO air quality standards.

33.2.2.2 Nitrogen Dioxide

NO_2 is one of several related oxides of nitrogen, collectively termed "NO_X," found in ambient air. USEPA decided to issue a NAAQS only for NO_2, however, as it is found at the highest concentrations. NO_2 is an irritant gas, and it is regulated in air based on its potential effects on respiratory health of children (who might be made more vulnerable to respiratory illnesses) and on pulmonary function in asthmatics and persons with chronic obstructive pulmonary disease.[3] Long-term exposure to NO_2 at much higher concentrations than are found in ambient air has produced emphysema-like changes in laboratory rodents. As of 1996, when the USEPA last reviewed the NAAQS for NO_2, (53 ppb as an annual average), the entire country was in compliance with the standard.[4]

33.2.2.3 Sulfur Dioxide

Analogous to NO_2, SO_2 is one of several oxides of sulfur, collectively termed SO_X, and is the one most present in ambient air. It is created primarily by combustion of fossil fuels and processing of ores. Air quality standards for SO_2 are intended to protect against possible mortality, aggravation of bronchitis, decreased lung function in asthmatics and/or children, and reduced capacity to respond to respiratory infections.[5] The standards are 30 ppb as an annual average and 140 ppb as a 24-hour average. The City is in compliance with the SO_2 NAAQS.

33.2.2.4 Particulate Matter

33.2.2.4.1 PM_{10} and $PM_{2.5}$

Unlike the other criteria pollutants, which are specific chemical molecules, PM refers to any of thousands of different solid particles or liquid droplets suspended in outdoor air. Various forms of airborne PM differ with respect to (1) size (with diameters ranging from about 0.001 to 100 microns [μm]), shape and surface characteristics; (2) water solubility and pulmonary persistence; (3) chemical composition, pH, and metal content; and (4) biologic and immunologic properties and potencies. Generally, airborne concentrations of PM are expressed as the total mass of all material (often smaller than a specified aerodynamic diameter) per volume of air (in units of micrograms per cubic meter, $\mu g/m^3$). Thus, PM_{10} refers to all particles and aerosols with diameters less than 10 μm, and $PM_{2.5}$ to all particles with diameters less than 2.5 μm.

In practice, $PM_{2.5}$ and PM_{10} are defined as all material collected and weighed using specific types of equipment and under specified conditions.[6] When samples of ambient air are collected and analyzed for purposes of NAAQS compliance, the specific physical, chemical and biological forms of PM are not determined.

Many observational, epidemiologic studies have reported weakly positive statistical associations between rates of mortality or morbidity in populations and moderate concentrations of total $PM_{2.5}$ and PM_{10} measured in ambient air near those populations.[7] These observational studies include cross-sectional studies[8] in which mortality in various metropolitan areas is associated

with ambient concentrations of PM in those areas, and time-series studies[9] in which daily mortality within a metropolitan area is associated with concurrent or lagged daily fluctuations in ambient PM concentrations. Similarly, some studies have correlated increased rates of hospital admissions for respiratory conditions, small decreases in lung function in children with or without asthma, and absences from school with changes in PM concentrations.[10] USEPA[11] stated that these statistical associations reflect cause and effect, and has established the PM NAAQS primarily on the basis of the associations.

For purposes of public health assessment, however, it is important to recognize that different forms of PM may pose markedly different risks to health. Airborne PM includes countless naturally occurring materials, such as thousands of species of viruses and bacteria, various molds and pollen fragments (from thousands of species of flowering plants), fragments of innumerable species of insects and bits of different types of sand and soil. Clearly, small concentrations of some forms of natural PM, such as tuberculosis bacillus, can be deadly, while other forms, such as suspended sea salt, are benign.

Pollution-derived PM is also a complicated mixture. Standard characterizations separate such PM into five categories – sulfates, nitrates, organic compounds, elemental carbon and "other."[12] Such characterizations belie substantial, underlying heterogeneity, however. For example, members of the "organic compounds" class of PM number in the thousands and are quite diverse in their structures and expected toxicities. Even members of a category as seemingly simple as the first (sulfates) differ in important features. Thus, most ambient sulfates (such as ammonium sulfate and sodium sulfate) are water-soluble, but a few (such as calcium sulfate) are not. The

[12] USEPA (1996).

solubility or insolubility of aerosols and particles is expected to be an important determinant of toxicity, as it is for airborne fibers.[13] Solubility aside, sulfate salts range widely in their effects on respiratory function and structure.[14]

Most of the PM emitted by the activities related to the Proposed Plan Facilities would be from diesel engine exhaust and, hence, in the form of DPM. This mixture of gases and particles has been unusually well-studied.

33.2.2.4.2 DPM

DPM consists primarily of soot (carbon particles) within which various organic compounds are absorbed.[15] Diesel particles are generally small enough to be counted as $PM_{2.5}$ and are emitted by diesel engines of all kinds, although different engines, loads, specific fuels and other factors result in DPM mixtures with varying chemical constituents. DPM is not a criteria pollutant, so there are no NAAQS for it, nor is it generally considered an HAP. Therefore, DPM impacts have not been quantitatively assessed in this FDEIS except as a component of $PM_{2.5}$.

The toxic effects of diesel engine exhaust – both DPM and the gases and vapors that comprise the bulk of the exhaust – have been evaluated in numerous acute and chronic studies. Laboratory animals are believed to be good models for humans with regard to their responses to DPM,[16] and some 17 chronic studies involving laboratory rats, mice, hamsters, guinea pigs, cats and monkeys have evaluated the respiratory and systemic effects of exposure to DPM.[17] Chronic exposures to large concentrations of DPM (in the presence of diesel engine exhaust gases) cause inflammation, fibrosis and functional changes in the respiratory system, and very large

concentrations cause premature death. The lowest observed adverse effect levels (LOAELs) and no observed adverse effect levels (NOAELs) for these effects are considerably in excess of ambient concentrations. Thus, the experimentally-derived LOAELs for pulmonary changes in rats are in the range of 800 to 3,000 μg DPM/m^3, while the levels at which these effects are not observed – that is, the NOAELs – range from about 100 to 500 μg DPM/m^3.[18] With regard to premature mortality due to lifetime exposure to DPM, the LOAELs are about 6,000 μg DPM/m^3 in rats[19] and 4,000 μg DPM/m^3 in mice[20], although other rodents tested in other laboratories showed no decreased survival even given lifetime exposures of some 7,000 μg DPM/m^3.[21] For purposes of public health assessment, application of typical safety factors to these data from laboratory rodents suggests that current ambient concentrations of diesel engine exhaust in New York State are not harmful. Nonetheless, current and proposed regulations that will substantially reduce the sulfur content of diesel fuel and will substantially control emissions of several pollutants from diesel equipment and vehicles are welcome improvements that will provide additional margins of safety and help to reduce regional haze.

Laboratory rats, though not necessarily other test species, develop lung tumors during lifetime exposures to very high concentrations of DPM. As noted by USEPA[22], the mechanism by which these tumors arise involves "particle overload and consequent persistent inflammation and cell proliferation, [which] supports a nonlinear mode of action for lung cancer in the rat (ILSI, 2000). The nonlinear cancer response is further characterized as occurring at relatively high exposures of diesel exhaust (>3500 μg DPM/m^3), which is far beyond the range of environmental levels. The rat tumor occurrences, thus, are not particularly influential in judging the hazards at

environmental levels of exposure." USEPA also notes that "while the weight of evidence indicates that DE [diesel engine exhaust] has the potential to pose a lung cancer hazard to humans at anticipated levels of environmental exposure, as shown by occupational epidemiology studies, a confident dose-response relationship based on occupational exposure levels is currently lacking." The National Toxicology Program classifies DPM as "reasonably anticipated to be a human carcinogen," but notes that the increased risk of lung cancer seen in epidemiologic studies of workers "cannot always be clearly ascribed to diesel exhaust exposure . . . [and] most studies used inadequate measures of exposure."[23]

Current ambient concentrations of DPM typically average about 1 to 10 μg DPM/m^3. The Proposed Plan Facilities analyzed would add less than 1 μg DPM/m^3, measured as $PM_{2.5}$, on an annual basis (see Section 33.2.3).

33.2.2.5 HAPs

Acetaldehyde, a widely used industrial chemical, is a component of vehicle exhausts and tobacco smoke, and is a metabolite of ethanol. That is, everyone who consumes alcohol generates acetaldehyde. At high concentrations of vapor, acetaldehyde is irritating to the respiratory tract. In animal studies, the most sensitive indicator of acetaldehyde toxicity is damage to the olfactory epithelium (i.e., part of the lining of the nasal passages). At higher exposure levels, animals also lost weight, showed signs of irritation and showed altered activity of certain immune cells in the lungs. USEPA considers acetaldehyde a "B2," or "probable" human carcinogen. No reliable human data indicate that acetaldehyde is carcinogenic, but animals forced to breathe acetaldehyde for at least one year developed nasal and laryngeal tumors. For non-cancer effects, USEPA has derived a concentration of acetaldehyde of 9 μg/m^3 (16 ppb) as a safe, long-term limit for the general population.[24] Recommended occupational limits for the workplace are 14 mg/m^3 (25 ppm) or less, as a ceiling concentration.[25]

[25] American Conference of Governmental Industrial Hygienists (ACGIH). Documentation of the Threshold Limit Values and Biological Exposure Indices, seventh edition and supplement. ACGIH: Cincinnati, OH. 2002; National

Acrolein is a flammable, volatile liquid. It is emitted in vapor form in fuel exhaust and cigarette smoke, and is found in very low levels in some foods and beverages. Because acrolein is chemically reactive, its toxicity in experimental animal studies has usually been exerted at the point of entry, for example, in the nasal passages and respiratory tract if exposure is by inhalation, or in the stomach if exposure is oral. Severity of lesions at these sites depends on the dose of acrolein. At the higher concentrations tested in such studies, acrolein increased the mortality rate of animals. USEPA does not consider acrolein a carcinogen because there is no useful human data on the subject, and cancer studies in animals have been deficient in design and/or conduct. USEPA has derived a concentration of acrolein of 0.02 $\mu g/m^3$ (0.008 ppb) as a safe, long-term limit for the general population.[26] The recommended occupational limit for the workplace is 0.25 mg/m^3 (0.1 ppm) as a ceiling concentration according to one group and an 8-hour average concentration according to another.[27]

Benzene, a volatile organic compound present in fuels and emitted in fuel exhaust, is one of the two known human carcinogens included in the HAPs analysis. Benzene is ubiquitous in outdoor and indoor air, occurs in cigarette smoke and is used in many heavy and light industrial processes. The damaging effects of exposure to high airborne concentrations of benzene have been known for about a century — high exposures cause severe blood diseases, such as aplastic anemia, and can be rapidly fatal. Lower airborne concentrations in workplaces (still much higher than those in outdoor air) have caused many cases of leukemia, principally acute myelogenous leukemia (AML).[28] The maximum allowable concentration of benzene in workplace air is now 1 ppm to guard against cancer risk and the risk of non-cancer blood diseases. There is no demonstrable adverse effect of ppb levels (or less) of benzene in air, such as occurs around the U.S., although cancer remains a theoretical concern.

The gas 1,3-butadiene is manufactured for various uses, including production of styrene-butadiene rubber. It is also present in vehicle exhausts. In long-term animal studies, the most sensitive indicator of 1,3-butadiene toxicity was atrophy of ovaries in female mice exposed

[27] ACGIH (2002); NIOSH (2003).

by inhalation to 6.25 ppm for up to two years. Testicular atrophy occurred in male mice exposed to even higher concentrations of 1,3-butadiene. In reproductive studies, the most sensitive indicator of 1,3-butadiene toxicity was decreased weight of mouse fetuses in dams exposed by inhalation during pregnancy. USEPA considers 1,3-butadiene to be carcinogenic to humans by inhalation based both on animal studies (in which various tumor types were produced) and on epidemiologic studies of workers in industries producing or using the chemical. The epidemiologic studies have found increased rates of lymphohematopoietic cancers (cancers of the blood and lymph systems).[29] For non-cancer effects, USEPA has derived a concentration of 1,3-butadiene of 2 $\mu g/m^3$ (0.9 ppb) as a safe, long-term limit for the general population, even for a lifetime. Recommended occupational limits in workplaces are 2 ppm (4.4 mg/m^3) or less averaged over eight hours.[30]

The toxicity of formaldehyde is qualitatively similar to that of a related chemical, acetaldehyde (discussed above). An irritating vapor, formaldehyde causes similar irritative symptoms and lesions in the respiratory tract.[31] It is considered by USEPA to be more likely than acetaldehyde to be a human carcinogen ("B1" rather than "B2") on the basis of several epidemiologic studies. Increased incidences of or death from lung, nasopharyngeal and buccal tumors in people with occupational exposure to formaldehyde were observed in some of these studies. Overall, however, USEPA characterizes the human evidence as "limited." Squamous cell carcinomas of the nasal cavities occurred in animals inhaling formaldehyde in several long-term experiments.[32] Recommended limits for formaldehyde exposure in workplaces are 0.3 ppm or less, as a ceiling concentration.[33]

Several of the HAPs evaluated in this FDEIS – benzo(a)pyrene, anthracene, benzo(a)anthracene, chrysene, dibenz(a,h)anthracene, phenanthrene and pyrene – are collectively known as polycyclic aromatic hydrocarbons (PAHs). PAHs are typically produced through combustion, whether of diesel fuel, wood, cigarettes or other organic matter. While no single PAH has been

shown to cause cancer in humans, they are collectively suspect because of their presence in cigarette smoke, soot and other materials known to be carcinogenic to people. In addition, some specific PAHs can cause cancer in laboratory animals. According to USEPA's traditional classification of chemicals in terms of carcinogenicity, benzo(a)pyrene, benzo(a)anthracene, chrysene and dibenz(a,h)anthracene are termed "B2" or "probable" human carcinogens, and anthracene, phenanthrene and pyrene are "D" or "unclassifiable."[34] However, NYSDEC or USEPA have made an estimate of cancer risk for only one of the PAHs evaluated in this FDEIS, that being benzo(a)pyrene.

Naphthalene is an odorous solid chemical used in certain types of mothballs and toilet bowl cleaners, and is emitted in fuel exhaust. Humans exposed to naphthalene vapors have developed headache, nausea, loss of appetite, acute hemolysis and lens opacities.[35] In animal studies, the more serious of these effects have not been observed following vapor exposure. Rather, in laboratory rodents, naphthalene vapors produce inflammation and regeneration in the respiratory epithelium. Unlike similar effects produced by acetaldehyde and formaldehyde, naphthalene's toxicity is probably not due to direct chemical attack on tissues; rather, it appears to require metabolism. There is no information about a risk of cancer in humans from naphthalene exposure, and USEPA states that the carcinogenic potential "cannot be determined" at this time. USEPA has derived a concentration of naphthalene of 3 $\mu g/m^3$ (0.6 ppb) as a safe, long-term limit for the general population.[36] The recommended occupational limit in the workplace is 50 mg/m^3 (10 ppm), averaged over eight hours.[37]

Propylene, a gas, is present in vehicle exhausts. At high concentrations (more than 20,000 ppm), propylene is explosive. Otherwise, propylene has no significant toxicity except as a simple asphyxiant when it is so concentrated that it reduces the amount of oxygen available for inhalation.

[37] ACGIH (2002); NIOSH (2003).

Toluene is a common solvent used in many industries and found in many consumer products, as well as in fuels and exhaust. Inhalation of large concentrations of toluene vapors is well known to affect the human central nervous system. In the case of people who abusively inhale toluene-containing products and are exposed to thousands of ppm vapor, significant brain damage has occurred. However, at lower levels found in many occupational settings, effects are either subtle (revealed by neuropsychologic testing) or transient (such as headache, dizziness and irritation). Abusive inhalation of toluene vapors has also been linked to birth defects. Toluene is not classified as a carcinogen (known, probable or possible) by USEPA. USEPA has derived a concentration of toluene of 400 $\mu g/m^3$ (105 ppb) as a safe, long-term limit for the general population.[38] Recommended occupational limits in the workplace range from 190 to 375 mg/m^3 (50 to 100 ppm) averaged over eight hours.[39]

Xylene is an aromatic solvent related to benzene and toluene and, like them, is found in fuels, fuel exhausts, and various commercial and industrial products. High concentrations of xylene in air (200 ppm or more) can cause watering eyes, sore throat, headache and mild nausea. In several studies of xylene exposure in rats, neurological effects were found to be the most sensitive indicator of possible toxicity. Rats repeatedly exposed to xylene vapors made fewer spontaneous movements than did unexposed animals, were unable to maintain their footing on rotating rods and performed worse in mazes. Xylene caused developmental toxicity in offspring of rats and rabbits exposed to vapors during pregnancy, but only at concentrations higher than those that cause the neurological effects. Xylene is not considered a carcinogen. USEPA has derived a concentration of xylene of 100 $\mu g/m^3$ (23 ppb) as a safe, long-term limit for the general population.[40] The recommended occupational limit in workplaces is 435 mg/m^3 (100 ppm), averaged over eight hours.[41]

33.2.3 Public Health Assessment of Air Pollutants of Concern

In this FEIS, the potential health impacts of the two sets of pollutants – criteria pollutants and HAPs – are assessed differently. In addition to having established NAAQS for the criteria air pollutants, USEPA has set significant impact levels (SILs) for CO, NO_2, SO_2 and PM_{10} For these criteria pollutants, estimated Proposed Plan Facility-related increases in concentrations can be added to the existing (background) concentrations and the total compared to the NAAQS (see table entitled "Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emission" of Chapters 4 through 16). The regulatory program for $PM_{2.5}$ is still under development and SILs have not yet been set. NYCDEP has proposed a draft policy for the assessment of $PM_{2.5}$ impacts; however, and NYSDEC has issued a final policy. In particular, the draft NYSDEC policy is that a "project . . .[with $PM_{2.5}$] air quality impacts equal to or less than two percent of the annual NAAQS standard of 15 $\mu g/m^3$ (0.3 $\mu g/m^3$) and equal to or less than 5 $\mu g/m^3$ on a 24-hour basis, would be considered to have insignificant impacts."[42] Similarly, NYCDEP's interim guidance value indicates that facility-related impacts on the nearest neighborhood no larger than 0.1 $\mu g/m^3$ assessed annually are to be considered insignificant. These all are referred to as interim screening threshold values (STVs) that are to be used as screening thresholds in impact evaluations until USEPA establishes national SILs. For a HAPs analysis, estimated increases are compared to benchmark concentrations established by NYSDEC that protect against cancer and/or non-cancer health risks.

33.2.3.1 Criteria Pollutants

Section 3.17 describes the air quality modeling methodologies used to estimate increases in airborne concentrations of criteria pollutants stemming from on-site activities (e.g., operation of heavy machinery) and off-site activities (e.g., emissions from truck traffic at critical intersections). For on-site analyses, sources of criteria pollutant emissions, such as collection vehicles, front-end loaders and tugboats, were catalogued for each Proposed Plan facility. The emission rates of criteria pollutants from each on-site source were combined in a USEPA-approved computer model with meteorological data (e.g., describing wind speed and wind directions) and maps of local land use to predict the increase in ambient pollutant

[42] Assessing and Mitigating Impacts of Fine Particulate Matter Emissions" undated. NYSDEC's Commissioner's Policy Proposed Draft available at: http://www.dec.state.ny.us/website/dar/drpm25.html.

concentrations at various off-site locations, called receptors. The time scale over which pollutant increments were calculated was dictated by the NAAQS for each pollutant. For example, 1-hour and 8-hour periods were evaluated for CO, while 24-hour and year-long periods were considered for PM_{10}.

The receptors with the greatest estimated pollutant increments due to on-site activities were then identified for each Proposed Plan Facility. Except for $PM_{2.5}$, these maximum increments were added to the existing (background) concentrations of criteria pollutants and the totals were compared to the appropriate NAAQS. The $PM_{2.5}$ increments were compared to the draft NYCDEP and final NYSDEC interim STVs. The summary tables of on-site results for each Proposed Plan Facility analyzed are presented in the table entitled "Highest Estimated Concentrations of the Criteria Pollutants from On-Site Emission" in Chapters 4 through 16, , as applicable.

As the tables demonstrate, in no case do the predicted total concentrations of criteria pollutants from on-site operations at the Proposed Plan Facilities analyzed exceed the NAAQS (for CO, NO_2, SO_2 and PM_{10}), and in no case do the maximum increments for $PM_{2.5}$ exceed the NYCDEP and NYSDEC screening thresholds proposed or established as the interim STVs. In the case of CO, NO_2, SO_2 and PM_{10}, the total worst-case pollutant concentrations due to on-site activities are well below all health-based limits. Because the USEPA establishes these limits with an ample margin of safety, no adverse effects are expected from on-site emissions of CO, NO_2, SO_2 and PM_{10}. In the case of $PM_{2.5}$, the increments are deemed acceptably small, according to the draft or final policies of NYCDEP and NYSDEC.

Similar analyses were performed for traffic-generated criteria pollutants at critical intersections, focusing on CO, PM_{10} and $PM_{2.5}$. The summary tables of off-site results for each Proposed Plan Facility analyzed are presented in the table entitled, "Maximum Estimated Pollutant Concentrations Near Selected Roadway Intersections" in Chapters 4 through 16, as applicable. Air quality impacts were evaluated for at least two intersections near each Proposed Plan Facility analyzed. In all instances, the anticipated total concentrations of CO and PM_{10} (traffic plus background) at these intersections are less than the applicable NAAQS. For all the Proposed Plan Facilities analyzed, then, no adverse health consequences are expected from traffic-related CO or PM_{10} emissions, because the expected concentrations are below the health-based limits.

For the $PM_{2.5}$ analyses, the incremental concentrations contributed by traffic related to the Proposed Plan Facilities were modeled, but not added to existing background levels. Rather, the increments were compared to the STVs described above. At all critical intersections, incremental concentrations of $PM_{2.5}$ are less than or equal to the STV values. In addition, the $PM_{2.5}$ contributions at these same intersections from the on-site operations of the Proposed Plan Facilities analyzed were evaluated. On-site operations from the Proposed Plan Facilities analyzed are not expected to cause exceedances of $PM_{2.5}$ STVs at any intersection. Furthermore, the combined $PM_{2.5}$ impacts at critical intersections from traffic and Proposed Plan Facility operations analyzed also do not exceed the STVs.

33.2.3.2 HAPs

The method used to estimate increases in airborne concentrations of HAPs is similar to that used to assess the impacts of on-site operations on off-site concentrations of criteria pollutants, except that emissions rates of the various HAPs from the different types of equipment were evaluated. In addition, only two time periods were used, a 1-hour average and an annual average. Then, where toxicologic benchmarks have been established by NYSDEC, they were compared to the predicted increases in HAPs concentrations over the 1-hour and annual averaging periods. NYSDEC's method of developing these benchmark concentrations ensures that the most health-protective values are selected from the range of possibilities, including the USEPA reference concentrations noted in the HAPs discussions above, and takes into account the carcinogenic and non-carcinogenic effects discussed in Section 33.2.2.5 above.[43] Note that cancer risk is calculated for both known and probable human carcinogens. The NYSDEC toxicity benchmarks are presented in Table 33.2-1.

[43] New York State Department of Environmental Conservation. (2000). DAR-1 AGC/SGC Tables. Division of Air Resources, Bureau of Stationary Sources.

Table 33.2-1
NYSDEC Toxicity Benchmarks For HAPs

HAP	NYSDEC Short-Term (1-hr) Guideline Concentration ($\mu g/m^3$)	NYSDEC Long-Term (Annual) Guideline Concentration ($\mu g/m^3$)	NYSDEC Unit Cancer Risk ($m^3/\mu g$)
Known or probable carcinogens			
Acetaldehyde	4,500	0.450	2.2×10^{-6}
Benzene	1,300	0.130	8.3×10^{-6}
Benzo(a)pyrene	NA	0.002	1.7×10^{-3}
1,3-Butadiene	NA	0.0036	2.8×10^{-4}
Formaldehyde	30	0.060	1.3×10^{-5}
Non-carcinogens			
Propylene	NA	3000	NA
Acrolein	0.19	0.020	NA
Anthracene	NA	0.020	NA
Benzo(a)anthracene	NA	0.020	NA
Chrysene	NA	0.020	NA
Dibenz(a,h)anthracene	NA	0.020	NA
Naphthalene	7,900	3.0	NA
Phenanthrene	NA	0.020	NA
Pyrene	NA	0.020	NA
Toluene	37,000	400	NA
Xylene	4,300	700	NA

Notes:

NA = Not applicable.

At all Proposed Plan Facilities analyzed, all 1-hour increments of HAPs are substantially below corresponding NYSDEC SGCs; similarly, all annual-average increments are substantially below AGCs. More importantly, in using the hazard index approach to sum the impacts of all HAPs, this study finds that the total hazard index at each Proposed Plan Facility is acceptable (less than 1.0) for non-cancer effects over both short-term and annual periods. (The site-specific HAPs results are presented in the table entitled "Highest Estimated Concentrations for the Criteria Pollutants from On-Site Emissions" in Chapters 4 through 16, as applicable.) In addition, the total (multi-pollutant) increase in estimated cancer risk (which assumes 70 years of continuous exposure) from exposure to carcinogenic HAPs is below the allowable limit at each Proposed Plan Facility. This HAPs analysis indicates, thus, that emissions of the chemicals studied from the on-site operations at all Proposed Plan Facilities analyzed are very unlikely to adversely affect health.

33.3 Public Health Evaluation of Noise

The major health concern posed by noise is hearing impairment, which can develop, usually over many years, following either continuous loud noise or brief exposures to extremely loud noise. (There are other causes of hearing impairment and loss, of course, such as injury, congenital defect and age.) Loudness of noise is measured in units called A-weighted decibels, or dBA, and the noise analysis methodology described in Section 3.19 quantifies facility-related noise in this unit. Long-term exposure to noise averaging 70 dBA or less is not thought to pose a risk of hearing impairment.[44]

Other health conditions that have been researched in relation to noise exposure include hypertension, heart disease, exacerbation of mental disorders and impairment of performance on cognitive tasks, such as reading and problem solving. Other adverse effects of noise include sleep disturbance, annoyance and inhibition of spoken communication. Production of such effects by noise is highly dependent on the individual and in some cases is not well understood. Adaptation to noise, even loud noise, can often occur. An international group of reviewers assessed as "sufficient" the evidence of a connection between noise and hearing impairment, hypertension, ischemic heart disease, annoyance and sleep disturbance.[45] The reviewers concluded that risk of hearing impairment, hypertension and ischemic heart disease was increased at average noise levels of 70 dBA or more.

The chief criterion by which noise impacts were assessed near the Proposed Plan Facility sites analyzed was whether on-site operations at peak levels were likely to increase the total noise at nearby receptors to: (1) a noise level greater than 65 dBA during daytime hours; (2) if the Future No-Build Condition noise level is equal to or greater than 62 dBA $L_{eq(1)}$ or if the analysis period is during the nighttime, the threshold for significant impacts from the proposed project will be an increase of by 3 dBA or more during what is otherwise the quietest hour of the day or night. This procedure determines the greatest (i.e., most noticeable) impact on noise levels At one Proposed Plan Facility, Hamilton Avenue Converted MTS, no receptors were located within or

[44] Berglund, B., Lindvall, T., and Schwela, D., editors. Guidelines for Community Noise. World Health Organization: Geneva, Switzerland. 1999.

near the 55 dBA contour of facility related noise, so no further assessment was required. At ~~two~~ three of the Proposed Plan Facilities, Southwest Brooklyn Converted MTS, ~~and~~ East 91st Street Converted MTS, and North Shore Converted MTS an on-site noise analysis was performed and the total noise or the incremental noise was estimated to ~~exceed~~ be below the ~~3 dBA~~ noise criteria described above ~~limit, so mitigation measures would be required~~. At three of the Proposed Plan Facilities, Southwest Brooklyn Converted MTS, Hamilton Avenue Converted MTS, and North Shore Converted MTS, ~~none of the Proposed Plan Facilities was~~ the average noise level, including the contribution from on-site operations, is ~~likely to~~ not predicted to exceed Zoning Code Performance Standards at the facility boundary. At the East 91st Street Converted MTS, the average noise level, including the contribution from on-site operations, is likely to exceed Zoning Code Performance Standards at the facility boundary. However, background noise levels are between 4.9 dB and 42.8 dB higher than the required standard. At these levels, the theoretical exceedance at the boundary cannot be perceived and, therefore, no impact is predicted. At ~~three~~ three of the Proposed Plan Facilities, Southwest Brooklyn Converted MTS, East 91st Street Converted MTS, and North Shore Converted MTS, ~~Proposed Plan Facilities – Southwest Brooklyn Converted MTS, North Shore Converted MTS and Hamilton Avenue Converted MTS –~~ the average noise level, including the contribution from on-site operations, is ~~was not likely to~~ not predicted to exceed the 70 dBA at the facility boundary. At Hamilton Avenue Converted MTS, the average noise level, including the contribution from on-site operations, is predicted to exceed the 70 dBA at the facility boundary. However, 24-hour background noise levels monitored at the site boundary are at levels between 81.0 dBA and 86.0 dBA. At these levels, the theoretical exceedance of the noise standard cannot be perceived at the property boundary and, therefore no impact is predicted. ~~At one Proposed Plan Facility, East 91st Street Converted MTS, the average noise level, including the contribution from on-site operations, would likely exceed 70 dBA at the facility boundary, so mitigations measures would be required.~~ With mitigation measures in place, on-site operations would contribute only minor increases in overall noise levels. Therefore, no adverse health impact from on-site noise from the Proposed Plan Facilities is anticipated.

[45] Passchier-Vermeer, W. and Passchier, W. (2000). "Noise Exposure and Public Health." Environ. Health Perspect. 108 (Suppl. 1):123-131.

The potential for adverse levels of noise due to facility-related traffic through critical intersections was also assessed for each Proposed Plan Facility analyzed. The potential for off-site noise impacts from deliveries of commercial waste to the Converted MTSs exists at certain hours and Converted MTSs between 8:00 p.m. and 8:00 a.m. The impacts are avoided by restricting the deliveries of commercial waste past specific sensitive receptors along the delivery routes during certain hours at the Converted MTSs. The limitations on specific hours, locations and Converted MTSs required to prevent the potential for off-site noise impacts of collection vehicles delivering waste to these facilities are included in the summary tables for the Commercial Waste Management Study in Appendix D to this FDEIS. For the remaining Proposed Plan Facilities analyzed, off-site noise from the DSNY and other agency collection vehicles would not cause an increase in noise levels above 3dBA, with some delivery restrictions. The delivery restrictions of DSNY collection vehicles for the Proposed Plan Facilities are provided in the noise sections of the site specific chapters. Therefore, no adverse health impacts from off-site noise is anticipated.

33.4 Public Health Evaluation of Odors

Non-living organic matter, such as food waste, is subject to bacterial degradation, especially if wet and/or exposed to air. This decay inevitably produces odors. While the potential for odorous emissions from the Proposed Plan Facilities are evaluated here primarily because of the nuisance and annoyance odors can cause, it is also the case that some odors, when sufficiently intense, can adversely affect health. The quality of an odor can be so obnoxious as to cause nausea, for instance. However, at sufficient concentrations, odorous chemicals can also irritate nerve endings in the respiratory tract, mouth or eyes and cause changes in breathing patterns, sneezing, swelling of nasal membranes, tearing of the eyes and other effects.[46] In most people, these effects disappear fairly soon after the odor dissipates, but in sensitive persons, such as those with asthma, the effects may be longer lasting. Of course, chemicals may adversely affect health independent of their odorous and irritating properties.

Transfer stations, such as the Proposed Plan Facilities, must incorporate design and operational features that would reduce both the potential for odors to develop and the potential for those odors to reach neighboring properties. Maintaining negative air pressure within the facility to prevent escape of odors, installing odor neutralizing systems to treat indoor air before it is exhausted from the waste processing building through vents, and practicing good housekeeping are three such features; these and other features are discussed in Section 3.18. In addition, the potential for noxious odors to reach receptors near each Proposed Plan Facility analyzed was examined in Section 16 of Chapters 4 through 16. For each Proposed Plan Facility analyzed, the analysis suggested that emissions would not pose a risk of detectable, let alone obnoxious, odors at the property boundary or nearby receptors. This being the case, the likelihood of chemical irritative effects is also small, and no adverse odor impacts are expected.

[46] Schiffman, S., Walker, J., Dalton, D., *et al.* (2000). "Potential Health Effects of Odor from Animal Operations, Wastewater Treatment, and Recycling of Byproducts." J. Agromed. 7(1):7-81.

33.5 Vermin Control Measures

Procedures to control vermin, such as rats and insects, would be or, in the case of existing facilities, are incorporated into the operating permit of each Proposed Plan Facility. Licensed exterminators would service each Converted MTS monthly. Exterminating logs kept at the Converted MTSs would provide documentation of their activities. The exterminators would evaluate potential pest and vector problems and apply bait and/or spray throughout the refuse handling area, the tipping floor, the lunch and locker rooms and administrative areas. Standing water in barges not being used would be treated with larvicide and pesticide spray when necessary. During normal operations, exterminating jobs are undertaken as part of a preventive maintenance cycle. Should additional emergency service be needed, additional visits by the exterminators would be made within two to three days. An inspection would then be conducted at the location to determine if baiting and spraying are required. If droppings were present in an area or areas, those areas would be baited. The NYSDEC and DSNY issue operating permits to the existing Proposed Plan Facilities that require procedures to control vermin at these sites. The effectiveness of these procedures is evaluated during facility inspections.

33.6 Public Health Concerns of Host Communities

33.6.1 Introduction

Asthma, especially among children, is a significant medical problem. Parents and public health officials have expressed concern that new industrial facilities might cause or exacerbate asthma either directly, due to emissions from industrial operations, for example, or indirectly, due to increases in vehicular traffic and emissions.

33.6.2 Traffic and Respiratory Health

A search of the scientific literature has not identified studies of the effects of municipal solid waste transfer stations on public health. However, during the last decade, scientists have been studying possible links between respiratory diseases or symptoms, such as cough, asthma and bronchitis, and levels of traffic nearby. Because the Proposed Plan Facilities would require that all solid waste be brought to them by truck, this "traffic literature" is relevant to the public health analysis.

The studies of traffic and respiratory health pertain to children[47] and occasionally to adults.[48] They were performed mostly outside the U.S.,[49] although two studies were performed recently in this country.[50] All of these studies are cross-sectional in design; that is, the respiratory health of the subjects and the levels of traffic nearby were assessed at the same time. Traffic studies that examine diesel traffic in particular are most relevant to this evaluation because the collection vehicles that would transport solid waste to the Proposed Plan Facilities are diesel-powered, as is the equipment used in waste processing operations, such as front-end loaders and tugboats. About half of the studies identified quantified diesel traffic in some manner.[51] In most cases, the health endpoints, such as asthma or allergic rhinitis, were investigated by asking either children or their parents to complete questionnaires that inquired about symptoms or diagnoses of

respiratory illness that occurred either in the last year or at any time. Some investigations used medical databases containing information on hospital visits for asthma[52] or prescriptions for asthma medication,[53] or had children undergo pulmonary function tests or tests for skin sensitivities (an indicator of allergy).[54]

Various methods of gauging traffic flow were used, and while some distinguished between truck and car traffic or focused on car traffic, others did not distinguish between these kinds of vehicles.[55] Regardless, when children were studied, traffic flow was estimated near either the child's school or home. In some studies, children were asked to rate the level of truck traffic near their homes, while in others, investigators used traffic counts made by cities and towns on specific roads, maps of traffic flows, or distances from home or school to highways or to the nearest busy street. In half a dozen investigations, air pollutants were either measured in air near schools and homes and then correlated to traffic flows, or estimated using information on local traffic. Indoor concentrations of air pollutants were determined in only a few studies.[56]

Most traffic studies found associations between some indicator of traffic near a child's home or school and some indicator of respiratory disease; a few found no evidence of an association.[57] Studies that found positive associations, however, were not necessarily consistent, and increases in the risk of wheeze, rhinitis, asthma, etc. were usually fairly small. The apparent effect of nearby traffic on health was frequently stronger in girls than boys.[58]

Studies of particular interest are those conducted in the United States and those in which truck traffic was quantified in some manner. Lin and colleagues (2002) studied white children aged 0 to 14 in Erie County, NY (excluding Buffalo) who were hospitalized for asthma between January 1990 and December 1993. Characteristics of traffic on state routes near the homes of these children were compared to such characteristics for children who were hospitalized during the same period for gastrointestinal illnesses, falls or other non-traffic-related accidents. The characteristics considered included: (1) distance from the child's home to a major state route;

[57] Livingstone *et al.* (1996); Waldron *et al.* (1995); Wilkinson *et al.* (1999).

(2) vehicle miles traveled on major state routes within 200 meters or 500 meters of the home; or (3) the proportion of heavy trucks passing within 200 meters or 500 meters of the home on a major state route. In comparisons between the two groups of children, age, sex, poverty level and lower education (the last two determined at the census-tract level) were controlled. Distance of the home from the nearest major state route did not significantly differ for children hospitalized for asthma or for other reasons, nor did traffic density on routes within 500 meters of home. However, the odds ratio (OR)[59] for an asthma hospitalization was statistically significantly increased by the presence of heavy trucks passing within 200 meters of home (OR = 1.43), and for high overall traffic density within 200 meters of home (OR = 1.93).

Children 14 years of age or younger in San Diego County, California, were studied by English *et al.* (1999). Children admitted to hospitals for asthma were compared to other children hospitalized for reasons other than respiratory disease or cancer. Information on traffic flow on virtually all county roads was collected by the county itself and seems to have included only cars. The distance from each child's home to each street within a 550-meter radius was determined, as were the number of cars per day on each of those streets. In contrast to expectations, children hospitalized for asthma were less likely than other children to live nearer to streets with the highest traffic flows or to have higher traffic flows nearby. No difference was found between groups of children for the average traffic volume on all streets within 550 meters of home, nor for the traffic volume on the busiest nearby street. However, among children hospitalized for asthma, children with two or more hospital admissions tended to have higher traffic volumes at the nearest street than did children with only one admission. This tendency was much stronger for girls than boys.

Several other investigations, but not all, found statistically significantly increased ORs for asthma (measured, for example, as current asthma, asthma ever, doctor-diagnosed asthma or hospital admissions for asthma) and various measures of traffic near homes or schools. For example, Nicolai *et al.* (2003) found an OR of 1.8 for asthma among children exposed to the

[58] Brunekreef *et al.* (1997); Kramer *et al.* (2000); Oosterlee *et al.* (1996); van Vliet *et al.* (1997); Venn *et al.* (2001).
[59] The odds ratio (OR) compares the chance of having the disease of interest in a group with an exposure of interest to the chance of having the disease in a group without the exposure. If the odds are the same, meaning there is no effect of exposure on disease, then the OR is 1.0. An OR greater than 1.0 indicates an increased risk of disease, given exposure. An OR of 1.5, for example, indicates a 50% increase in risk.

highest of three categories (i.e., tertile) of car traffic counts and an OR of 1.8 for those exposed to the highest tertile of soot concentration. Buckeridge *et al.* (2002) measured an OR of 1.2 for respiratory hospital admissions per $\log_{10}$ vs. order of magnitude increase in modeled $PM_{2.5}$ concentrations. Wheezing was often assessed separately from asthma. For example, ORs for wheezing of about 5 were found for girls but not boys living near busy streets compared to children living along quiet streets, according to Oosterlee *et al.* (1996). Nicolai *et al.* found an odds ratio of 1.7 for wheezing among children exposed to the highest tertile of car traffic counts. An OR for wheezing of 15 was found by Kramer *et al.* (2000) in association with an increase in outdoor, urban NO_2 of 10 $\mu g/m^3$.

Overall, most studies of traffic and children's respiratory health find some associations between traffic characteristics (such as distance to roads, traffic volumes or truck traffic volumes) and respiratory morbidity measures (such as allergic rhinitis, wheezing or cough), although results can vary a good deal from study to study. However, some weaknesses in the literature must be mentioned.

First, an association, even if statistically significant, does not necessarily indicate cause and effect, particularly in a cross-sectional study. There may be factors, called confounders, that are both associated with residence or schooling near heavy (truck) traffic and that cause or aggravate disease. For example, it is possible that people living near busy streets or highways keep windows closed more than do people who live in quieter neighborhoods. Concentrations of indoor pollutants and agents that may contribute to respiratory illness, such as pet allergens or cigarette smoke, might therefore be higher in homes near heavily trafficked streets. Some of the traffic studies cited in this discussion (particularly those that studied hospitalization rates) were not able to gather information on personal exposure to indoor pollutants. There is also a general concern that differences in socioeconomic status, which likely varies with distance of residence to heavily traveled streets and is associated with health, may not have been adequately controlled.

Second, studies in which information on the exposure of interest and/or the health endpoints of interest are gathered in questionnaires can be vulnerable to bias. If people living near busy streets are already concerned about a potential effect of air pollution on health, they may unconsciously overestimate the level of traffic or severity of illness.

Third, most studies did not distinguish between truck traffic and car traffic. We cannot determine from these studies if associations between car traffic and illness would be relevant to concerns about truck traffic, given differences in the pollutants emitted.

Finally, as most studies were performed outside of the U.S., relevance to the U.S. situation depends on essential similarity between the types of fuels and engines used and pollutants emitted in these parts of the world.

33.6.3 Asthma Causes and Triggers

Asthma is a chronic, inflammatory disease of the small airways characterized by episodic and reversible restriction of breathing passages. Symptoms include difficulty in breathing (which may range from mild to life-threatening), wheezing and coughing. Asthmatic episodes may be triggered by specific substances, environmental conditions and stress, as is discussed below.

The prevalence of asthma and the amount of poorly controlled asthma requiring hospitalization among children has risen significantly in recent decades.[60] In the U.S., approximately five million children (7% of children under age 18) have asthma, and New York is thought to be the state with the second-largest number of affected children.[61] The rate of asthma is increasing most rapidly in children under age five.[62] Asthma exacerbations resulting in hospitalizations appear to be particularly frequent and severe among minority, inner-city children.[63] In the City in

[63] Lobach, K. (1996). Providing a "Medical Home." City Health Information: Childhood Asthma. New York City Department of Health.

particular, several groups of researchers have analyzed the distribution and factors affecting asthma hospitalizations and mortality.[64] Asthma prevalence in the City correlates strongly with socioeconomic status, and several factors link asthma with poverty. Factors that related to asthma risk in low-income areas were the number of occupants per apartment (related to bacterial and viral exposures), water leaks (related to fungal exposures), moist basements (related to fungal exposures), deteriorating building materials (related to fungal and mite exposures) and house dust exposure (containing insect parts, animal dander and rodent excreta). Recent statistics on childhood and adult asthma prevalence in the City boroughs are given in Section 33.6.4 below.

The dramatic increase in asthma among children has spurred scientists and clinicians to search for causes and risk factors for the disease, as well as therapies and interventions. The reasons for the rise in the prevalence and severity of asthma are not understood. Suspected factors include changing patterns of childhood illnesses, changing diet, increasing rates of obesity, changing exercise patterns, changing housing, increased vaccinations against childhood respiratory disease, increased survival of very low birth weight babies and increased exposure to indoor-air allergens. Current hypotheses tend to focus on three areas: (1) increases in individual sensitivity (possibly due to reduced respiratory infections); (2) increases in exposure to allergens (due to changes in ambient air pollution and/or indoor air quality); and (3) increases in airway inflammation of sensitized individuals (due to factors such as viral infections). No single factor is likely to explain the increased rates of asthma, however, and various factors would dominate in specific areas, homes and individuals.

In theory, one can distinguish between "causes" and "triggers" of asthma. Causes would be those factors that make a person susceptible to asthmatic attacks in the first place, while triggers would be those factors that elicit asthmatic symptoms at a particular time. Triggers are more easily studied, but may not be the underlying causes of the disease. For example, although a genetic predisposition to allergies is an important risk factor for developing asthma, there may have been no real increase in the number of genetically susceptible children, but rather a growth

[64] Carr, W., Zeitel, L., and Weiss, K. (1992). Variations in Asthma Hospitalization and Deaths in New York City. *Am J Public Health* 82:59-65. de Palo, V.A., Mayo, P.H., Friedman, P., and Rosen, M.J. (1994). Demographic Influences on Asthma Hospital Admission Rates in New York City. *Chest 106*:447-451.Claudio, L., Tulton, L.,

in the prevalence of factors that promote asthma development or trigger an attack. For a child suffering from asthma, however, identification and elimination of triggering factors is of greatest practical importance.

Allergens in the indoor environment are definitely important triggers of asthma in the United States. Organic materials that cause the immune system to overreact, such as cockroach antigen, dust mite antigens, molds, pet and rodent dander and urine, are the principal triggers of asthma attacks in children. Some of these antigens are probably more common in poor quality housing, which could explain, in part, why poor children suffer high rates of asthma. Other indoor pollutants, such as tobacco smoke and natural gas combustion products, can also exacerbate asthma symptoms. "Improvements" in housing, such as increased insulation and reduced ventilation to save on energy costs, and increased amounts of wall-to-wall carpeting and stuffed furniture, may have had the unintended effects of promoting the growth of dust mites and molds, and of concentrating antigens, irritants and PM indoors.[65] These changes in housing over recent decades could help explain the widespread increases in asthma rates. In addition, the effect of indoor pollutants may be increased by the growing amount of time that children spend indoors, which increases a child's exposure to antigens, and by lack of exercise, which might increase the respiratory system's sensitivity to allergens.[66]

Some aspects of outdoor pollution are capable of triggering asthma attacks, such as pollens. Some researchers have suggested that outdoor air pollution *per se* is not likely to contribute significantly to the asthma epidemic, however, because air pollution has decreased on the whole while asthma rates have increased.[67] It is nonetheless possible that specific pollutants, such as ozone or diesel exhaust, enhance the effects of other factors, such as allergens, even if the pollutants themselves are not triggers of asthma. In addition, weather conditions, and cold air in particular, can elicit asthmatic symptoms independent of air pollution.

[65] Bielory, L. and Deener, A. (1998). Seasonal Variation in the Effects of Major Indoor and Outdoor Environmental Variables on Asthma: Review Article. J. Asthma 35(1):7-48.

[66] Crater, S. and Platts-Mills, T. (1998). Searching for the Cause of the Increase in Asthma. Curr. Opin. Pediatr. 10:594-599.

An additional hypothesis described by Cookson and Moffatt (1997) suggests a link between the increase in asthma and the decline of respiratory infections in modern society, which could shift the balance of the immune system in favor of factors that predispose persons to asthma and allergy.[68] Infectious disease has been dramatically reduced in our society by the use of antibiotics and immunization programs.

Experimentally, exposure to diesel exhaust particles increased airways resistance in mice,[69] while other studies of mice and humans showed that diesel exhaust particles can enhance responses to allergens.[70] Experiments in which non-asthmatic adults were exposed for an hour to diesel engine exhaust (containing particles and gases) found increased airways resistance[71] and some cellular indicators of inflammatory response;[72] however, these subjects did not experience asthma.

Causes, triggers and prevention of childhood asthma in the City are the subjects of active research.[73] For example, researchers are investigating the possible influence of prenatal exposure to antigenic materials; collecting air pollution measurements in areas of the City with high rates of asthma; testing infants and children for respiratory symptoms; measuring pollutant levels in urine as an indicator of exposure to diesel exhaust; and cleaning, repairing, and addressing pest infestations in apartments of families with asthmatic children. It is hoped that this research would not only help identify the most significant factors leading to asthma but also identify effective prevention measures.

Environ. Health Perspect. 110(2):197-204.

City officials are well aware of the epidemic of childhood asthma in the City's many boroughs and communities. As reported by the New York City Department of Health and Mental Hygiene (DOHMH) on its web site (www.nyc.gov/html/doh), asthma is a common disease among the City's children and adults. Asthma is a leading cause of missed school among school among children and is the most common cause of hospitalization for children 14 years and younger. Among adults, asthma causes missed work, emergency department visits, and limitation of activity. In the past two decades, the number of people with asthma has increased, although some improvements, such as fewer hospitalizations, have occurred in recent years. Although it is not yet known how to prevent asthma, it is known that asthma can be controlled both by avoiding exposure to triggers and by taking anti-inflammatory medicines. With good control, almost all people with asthma can lead normal, active lives.

Under the direction of the NYCDOH, the City began an aggressive Childhood Asthma Initiative NYCCAI) in 1997. NYCCAI is a public health effort to reduce asthma morbidity among children 0 to 18 years of age. Expected outcomes of the NYCCAI include reductions in hospitalizations, emergency department visits and school absences due to asthma and, relatedly, improvements in management of childhood asthma among families. NYCCAI is building on existing research education and clinical efforts, resulting in a coordinated and comprehensive effort to understand, treat and prevent asthma in New York City.

NYCCAI is currently working to:

- Improve family management of asthma
- Promote state-of-the-art medical diagnosis and treatment
- Reduce exposure to asthma triggers in both homes and communities
- Increase coordination among families, schools, daycares, medical providers, pharmacists, community-based organizations, housing agencies, managed care organizations, and others
- Monitor and track the number of children with asthma. [74]

[74] New York City Department of Health and Mental Hygiene (May 2003). Asthma Facts, Second Edition. Available at http://www.nyc.gov/html/doh/pdf/asthma/facts.pdf.

Clearly, asthma among children is a major public and personal health problem in the City. Yet the causes of asthma and its increase over the last two decades are not known, and the triggers for exacerbation are only partly understood. The potential relationship between vehicular exhaust resulting from increased truck traffic and asthma, especially in communities with high rates of asthma, requires further study.

33.6.4 Asthma Morbidity and Mortality in Host Communities

The DOHMH provided preliminary, recent statistics on asthma for the City.[75] Information is collected on the fraction of children and adults with asthma (prevalence), discharges from hospitals after asthma-related illness (morbidity) and deaths from asthma (mortality). The numbers of children with asthma are determined from school health examination forms, usually submitted when children are four or five years old, while numbers of adults with asthma are determined from a telephone survey.

A summary of asthma prevalence among children 4 to 5 years old in areas potentially affected by the Proposed Plan Facilities is provided in Table 33.6-1. The Hunts Point-Mott Haven and Williamsburg-Bushwick neighborhoods show child asthma prevalence considerably above the City average.

A summary of asthma prevalence data for adults in areas potentially affected by the Proposed Plan Facilities is provided in Table 33.6-2. Adults are markedly less likely than children to have an asthma diagnosis. Adult asthma is considerably more prevalent in the South Bronx and Brooklyn Downtown-Heights-Slope neighborhoods than in the City overall.

[75] Personal communications from Dan Kass, DOHMH, to Sarah Armstrong, Cambridge Environmental, Inc., 2003.

Table 33.6-1
Asthma Prevalence Among Children 4 to 5 Years Old

New York City Area	Percent with Asthma in 1999
All of New York City	9.1
Bronx	15.5
Hunts Point-Mott Haven neighborhood	17.1
Brooklyn	8.8
Greenpoint neighborhood	8.9
Williamsburg-Bushwick neighborhood	15.5
Downtown-Heights-Slope neighborhood	9.3
Bensonhurst-Bay Ridge neighborhood	5.2
Sunset Park neighborhood	8.9
Manhattan	11.9
Upper East Side neighborhood	6.4
Queens	5.6
Flushing-Clearview neighborhood	2.6
Long Island City-Astoria neighborhood	5.2
West Queens neighborhood	5.7

Table 33.6-2
Asthma Prevalence Among Adults

New York City Area	Percent with Asthma in 2002
All of New York City	4.4
Bronx	6.2
South Bronx, including the Hunts Point-Mott Haven neighborhood	7.1
Brooklyn	3.7
Greenpoint neighborhood	3.1
Williamsburg-Bushwick neighborhood	6.1
Downtown-Heights-Slope neighborhood	8.0

Manhattan	4.5
Upper East Side neighborhood	2.7
Queens	3.7
Flushing-Clearview neighborhood	2.3
Long Island City-Astoria-West Queens neighborhood	4.2

Rates of asthma hospitalization among children aged 0 to 14 dropped markedly between 1997 and 2000 in all the neighborhoods that are potentially affected by the Proposed Plan Facilities. In these neighborhoods, decreases in hospitalization rates ranged from 22% to 56%. The rate decreased the most in the Hunts Point-Mott Haven area, in which DOHMH began a major childhood asthma initiative in 1998. The hospitalization rates for specific zip code areas in 2000 are provided in Table 33.6-3. Hospitalization rates in three zip codes, in the Hunts Point-Mott Haven neighborhood (19454 and 10474) and in the Williamsburg-Bushwick neighborhood (11237), are higher than for the City as a whole.

Asthma mortality data for 2000 are not available by neighborhood. By borough, mortality rates from asthma (deaths per 100,000 people) for people of all ages were 4.9 in the Bronx, 2.9 in Manhattan, 2.2 in Brooklyn and 1.6 in Queens. During the 1990s, asthma mortality rates decreased by about 25% in both sexes in the City. Rates of death from asthma increased with age, being highest among people aged 65 or older.

Table 33.6-3
Hospitalization Rates for Selected Zip Codes

New York City Area or Zip Code	Asthma Hospitalization Rate, Per 1,000 Children Ages 0-14, in 2000
New York City	6.1
10128	2.5
10454	11.2
10474	9.0
11101	6.7
11214	1.1
11215	2.3
11222	2.3
11232	2.7
11237	12.8
11354	4.9
11378	2.7

33.7 Conclusions

This chapter presented a review of scientific information regarding the toxicity of various air pollutants and epidemiologic studies relating traffic to respiratory health, as well as the predicted impacts of the Proposed Plan Facilities' operations and associated traffic on air quality, noise and odor. Recent information on rates of asthma in neighborhoods that may be affected by the Proposed Plan Facilities was also presented. None of the air quality, noise or odor impacts predicted in this FDEIS are believed to be of public health significance. Regarding existing, permitted facilities in the Proposed Plan not analyzed in this FDEIS, it is assumed that these facilities underwent appropriate environmental review and were determined not to create significant impacts on public health. If one of the Alternative Facilities is selected as a Proposed Plan Facility, a supplemental Public Health analysis will address its air quality, odor and noise impacts.

CHAPTER 34 EVALUATION OF THE PROPOSED ~~PLAN~~ACTION

34.1 Potential Impacts of the Proposed ~~Plan~~Action

The Proposed ~~Plan~~ Action would meet the City's long-term waste export needs through a system that utilizes existing waste transfer sites (public and private), including four of the City's Converted MTSs, the Staten Island Transfer Station and sites to be identified as part of future procurements. (See Chapter 1 for a full description of the Proposed ~~Plan~~ Action and its components.)

The Proposed Action, in summary, is to:

- Improve DSNY's Curbside Recycling Program through the award of a 20-year ~~processing~~ contract ~~and~~ for the development of a new ~~in-City~~ Recyclables ~~processing~~ Processing facility at the South Brooklyn Marine Terminal in Brooklyn ~~as well as a~~ and the development of a ~~Manhattan~~ Recyclables Acceptance Facility ~~–~~at the Gansevoort Street peninsula in Manhattan.

- Implement the City's Long Term Export Program through: the development of four Converted MTSs at the Hamilton Avenue (Brooklyn), Southwest Brooklyn (Brooklyn), East 91st Street (Manhattan) and North Shore (Queens) existing MTSs; the award of up to five contracts with private transfer stations for barge or rail export of DSNY-managed Waste for disposal; and~~, enter into~~ the execution of an intergovernmental agreement to dispose of a portion of Manhattan's DSNY-managed Waste at ~~a WTE~~ the Essex County Resource Recovery F~~f~~acility in Newark, New Jersey.

- Provide ~~the capacity~~ for the barge export of containerized putrescible C~~c~~ommercial ~~w~~Waste from the four Converted MTSs, and ~~the City at one existing Manhattan~~ from the West 59th Street MTS site in Manhattan through the solicitation of proposals from private waste management companies for the use of this MTS site for this purpose~~as well as the four Converted MTSs~~.

Any impacts that would result at in-City sites (designated in the Proposed ~~Plan~~Action) where new construction would likely occur are capable of being mitigated. The remaining potential in-City sites, which could be selected pursuant to a future procurement, either had no impacts or the impacts found would be mitigable. A summary of the impact assessment is provided in Tables 34.1-1 and 34.1-2.

Notes:
N indicates no adverse impact.
~~MI indicates a significant mitigated environmental impact.~~
N/A indicates not analyzed.
PA = Analysis in this FEIS not required based on prior environmental review.

The Proposed ~~Plan~~ Action results in a ~~r~~Recycling, ~~waste~~ Long Term ~~e~~Export and ~~c~~Commercial ~~w~~Waste management system in which the "burden" of processing facilities is more equitably distributed among the City's boroughs. Operations at the sites/facilities named in the Proposed ~~Plan~~ Action would serve distinct wastesheds and are generally located some distance from each other (more than two miles away).[1] The sites/facilities are geographically distributed throughout the boroughs ~~to the maximum extent possible~~, located along the waterfront in industrial zones. Furthermore, by utilizing existing facilities and sites (in heavily industrial areas), the ~~Plan~~ Proposed Action substantially minimizes or eliminates any potential impacts to neighborhood character.

The Proposed ~~Plan's~~ Action's reliance on marine and rail export differs from the Interim Export's truck-dependent export activities. Whereas waste is collected and transferred to long-haul trucks or hauled directly to disposal via collection trucks under Interim Export (except for rail export from ~~one~~ two sites in the Bronx), the Proposed ~~Plan~~ Action would utilize the City's rail and marine export potential. This would reduce the number of trucks from what is currently required to provide waste collection and transfer services and result in an approximate 2.8 million mile reduction in vehicle miles traveled. ~~As a result, traffic and air quality conditions on City streets would likely improve overall within the City with the implementation of the Proposed Plan.~~

[1] The Alternative sites considered in northeastern Brooklyn/western Queens, along Newtown Creek, may be within ½-mile of each other. Given the heavily industrial environs and analytical findings of no significant impacts at either the Review Avenue, Scott Avenue/Scholes Street or Scott Avenue sites, no cumulative impact would be expected.

CHAPTER 35 UNAVOIDABLE ADVERSE IMPACTS

Unavoidable adverse impacts are defined as those that meet either of the following two criteria:

- There are no reasonably practicable mitigation measures to eliminate the impact; or
- There are no reasonable alternatives to the proposed project that would meet the purpose and need of the action, eliminate the impact, and not cause other or similar significant adverse impacts.

Site-specific analyses predict that any impacts identified are capable of being mitigated. Therefore, there are no unavoidable adverse impacts associated with the development of any facility option or with the implementation of the Proposed Plan Facilities overall.

CHAPTER 36 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

There are several resources, both natural and man-made, that would be expended through Plan implementation. These resources include the land that makes up the proposed facility sites; building materials used in construction of the facilities; energy in the form of gas and electricity consumed during the construction and operation of each facility; the fossil fuels used in tugs, trains and trucks transporting waste or construction materials; and the human effort required to develop, construct and operate the facilities and means of waste transport. All of these resources are considered irretrievably committed because their reuse for some other purpose, once exploited for the project, would be highly unlikely.

Development of the Harlem River Yard Site, East 132nd Street Site, Scott Avenue TS, Review Avenue TS, or Scott Avenue/Scholes Street TS, or use of any existing MTSs as part of Plan implementation, would not be new commitments of land to industrial use because those facilities would exist without Plan implementation. While all other sites proposed for development would be Plan-induced commitments, such as the Converted MTSs, they would also be re-activation of industrial uses in areas zoned for heavy industry.

Generally, the soil, shoreline and natural waterways in the areas of the proposed new facilities and the MTSs could be described as having been, in effect, already committed to industrial use as a result of prior industrial activities. The redevelopment and use of abandoned, derelict or underutilized infrastructure, therefore, could be considered the reclamation of the "working waterfront," a man-made resource of economic importance to the City. It is within this planning and development context that the proposed developments could be considered improvements of their respective sites and waterfront areas, particularly as they utilize and often upgrade the existing rail and water transport infrastructure.

CHAPTER 37 GROWTH-INDUCING ASPECTS OF THE ~~PLAN~~SWMP

The Proposed ~~Plan~~ Action~~facilities~~ would replace ~~some publicly inaccessible waterfront areas~~ four existing MTSs with Converted MTSs, ~~and~~ potentially modify some portions of existing private transfer station~~s sites~~ in the City to enable truck-to-rail/barge export ~~transfer~~ from these facilities, would develop a Recyclables Acceptance Facility in Manhattan for barge transport of Recyclables to processing facility, and would develop a Recyclables Processing facility at the South Brooklyn Marine Terminal to receive and process barge-delivered Recyclables from other acceptance facilities in the City. With the exception of the Recyclables Acceptance Facility in Manhattan, which is subject to further environmental review as the design is developed, ~~T~~these new facilities would: (1) not involve substantial new land uses at the designated sites; (2) be compatible with existing surrounding land uses; (3) not introduce new residents to or significantly increase employment in the surrounding areas; and (4) not require that any new support uses be located nearby (although DSNY or other private waste-related facilities already exist near some sites).

These Proposed ~~Plan~~ Action facilities located on under-utilized or unused sites may require infrastructure improvements (e.g., sewer connections, etc.), but these upgrades would not necessarily encourage off-site development. Development of some facilities may require dredging on site. Waterfront Revitalization Program consistency review concludes that while no ~~Proposed Plan~~ facility would specifically require the siting of any additional water-dependent uses, certain ~~Proposed Plan~~ facilities would not necessarily preclude the siting of these uses either. For example, the four Converted MTS facilities ~~in the Proposed Plan~~ could increase the demand for barge repair and maintenance facilities at sites that are appropriately zoned for this activity, but whether the locations of these facilities are near the proposed sites or are within the City cannot be foreseen at this time.

The Proposed ~~Plan facilities~~ Action would be compatible with existing public plans and policies for planned improvements in the City's freight rail infrastructure and/or in waterfront infrastructure related to barging of containerized freight. These infrastructure improvements may occur in Staten Island, the Bronx, Brooklyn and Queens, where these improvements are consistent with current and planned land uses. Specifically, the NYCEDC and/or the Port Authority of New York and New Jersey is planning or implementing: (1) ~~track upgrades in the~~

~~Harlem River Yard in the Bronx to enable Canadian Pacific Railroad to serve freight customers in the City from the Hudson North Line; (2)~~ upgrades on the Metro-North and CSX-owned Hudson North lines to facilitate freight traffic into the Bronx; (~~3~~2) upgrade of the Staten Island Railroad (SIRR) and connections to SIRR from New Jersey freight rail lines to facilitate freight traffic on and off Staten Island; and (3~~4~~) upgrades of intermodal terminal capacity at Howland Hook or in the immediate vicinity.

These ~~NYCEDC's~~ plans would potentially facilitate the operation of Plan-related rail facilities in the Bronx, Queens and Staten Island. However, these are being pursued independently by the NYCEDC and other parties ~~as a consequence of the acquisition of Conrail by CSX and the CSX's agreement. These improvements include providing trackage rights to the Canadian Pacific Railroad into the Harlem River Yard, mitigating height restrictions on Metro-North's Hudson River North Line and increasing the number of freight train movements into and out of the Harlem River Yard.~~

~~Additionally, to operate the Staten Island Transfer Station in a rail transfer mode, off-site rail improvements are underway to extend the Travis Branch of the SIRR from its current terminus at the NRG generating plant on Staten Island through the Visy Paper plant and across a vacant parcel of Consolidated Edison-owned land abutting the Staten Island Transfer Station site. These improvements are in addition to the previously initiated NYCEDC improvements to the SIRR and are compatible with the planned expansion of the Visy Paper plant, which would abut the proposed rail extension. These improvements were evaluated in the 2000 SWMP FEIS and are fully permitted.~~

~~It is also possible that~~ The intra-harbor barging of containerized waste from ~~truck-to-barge transfer facilities~~the four Converted MTSs~~, which could be developed in the future in the Bronx, Brooklyn and Queens,~~ would utilize intermodal facilities in the harbor to transfer these containers to oceangoing barges or to rail cars. This activity would be compatible with the City's overall plan for port development.

TECHNICAL APPENDIX DOCUMENTATION (AVAILABLE ON COMPACT DISK)

Traffic and Transportation

Henningson, Durham & Richardson Architecture & Engineering, P.C. Urbitran and Parsons Brinkerhoff prepared the following files for all applicable sites and submitted them to the NYCDOT for review in early 2004.

- Electronic and printed copies of Highway Capacity Software Output files;
- Spreadsheets showing temporal distribution of traffic and calculations to determine peak hours, future baseline and future build conditions; and
- Maps depicting routes and temporal distribution of Department Collection vehicles

Air Quality

Henningson, Durham & Richardson Architecture & Engineering, P.C. and Parsons Brinkerhoff prepared the following files for all applicable sites and submitted them to the NYCDEP for review between January 2004 and October 2004

On-Site Air Quality Analysis

- Methodology
- Emission calculations spreadsheets;
- Site maps with source coordinates; and
- ISCST3 input and output air quality files.

Mobile Air Quality Analysis

- Electronic copies of Highway Capacity Software Output files;
- Electronic copies of CAL3QHC files for CO and PM_{10};
- CAL3QHCR output files for PM_{10};
- Electronic copy of Part 5 file; and
- Emissions calculations spreadsheets.
- Electronic copy of Mobile 6.2 file

Odor

Henningson, Durham & Richardson Architecture & Engineering, P.C. prepared the following files for all applicable sites and submitted them to the NYCDEP for review between January 2004 and October 2004.

- Electronic copies of ISCST3 input and output air quality files; and
- Emission calculation spreadsheets and site maps with source coordinates.

Noise

Henningson, Durham & Richardson Architecture & Engineering, P.C. and Parsons Brinkerhoff prepared the following files for all applicable sites and submitted them to the NYCDEP for review between November 1999 and February 2000:

- Noise Impact Calculation Spreadsheets; and
- C++ input/output files used to calculate the 55 dBA contour.
- TNM noise model input/output

Hazardous Materials

1. New York City Land Use Maps (NYC Department of Planning, 1988).

2. Sanborn Fire Insurance atlases dated 1908, 1951, 1979, and 1989.

3. Sanborn Fire Insurance atlases dated 1906, 1951, and 1990.

4. Sanborn Fire Insurance atlases dated 1915, 1935, 1951, 1979, and 1989.

5. South Bronx Marine Transfer Station (MTS) Solid Waste Management Facility permit renewal report dated October 1995. This report was prepared by the City of New York Department of Sanitation for New York State Department of Environmental Conservation (NYSDEC) in accordance with the provisions of 6 NYCRR Part 360.

6. Southwest Brooklyn Marine Transfer Station (MTS) Solid Waste Management Facility permit renewal report dated October 1995. This report was prepared by the City of New York Department of Sanitation for New York State Department of Environmental Conservation (NYSDEC) in accordance with the provisions of 6 NYCRR Part 360.

7. Toxics Targeting, Inc., Computerized Environmental Report, Farragut Street, Bronx, New York. February 17, 1999.

12. Toxics Targeting, Inc., Computerized Environmental Report, 65th Street & Upper New York Bay, Brooklyn, New York. March 4, 1999.

13. Toxics Targeting, Inc., Computerized Environmental Report, 38-50 Review Avenue, Queens, New York. March 19, 1999.

14. Toxics Targeting, Inc., Computerized Environmental Report, Fresh Kills landfill, Staten Island, New York. March 22, 1999.

15. Toxics Targeting, Inc., Computerized Environmental Report, Hamilton Avenue Marine Transfer Station, Brooklyn, New York. July 22, 999.

16. United State Geological Survey topographic quadrangle maps.

CHAPTER 39 LIST OF PREPARERS

39.1 Introduction

Henningson, Durham & Richardson Architecture & Engineering, P.C. in association with HDR Engineering, Inc. (HDR) as consultant to the DSNY provided overall management, quality control and document production responsibility for the preparation of this FEIS and provided certain of the technical and engineering analyses contained in various sections of this FEIS, as described below. HDR was assisted in this effort by the following subconsultants:

- Parsons Brinckerhoff Quade & Douglas, Inc. (PB)
- HydroQual, Inc. (HydroQual)
- EEA, Inc. (EEA)
- Urbitran Inc. (Urbitran)
- Cambridge Environmental, Inc. (Cambridge Environmental)

39.2 Prime and Subconsultant Responsibilities

The following summarizes the contributions of the prime consultant and subconsultants in the categories of environmental review presented in this FEIS.

The DSNY's design consultant, Greeley and Hansen LLC and its subconsultant team prepared the detailed designs of the eight Converted MTSs. Owners of private transfer stations (vendors) who submitted proposals in response to the DSNY's 2003 RFPs for waste export alternatives hired other consultants to prepare designs for the facilities evaluated in this FEIS. HDR evaluated the potential impacts of: (1) off-site Air Quality and Noise emissions, and Traffic and Transportation (where required) for the facilities located in Brooklyn and Queens; and (2) on-site Air Quality, Odor and Noise for facilities located in Manhattan, Brooklyn and Queens; and (3) on-site Odor in the Bronx. HDR conducted engineering reviews of the vendor-proposed options evaluated in these chapters to establish a consistent basis for analyzing all of the alternative sites/facilities considered.

PB evaluated the potential impacts of off-site Air Quality and Noise emissions, and Traffic and Transportation (where required) for the facilities located in Bronx and Manhattan; and (2) on-site Air quality and Noise for facilities located in the Bronx; and (3) on-site Noise for one facility in Manhattan. PB also conducted environmental reviews for the facilities analyzed in all boroughs in the areas of Land Use, Zoning and Public Policy, Socioeconomic Conditions, Community Facilities and Services, Open Space, Cultural Resources, Urban Design, Visual Resources, and Shadows, and Neighborhood Character.

Urbitran conducted Traffic and Transportation analyses for the facilities located in Manhattan.

HydroQual conducted environmental reviews for the facilities analyzed in all boroughs in the areas of Infrastructure, Solid Waste and Sanitation Services and Energy, Water Quality and the Waterfront Revitalization Program. HydroQual was also responsible for the assembly and final production of all graphic figures in this FEIS.

EEA conducted environmental reviews for facilities analyzed in all boroughs in the areas of Natural Resources (including Endangered Species and Habitats) and Hazardous Materials.

Cambridge Environmental provided the discussion of Public Health issues in Chapter 33.

39.3 Preparers

The following personnel contributed to the preparation of this FEIS.

39.3.1 HDR

- Daniel A. Harkins, MBA, B.A., Vice President, served as Project Manager for the FEIS effort. Mr. Harkins has 25 years of experience in the management of solid waste planning projects and solid waste facility development including procurement and permitting.
- Joyce M. Mariani, P.E., M.S. (Environmental Engineering), B.S. (Civil Engineering), Vice President, served as Assistant Project Manager for the FEIS effort with primary

responsibility for directing technical analyses in the areas of air quality, odor, noise and traffic. Ms. Mariani has 13 years of experience in solid waste/environmental review, permitting and analysis.

- Elena Barnett EIT, M.S. (Environmental Engineering), Project Engineer, served as Deputy Assistant Project Manager for the FEIS effort with assistant responsibility for directing technical analyses in the areas of air quality, odor, noise and traffic. Ms. Barnett has 7 years of experience in solid waste/environmental review, permitting and analysis.

- Lorraine Anderson, B.S. (Mathematics), Editor, served as Technical Editor for sections of the FEIS document. Ms. Anderson has 18 years of experience in technical writing and editing.

- Timothy Casey QEP, B.S. (Biology), Senior Environmental Scientist, served as a consultant to noise analysis team. Mr. Casey has 15 years of experience in noise monitoring and modeling.

- Grey Noemi Castillo EIT, M.S. (Environmental Engineering), Project Engineer, served as Task Leader for the noise analysis. Ms. Castillo has 4 years of experience in environmental analysis and site assessment work.

- Alan Cohen, Ph.D. (Industrial Engineering and Management Sciences), M.S., B.S., Vice President, served as Team Leader for the economic analysis. Dr. Cohen has 33 years of experience in systems analysis and economic modeling.

- Elo Comfort, EIT B.S (Civil Engineering), Project Engineer, served as task leader for the traffic analysis and a technical resource for facility operations. Mr. Comfort has 4 years experience in environmental analysis and civil site design work.

- Erik Grimm EIT, M.S. (Environmental Engineering), Project engineer, performed modeling for the off site air quality analysis. Mr. Grimm has 1 year of experience with air quality modeling.

- Bruce Howie, P.E., M.S. (Chemical Engineering), Senior Project Engineer, served as Task Leader for the off-site air quality analysis and a technical resource on the facilty designs. Mr. Howie has 7 years of experience in air quality analysis work and 5 years of experience in solid waste facility design/operation work.

- Edward Liebsch, M.S. (Meteorology), B.A. (Earth Sciences), Senior Air Quality Scientist, served as Team Leader for air quality analyses. Mr. Liebsch has 24 years of experience in air quality analysis and permitting.

- Stephanie C. Nakai, B.A. (Geology), Hydrogeologist, served on the noise analysis team. Ms. Nakai has 2 years of experience in environmental analysis and site assessment work.

- Mike Parsons, EIT, B.S. (Civil & Environmental Engineering), Environmental Engineer, served as a consultant to noise analysis team. Mr. Parsons has 5 years of experience in noise modeling and monitoring.

- Beth Regan, CIH, B.A. (Biology), Environmental Scientist, served as technical resource for Noise Analysis. Ms. Regan has 4 years experience in stationary and mobile noise source monitoring and modeling.

- Geneen Robbins, Project Assistant, served as document control and production manager for the FEIS. Ms. Robbins has 13 years of experience in administrative assistance.

- Bonnie Shulman, B.S. (Hotel, Restaurant, and Travel Administration), Editor, served as Technical Editor for sections of the FEIS document. Ms. Shulman has 23 years of experience in technical writing and editing.

- Udomlug Siriphonlai EIT, M.S. (Chemical Engineering), Project Engineer, served as Task Leader for the stationary air quality analysis. Ms. Siriphonlai has 4 years of experience in solid waste, environmental analysis and site assessment work.

- Thomas Young, B.S., Environmental Scientist, served as Associate Scientist for the FEIS effort. Mr. Young has 3 years of experience in water and wetland resources and field technologies.

- Scott Zilka, B.S. (Meteorology), Senior Environmental Scientist, served as a technical resource for air quality analyses. Mr. Zilka has 11 years of experience in mobile and stationary air quality analysis.

39.3.2 PB

- C.G. Balachandran, Ph.D., M.P., B.S., Lead Noise and Acoustic Specialist, served as PB Team Leader for noise analysis. Mr. Balachandran has 39 years of experience in noise, vibration, and architectural acoustics.

- James R. Brown, B.S., Vice President, served as PB Principal-in-Charge for the FEIS effort. Mr. Brown has 30 years of experience in managing projects in the environmental and planning fields.

- Helen Ginzburg, M.S., Senior Air Quality Scientist, conducted mobile and stationary air quality analyses. Ms. Ginzburg has 22 years of experience in air quality studies, mathematical modeling, and environmental impact statement preparation.

- Cade Hobbick, AICP, M.U.P, B.A., Senior Planner and certified Project Manager, has 8 years experience in planning and environmental analysis and served as PB Deputy Project Manager in the FEIS effort. Mr. Hobbick conducted and led land use and related studies.

- Sandor Juhasz, B.S., Senior Environmental Engineer, conducted field noise monitoring and equipment noise measurements, and performed stationary source noise analysis. Mr. Juhasz has five years noise experience in PB.

- Vadim Kogan, Ph.D., M.S., Senior Environmental Engineer, conducted stationary air quality analyses for the FEIS effort. Mr. Kogan has 30 years of technical experience in the air quality field.

- Sam Less, AICP, M.S., B.A., Senior Project Manager, assisted the PB Project Manager, providing QC for planning and environmental tasks. Mr. Less has over 20 years of experience in the field of environmental analysis.

- Jules Loweff, M.C.R.P., B.A., Supervising Planner, provided GIS support for the FEIS effort. Mr. Loweff has more than 19 years of experience with geographic information systems for urban applications, regional economic development and planning environmental studies.

- Arthur Morrone, M.S., B.S., Lead Meteorologist/Environmental Scientist, assisted in noise analysis. Mr. Morrone has 20 years of experience in traffic noise impact assessment and abatement.

- Stamatia Petsios, B.S., Lead Air Quality Engineer, conducted mobile air quality analysis. Ms. Petsios has 20 years of experience in the air quality analysis of mobile sources for diverse transportation projects.

- Esther R. Schwalb, M.S., B.A., certified Project Manager, served as PB Project Manager for the FEIS effort. Ms. Schwalb has 22 years of experience in preparing environmental impact statements for public programs and private development projects.

- Luc Senh, M.S., B.E., Lead Transportation Engineer, served as PB Deputy Team Leader for traffic analysis. Mr. Senh has 14 years of experience in transportation engineering planning.

- Joseph N. Setteducato, P.E., M.S., B.S.C.E., Senior Traffic Engineering Manager, served as PB Team Leader for traffic analysis. Mr. Setteducato has 30 years of experience in the planning and analysis of transportation facilities

- Joel Soden, P.E., D.E.E., M.S., B.S., Senior Supervising Air Quality Engineer, served as PB Team Leader for mobile and stationary air quality analysis. Mr. Soden has 30 years of experience in air quality analysis.

39.3.3 HydroQual

- J John P. Cariou, served as a GIS/CAD Analyst and was involved in the preparation of maps and figures. Mr. Cariou has 10 years of experience in Geographical Information Systems (GIS) and computer aided drafting (CAD).

- Charles L. Dujardin, M.E. (Environmental Engineering), B.Ch.E. (Chemical Engineering), served as the Water Quality Project Director and was involved in addressing water quality issues. Mr. Dujardin has 32 years of experience of water quality studies and mathematical modeling, primarily within the New York/New Jersey metropolitan region.

- Brian S. George, M.P.S. (Environmental and Resources Engineering, Mapping Sciences), B.S. (Environmental Studies, Information and Technology) served as a GIS Analyst and was involved in the preparation of maps and figures. Mr. George has 8 years of experience in GIS and programming.

- Kevin D. Keane, M.S. (Plant Pathology), B.A. (Biology), served as the overall HydroQual Project Leader and was involved in addressing Waterfront Revitalization and Infrastructure and Energy issues. Mr. Keane has 20 years of experience in environmental licensing and permitting and environmental impact assessment.

- Eileen T. La Rosa, B.S. (Wildlife Biology), served as the Waterfront Revitalization Analyst and was involved in addressing waterfront policies. Ms. La Rosa has 6 years of experience in natural resources and environmental permitting.

- Eileen F. Lucier, B.S. (Environmental Engineering), served as a Water Quality Analyst and was involved in water quality modeling and addressing water quality issues. Ms. Lucier has 6 year of experience in environmental science and water quality.

- Virginia A. Michelin, B.S. (Environmental Planning and Design), served as the Project Manager and was involved in the preparation of maps and figures and coordinated GIS activities as well as coordinating the day-to-day activities. Ms. Michelin has 9 years of experience in environmental planning and GIS development.

- Maureen C. Migliorini, M.S. (Environmental Engineering), B.S. (Biology), served as Water Quality Task Leader and was involved in addressing water quality issues. Ms. Migliorini has 24 years of experience in water quality studies, mathematical modeling, wastewater treatment, site investigations and remediation.

- Melissa E. Morrone, B.S. (Environmental Engineering), served as an Infrastructure and Energy Analyst and was involved in addressing infrastructure issues, specifically water/wastewater, solid waste, and power requirements. Ms. Morrone has 4 years experience in environmental engineering.

- Philip W. Simmons, B.A. (Environmental Studies), served as the Infrastructure, Solid Waste and Sanitation Services, and Energy Existing Conditions task leader and was involved in addressing infrastructure issues, specifically waste/wastewater, solid waste, and energy requirements. Mr. Simmons has 13 years of experiences in environmental operations, permitting and solid waste management.

39.3.4 EEA

- Robert Clifford, Jr., REP, B.S., M.S., Senior Environmental Scientist, served as Senior Investigator for the FEIS effort. Mr. Clifford has 15 years of experience in assessment and remedial evaluation, regulatory compliance audits, permitting of air, water, and wetland discharges and environmental management systems.

- Richard Fasciani, B.A., Environmental Scientist, served as Investigator for the FEIS effort. Mr. Fasciani has 6 years of experience.

- Leland Hairr, B.S., M.S., Ph.D., Principal, served as QA/QC Reviewer for the FEIS effort. Dr. Hairr has more than 25 years of experience in the fields of hazardous materials, air pollution, and environmental noise.

- Anthony Lucchese, B.S., M.S. (Pending), Senior Environmental Scientist, served as Investigator for the FEIS effort. Mr. Lucchese has 12 years of experience.

- Todd McArthur, B.S., M.S., Senior Environmental Scientist, served as Investigator for the FEIS effort. Mr. McArthur has 10 years of experience.

- Michelle Nannen, M.S., Marine Ecologist, served as Environmental Scientist for the FEIS effort. Ms. Nannen has 3 years of experience in marine and environmental investigations.

- Laura Schwanof, R.L.A., B.S., Environmental Scientist, served as Environmental Scientist for the FEIS effort. Ms. Schwanof has 18 years of experience related to natural resources inventory, environmental planning and design.

- Allen Serper, P.E., B.S., M.S., Principal, served as Principal Engineer for the FEIS effort. Mr. Serper has more than 30 years of experience in solid waste management studies (i.e., economic, technical and environmental assessments of landfills and resource recovery/combustion disposal facilities).

- Jeffrey Shelkey, B.S., Senior Environmental Scientist, served as Project Manager for the FEIS effort. Mr. Shelkey has 18 years of experience in technical and program management of remedial action cleanups, site closures and corrective actions at active and inactive hazardous waste sites.

- Neal Stark, A.S., B.A., M.A.L.S., Environmental Scientist, served as Senior Scientist for the FEIS effort. Mr. Stark has 15 years of experience.

- Roy Stoecker, B.S., M.S. Ph.D, Principal, served as Principal Scientist for the FEIS effort. Dr. Stoecker has more than 25 years of experience in the fields of wetlands and marine ecology, water quality, and environmental health.

39.3.5 Urbitran

- Shakil Ahmed, NICET III, M.S., N.E.D, B.A., Supervised the traffic analysis technical work for transfer stations. He has 15 years of experience in traffic analysis.

- Charles Benson III, A.I.C.P., B.S., Mr. Benson has had 8 years in various project management roles on transportation planning projects. He provided general oversight for transfer station trip generation and access analyses.

- David Cuff, M.U.P., B.A., Mr. Cuff was responsible for the alternative fuels analysis. He has 6 years of experience preparing environmental assessments and analysis of transit operations.

- Elizabeth Johnston, B.A., prepared the enforcement section of the commercial waste study. Ms. Johnston, has 2 years of experience preparing environmental assessments.

- Robert Michel, A.I.C.P., M.C.P., M.A., B.A., served as project team leader on the Urbitran tasks. Mr. Michel has had over 18 years of experience in preparing planning, environmental and transportation studies.

- H. Joon Park, P.E., Ph.D., M.S., served as primary traffic engineer on MTS studies, including preparation of truck trip generation estimates and highway capacity analyses. Mr. Park has approximately 5 years of experience with Urbitran.

39.3.6 Cambridge Environmental

- Sarah R. Armstrong, M.S. (Biology), M.S. (Health Policy and Management), D.A.B.T., Senior Scientist, served as task manager and primary writer for the public health analysis. Ms. Armstrong has 14 years of experience in environmental toxicology and risk assessment.

- Laura C. Green, Ph.D. (Food Science and Technology), D.A.B.T., President and Senior Scientist, served as a contributor and technical reviewer for the public health analysis. Dr. Green has more than 20 years of experience in toxicology, risk assessment, and risk communication.

CHAPTER 40 – RESPONSIVENESS SUMMARY (NEW CHAPTER)

40.1 Introduction

Both the Draft New SWMP and the DEIS were issued on October 22, 2004. Pursuant to CEQR/SEQRA procedures, DSNY established a public comment period extending from October 22, 2004 to January 24, 2005, a total of 94 days. During the public comment period, between December 1 and December 20, 2004, DSNY held 8 public hearings at which oral testimony was received in each of the potential project areas where long term export facilities were proposed. Additional written comments were accepted by mail, email and fax until the close of the comment period. This section presents responses to all the public comments received. It is organized as follows:

- Section 40.2 provides an index of comments received, both orally during the public hearings, or written, by source, organization and/or individual. The index refers the reader to the numbered comment where a response is provided. Because numerous comments were received on the same issue, the comments stated in this section condense and distill the submitted comments, while stating the essence of the commentator's question. A verbatim compendium of all the comments received in the form of transcripts of testimony at the pubic hearings and written comments submitted is provided in Appendix G to this FEIS.

- Section 40.3 contains comments and responses, organized into the following major categories:

  → Section 40.3.1 lists general comments organized by the following topics: Facility Capacity and Design, Alternatives Analysis, Waste Reduction and Recycling, Enhanced Public Participation, Borough Self-sufficiency, Public Health, Odor, Air Quality, Traffic, SWMP Process and Objectives, and Costs.

  → Section 40.3.2 list site-specific comments and is organized by borough and by site within each borough.

  → Section 40.3.3 provides comments by Involved Agencies, inclusive of: (i) comments from NYSDEC, NYCDOT, and NYCDPR; and (ii) comments received by the City Planning Commission during the ULURP application review process.

  → Section 40.3.4 contains comments from the Commercial Waste Management Study and includes: (i) a subsection containing an undated report from OWN that followed publication of this Study in March of 2004 and a subsection containing DSNY's response to that report; and (ii) comments received during the DEIS public comment period.

- → Section 40.3.5, Transfer Transport and Disposal Plan, is a report prepared in response to a request from NYSDEC during its review of the draft Part 360 Permits to provide information on the intermodal transfer, barge and/or rail transport, and disposal requirements for handling containerized waste from the Converted MTSs. This report also addresses comments on this topic received during the public comment process.
- → Section 40.3.6 describes the enhanced public participation program that DSNY conducted during the public comment process. This program was implemented in all the potential project areas where public hearings were conducted. The information in this section is supplemented with examples of materials used in conducting this outreach program.

40.2 Comment Index

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
Staten Island	Councilman Oddo		1. The Staten Island TS should only accept waste from Staten Island. 2. Trucks should utilize major roads instead of local streets to get to the TS	360 361
	Councilman McMahon		1. Borough-based self sufficiency is critical. 2. Completion of the rail connection. 3. The Staten Island transfer station must only take waste from Staten Island. 4. Where will the waste go?	45 362 360 70
	Barbara Warren	OWN, Zero Waste	1. Why should waste be handled by private companies, if costs have risen? 2. Analysis of costs and terms of the contracts is needed. 3. Plan needs to address alternatives 4. Support the 70% recycling goal. 5. Create industries that use waste. 6. Need new composting facilities. 7. Manhattan needs a more adequate waste infrastructure. 8. The 59th Street MTS should allow containerization. 9. There are no concrete plans for reducing capacity of private waste TSs 10. SWMP is vague and needs more detail on Zero Waste. 11. Why don't the MTSs have compacting	102 103 8 9 10 11 44 305 2* 71 3

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			capability? 12. The Staten Island transfer station should not be operated by a private entity. 13. State-of-the-art waste processing systems should be included in the SI TS.	 363 364
	John Arntzen	ACTA Maritime Development Corporation	1. Support of the marine system	72
	Helen Bialer	Staten Island Citizens for Clean Air	1. SWMP failed to address alternatives.	8
	Joe Valentin		1. SWMP needs to address better ways to recycle and add materials.	12
	Nick Dmytryszyn		1. Borough-based self sufficiency is critical. 2. Plan must clearly state that Fresh Kills won't reopen. 3. Trucks should use the streets of Travis, and utilize internal landfill roads.	45 73 361
Greenpoint, Brooklyn	Alison Hirsh	Assemblyman Vito Lopez	1. SWMP is a step forward towards borough self sufficiency. 2. Unacceptable to have both sites remain open. 3. SWMP does not discuss closure of the commercial waste sites. 4. DEIS says that the 2 sites will process waste that Greenpoint MTS is processing, but MTS has not operated in five years. 5. If either of the 2 sites are chosen there would need to be mitigation measures.	45 131 79 131 132

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			6. Would like a community advisory board.	133
	Joseph Lentol	State Assemblyman	1. Opposed to opening of any private transfer stations in CB1. Should be in other areas. 2. Needs an environmental review that looks at cumulative impacts.	134 81
	Diana Reina	City Council member	1. Concentrations of waste transfer stations in Williamsburg, Greenpoint and the South Bronx are discriminatory. 2. The EIS must account for true impacts, not just geographic proximity. 3. Need continued community involvement.	134 81 133
	Ana Zak	State Senator Martin Dilan	1. Will not support the plan unless there is reduction of waste in the community. 2. Unfair to have two transfer stations in the community when others could open.	134 131, 134
	Judd Schechtman	Borough President Marty Markowitz	1. Brooklyn has been shouldering the burden of waste for years. 2. Requires certainty that Manhattan's MTSs open, and that there is a decline in receipt of Manhattan's waste. 3. Need commercial haulers to utilize the MTSs, then a phased shut-down of land-based stations. 4. City should enforce regulations at the existing facilities, and ensure that DSNY's facilities also operate under stringent standards. 5. One marine or rail facility, not two would be acceptable.	135 135 136 83 131

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
	Ray Kairys	Chairman of OUTRAGE	1. Community is overburdened by land-based transfer stations, resulting in traffic, air, odor and noise pollution.	134
			2. SWMP must permanently reduce commercial and residential waste processed in the community. Any expansion of capacity must have an offset.	79, 131
			3. Manhattan must handle its own waste.	45
			4. Open the Brooklyn MTSs before any of the alternatives to reduce waste in the neighborhood as quickly as possible.	136
			5. Opposed to the opening of two private facilities in Williamsburg/Greenpoint.	131
			6. Need dedicated ingress and egress from highways.	132
			7. Traffic impacts from Kosciusko Bridge must be considered.	137
			8. Wants a community advisory group.	133
	Deborah Masters	Chair or CB1 Environmental Committee	1. CB1 handles 45% of waste, which results in health concerns to the community.	138
			2. There are many questions which need to be answered to make the process work.	139
			3. The community wants to be involved in the decision-making process.	133
			4. Health issues are a concern.	140
			5. The permit applications must include an analysis of $PM_{2.5}$ and H_2S.	140
			6. Any facility must be equipped with the best particulate controls.	141

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			7. Issues related to trucking are the major concern: emissions, vehicle speed and accidents, etc.	132
			8. Impact of major local projects was not considered in the DEIS.	132
			9. DSNY trucks must stagger deliveries.	142
			10. Questions regarding dredging of Newtown Creek.	143
			11. If BFI is chosen, what is the plan to minimize congestion in Harlem River Rail Yards?	144
			12. What are the alternative plans in case of breakdowns?	145
			13. Recommendations for house-keeping of the facility.	146
	Sister Veronica Hammond		1. The high number of trucks is a real problem in the neighborhood.	132
			2. Its an injustice that Manhattan sends its waste elsewhere.	135
			3. There should be no more than one transfer station in this neighborhood.	131
			4. The traffic on Metropolitan Avenue is a problem.	132
	Delia Lopez		1. Odors are a problem in the neighborhood.	147
	Shannon Stone	Waste Prevention Coalition	1. Need aggressive advancement of waste prevention, reuse and recycling.	8
			2. There are no details on how to achieve the 70% recycling goal.	9
			3. Draft SWMP omits the waste prevention	14

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			coordinators programs. 4. The title of Chapter 2 of the SWMP omits the word "reuse". 5. A waste characterization study should be conducted every five years. 6. SWMP needs much more education on waste prevention, reuse and recycling programs. 7. In favor of annual HHW collection days, but recommend additional items for collection. 8. Reuse is more cost effective than landfilling.	 15 16 17 18 12
	Guido Cianciotta		1. There are too many transfer stations in the neighborhood. All of the MTSs should be opened, to ease the burden. 2. The traffic on Metropolitan Ave. is too heavy. 3. The heavy traffic, opening two TSs and two garages in one area is too much.	45 132 131
	Theresa Cianciotta	Concerned Citizens of Whithers Street and the area block association	1. Concern with air quality, traffic, noise and rats from all of the additional trucking. The new garage on Varick will bring even more trucks into the area. 2. The commercial trucks aren't properly covered and don't stay on truck routes. 3. We don't want 2 transfer stations.	132, 131 132 131
	Rebecca White	North Brooklyn Greens	1. We want our fair share; not all of the waste. Existing stations must be closed. 2. The number one goal is a permanent reduction in waste handling capacity. 3. An MTS should be sited in lower Manhattan.	131 134 135

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			4. Trucks need to avoid residential streets. 5. DEIS is erroneous to say there are no negative health impacts. 6. Waste prevention is key. 7. Need to reduce emissions of waste vehicles.	132 138 12 10*
	Laura Hoffmann	Barge Park Pals	1. Need a net reduction of solid waste handling in the community. 2. City must choose only one facility for the area. 3. If the BFI facility is chosen, DSNY must ensure it is state-of-the-art. 4. Manhattan must have its own MTS. 5. The Greenpoint MTS must not open. 6. Community involvement is needed for disposition of the Greenpoint MTS site. 7. Communities affected by the SWMP facilities should receive amenities. 8. The EIS must consider the Cross Harbor project impacts. 9. The Williamsburg/Greenpoint rezoning may affect the SWMP. 10. Truck traffic must stay off residential streets.	134 131 148 45 149 149 80 137 137 132
	Carlotta Giglio		1. Truck traffic on Metropolitan is unbearable. 2. The traffic noise affects the school on (or near) Metropolitan 3. The truck rumbling has caused cracks in some area homes.	132 150 132
	Alison Cordero	St. Nicholas	1. Need a reduction in waste facilities in the	134, 131

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
		Church	neighborhood. 2. Need a fair share of facilities. 3. Clean fill transfer stations need to be addressed. 4. We have nonconforming uses which are affected by the private transfer stations. 5. Wants one facility, not two. 6. Community needs mitigation and compensation. 7. Use of green trucks at the new garage facility. 8. Need a community advisory board. 9. Continue with waste prevention.	 45 4* 151 151 80 82 133 12
	Dr. Edward Fishkin	Medical Director of Woodhull Hospital	1. Concerned with the truck traffic, and its affect on asthma rates. 2. Need fair share of facility distribution.	152 45
	Carina Sciangola		1. Take the trucks off the street and barge the waste. 2. Need better odor controls, monitoring and enforcement.	132 141, 132
	Dominick Sciangola		1. Need a reduction in the number of transfer stations, and a cap on capacity. 2. More enforcement of existing laws. 3. Must reduce truck traffic.	131, 134 2* 132
	David Yassky	City Council member	1. This CD needs relief from waste transfer; offsets for any new facility. 2. All MTSs must open.	134 135
	Evelyn Cruz	Congresswoman Valezquez	1. Must permanently reduce land-based facilities, and address their closure.	131

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			2. Must have borough self-sufficiency.	45
			3. The waste transfer stations and clustering of other facilities is damaging the environment and health.	134
			4. Must have a tonnage offset.	131
			5. Commercial waste should be handled at all MTSs.	5*
			6. DSNY must evaluate the private land-based transfer stations and regulations.	79
			7. Enforcement needs to be stepped up.	83
The Bronx	Paula Laura Kaplan	Bronx Borough President Adolfo Carrion	1. Approval of several key aspects of the Plan.	45, 110, 5*
			2. DEIS inadequately analyzes HRY and 132nd Street site.	111
			3. Need a comparative assessment between the two sites.	112
			4. DEIS failed to analyze $PM_{2.5}$ at 132nd Street	113
			5. Barge-to-rail would contradict the fair share objectives of the plan.	114
			6. The plan fails to identify disposal sites.	70
			7. How will the 70% recycling rate be achieved?	9
			8. Waste reduction is inadequately addressed.	12
			9. The DEIS undervalues the correlation between diesel fumes and asthma.	49
			10. The DEIS fails to analyze the impact on the redevelopment in Port Morris.	115
			11. The impacts to Randalls Island must be addressed.	116
			12. While not part of the proposed plan, the	117

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			DEIS makes statements about the South Bronx MTS impacts which are not true. 13. The DEIS states that the existing MTS would remain standing, which contradicts the Hunts Point Vision Plan.	 117
	George Torres	Council member Jose Serrano	1. The plan is vague. 2. Both facilities should not be receiving waste, only one. 3. Is the development of an intermodal facility at HRY a reality?	118 118 119
	Marion Feinberg	Carlos Alicea	1. Exporting waste will impose environmental burdens on other communities. 2. It is disingenuous to say there is no permit expansion, since a permit expansion just took place. 3. Need to implement more reuse and recycling programs. 4. The plan includes a South Bronx staging area, so waste from other boroughs will come to the Bronx. 5. Manhattan waste will go to the incinerator in Newark, and this is an unhealthy strategy to dispose of waste. 6. The 20-year plan will guarantee a lot of money to private corporations, and specifically to Waste Management. 7. Poor and nonwhite depressed communities will bear the environmental impacts. 8. There is no cohesive plan for zero waste.	84 120 8 114 84, 85 84 37 71

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			9. Cannot support a plan that gives waste control to Waste Management	121
			10. The plan claims to be fair but locations of facilities are all in areas of low-income.	37
			11. When the East 91st Street MTS doesn't get built, where will the waste go?	45
			12. It is not fair that the waste goes to landfills also sited in poor communities.	37
			13. There is an odor problem at the Waste Management facility.	121
			14. There is insufficient rail capacity out of HRY and the City. Waste will back up.	121
	Harry J. Bubbins		1. A capacity expansion was allowed, and a full EIS was not done.	111, 120
			2. If CB1 is to get all of the waste, there needs to be mitigation and benefits to the community.	80, 122
			3. There should be a local neighborhood advisory council.	122
			4. There should be a barge option in addition to rail.	127
			5. The two proposed facilities occupy much of the waterfront; access is needed where space is not utilized.	123
			6. City should look at initiatives to pressure companies to reduce packaging; reduce waste generated.	19
			7. Biodiesel should be looked at to reduce emissions.	82

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
	Silkia Martinez		1. All of these facilities are put in low-income communities. 2. The facility will affect the asthma rates. 3. The Hunts Point community has 15 stations and doesn't need any more.	37 49 124
	Marta Rodriguez	Sustainable South Bronx	1. In favor of the MTS or the alternatives if private land-based transfer facilities close. 2. How can there be no impacts from all these facilities?	124 113
	Elena Conte	Sustainable South Bronx	1. Need to aggressively pursue zero waste. 2. Need to reduce the putrescible waste capacity in the Bronx to 4,000 tpd, by closing land-based stations. 3. Need to strictly adhere to borough self-sufficiency. 4. Willing to accept fair share of waste if operation of facilities is improved. 5. Host community benefits are needed for areas accepting the facility. 6. Opening a new facility needs to be done at the same time as closure of land-based facilities. 7. City should develop a community advisory group. 8. Only one company should get Bronx waste. 9. The proposed intermodal facility in the Harlem River Yard needs to be discussed. This facility violates borough self-sufficiency, and is unacceptable.	12 124 124 125 122 124 86 118 119, 114

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			10. How can it be that the intermodal facility is not subject to environmental review?	114
			11. The DEIS refers to previous studies but doesn't provide an analysis of current impacts.	111
			12. None of the historical studies have examined off-site impacts; it needs a full analysis.	111
			13. New truck traffic on Bruckner and Barry is not analyzed. Changing the traffic signal will not mitigate the problem.	112
			14. Need more controls on existing facilities.	121
			15. The environmental impacts of transfer station siting and operational regulations need to be assessed as part of the SWMP.	79
	Sharon Josln		1. We are suffering from the current conditions in the South Bronx.	124
			2. NYC needs to be more creative in waste management.	87
			3. The quality of life needs to be considered.	123
	Timothy J. W. Logan	Consumer Policy Institute of Consumers Union.	1. Only the MTSs are discussed in the SWMP.	87
			2. Diversion strategies are needed.	8,9
			3. Zero waste was dismissed.	12
			4. There is no detail on how to get to the 70% and 35% diversion rates.	9
	Timothy Logan for Yolanda Gonzalez	Bronx SWAB	1. Support of waste export by barge or rail.	72
			2. Need a comparative environmental analysis of the two sites.	112
			3. Concern with HRY as an intermodal site,	114

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			taking waste from other boroughs. 4. Supports the transfer station in Manhattan. 5. Supports the composing projects and recycling goals but wants details. 6. City should develop borough-based recycling industrial parks. 7. Need greater attention on food waste composting. 8. SWMP needs to address commercial waste prevention and recycling. 9. Increased transfer station revenues need to be dedicated to commercial prevention and recycling programs. 10. SWMP needs to investigate commercial waste franchising. 11. City should pursue local EPR legislation. 12. City support for expansion of the State's bottle bill is needed. 13. Plastic packaging needs to be addressed. 14. Anaerobic digestion should be pursued, not types of incineration.	 126 71 20 11 9 88 5* 21 12 12 87
Review Avenue, Queens	Jerel Klue	Council member Eric Gioia	1. SWMP will add more traffic to already crowded streets. 2. We don't want facilities to affect the waterfront.	352 354
	Joe Conley	Chairperson of Queens CB2	1. Truck traffic is already a big problem. 2. The Plan will affect revitalization of the area.	352 354
	Joseph Ruzalski	United 40s	1. Plan will cause traffic problems on Review	353

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
		Civic Association and CB5	Avenue, Greenpoint Avenue; too much congestion, too many projects.	
	Dorothy Morehead	Chair of Environmental Committee of CB2	1. Problems with trucks, resulting in LIC having worst air pollution in the City. 2. Truckers don't stay on truck routes, and travel on regular streets. 3. The siting is disastrous; should transport by rail.	352, 355 355 353
	Don McCallian	Member of United 40s	1. Truck traffic is currently horrendous; 48th Street, 43rd Street, 39th Street and Review Ave. cannot take more traffic.	352
	Gertrude McDonald		1. Streets cannot withstand heavy trucking. 2. Is the City paying attention to our problems?	352 356
Hamilton Avenue	Fred Xuereb		1. Manhattan facilities won't be built, resulting in trucks coming to Brooklyn. 2. There are trains in Bay Ridge Yards now, with waste protruding from the cars. 3. Why does Sunset Park get all of the barge facilities, when other areas, like the Arthur Kill could be utilized? 4. The DEP or EPA should be involved with assurances on idling trucks.	154 155 158 171
	Nancy Walby	Brooklyn SWAB	1. The Plan for moving waste by barge or rail from enclosed facilities is a good one. 2. How can the community be assured that Hugo Neu's operation will be clean? 3. Concern with truck queuing on Hamilton	72 159 162

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			Avenue. 4. Concern with enforcement of air, noise and traffic pollution. 5. SWMP is not aggressive enough in plans for composting and recycling.	 162 8
	Felecia Campasano	Board President of Bay Ridge Towers	1. What type of waste will be in the containers; how many trains and barges? 2. What happens if it is snowing or icy? 3. What guarantee is there that the containers will be sealed?	155 155 155
	David Rizutto	Property manager of the Towers of Bay Ridge	1. How can there be no need for an environmental study for an intermodal yard? 2. Where does the waste that is currently on the rails under the building come from? 3. How frequently will the barges take the containers away?	156 155 155
	Antonia Smith		1. How will waste at 65th Street be transferred? 2. How can we be assured the containers will be enclosed? 3. How many trucks and trains will be moving in the area? 4. Have surveys been performed of the building structure to ensure that the train traffic won't damage the buildings? 5. How can be we sure that there won't be noise or odor impacts? 6. We are concerned with an increase in rodents.	155 155 155 156 156 155
	Nicole Tai	Chair of Sanitation	1. How much money will be put into fixing the streets?	162

Index of Oral Comments at DEIS Hearings

		committee for CB7	2. How can we be assured that trucks won't be using alternate routes?	162
			3. Locating four facilities in the neighborhood is an overburden. Has the EIS addressed the cumulative impacts of all four?	164
			4. We did not receive the SWMP or any of the appendices to the DEIS.	165
			5. Is there potential for the 52nd Street barge staging area to be a source of traffic?	157
			6. Will the 65th Street intermodal yard be a source of traffic?	155
			7. If the Manhattan facilities don't open, will all the trucks go to Brooklyn?	154
			8. When will the Hugo Neu facility open?	159
			9. More is needed on waste prevention, recycling and reuse.	12
			10. There is no mention of many facilities that accept recyclables.	12
			11. There is no mention of the cost of waste prevention initiatives. No legislation.	9, 17
	Gloria Flora Nicolich		1. The Sunset Park area has become a dumping ground, home to all types of detrimental facilities.	164
			2. The community does not want the facility because it will bring traffic, vermin, and pollution to the area.	159
	Edward Wade		1. There is concern that the Hamilton Ave. facility will have more trucks than East 91st Street, so will be open longer.	163

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			2. The SWMP says that Manhattan recyclables will be trucked to Brooklyn.	160
			3. Hamilton Avenue will be crowded with trucks from every Borough.	163
			4. No other CD is getting four facilities, only CD7.	164
			5. Why are there to be two truck weighing stations at the 30th Street pier, if there are no trucks?	160
			6. Concerning 52nd Street, why build a 500-ft long, 60-ft wide pier, to tie up a barge?	157
			7. The 65th street rail yard has no cranes, so how can the containers get off the barge?	155
			8. The containers from Hamilton Ave. will be trucked to 65th Street, creating a lot of traffic.	160
	Timothy Logan	OWN, NYC Zero Waste Campaign, Consumer Policy Institute	1. The DEIS fails to examine siting regulations and phasing out of truck-based facilities.	79
			2. The findings of no significant adverse impacts did not take into account the Gowanus redecking or the plan for closure of land-based transfer stations.	166
			3. There are conflicting numbers for truck trips for the Hugo Neu site.	160
			4. Only about one-third of Brooklyn should be going to Hugo Neu by truck…the rest should be barged.	160
			5. SWMP needs more on reuse, recycling and composting.	8, 12
			6. SWMP fails to address zero waste.	12

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			7. Manhattan needs to deal with its own waste. 8. 70% diversion goal provides no detail. 9. More discussion is needed on composting. 10. Commercial waste and C&D streams need to be addressed in terms of diversion. 11. Commercial waste franchising should be investigated. 12. City should pursue local EPR legislation. 13. SWMP should support the State's bottle bill. 14. Policy is needed to address plastics. 15. Alternative technologies should not include combustion; anaerobic digestion should be pursued.	45 9 13 9 5* 21 12 12 87
	Dyhalma Anaya	Youth organizer at UPROS	1. Open the barge-fed MTS, and close the transfer station on 50th Street.	166
	Irene Shen	UPROS	1. Concerned with the truck traffic in the neighborhood. 2. Need to close land-based stations, and open the Manhattan facilities.	154 154
	Jeremy Laufer	District Manager of CB7	1. Under this SWMP, waste will go from Manhattan to Brooklyn, but not the other way around. 2. No other CD is asked to host four facilities. 3. Never received notification of ULURP certification. 4. Need an EIS for the 52nd Street staging area and the 65th Street Intermodal yard. 5. Need to address the cumulative impact of all these facilities in the neighborhood.	47 164 165 156 164

Index of Oral Comments at DEIS Hearings

			6. The land-based facility in the area is too close to people's homes.	2*
			7. The 25 trucks coming to Hugo Neu seems too low a number.	160
			8. The replacement of the drawbridge will occur at the same time as the MTS will come on line. What will the impact be?	166
	Chaplain Viviania Hernandez		1. Plans for Sunset Park indicate no barges and cleaner air. This conflicts with the SWMP.	167
			2. Not fair to have four facilities in Sunset Park.	164
			3. Each borough must recycle its own recyclables.	47
			4. Community Development revitalization project, 197A is in direct opposition to the SWMP.	167
			5. There will be construction impacts during park development which are not taken into account.	167
			6. The area has deteriorated roadbeds and antiquated infrastructure.	162
			7. Traffic congestion already results in air pollution.	162
	Judd Schechtman	Borough President Marty Markowitz	1. Hugo Neu facility will burden the area.	164
			2. CDs 6 and 7 already handle more than their fair share of waste.	164
			3. Brooklyn will get more facilities than any other borough.	168
			4. Require assurances that any planned facilities operate under the strictest environmental	168

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			standards. 5. The plan must be undertaken in its entirety; Manhattan facilities must open. 6. Must guarantee offset in the total amount of waste handled. Close 50th Street and 577 Court Street facilities. 7. Reduce truck traffic; use marine facilities. 8. Gansevoort Street facility must open. 9. Must coax the commercial haulers to utilize the Converted MTSs. 10. Best practices must be utilized to eliminate fugitive debris at the MTS. 11. Would like the Hugo Neu facility totally enclosed and preferably containerized. 12. What will happen to the 20% of material considered residue at Hugo Neu? 13. Don't want floatables in the harbor. 14. Need effective regulation of private facilities. 15. Need a citizen enforcement system. 16. Want host community compensation.	 154 166 162 154 5* 170 159 161 159 2* 162 168
	Leonard Silver		1. Why can't the facilities be sited in areas where there are no residents?	164
North Shore	Robert LoPinto	Chair, CB7 Environmental committee and Queens SWAB	1. More emphasis on waste prevention is needed. 2. The CD already has a number of facilities, including the MTS and a garage for another CD.	12 345

Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			2. The 4 MTSs dropped from the plan were dropped because they were in residential communities, yet this is a residential community too.	210
			3. Failure to address waste reduction strategies.	8, 12
			4. Expand usage of garbage grinders.	13
			5. Trucks will be lining up on York Ave., and won't be accommodated on the ramp, adding to traffic issues.	207
			6. The ramp to the facility should not be covered.	216
	Eve Moskowitz	City Council	1. The MTS is a bad idea for many reasons.	206
			2. Need to find a collective solution to waste disposal	74
			3. The DEIS doesn't take into account the real picture.	207
	Jessica Lappin	Speaker Gifford Miller	1. Opposed to the East 91st Street site	206
			2. Favors use of marine system for waste removal.	72
			3. Zoning should matter; MTS can't open in a residential area.	206
			4. New MTS will take 2 to 4 times what it used to take; how can that have no impact?	209, 1
			5. Truck traffic will significantly impact York avenue.	207
			6. DEIS fails to address the negative impact of the MTS on local parks.	211
			7. More sensible alternatives exist for Manhattan's waste.	212

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
	Micah Kellner	Congresswoman Carolyn Maloney, 14th Congressional District	1. This is the only MTS planned for a residential neighborhood. 2. The DEIS contains significant flaws that reflect deference to political concerns. 3. The DEIS does not reflect the true impacts on air quality, traffic patterns, pediatric health, open space and public health. 4. The rates of asthma are among the highest in the U.S. 5. Neighborhood was very different when the facility was first built. 6. DSNY's siting rules do not permit a private transfer station within 400-ft of a park. 7. No justification is given for why this site is suitable. 8. The DEIS doesn't consider an analysis of the facility at full capacity. 9. The DEIS fails to address the impacts of demolition of the existing facility, particularly on Asphalt Green. 10. The DEIS fails to analyze odor impacts on recreational facilities. 11. The DEIS inadequately describes the dimensions and appearance of the new MTS, and its impact. 12. Having an MTS in each borough results in impacts to this residential community.	206 213 206 214 209 211 206 1, 209 215 211 216 46
	Rick Muller	Manhattan Borough	1. Opposed to this facility in densely residential neighborhood.	206, 211

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
		President C. Virginia Fields	2. The DEIS analyzes for less than half of the capacity. 3. Access to the facility cuts through Asphalt Green, and this is not adequately addressed. 4. DEIS needs to analyze air quality and noise of commercial vehicles. 5. Disclose why East 91st Street was selected, but not West 135th Street. 6. Manhattan SWAB identified 4 additional sites in Manhattan which were not suitable; these sites should be evaluated as well as the four sites in the CWMS.	215 216 217 210 218
	Jackie Ludorf	CB8 Chair of the Environmental and Sanitation Committee	1. DEIS analysis is at a lesser capacity than the intended design. 2. Inadequate analysis of alternatives. 3. DEIS lacks a comprehensive cost/benefit analysis. 4. What are the details of the traffic analyses performed? 5. What is the impact to delivery trucks? 6. No mention of odors from trucks. 7. While businesses that generate waste are located in CB8, the people come from all over the City. 8. Noise will be an issue. 9. Will diesel trucks be transporting waste from other areas?	215 210, 211 104 219 211 220 221 222 221
	Philip Opher		1. Clarify the definition of a buffer zone in the siting rules.	211, 223

			3. Site was chosen for political reasons.	213
	Council Member Gale Brewer	West side of Manhattan	1. Would like commercial trucks to use alternative fuels. 2. Doesn't want all commercial or residential waste in one place.	10* 226
	Tony Ard	President of Gracie Point Community Council	1. The City's planning has pitted one neighborhood against another. 2. Studies have been done at Columbia University identifying alternatives that are less destructive.	74 212
	Carol Tweedy	Executive Director of Asphalt Green	1. How can the facility be sited in Asphalt Green? It is a City asset. 2. Need an analysis of economic impacts at Asphalt Green. 3. The facility conflicts with siting rules. 4. DEIS fails to analyze traffic on Saturdays, odors on Asphalt Green. 5. Ramp construction will interfere with the fields.	206 211 211 211 211
	Richard G. Leland	Attorney for Gracie Point Community Council	1. The DEIS, if submitted by a private developer would not have been accepted as complete. 2. DEIS lacks information on where waste will go. 3. There is no evidence that the Plan makes economic sense. 4. Underestimation of the true impacts and capacity of the facility. 5. DSNY believes it is exempt from full and	74 70 104 215 41

Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			proper compliance with CEQRA.	
	Dr. E. Arthur Livingston		1. The DEIS was not objective; DSNY "cooked the books". 2. The MTS will destroy the area.	41 209
	Kathryn R. Edmunds		1. The study area for this project is three times more populous as the next most populated study area. 2. Much of the data in the DEIS is given as a percentage, instead of as an actual number of people affected. 3. The area is far too populated to accommodate the proposed MTS.	227 228 227
	Kendall Christiansen	Insinkerator	1. DEIS and SWMP failed to address food waste diversion. 2. Food waste should be handled separately. 3. SWMP doesn't even propose looking at what other cities are doing.	13 13 13
	Evan Firestone		1. DEIS understates the affected community. 2. No other borough is affected by Manhattan's current disposal of waste. 3. Real life data shows that there will be impacts. 4. How can the ramp be widened? 5. The facility will create gridlock on the entire Upper East Side. 6. Commercial waste was not adequately studied. 7. There are alternative waterfront sites in Manhattan.	227 229 209 230 219 3* 218

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
	Neal Flomenbaum		1. The MTS will create serious adverse health impacts. 2. The DEIS is seriously flawed. 3. The MTS is a new facility, not a converted MTS. 4. New MTS poses greater damage to health than a nuclear reactor.	214, 206 213 209, 211 214
	Benjamin Miller	Columbia University School of Engineering Center	1. The plan will be a significant environmental and economic benefit. 2. DEIS fails to address zoning for disposing of waste; City should not be dependent on private landfill market. 3. Landfill will be the most expensive alternative; the City should acquire capacity within the State. 4. Waste-to-energy is preferable.	231 76 76, 77 77
	Charles Emma		1. Randalls Island would be suitable for an MTS.	218
	Richard Marlin	President of 535 East 86th Street	1. The MTS will create problems worse than there were previously.	209
	Dr. Clifford Bluestein		1. The MTS will create major health risks.	214
	Mary Fliegir	Trustee of the Gil N. Brewer School	1. The MTS will create problems for our special needs children.	232
	Alice Konorezov		1. There were terrible odors when the MTS was previously opened. 2. How will trucks get to the facility given the tremendous congestion that exists?	209 207

Index of Oral Comments at DEIS Hearings				
Hearing Location	**Speaker/Author**	**Representing**	**Summary of Issues**	**See Comment Number**
			3. Increased traffic on the river is a hazard.	233
	Heleen Brody	Vice President of 180 East End Tenants Association	1. DSNY is ignoring its own siting rules. 2. Analyzed the MTS at only a portion of its capacity. 3. An analysis of odors on the parks was not undertaken. 4. Does <u>not</u> advocate sending Manhattan's waste to other boroughs.	211 215 211 226
	Timothy Logan	Consumers Union, New York City Zero Waste Campaign, and Organization of Waterfront Neighborhoods	1. Disapproval of the plan without alternative sites is unconscionable. 2. Best available control technologies should be utilized at all MTSs, including routing of trucks. 3. There should be planned closure of truck-based facilities in conjunction with reopening of the MTSs. 4. Community mitigation programs need to be included in the Plan. 5. Zero waste should be embraced.	234 78 79 80 12
	Dr. Marjorie Clarke	Manhattan SWAB and Waste Prevention Coalition of New York City	1. Consider an alternate vision for the ramp. 2. Evaluate the feasibility of a number of small sites for recyclables and waste. 3. Stagger shifts to avoid queuing. 4. As new trucks are purchased, they should use alternative fuels. 5. The EIS should delineate cumulative emissions in all parts of New York from the no action alternative. 6. Strive for zero waste.	235 81 78 82 90 12

	Bauer, Ilene		1. Previous MTS operated poorly. 2. Should not be in a residential area.	209 206
	Belina, Peter		1. The trucks coming to the facility will pose a danger to the children at Asphalt Green.	206, 211
	Blachere, Nathalie and Maki, Robert		1. The MTS may affect Carl Shurz Park and Asphalt Green. 2. Alternative location at the cement plant north of northern end of 1st Avenue.	211 218
	Bleustein, Clifford		1. Diesel exhaust will affect asthma rates. 2. Conclusions drawn from PM analysis are flawed; the effects from diesel exhaust at the MTS and surrounding area has not been assessed. 3. The $PM_{2.5}$ analysis is based on false assumptions; the contribution from the facility needs to be added to the background and a cumulative PM analysis needs to be done. 4. There are too many trucks not to have queuing.	214, 49 51 237 238
	Borrell, Wendy		1. Facility is sited in a densely populated area. 2. Tonnages vary at each presentation.	206, 227 215
	Brand, Susan		1. Asphalt Green will not be a safe and healthy place if	206

			the MTS gets built.	
	Bulua, Stan		1. The impacts are underestimated because the throughput is less than capacity. 2. There is no analysis of why the site was chosen. 3. DEIS did not address impacts to the residential area and parks.	215 210 209
	Bulua, Gail		1. The facility should not be sited in a residential area. 2. MTS siting does not meet current zoning laws.	209 209
	Chadwick, Knox		1. Don't build the facility.	206
	Chase, Norman and Joan		1. The facility should not be sited in a residential area. 2. There is already too much traffic. 3. Should examine alternative method and alternative sites.	206, 209 207 87, 218
	Clarke, Maggie		Refer to oral testimony.	---
	Adams, Joan; Angelo, Casey; Angelo, Lauren; Arkin, Hadara; Atkind, David; Auerbach, Jacqueline; Baker, Patricia; Bandler, Babette; Bartlett, Scott; Baum, Deborah H.; Blasi, Roberta D.; Blau, Joan; Bleustein, Clifford; Bleustein, Sheri; Braverman, Ellen J.		1. The facility should not be sited in a residential area. 2. It falsely assumes that one third of the capacity will be used. 3. The DEIS should look for other waterfront sites. 4. Mitigation is inadequate, impractical and unenforceable. 5. Site would not be acceptable if it were a private transfer station.	209 215 218 236 223

	Zanghellini, R.; Zazosi, Tammy; Zimmer, Samantha; Zimmer, Virginia			
	Curtis, James		1. The facility should not be sited in a residential area, near a historic landmark, or next to a park.	206
	Curtis Jr., James and Rachel		1. The MTS will have severe environmental impacts.	206
	DeCosse, Sheila		1. The MTS should not be near a park.	211
	Duff, Patricia		1. Opposed to the MTS because of severe traffic. 2. The diesel emissions will pose a health risk. 3. Vermin and extermination poisons will pose a health threat. 4. Noise will be a problem. 5. The large volume of sanitation trucks will pose a danger.	207 214 209 207 207
	Edmunds, Kathryn R.		1. This study area is 3x more densely populated than any other study area. 2. Pier 42 should be looked at as an alternative site. 3. East 91st Street includes an EJ community, so outreach should be the same as for other areas. 4. PCEs for sanitation trucks were inappropriate. 5. There were differences in evaluating sites. 6. No buses were counted on 1st, 2nd or York Avenues. 7. Pedestrian counts seem inadequately estimated. 8. Commercial trucks are heavier, so studies need to be adjusted. 9. No information provided on trucks for recycling facility.	227 218 242 65 66 243 243 66 67

40.3 Comments and Responses

40.3.1 General Comments

40.3.1.1 Facility Capacity and Design

1. Comment: Several comments expressed concern that the DSNY intended to process 4,290 tpd at each of the Converted MTSs and was being inconsistent in its presentation of the capacity it intends to permit at these facilities.

Response: The F~~D~~EIS and the Draft New SWMP explain that each of the Converted MTSs will handle the respective wasteshed historically served by the existing facilities and limited quantities of Commercial Waste, acceptance of which the environmental review in the ~~D~~FEIS shows would not cause any potentially significant unmitigatable adverse impacts. The proposal to process commercial waste at the Converted MTSs responds to the requirements of Local Law 74 of 2000, which directed that DSNY evaluate this issue as a potential means to reduce impacts from the presence of multiple transfer stations in certain neighborhoods of the City.

To dispel confusion on the issue of the permitted capacity that DSNY seeks in the Part 360 permit application pending before NYSDEC, the following presents the anticipated throughputs under various operating conditions and describes DSNY's proposal on the permit limits both on a weekly and on a daily basis for all the Converted MTSs. NYSDEC, as the permit issuing authority, will make the final determination on permit issuance and limits.

This describes the capacity requirements and the DSNY proposed permit limits for each of the four Converted MTSs designated in the Proposed Action, as described in the Draft New SWMP and supporting F~~D~~EIS. These facilities are:

- The North Shore Converted MTS;
- The Hamilton Avenue MTS;
- The Southwest Brooklyn, and
- The East 91st Street MTS.

Table 40.3-1 provides information on the waste flows for DSNY-managed Waste that DSNY would expect to process at each of these facilities under various scenarios that are typical of DSNY operations. Additionally, the maximum daily volumes of Commercial Waste that would be delivered by private carters to each facility, consistent with the analysis of off-site impacts in the ~~D~~FEIS, is listed in the table. Finally, the on- and off-site impact analyses for traffic, air quality, odor and noise as evaluated in the ~~D~~FEIS are listed. The table notes following Table 40.3-1 provide additional information on the sources, underlying assumptions and application of the data in the table.

Table 40.3-2 presents the permit limits that DSNY has proposed to NYSDEC, which is in the process of reviewing a Part 360 Solid Waste Facility Permit Application for each of these facilities. When NYSDEC deems the application complete, it will hold public hearings on each of the applications. If NYSDEC's permit review and hearings process results in a permit issuance, permit conditions will apply to the operation of each facility and the waste types and volumes that can be processed under stipulated conditions. The table notes following Table 40.3-2 provide additional information on the proposed application of these Permit Limits.

Table 40.3-3 presents the Permit Limits that DSNY has proposed to NYSDEC to address a circumstance when there is a disruption in an element of the overall DSNY waste management system or when a public emergency requires that DSNY, acting on the basis of protecting the public health, must use the maximum design capacity at all facilities to remove accumulated refuse from the streets as quickly as possible. The classic example of this Emergency Condition is refuse collections after an extended snow emergency, when refuse has accumulated on the streets. The table notes following Table 40.3-3 provide additional information on the proposed application of these Permit Limits.

Table 40.3-1
Converted MTSs
DSNY and Commercial Waste Anticipated Capacity Requirements
and
Capacities Evaluated in the New SWMP DEIS

Converted MTS Location	DSNY-Managed Waste			Potential Commercial Waste (Noise Constrained) (tpd)[4]	Maximum Daily Waste Evaluated in DEIS for Off-Site Impacts (tpd)[5]
	DSNY Average (tpd)[1]	Average Peak Day (tpd)[2]	DSNY Holiday Week Peak (tpd)[3]		
Hamilton Avenue	1,900	2,280	2,850	1,274	~~**4,100**~~ **3,522**
Southwest Brooklyn	950	1,140	1,425	718	~~**3,451**~~ **2,106**[~~6~~]
East 91st Street	720	864	1,080	780	~~**2,892**~~ **1,873**
North Shore	2,200	2,640	3,300	1,000	~~**3,991**~~ **3,672**

Table Notes:
tpd = tons per day

1. The DSNY average ton per day (tpd) values are based upon an analysis of the historical volumes of DSNY-managed Waste generated annually averaged over 302 days per year in the respective MTS wastesheds.
2. The Average Peak Day (tpd) in column 2 is approximately 20% higher than the Average Day and reflects the daily and seasonal variability in DSNY's weekly collections as well as the potential growth waste generated over time, as a function of future population growth.
3. DSNY experiences a holiday week collection peak day, column 3, when a scheduled holiday reduces six days of collection activity to five days. Post-holiday day peak day collections can be approximately 50% above the annual average day.
4. Column 4 is the quantity of Commercial Waste that could be processed during the 8:00 p.m. to 8:00 a.m. time period without causing off-site noise impacts and was presented in the Summary Report in Volume III of the Commercial Waste Management Study, and also reevaluated in the FEIS. This 8:00 PM to 8:00 PM time period is the period when commercial carters collect waste in the City and DSNY collection operations are at their lowest volume. Local Law 74 of 2000 directed that DSNY evaluate the potential to process commercial waste at the MTSs. The arrangements under which processing of commercial waste would occur will be the subject of discussion between DSNY and the City Council during the adoption of the New SWMP.

Table Notes for Table 40.3-1 (Continued):

5. The Maximum Daily Tonnage Evaluated in the FEIS for Off-Site Impacts, Column 5, is the sum of data derived from the following sources and methods: (i) a calculated value from a sample of available, historical 1998 data for the Average Peak Day for DSNY-managed Waste in the Converted MTS wastesheds plus a 20% contingency allowance that reflects variations in the waste stream and a margin of conservatism in the analysis of the potential for significant adverse *off-site* impacts related to traffic, air quality, and noise (essentially DSNY collection vehicle traffic to and from the Converted MTS); and (ii) the Commercial Waste Tonnage identified in column 4. Note that the historical 1998 data for the Average Peak Day for DSNY-managed Waste evaluated in the FEIS exceeds the value listed in Column 2 for the Average Peak Day.

~~6.This total is restricted for off-site noise analyses to 3,341 tpd, but was analyzed for all other off-site impacts at 3,451 tpd.~~

Table 40.3-2
Converted MTSs
DSNY-Proposed Weekly and Daily Permit Limits

Proposed Permit Limit	Weekly Limit – tpd times 6 days per week Tons per Week[(1)]	Maximum Peak Day (tpd)[(2)]
Hamilton Avenue	21,324	~~4,100~~ 3,522
Southwest Brooklyn	11,148	~~2,143~~ 2,106
East 91st Street	9,864	1,860
North Shore	21,840	~~3,991~~ 3,672

Table Notes:

tpd = tons per day

1. The Weekly Limit (column 1) proposed is the sum of: (i) the DSNY Average TPD amount shown in Column 1 of Table 40.3-1 multiplied by 6 days per week and increased by a 20% contingency factor to allow for seasonal variability, growth in waste generation and system redundancy; and (ii) the Maximum Commercial Waste in Column 4 of Table 40.3-1 multiplied by 6 days per week. This limit would not be exceeded in any calendar week, except for an Emergency Condition.

2. The Maximum Peak Day TPD limit (column 2) is proposed as the level sufficient to enable DSNY to process holiday-week peak day tonnage which, based on DSNY historical data, is often 150% of average TPD throughput. This limit is calculated as the lesser of: (i) the sum of the 150% of Average TPD for DSNY-managed Waste plus the Commercial Waste from column 4 of Table 40.3-1; or (ii) in the case of Hamilton Avenue, Southwest Brooklyn and North Shore, the maximum capacity evaluated in the FEIS (from Column 5 of Table 40.3-1) for off-site impacts and shown to have no significant adverse impacts.

Table 40.3-3
Converted MTSs
DSNY-Proposed Emergency Permit Limits

Proposed Permit Limit	Upset Condition Limit (Time Limited tpd)[(1)]	Emergency Condition limit (Time Limited tpd)
Hamilton Avenue	4,290	5,280
Southwest Brooklyn	4,290	5,280
East 91st Street	4,290	5,280
North Shore	4,290	5,280

Table Notes:
tpd = tons per day

1. The Upset Condition Limit would be defined as an infrequent, short-term event causing a reduction in the processing capacity of an element of the DSNY waste management system, such as a fire or equipment outages, requiring a temporary re-allocation over a period of few days duration, during which the tonnage normally processed by the affected element of the system is diverted to other unaffected elements of the system. The proposed Upset Condition Limit is the capacity of the Converted MTSs as documented in the Basis of Design discussion in the permit application, which is 4,290 tpd for all the Converted MTSs. The FEIS evaluated the potential for significant adverse impacts *on-site* related to air quality, odor and noise, assuming the facility were operated at its design capacity. The analysis evaluated emissions from all on-site sources, including equipment trucks inside the processing building and tugs servicing barges that would result from operating the facility at its design capacity.

   The basis of design for the proposed MTS considered hourly and daily peak arrival rates for DSNY collection vehicles and tons of DSNY-managed Waste. The hourly throughput rate was established to ensure that the MTS could process anticipated peak hour deliveries of DSNY-managed Waste. This peak arrival rate for DSNY collection vehicles occurs during the second shift, typically for one hour between the hours of 8:00 a.m. to 12:00 p.m. Given on-floor storage capacity, the number of tipping bays and on-site truck queuing space on the ramps, this arrival can be accommodated without any off-site queuing. Daily capacity is a function of the number of operating shifts and shift hours during the day.

   The MTS would operate for three shifts to accommodate anticipated deliveries of DSNY-managed Waste over a 24-hour period. Given these parameters for receiving and containerizing DSNY-managed Waste, there is also the potential for deliveries of Commercial Waste to the MTSs during nighttime periods between 8:00 p.m. and 8:00 a.m. when deliveries of DSNY-managed Waste are substantially less than the facility's available capacity.

Table Notes for Table 40.3-3 (Continued):

Hourly throughput and daily design capacity are based on the following assumptions:

- The MTS would process 10 containers per hour using three loading slots with the fourth maintained in a spare mode.
- The loader level would be kept as clear of waste as possible during processing hours by loading all waste received into containers as soon as possible and keeping stockpiles at a minimum.
- Each container would be loaded with approximately 20 to 22 tons of waste.
- Each barge would be loaded with 48 containers of waste.
- Barge switches would not interrupt waste processing operations.
- Employees would effectively work 6.5 hours out of an 8-hour shift due to shift changes and break time during the shift, resulting in 19.5 operating hours per 24-hour day.

Using these parameters, hourly throughput approximates 220 tons and the average design capacity is 4,290 tpd (220 tons per hour x 19.5 hours per day) for the four Converted MTSs.

Because a Converted MTS could operate at its design capacity of 4,290 tpd, the FEIS evaluated the on-site impacts associated with operating at this 4,290 tpd level to determine the potential for adverse impacts. The analysis accounts for air, odor and noise emissions related to all on-site indoor and outdoor equipment, including DSNY collection vehicles inside the building and queuing on the ramps to the processing building, and tugs and cranes servicing barges at the facility. These on-site air quality, noise and odor analyses found no unmitigable significant potentially adverse impacts. This result eliminated the need for further more refined analyses of on-site impacts at lower waste throughputs.

2. The Emergency Condition Limit would be defined as a rare, public emergency event affecting the entire or a large part of the waste management system. An emergency event would allow DSNY, acting on the basis of protecting the public health, to use of the maximum design capacity at all facilities to remove accumulated refuse from the streets as quickly as possible. The classic example of this Emergency Condition is refuse collections after an extended snow emergency, when refuse has accumulated on the streets. The maximum design capacity at the four Converted MTSs is 5,280 tpd as documented in the Basis of Design discussion in the permit application, assuming the facility is staffed for an emergency to operate with three full shifts and no break time, i.e., 24 hours a day.

   Because neither of these conditions is typical of how the Converted MTSs would normally operate, CEQR does not require impact analyses that evaluate an abnormal event scenario.

2. **Comment:** The design of the MTS seems lacking in durability and reliability in terms of the containerization process and its operation will have serious impacts on the surrounding community. It appears that the containers can be easily damaged, the lidding operation is dangerous to the work crew, and the wheeled transfer platforms are susceptible to malfunction. During icy, rainy, or snowy conditions, it appears that there may be service interruptions or a high risk of injury to operating staff.

Response: The design features of the facility that insure reliability in operations and minimize the potential for impacts on neighboring communities include the following:

- The Converted MTS is designed to receive and process up to 36 collection vehicles an hour, more than anticipated in the peak hour. Trucks queuing outside the old MTS buildings were a frequent source of complaints. Accordingly, the new tipping floor for the Converted MTS is designed with a large maneuvering area and six tipping bays to unload six trucks at a time.

- The tipping floor is 12 feet above the loading floor, which accelerates the unloading process by eliminating potential interference between collection vehicles and mobile waste processing equipment. Truck turnaround time is also improved through the use of automated scales in contrast to the manual weigh-in – weigh-out system at the old MTSs. Finally, should the arrival rate ever exceed the 36 trucks per hour design criteria, the ramp is structurally strong enough to hold queuing trucks. Although the peak arrival rate occurs during only one hour a day, the need to accommodate this peak rate, maintain the efficiency of DSNY collection operations and avoid on-street queuing problems were all important considerations in the design of the building.

- The loading floor is designed to process 220 tons per hour into containers, using three of four processing lines with one held in reserve as a spare. The floor can also provide approximately 760 tons of on-floor storage in the event of a delivery surge or a delay in barge arrival. These design criteria enable the facility to manage maximum expected arrival rates without excessive queuing or turning away trucks. The fourth processing line provides redundancy in the event of mechanical problems affecting one of the other processing lines.

- Container loading and lidding operations occur on the level below the loading floor and are within the enclosed building to prevent the escape of litter and odors to the outside environment. The through-the-floor loading system is a simple, fast, gravity-based process to assure a high degree of reliability.

- The building's ventilation system is designed to maintain negative pressure in the building at all times, even when doors are open with the capability to provide 12 air changes per hour, compared to the code standard of 6. It is also equipped with an odor neutralizing system that treats air as it is exhausted from the building to remove 90% to 99% of the odors from the building's exhaust air. The neutralizing system uses a natural neutralizing agent that is made from a plant compound.

Additionally, the facility will have the following state-of-the-art environmental controls:

- An advanced odor control system; and
- A ventilation system exceeding building code standards that maintains negative pressure to prevent the escape of odors to the outside under all conditions.

The components of the containerization process, including the containers, lids, shuttle cars, lidding hoists and gantry cranes, are all designed for extreme continuous duty in harsh marine environments.

The containers are specifically designed to handle municipal solid waste (MSW). Their strength is much greater than standard traditional cargo containers found at most marine terminals. These high strength environmental containers meet the American Railroad Association (ARA) and the American Bureau of Shipping (ABS) standards, and are industry standard equipment in many intermodal transfer operations.

The container lid is designed for high strength, water tightness and odor control. The lid design also incorporates a twist lock latch system currently used in the industry to fasten containers to transport trailers and rail cars. This new lid and latch system eliminates the need for workers to manually remove and reattach the lids. In this design the lids will be mechanically removed and reattached to the containers by an electric hoist attached to a spreader mechanism and locking device that will automatically position itself and automatically lock itself to the lid.

The entire process, including shuttle car operations, lidding/unlidding operations, container filling, and barge loading/unloading, will be controlled automatically or manually by operations staff located in safe controlled environments.

The shuttle cars designed for this process are simple, rugged and reliable. Their design is based on similar cars used in the paper and steel mill industries to automatically move large heavy materials. They are battery powered remotely and automatically-controlled vehicles designed to handle the rigors of constant heavy use in all weathers and environments. Use of the shuttle cars for container movement is a safety improvement for the operating staff.

The MTSs are designed with considerable flexibility and redundancy to allow for mechanical failure, proper maintenance operations, and other process-related interruptions that may occur, such as inclement weather. Each equipment system has been carefully designed for the harsh marine environment it will be exposed to. Components have been specified to be of extreme duty construction, supplied by manufacturers who have experience building this specific equipment.

3. **Comment:** Why are none of the new MTSs planned to have compacting capability?

Response: Compaction of waste is part of the process operation at all of the new MTSs. Waste material will be compacted by tamper/excavators as each container is loaded to its capacity. In addition, the loading floor and the operation of the wheel loaders have been designed for pre-crushing and compaction of the waste before it is pushed into the containers.

4. **Comment:** The safety and well-being of any neighborhood includes that of the workers at the MTSs and private transfer station sites, who deserve prevailing wages, uncompromised safety protocols and other basic rights.

Response: DSNY is highly committed to worker safety. The safety and well being of the DSNY and private employees who would staff the Converted MTSs and container loading piers, respectively, are protected by applicable law and by collective bargaining

and employee agreements. The safety of the employees of private transfer stations is protected by employee agreements and by applicable law.

5. **Comment:** All methods used for long-range transport must have hard/fixed type covers to control odors and spillage. In terms of rail transport, full rail cars must not be permitted to sit at any location longer than 6 hours.

Response: All containers used at the Converted MTSs will be sealed and leakproof as required under 6 NYCRR Part 360, Subpart 360-11 and conform to ARA and ABS standards. All waste will be loaded into these containers within 24 hours of its receipt. Containerized waste will be removed from the Converted MTSs by barge as soon as the barge is full. In the case of truck-to-rail facilities, the containers will be removed from the site when the rail cars are full, or within seven (7) days, whichever comes first, in accordance with Subpart 360-11. There are no provisions in the current regulations governing solid waste facilities that require rail cars to be moved from a location after 6 hours.

6. **Comment:** The MTS facilities should allow flexibility for the City to use them for the movement of recyclables and compostables.

Response: The Draft New SWMP describes the facilities and services that exist or are elements of the Proposed Action for Recycling and also provides extensive information on DSNY's composting activities. The intended purpose of the Converted MTSs is not to process these materials. DSNY has other dedicated other facilities for this purpose.

40.3.1.2 Alternatives Analysis

7. **Comment:** A number of comments stated that the DEIS is inadequate in assessing alternatives to the Proposed Action. Many indicated that the only sites evaluated were the existing MTS sites, and the only alternative examined for handling the City's waste was long-term export.

Response: Chapter 1, Section 1.3 of the FEIS incorporates revisions that clarify the Alternatives considered in formulating the Proposed Action for Long Term Export. The following is a summary explanation.

In July 2001, Mayor Michael Bloomberg completed an evaluation of the Long Term Export Program and directed DSNY to evaluate waste containerization and export from the City's eight existing Marine Transfer Stations (MTSs). The Long Term Export Program was an element of the City Council and State approved 2000 SWMP Modification supported by an October 2000 FEIS that analyzed long term export options at some 20 different sites with 25 different facility options across the City. (The 2000 SWMP Modification and supporting FEIS are available from DSNY on request.) The Mayor's decision to pursue containerization at the MTSs was made after a determination that insurmountable problems prevented the implementation of the Linden EBUF project. The Linden project, a key component of the 2000 SWMP Modification, would have received waste from five existing MTSs, three in Manhattan, Hamilton Avenue and North Shore. The Alternatives evaluated in the 2000 SWMP FEIS were not acceptable substitutes for Long Term Export from the three Manhattan and the North Shore MTS wastesheds, which comprised four of the five MTSs wastesheds that the Linden Project would have served.

In July 2002, the Mayor announced that the City would move in a new direction by redeveloping all eight of the MTSs as facilities capable of containerizing waste for intermodal transport by barge or rail to out-of-City disposal facilities (Converted MTSs). Since that announcement, DSNY has worked diligently with NYCEDC, the Law Department and other City agencies to implement the Mayor's policy directive.

In the course of this work, DSNY has considered Alternatives. DSNY has proposed to implement four Converted MTS projects, not eight. Other Long Term Export options have been identified to serve the West 135th and West 59th Street wastesheds in Manhattan, and the wastesheds formerly served by the South Bronx and Greenpoint MTSs. These options are now part of the Proposed Action, because DSNY believes they

can be implemented more quickly, are more cost effective than developing Alternative Converted MTSs for those wastesheds and also avoid adding new in-City waste transfer capacity, particularly in the Bronx and Brooklyn where there is a relative concentration of private waste transfer stations.

Additionally, DSNY included an investigation of alternative rail or barge export sites in Manhattan in the Scope of the CWMS. Three of the four sites investigated, West 140th Street (between the North River Water Pollution Control Plant on the Hudson River and the Henry Hudson Parkway), West 30th Street and Pier 42 on the East River were found to be infeasible. The reasons for that finding are reported in the CWMS, Volume V, Manhattan Siting Study that is included as Appendix I in this FEIS. Finally, during the re-procurement of Interim Export contracts for DSNY-managed Waste from Manhattan awarded in November 2004, DSNY established that the LIPCo/Covanta waste-to-energy facility in Rahway, New Jersey, had insufficient capacity to serve as a primary disposal facility. This facility was awarded an Interim Export contract for backup capacity in the amount of 125 tpd, substantially less than is generated in any of Manhattan's three wastesheds.

40.3.1.3 Waste Reduction and Recycling

8. **Comment:** The City's Solid Waste Management Plan has failed to address alternatives to export for disposal. This is in violation of the State's Solid Waste Management Act. In 2000, DSNY's SWMP focused on long term export due to critical time constraints, but they promised that the next plan would be more comprehensive. The Plan needs to more adequately address the alternatives to long-term export, focusing on waste reduction, re-use, recycling and composting. It will be more difficult to institute these types of programs once the long-term export facilities are built. The contracts should be written in a way to encourage and reward recycling. By way of contrast, the 1992 Comprehensive Waste Management plan offered 86 ambitious waste prevention and recycling initiatives. The 1995 update had 47 milestones, some of these goals were accomplished and most were delayed or forgotten. The New SWMP lists 22 reduction milestones, of which only

4 are new concepts (electronics recycling, paper-bagged yard waste, an annual electronic newsletter, and revisions to LL19), and only one of which reduces tonnage. This is not progress.

Response: Waste reduction, reuse and recycling are important components of the proposed New SWMP. The number of recycling and waste reduction alternatives to disposal in successive SWMPs has not decreased because of the city's diminished commitment to such alternatives. The number of alternatives has been reduced because over the period of time discussed many have been adopted as programs and many others have proven themselves to be incapable of practical implementation. The change reflected in the City's various SWMPs over time and is informed by the results of the conduct of numerous SWMP-related pilots, initiatives and studies that have focused on the feasibility of alternatives.

9. **Comment:** A number of speakers supported the 70% recycling goal to be met by the year 2015; but thought that the SWMP should include the supporting details as to how to achieve this goal. Costs should be provided, along with plans for improvement of the existing system. There is a lack of information on how the City intends to establish the infrastructure necessary for greater reuse, composting and recycling. Assuming that construction and demolition waste and fill material constitute a large share of the 70%, the SWMP must address these types of transfer facilities and recycling of the commercial waste stream.

Response: The statement is correct that recycling of construction and demolition waste and clean fill material is essential to achieving the 70% city-wide recycling target proposed. The Draft New SWMPs' 70% overall recycling can be achieved over time through Existing Programs and New Initiatives. The citywide recycling average, based upon NYSDEC's own accounting system for recycling is currently in excess of 62%. Therefore, DSNY believes the gain of eight additional percentage points over the time period discussed in the Draft New SWMP is a reasonable goal.

10. **Comment:** The City should consider the merits of investing dollars within New York City to create industries that use our waste materials to manufacture new products instead

of sending dollars out of the City to export waste. Specifically, borough-based eco-industrial parks could be developed. An analysis of the benefits and costs of choosing an economic development path are completely absent from the SWMP.

Response: The private sector is already an active participant in the recycling industry, where the economics are justified. The City actively seeks opportunities to foster economic development that would utilize waste materials as a resource. A notable success has been the Visy/Pratt Industries paper manufacturing plant on Staten Island, which was financed with City assistance and which currently recycles waste paper under contracts with DSNY. Additionally, the City will soon be entering into a 20-year contract with Hugo Neu to recycle the City's metal, glass and plastic and a portion of the City's paper stream. A recent publication issued by DSNY, *Processing and Marketing Recyclables in New York City*, available on the DSNY's website at: http://www.nyc.gov/html/dos/html/recywprpts.html#1 provides useful information on the economics of recycling in NYC.

11. **Comment:** How long will the City talk about studying composting at Hunts Point without developing any new facilities? The Riker's Island Project was supposed to be the test facility with commercial scale facilities to follow. Greater attention is needed in the SWMP on composting of food waste.

Response: With the recent increase in the regulated commercial carting fees for wet waste, including food market waste, economic incentives exist for the Hunts Point Market Cooperative to consider composting as a less expensive disposal alternative. Rikers Island was the test facility for a particular type of compost technology (in-vessel composting), but is not one of the technologies proposed for use at Hunts Point.

12. **Comment:** The City should adopt the Zero Waste initiatives and the SWMP should examine better ways to recycle and prevent waste, since waste prevention, was key to reducing costs. The City should be more aggressive in its programs: target food and yard waste for composting, recycle textiles and more types of plastics, and support of State-level efforts like expanding the "bottle bill". Commercial and institutional recycling should be improved through the establishment of recycling programs at major

transportation hubs and parks and stadiums, increasing the number of collection and distribution sites for special recyclable collections such as hazardous material or new compost, and an analysis of programs which currently recycle waste, but were not discussed. The DEIS needs to study the impacts of increased recycling and how it would reduce truck traffic and the need for disposal sites. There needs to be an organized system for diverting loads from the MTS that contain large quantities of recyclables.

Response: Waste reduction, reuse, and recycling will continue to be central to waste management under the New SWMP, which contains several initiatives to expand what is already by far the largest mandatory recycling program in the nation. As the cost of waste disposal increases, the economics of recycling and waste reuse improves, in addition to the environmental benefits of resource conservation. DSNY actively follows recycling markets to determine whether designation of additional items for recycling makes sense.

With the recommencement this year of weekly collection for Curbside Recyclables in all boroughs, the City has made a significant financial commitment to building a Recycling Program that is and will remain an important element of its waste management strategy. That commitment is reinforced by related commitments in the Draft New SWMP to several important actions and initiatives. As discussed in the Draft New SWMP, the following commitments are major steps toward attaining substantially higher waste diversion rates. The commitments to significantly higher waste diversion goals are ambitious goals that reflect a comprehensive, experienced and realistic assessment of what the City can attempt to achieve.

<u>Significantly Increased, Percentage Based Waste Diversion Goals</u>

The Draft New SWMP sets a 70% diversion goal for the combined Commercial and DSNY-managed Waste streams to be achieved by 2015. In the near term, the City should meet a 25% diversion goal for the curbside and containerized waste generated by residents and institutions, and a 35% diversion goal for the total DSNY-managed Waste stream by 2007.

South Brooklyn Marine Terminal Materials Processing Facility

As noted in the Draft New SWMP, DSNY with NYCEDC proposes to develop a Materials Processing Facility at the South Brooklyn Marine Terminal in Brooklyn through a public-private partnership involving a 20-year service agreement with a private recyclables processor, Hugo Nue Corp (HNC). This is an important element of the foundation for increased diversion rates for curbside and containerized waste through DSNY's Curbside Recycling Program. The long-term commitment to a Materials Processing Facility will facilitate the development of state-of-the-art processing infrastructure in the City, which in turn will generate the consistent streams of materials necessary to foster reliable secondary materials markets and enable the diversion of Curbside materials that are now discarded.

As noted in the Draft New SWMP, the major advantages of this commitment to develop a Materials Processing Facility are:

- Commits the City to maintain its Curbside MGP Program over the next 20-years.
- Creates a relationship in which the processor has economic incentives to expand product markets and thereby increase the net recovery rate for MGP. Historically, DSNY has had considerable difficulty in establishing stable and cost-effective relationships with the contractors that have processed its Curbside MGP, in part due to the practice of contracting for a five-year term with a short-notice cancellation clause. This created economic uncertainty for the contractor and discouraged investments in facility upgrades to improve recovery rates. The 20-year term of the service agreement removes these disincentives and will create a relationship in which the processor has economic incentives to expand product markets and thereby increase the net recovery rate for MGP processed.
- Enhances the opportunity to produce and market new products by recovering materials that are now marginal. The City's Curbside MGP collections have high proportions by weight of glass, particularly mixed-color, broken glass, a material which does not have economic markets. Better technology to be used in the proposed materials processing facility, in addition to aggressive research and development – both afforded by a long-term contract – is expected to improve the sorting of glass and help address this situation.

- Secures competitive price terms for the City and stabilizes costs over the long term.

The long-term contract is expected to lower the City's cost for processing MGP recycling to approximately $48 per ton, compared to $51 per ton under current contracts, and $59 less per ton than the $107 that the City was facing before the program was suspended two years ago. Note: This does not include the City's proposed contribution to site improvements for this project.

Waste Composition Study

DSNY is currently performing a four-season Citywide Waste Composition Sort (WCS),[1] involving the sorting of both residential refuse and recyclable streams. This study, an update of the WCS first undertaken in 1989-1990, will provide essential data to solid waste planners, especially in the recycling field. The 2004 Spring Sorts found that 21% of the MGP stream consisted of non-designated materials. Much of that figure consisted of materials that potentially could be designated for recycling some time in the future, depending upon markets and advances in sorting technology. Nevertheless, one of the major goals of the Recycling Program over this 20-year SWMP planning period must be to reduce this rate as much as possible. This can be accomplished through the sustained public education and enforcement efforts described later in this section.

The WCS data will inform the City's ambitious diversion goals, as well as the choice of programs necessary to reach these goals over the course of this new SWMP planning period. For example, 12.2% of the non-designated material category consists of refuse thrown into the recycling bin, the next largest category (6.5%) consists of plastic containers that are not currently designated for recycling collection. DSNY currently asks residents to separate #1 and #2 plastics in the form of narrow-neck bottles; previous vendors relied largely on manual sorting of plastics and it was easier for sorters to recognize a shape than read a number on the bottom of a container. However, HNC has expressed interest in testing more sophisticated sorting technologies that may facilitate

[1] Among the requirements of a SWMP are to "characterize the solid waste stream to be managed in the planning period." (New York State Environmental Conservation Law, Section 27-0107, Subsection 1.b.i.).

the addition of other plastic types (#3 to #7) in the future. This move would increase diversion and reduce the non-designated material rates.

Regarding yard waste, the Spring Sorts took place in May and June 2004 and therefore will likely reflect a higher percentage of yard waste, including leaves, grass and prunings, than will probably be found in the other three seasonal sorts that followed. What is noteworthy, however, is that the percentage of yard waste in the total spring waste stream (7.7%) is substantially higher than in the Spring Sort, conducted as part of the 1989-1990 Study (4.1%).

The organic fraction of the waste stream will play an important role in meeting the diversion goals of this SWMP. To keep yard waste out of the waste stream, DSNY is restoring funding to its backyard composting and "Leave in on the Lawn" education programs and its subsidized compost bin promotional programs. In addition, DSNY will continue to promote its compost facility to residential landscapers.

Appliances and electronics, a category not assessed in 1990, comprised a very small fraction of the overall waste stream in the 2004 Spring Sorts – 0.92%. Nevertheless, electronics are a growing and potentially toxic fraction of the City's waste stream. To deal with this issue, DSNY is undertaking the electronics-recycling initiative described in Section 2.4.5 of the Draft New SWMP.

Finally the Draft New SWMP outlines a series of ongoing waste prevention, market research and public education initiatives that are necessary elements of a strategy to increase waste diversion rates.

13. **Comment:** The DEIS and SWMP fail to address proven methods for diverting food waste, such as the use of garbage grinders. The SWMP should examine effective programs in other cities, for handling food waste.

Response: Residential garbage grinders became lawful in New York City recently and are just beginning to reduce curbside organic waste from households. However, such grinders neither prevent waste nor pollution, and just change its form and require

handling by the City's wastewater treatment plants rather than its solid waste management system. NYCDEP studied the long-range effects on the City's wastewater system of the use of garbage grinders in households and agreed to absorb the potential diversion of household food waste through the permissible installation of garbage grinders in City households. NYCDEP did not approve the use of garbage grinders for commercial users and has not agreed to absorb the increased demands on the City's wastewater system from the installation of garbage grinders for commercial establishments. DSNY is proposing a pilot program to compost commercial food waste from the Hunts Point Market in the Bronx.

14. **Comment:** The draft SWMP did not discuss the waste prevention coordinators program. We recommend that the program be reestablished and expanded so that there is one waste prevention coordinator in every community district, whose responsibility will be to increase waste prevention in the residential sector.

Response: The Waste Prevention Coordinators Program results are described in public reports (see DSNY web page). Reports highlighting their various program efforts over the one year of funding made available by the Council have been widely circulated within the waste prevention community. As each ton of waste prevented cost an average cost per ton of $750, this program proved to be prohibitively expensive and is not proposed to be replicated in a city-wide publicly-funded program

15. **Comment:** Chapter two of the SWMP should be entitled "Waste prevention, reuse and recycling". The omission of the term "reuse" coveys a lack of understanding about the waste management hierarchy. The development of a community reuse complex should be included in this section.

Response: Duly noted, refer to content of programming. No community reuse complex is proposed at this time, but could be considered in the future.

16. **Comment:** The SWMP fails to discuss the need for the conduct of a waste characterization study every five years.

Response: The current study is expected to cost as much as $5 million, and the results, which build on a similar study conducted in 1989 – 1990, will be useful as a basis for making programming decisions and data comparisons for as many as twenty years. Unless circumstances change rapidly, DSNY sees no need to conduct a waste characterization study every five years.

17. **Comment:** More marketing research on achieving greater public education is needed. The general public needs to be better educated about waste prevention, recycling and reuse. Reuse should be particularly stressed in children's educational programs.

Response: The New SWMP would continue DSNY's outreach and education efforts about waste prevention, reuse and recycling. These include outreach to schools. DSNY is in the process of conducting further market research as noted in the Draft New SWMP. Market research, conducted in the past (see report on DSNY web page) indicated that most New Yorkers, a diverse, dynamic and extremely mobile population, are in fact very aware of the requirements of recycling in NYC. The reasons why many New Yorkers do not fully recycle has a great deal more to do with lack of convenience and personal motivation; much more difficult challenges to overcome than mere lack of knowledge.

18. **Comment:** It is good that DSNY is instituting an annual household hazardous waste collection day, but it is recommended that additional items be added for collection. Electronic waste should be included in pick-ups.

Response: Electronic waste represents a very small (less than 1%), but potentially toxic fraction of the waste stream. DSNY is exploring the possibility of including these items in its collection programs, as well. See Draft New SWMP section 2.4.5.

19. **Comment:** The City should enact legislation which would pressure companies to reduce packaging and waste. Businesses should be encouraged to generate less waste, and should be responsible for the waste they create.

Response: The suggested approach is unfortunately not feasible at the municipal level. The City cannot act in isolation from the federal and state government on this type of legislation without creating an incentive for City manufacturers to relocate.

20. **Comment:** The City should develop additional recycling capacity in each borough through borough-based recycling industrial parks.

Response: To evaluate this goal and for a basic understanding of the economics of recycling in NYC the author of this comment is referred to DSNY's recent publication, *Processing and Marketing Recyclables in New York City*, available on the DSNY's website at: http://www.nyc.gov/html/dos/html/recywprpts.html#1. The report also provides a discussion of the current economic constraints that govern the processing and marketing of recyclables. See also response to Comment #15, above.

21. **Comment:** The Plan states that the City supports Federal legislation to establish producer responsibility for electronic waste. The City should be pursuing local EPR legislation. In addition there should be means of picking up electronic waste on a regular basis.

Response: Department of Sanitation continues to pay close attention to the emerging issue of electronic waste, which is less than 1% of the household waste stream. The Draft New SWMP clearly expresses the City's preference that manufacturers deal with electronic waste themselves. The City is willing to work with the manufacturers and distributors of electronics in the absence of regulation to assist in the proper disposal of electronics, but not to bear the full financial burden of operating separate electronic waste collection and disposal programs, which would be prohibitively expensive. Collection costs are the greatest share of recycling program, primarily due to the fact that less than 50% of what was formerly waste is targeted at each household in a recycling program. The collection costs associated with targeting less than 1% of household waste, for separate collection is not practicable. See also response to Comment #12, above.

22. **Comment:** Future improvements to the City's recycling rate are put into question by the City's plan to modify Local Law 19. This is a major undertaking. Local Law 19 should only be amended if it will improve the City's recycling program.

Response: The proposal to modify LL 19 is separate from the success of the City's recycling program and the proposal to achieve even higher diversion rates in the future. As explained in the draft New SWMP, Local Law 19's tonnage mandate is based upon an inaccurate refuse tonnage assumption. Unachievable mandates can have the effect of undermining support for the recycling program. Rather than mandates, the Draft New

SWMP proposes achievable goals that can be strived for over a reasonable period of time. The goals suggested in the Draft New SWMP are both ambitious and within the City's reach.

23. **Comment:** The Draft New SWMP should include a discussion on the greatest cost component of recycling, i.e., collection. Means of reducing costs should be examined, such as the use of dual bin trucks, or other alternatives.

Response: DSNY has tested out a number of alternative vehicles over the last 15 years and currently uses the suggested dual bin vehicle in over 21 of the city's 59 community districts to collect recyclables.

24. **Comment:** There are no details provided on the Hugo Neu contract, specifically if the contract is flexible enough to adapt to the changing technologies and characteristics of the City's waste generation. Will there be adequate incentives for Hugo Neu to maintain and upgrade its facilities, if the City's economic circumstances change?

Response: Details of the contract are still subject to negotiation. However, the types of incentives suggested will be included in the structure of the 20 year agreement. For more information, see the Response to Comment #12.

25. **Comment:** Each of the components of the waste stream (residential and commercial) should be examined for (1) the amount generated, and its rate of change over time; (2) the frequency of collection; (3) its destination; (4) its salability and time/value changes; (5) effect of volume changes on buildings, and equipment requirements, and (6) impacts of commercial waste. Then the most optimal recycling system can be determined.

Response: The City's public and private recycling efforts are robust, as evidenced by the 62% diversion rate for the City reported by the Department of Environmental Conservation. The Draft New SWMP Proposed Action for recycling reflects the results of considerable analysis and practical experience in implementing and operating a recycling program in the City for 15 years. DSNY's recent publication, Processing and Marketing Recyclables in New York City is available on the DSNY website at: http://www.nyc.gov/html/dos/html/recywprpts.html#1.

26. **Comment:** There needs to be more emphasis in providing recycling information in foreign languages. Fliers in languages other than English or Spanish aren't always available. There seems to be a lack of information in Chinese, Korean, and Arabic. Television spots on foreign language channels should also be implemented.

Response: The comment is duly noted. The Department of Sanitation makes publications available in multiple languages to target foreign language audiences as appropriate. For more information, please refer to a series of DSNY publications posted on the Department's website, that provide some missing background on the Department's public education efforts to date and market research about what New Yorkers know and don't know about recycling: http://www.nyc.gov/html/dos/html/recywprpts.html

27. **Comment:** The SWMP does not adequately address waste prevention and diversion in the commercial and construction sectors, given the huge volume of redevelopment and new construction anticipated. This increased quantity of waste will impose an unacceptable burden on the City's EJ communities, absent a more comprehensive plan for commercial waste diversion. The Plan's proposal to increase transfer station fees should be linked to the expansion of commercial waste prevention and recycling, dedicating the revenue stream from those fees to the development of those programs.

Response: Because economics drive waste prevention in the commercial sector, unlike the government sector, as disposal costs rise in the New York metropolitan area more and more waste prevention and recycling will necessarily occur, without direct government intervention in the form of regulation and its enforcement. Construction and Demolition processing facilities currently recycle approximately 50% of the waste they receive with some such facilities in the metropolitan area recycling over 80%. Clean fill transfer stations typically recycle nearly all of the waste they receive.

28. **Comment:** The DEIS does not evaluate the change in paper flow, from 10 current locations, to four facilities (Gansevoort and the three Hugo Neu facilities) used in the future, even though paper is the second largest component of municipal waste. This reallocation of recyclables needs to be examined in the same manner as the other facilities are examined. The environmental review of the Visy plant was based on

material arriving by barge from Manhattan and by truck from Staten Island. But DSNY amended the Visy agreement in 2003 to re-designate paper from seven western Brooklyn districts to be trucked to Staten Island.

Response: See response to Comment #32 below.

29. **Comment:** The discussion of the existing system notes that about 27% of putrescible waste is recycled. However, there is no discussion of the huge amount of separately collected paper that is recycled.

Response: As the Draft New SWMP incorporates by reference the 1992 SWMP and subsequent modifications and updates, much information that describes the evolutions of the City's paper recycling program has not been repeated. It is true that the City's revenue producing paper recycling program is particularly successful, in part due to the fact that a degree of cost and processing stability has been achieved through long-term contracting.

30. **Comment:** The City rejected composting claiming that it was studied extensively in an earlier report, but in that previous report only one method was studied – static pile composting. Composting by other means needs to be evaluated.

Response: More than one method of composting has been studied by the City. Please see the reports published by DSNY that contain extensive discussions and analysis of a number of alternative composting technologies at: http://www.nyc.gov/html/dos/html/recywprpts.html

31. **Comment:** What will be done with the large amounts of fill material that are currently recycled at Fresh Kills as landfill cover and road building material?

Response: Some of the generators of this material are already reducing the amount produced by changing their operating procedures, in anticipation of the eventual discontinuation of these programs. For the time being alternatives methods for recycling and/or disposal of this material are being explored.

32. **Comment:** The DEIS states that the potential traffic, off-site air and off-site noise impacts associated with the changes in delivery of Curbside Recyclables by DSNY collection vehicles from current destinations to new facilities are evaluated in this DEIS. However, these impacts are not evaluated. The Agreement between the City and Visy directs DSNY to deliver 34,000 tpy of waste paper to Visy from 7 Brooklyn districts. DSNY delivers those Districts to Visy. However, DSNY does not yet deliver the entire 66,000 tpy over and above that amount which is also mentioned in the Amendment. Not only is there no analysis of the 66,000 tpy, but there was never an analysis of the traffic, air and noise impacts of diverting the initial 34,000 tpy of Brooklyn mixed paper that is being trucked by DSNY over the Verrazano Bridge to Visy. DSNY must evaluate the impacts of the 100,000 tons per year of Brooklyn-based mixed paper while keeping in mind the stated goal of reducing truck traffic and congestion. One may want to compare delivery costs and revenues generated for DSNY taking this material to Visy as opposed to the Brooklyn facilities.

Response: The DEIS and this FEIS evaluates sending only MGP from the Brooklyn Community Districts that would deliver by truck to Hugo Neu at the SBMT. Any delivery of paper to the proposed processing facility at SBMT that may make occur in the future would be subject to environmental review when and if that decision is made. The current delivery of 34,000 tpy of Brooklyn mixed paper to Visy is an Existing Condition and, as such is not subject to environmental review in the New SWMP DEIS/FEIS.

33. **Comment:** DSNY should use its transportation model to determine if it would be more efficient for the recyclables in certain districts of Manhattan to be driven directly to the Hugo Neu facility located in the Bronx. The EIS should evaluate potential additional marine and rail sites in Manhattan, and should consider the creation of a number of smaller facilities for Manhattan recyclables.

Response: DSNY has already used the transportation model for this effort and the results are reflected in the SWMP. The DEIS evaluates the Proposed Action and reasonable alternatives. The proposed development of the Gansevoort Recyclables Acceptance facility will be subject to supplemental environmental review, including any required consideration of reasonable alternative.

34. **Comment:** The SWMP failed to disclose that the Spring Creek composting facility may never be permitted, due to the ruling in August 2004 that found that the project would likely constitute an illegal alienation of parkland. The SWMP and DEIS should accurately describe how composting will be managed should the site not be available for the above-noted reasons.

Response: DSNY expects that the Spring Creek leaf and yard waste composting facility will be permitted eventually to accept leaves from Brooklyn and Queens, as proposed. In FY'05, leaves from these Boroughs were delivered mainly to DSNY's composting facility at Fresh Kills on Staten Island. The comment refers to a ruling in a permit proceeding that the joint DSNY-Parks Department effort to use a portion of unconstructed parkland on former landfill for leaf composting to generate compost for park improvements must be adjudicated to determine whether it is a lawful park use. The proceeding is still pending and no final ruling has been issued. If it is not permitted, the city will need to re-evaluate the feasibility of continuing to seek to expand its program to collect leaf and yard waste for composting at appropriate locations in the City to generate a useful soil amendment.

35. **Comment:** DSNY trucks typically make 10 trips down most neighborhood streets each week: six to pick up refuse on different sides of the streets, two to pick up MGP, and two to pick up paper. By using more efficient single-stream or co-collection approaches, such as used in San Francisco and Chicago, truck traffic and emissions could be dramatically reduced. It could also reduce collection costs by tens of millions of dollars and help make recycling cost-effective. A good chance to consider either single-stream or co-collection might be in conjunction with the planning now being done for the waterfront facility in Brooklyn.

Response: The comment correctly assumes that collecting solid waste and recyclables together would reduce truck traffic, air emissions and collection costs. However, co-collection would require the siting and construction of special materials recovery facilities known as "dirty MRFs" to separate recyclables from regular household refuse, as Chicago has done. Such facilities do not exist in the City and would constitute a change to the SWMP that is well beyond the current Proposed Action. In addition, such

an approach can lead to reduced value of the recyclables due to contamination by refuse and correspondingly diminished revenues, and this must be taken into consideration in evaluating cost and emissions savings with such an approach.

Many areas of the City (particularly outside Manhattan) receive refuse collection only twice per week and have their recyclables collected with a single dual bin collection vehicle once per week (21 out of the City's 59 community districts); for a maximum of six collection vehicle trips down the block in that neighborhood per week.

There is currently no processing facility in the City set up to handle a mixed stream of MGP and paper. There have been conversations with Hugo Neu about designing their new MRF to have the flexibility to handle a single collection stream, should the City choose to do so. Municipalities are moving away, not toward single stream collection (with the notable exception of San Francisco) due to the loss of value to the mixed paper stream, an important source of revenue for NYC's recycling program.

40.3.1.4 Enhanced Public Participation

36. **Comment:** Environmental justice issues apply to the East 91st Street community because the parks are used by low-income groups as well.

Response: DSNY considers fairness and equity to be essential aspects to the Proposed Plan, including the proposal for East 91st Street. The East 91st Street site was approved for a marine transfer station over 60 years ago and this was reaffirmed by the City Council in 2000. The DEIS shows that use of the proposed Converted MTS will not result in any significant adverse impacts with the mitigation proposed. The Environmental Justice and Permitting Policy (EJ Policy) promulgated by NYSDEC (see NYSDEC's website http://www.dec.state.ny.us/website/ej/ejpolicy.html) applies in an environmental review process where NYSDEC is the lead agency. DSNY is the lead agency for this FEIS and, although technically not subject to the EJ Policy, DSNY determined that an enhanced public outreach program in the Draft New SWMP DEIS Scoping and Public Hearing processes would be beneficial. DSNY has followed this program in all the communities affected by the Proposed Action for Long Term Export,

including the East 91st Street community. Accordingly, DSNY conducted ten DEIS Scoping Meetings and eight DEIS Public Hearings. These meetings were preceded by extensive public notices, mailed invitations to thousands of stakeholders and placement of the DEIS and draft permit applications in accessible public repositories in each project area. During the meetings DSNY provided extensive public information materials and multilingual translation services. Section 40.3.3.1, item #18 of this Chapter provides a more extensive description of DSNY's enhanced public outreach program. In addition to the DEIS Scoping and Public Hearing process, DSNY supported enhanced outreach for the four Community Board Hearings during January 2005 on the ULURP applications for the Converted MTS Program.

It should be noted that NYSDEC's EJ Policy establishes specific demographic criteria related to the percentage of low income and minority persons residing in the community to determine whether an area qualifies as a Potential Environmental Justice Area. Based on these criteria, the East 91st Street community did not technically qualify, but was deemed an EJ community for this purpose nonetheless.

37. **Comment:** The SWMP claims to be fair by having each borough handle its own waste, but all of the facilities are located in low-income communities of color. Additionally, the communities that will be receiving the waste are also poor, non-white and depressed communities.

Response: The criteria used in selecting the sites that are subject of the Proposed Action for Long Term Export included: historical and recent use as an MTS site; and for those sites that DSNY would contract with private companies for export, access to barge or rail transport, appropriate manufacturing use zoning and the potential to avoid significant adverse impacts. The demographic and socioeconomic characteristics of the surrounding area for each of the long term export facilities is provided in the DEIS and this FEIS. All are not in low-income communities of color.

38. **Comment:** One comment stated that contacting the community district managers is not the only way to identify stakeholders and other interested parties and is not "fair" across all community districts. The involvement of district managers varies. Some districts are quite large and have sub populations, and not every district manager is going to be interested in the well-being of district residents who live on the edge of the district or who don't fit the profile of the majority of residents. Moreover, there can be a language barrier. Since stakeholders include those who have attended the meetings, a significant proportion of flyers are sent to those who are already aware of some of the issues. Additionally, the drawing on the flyer for East 91st Street appears to be reversed compared to the one shown at the Scoping hearing, and it is difficult to assess what has changed. It is inconsistent with EJ Policy to send deceptive fliers.

Response: See Section 40.3.3.1, item #18 of this Chapter for a more extensive description of DSNY's enhanced public outreach program.

39. **Comment:** DSNY needs to clarify what aspects of its SWMP will comply with DEC Commissioner Policy 29: Environmental Justice and Permitting Policy". Permit applicants are required to submit a formal public participation strategy, and DEC has not approved an EJ participation plan for any of DSNY's actions. Therefore the SWMP and DEIS comment period must remain open until DSNY complies with CP-29. DSNY must explain in the SWMP how it plans to comply with the requirements of CP-29, and which actions are subject to the policy.

Response: See the Response to Comment #36 and Section 40.3.6 of this Chapter.

40. **Comment:** DSNY has handled the public testimony from the Scoping Hearings poorly. The testimonies were put onto a CD but were not distributed to the public with the Final Scoping Document. Most of the comments in the Comments and Responses section were rejected or were completely misunderstood.

Response: CEQR does not require that the lead agency publish a response to each comment received during the Scoping process, only that it consider comments received in publishing a final Scope. However, in the Final Scoping Document, DSNY did summarize comments received and provide a response to those summarized comments in

the Final Scoping Document. The comment and response section along with the rest of the Final Scoping Document were placed in two conveniently located public repositories in each project area. Copies were available on request and the Final Scoping Document also appeared on the DSNY Web site.

41. **Comment:** DSNY seems to believe that as a government agency it is somehow exempt from full and proper compliance with CEQR. The analyses contained in the document did not represent the real situation.

Response: The DEIS and this FEIS analyzed potential impacts based upon information available for each facility in accordance with methodologies reviewed by City agencies (NYCDEP, NYCDOT) that followed the 2001 CEQR Technical Manual.

42. **Comment:** Several people requested an extension of the comment period beyond January 24, 2005, claiming that they learned about the project too late to comment due to unpublicized notices and hearings.

Response: The comment period on the DEIS opened when the DEIS was published on October 22, 2004 and closed on January 24, 2005, a period of 94 days. This period exceeds the 30 days required under CEQR for Public Comment. During this period, DSNY also held eight public hearings in the affected communities and conducted an extensive public outreach program. Those requesting an extension were advised that additional public processes would be conducted by the State NYSDE as part of its permit review and public hearing processes to be conducted in connection with each of the permit applications for the four Converted MTSs.

43. **Comment:** Several people complained that the information contained in the public repositories was not complete. Key documents were missing, including the FEIS for the 2000 SWMP, as were other documents referenced in the DEIS and SWMP. Additionally, the repositories only held the permit application for the nearest MTS and not for all of them, but having all of them was critical to analyzing the plan in its entirety. Why would DSNY want to limit access to critical information regarding this plan? The DEIS failed to meet the requirements of 6 NYCRR Part 617, which states that referenced documents must be made available for inspection by the public at the same places where the agency

makes available copies of the EIS. Once these documents are made available, DSNY must issue a new public comment period.

Response: DSNY's extensive public outreach and multiple public repositories evidence no attempt to limit public access to New SWMP information and Converted MTS permit applications. As required, the draft permit applications for the Converted MTSs were located in accessible public repositories for the affected communities where the respective facilities are proposed to be located, along with copies of the New Draft SWMP and DEIS. After documents were placed in repositories, DSNY checked on the status of documents in the public repositories and confirmed that they were available. To assist the affected communities, a toll free hotline was also established and featured in mailings to stakeholders. Through the hotline, DSNY sought to provide a forum to respond to questions regarding, among other things, the availability of public documents. Since their issuance, the 2000 SWMP Modification and FEIS have been and continue to be available to anyone upon request. Further, the DEIS and this FEIS refers to the 2000 SWMP Modification FEIS to explain the history of its planning efforts in analyzing reasonable alternatives; to support the continuation of existing DSNY programs and to provide context for the Proposed Action. A review of the multi-volume 2000 FEIS is not necessary to understand the analysis of potential impacts of the Proposed Action.

40.3.1.5 Borough Self-sufficiency

44. **Comment:** The SWMP for Manhattan proposes the construction of only one marine transfer station, and that is the smallest of any of the converted MTSs. The largest amount of residential and institutional waste will continue to be trucked on congested streets to the incinerator in New Jersey. Manhattan needs more adequate waste infrastructure, and needs to handle its own waste, like the other boroughs.

Response: The Proposed Action in Manhattan also includes the potential redevelopment of the West 59th Street MTS site as a facility that would export Commercial Waste from Manhattan and the development of a Recyclables Acceptance Facility at the Gansevoort peninsula for receiving Curbside Recyclables collected in Manhattan and transferring them by barge to the proposed Materials Processing Facility at the SBMT in Brooklyn.

45. **Comment:** The idea of borough-based self-sufficiency is critical in the New SWMP, and a positive step. Each borough must handle its own waste in order to comply with the City Charter's Fair Share provision. A number of speakers stated that would support the SWMP as long as all of the MTSs and the private marine and rail-based alternatives open, for both residential and commercial waste, to ease the burdens to other areas.

Response: Comment noted; the concept applies to DSNY-managed waste and to commercial waste accepted at any Converted MTS.

46. **Comment:** While we are glad that the Mayor has taken on the task of devising a solid waste management plan for the entire City, in striving for fairness by having an MTS in each borough, he is being unfair to the Manhattan community where the MTS is sited, which is located in a residential area.

Response: The East 91st Street Converted MTS in Manhattan is located in an (M 1-4) zone adjacent to the FDR Drive. Approximately 140,000 cars drive by this site every day. The site has been used as a solid waste facility for over 50 years and while DSNY is currently not operating the facility, it continues to hold a permit to operate a transfer station at this site. The existing permit issued by NYSDEC allows it to process 4,800 tons per day. The past problem with DSNY collection vehicles queuing on York Avenue will be eliminated through a combination of the facility's design features and the limitations that DSNY proposes for the facility's permitted capacity at this facility. Accident records were researched for the intersection of York Avenue and 91st Street at the MTS entrance. When the MTS operated previously, this intersection was not a high accident location. The annual average number of reportable accidents was just over 4 per year for the years 1997, 1998 and 1999 and none involved DSNY vehicles. During that period only one accident involved a pedestrian. In the year immediately after closure (2000), there were 8 reportable accidents, 2 of which involved pedestrians. In the future, DSNY enforcement personnel will manage truck and pedestrian traffic at the entrance on York Avenue at 91st Street to ensure that it continues to operate safely. See Section 40.3.1.1 for a description on the design features of the Converted MTS that represent significant improvements over the existing facility.

47. **Comment:** The SWMP indicates that waste and recyclables will move from Manhattan to Brooklyn, but none will go from Brooklyn to Manhattan. This is not fair. Each borough should be responsible for handling its own recyclables.

Response: The statement that Manhattan recyclables will be delivered by truck to Brooklyn is in error and has been corrected in this FEIS. The proposed Materials Processing Facility at the South Brooklyn Marine Terminal would receive delivery of Recyclables by barge from other boroughs, thereby eliminating the potential for any local traffic impacts. It would be economically infeasible to provide each borough with a processing facility for its own Recyclables.

48. **Comment:** A barge-to-rail facility at the Harlem River Yards would undermine the fair share principle, since the Bronx would be handling waste from other boroughs.

Response: DSNY does not contemplate using this facility and it is not part of the Proposed Action.

40.3.1.6 Public Health and Safety

49. **Comment:** A number of speakers in various neighborhoods throughout the City were concerned with the increased diesel emissions from truck traffic and its resultant increased risk of asthma, lung cancer and heart disease in the neighborhood, especially as it would affect children, the elderly, pregnant women and their unborn children. What would the long-range health effects be from operation of an MTS in the neighborhood?

Response: As detailed in Chapter 33 (Public Health Evaluation) of the FEIS, reactivating the prior MTS use at the four MTS sites (which will use the more environmentally protective converted MTS design and modern clean diesel technology) is not expected to harm the public health. Although New York City air quality is currently out of compliance with the National Ambient Air Quality Standards for $PM_{2.5}$, the relatively small amounts of particulate air emissions from the proposed MTSs can fairly be called insignificant, which is what the air quality analysis for the MTSs reasonably concluded. The City's air quality is expected to improve as new federal requirements for ultra low sulfur diesel fuel and diesel engines phase starting in 2006. The primary pollutants

associated with the MTSs are those emitted by diesel engines, and the results of scientific studies of diesel engine exhaust in sensitive laboratory animals are summarized in Section 33.2.2.4.2 of the FEIS. Diesel emissions contribute to ambient concentrations of criteria pollutants, such as NOx and particulate matter (PM_{10} and $PM_{2.5}$), and hazardous air pollutants (such as benzo(a)pyrene and formaldehyde), and health-based benchmarks are used in this FEIS to assess these constituents. Ambient standards for criteria pollutants (NAAQS) take into account research on potentially sensitive groups, such as children. The analyses of potential project emissions suggest that changes to air quality will be quite small, and, as such, are not anticipated to harm public health.

Regarding fine particulate matter more generally, concentrations of $PM_{2.5}$ in ambient air in NYC are currently small (both in absolute terms and relative to comparable cities in Europe and elsewhere), and are some 30% lower than estimates from the 1970's and 1980's (see, for example, http://www.epa.gov/airtrends/pm.html). National regulations will soon further reduce airborne concentrations of diesel particulate matter (DPM), due to reductions in the sulfur content of diesel fuel, engine redesigns, and pollution control devices, such as catalytic converters. Levels of DPM in New York are smaller than DPM levels in comparable European cities, given the heavy reliance on diesel-powered cars in Europe. Moreover, although PM concentrations have *decreased* over the past three or four decades in New York and throughout the U.S., asthma rates have *increased* during this same time period. Thus, although working to further decrease particulate pollution can be a worthwhile effort, there is neither evidence nor reason to suggest that so doing will decrease asthma incidence *per se*.

Asthma was addressed in detail in the DEIS and in this FEIS. Overall, it is noted that while asthma among children is a major public and personal health problem, its causes are complex and only incompletely understood or controllable. As noted in a recent review (Kaiser, 2004)[2], for example:

[2] Kaiser HB. Risk factors in allergy/asthma. *Allergy Asthma Proc*. 2004 Jan-Feb; 25(1):7-10.

> Family history is the strongest risk factor for the development of allergies/asthma. . . . Environmental issues and lifestyle changes are becoming increasingly more important as significant risk factors but the evidence can be confusing, controversial, and even contradictory. There is overwhelming evidence that sensitization to indoor allergens is a major risk factor for the development of clinical atopic disease in genetically susceptible individuals.

Researchers with the Inner City Asthma Study (Gruchalla *et al.*, 2005)[3] have investigated the relationships among indoor allergens and asthma among almost 1,000 children aged 5 to 11 years old with moderate to severe asthma. These researchers found:

> . . . cockroach sensitivity to be highest in the Bronx, New York, and Dallas (81.2%, 78.7%, and 78.5%, respectively), while dust mite sensitivity was highest in Dallas and Seattle (83.7% and 78.0%, respectively). A majority of homes in Chicago, New York, and the Bronx had cockroach allergen levels greater than 2 U/g: cockroach allergen levels were highest in high-rise apartments, whereas dust mite allergen levels were highest in detached homes. Children who were both sensitive and exposed to cockroach allergen had significantly more asthma symptom days, more caretaker interrupted sleep, and more school days missed than children who were not sensitive or exposed. . . . Cockroach allergen appears to have a greater effect on asthma morbidity than dust mite or pet allergen in these children.

With regard to outdoor air, summertime increases in ozone can also exacerbate asthma, at least for a subset of patients. Ozone formation in NYC air will not be measurably affected by the proposed facilities or the trucks and other equipment associated therewith.

The very small increases in particulate matter (PM) from diesel engine exhaust from trucks and other equipment associated with the proposed facilities are not expected to exacerbate asthma. Experimental evidence from human volunteers indicates that people with asthma show little or no response during voluntary exposure to *much* higher levels of airborne particulate matter (PM) than are characteristic of the outdoor environment in New York or elsewhere in the U.S. Studies in a number of laboratories (Avol, *et al.*,

[3] Gruchalla RS, Pongracic J, Plaut M, Evans R, Visness CM, Walter M, Crain EF, Kattan M, Morgan WJ, Steinbach S, Stout J, Malindzak G, Smartt E, Mitchell H. Inner City Asthma Study: Relationships among sensitivity, allergen exposure, and asthma morbidity. *J Allergy Clin Immunol.* 2005 Mar; 115(3):478-85.

1990; Hanley *et al.*, 1992; and Koenig *et al.*, 1989)[4] have compared the pulmonary response of asthmatics to that of non-asthmatic subjects in chamber studies, where volunteers are exposed to measured, controlled concentrations of various airborne substances. Although asthmatics were more sensitive to high concentrations of *highly acidic* aerosols (such as aerosols of sulfuric acid) than non-asthmatic subjects, neither asthmatics nor non-asthmatic subjects exhibited decrements in pulmonary function after exposure to mildly acidic airborne particulate matter (the vast majority of ambient particles are either neutral or only mildly acidic). The concentrations used in these experiments ranged from 100 to 1,000 $\mu g/m^3$ — *much* higher concentrations than those present in outdoor air in New York City.

With regard to lung cancer or heart disease, the weight of reliable scientific evidence indicates that emissions from the proposed facilities, including from trucks and other equipment, will not exacerbate these important problems. Lung cancer is, of course, overwhelming caused by cigarette smoking, and smoking is an important cause of heart disease as well. Fortunately, rates of smoking among adults and adolescents have fallen in recent years, and New York City's Smoke-Free Air Act will hopefully accelerate this health-protective trend.

Data from some observational (as opposed to controlled, randomized, or experimental) epidemiologic studies suggest that tiny increases in particulate matter, or any other "criteria pollutant," in ambient air correlate with increases in rates of death or serious disease. It is therefore *statistically* possible to "predict" that any increase in ambient concentrations of any air pollutant will increase rates of death or disease, or, by the same logic and with the same data, that any decrease in any air pollutant will decrease rates of death or disease (see, for example, http://www.epa.gov/air/clearskies/benefits.html). But, for

[4] Avol, E.L., Linn, W.S., Shamoo, D.A., Anderson, K.R., Peng, R_C, and Hackney, J.D. (1990). Respiratory responses of young asthmatic volunteers in controlled exposures to sulfuric acid aerosol. *Am Rev Respir Dis 142*:343-348. Effects on inhalation of acidic compounds on pulmonary function in allergic adolescent subjects. *Environ Health Perspect 79*:173-178.

several reasons, such predictions rest on very uncertain grounds, and may yield unreliable results. As noted above, these predictions are clearly incorrect for asthma, the incidence of which has been increasing in the U.S. and throughout the "developed world" for the past three or four decades, at the same time that concentrations of air pollutants have been decreasing. With regard to other diseases and causes of death in the U.S., the above-noted observed correlations (i) are very weak, (ii) are *not* found in all relevant and highly sophisticated studies (see, for example, Sullivan *et al*., 2005)[5], (iii) suffer from residual confounding by genuine causes of disease and death (see, for example, Moolgavkar, in press, 2005)[6], (iv) imply, illogically, that ambient air gases and particles are somehow vastly more toxic than the same gases and particles present in cigarette smoke (see, for example, Gamble and Nicolich, 2000)[7], and (v) are not supported by abundant clinical and toxicologic evidence and experience indicating a lack of harm to health due to vanishingly small concentrations of ordinary air pollutants (Green and Armstrong, 2003)[8].

50. **Comment:** The DEIS does not assess the impacts of vectors in the vicinities of the MTSs, and the transfer stations are likely to create and exacerbate vermin problems in surrounding areas. The insecticides used to control the vermin will also create a hazard. The MTS will also increase the mosquito population, and hence exposure to the West Nile Virus. These issues must be addressed.

Response: Although poorly managed putrescible waste can attract rats and insects, proper design and maintenance of modern solid waste transfer stations help ensure that vermin do not become a significant problem. We know of no evidence that modern transfer stations increase infestation rates in neighboring residences. Certain pests, such as mosquitoes that do or may carry West Nile virus, are typically present in New York City (and elsewhere) during the summer and early autumn, regardless of the presence or

absence of transfer facilities: the public health effects of this problem — and of the treatment of this problem by spraying of residential neighborhoods in New York City (NYC) with pyrethroid pesticides — have been studied by scientists from the New York City Department of Health and Mental Hygiene and elsewhere (Karpati *et al.*, 2004)[9]. In particular, Karpati and colleagues investigated whether the widespread use of pyrethroid pesticides NYC (during the summer of 2000) was associated with increased rates of hospital emergency department visits for asthma or for chronic obstructive pulmonary disease. They found that it was not.

51. **Comment:** Diesel exhaust will be increased, and will affect pulmonary diseases including asthma and emphysema as well as the potential for miscarriage. These emissions are of particular concern because this particulate matter can lodge deep in the lungs, and may stay there for a long period of time. Children are particularly vulnerable to the effects of these pollutants. The Department of Public Health at Columbia University has published extensively on the impact of diesel emissions. Within diesel exhaust are particles that make the immune system more susceptible to inhale allergens like pollen and mold. The impact of allergens from vermin has been demonstrated in studies at Johns Hopkins Medical Center. These studies must be taken into account in the EIS. The conclusion in the DEIS states that "for the purposes of public health assessment, application of typical safety factors to these data from laboratory rodents suggest that current ambient concentrations of diesel engine exhaust in New York State are not harmful**."** This does not, however address the exhaust levels within New York City.

Response: The approach to evaluating the health impacts of diesel emissions is reviewed above. The possibility that diesel exhaust exacerbates the effect of allergens and triggers asthma was mentioned in section 33.6.3 of the Public Health Evaluation, as was the evidence linking *indoor* vermin allergens to asthma. It is true that very high concentrations of some chemicals within diesel exhaust can trigger immune system

[9] Karpati AM, Perrin MC, Matte T, Leighton J, Schwartz J, Barr RG. Pesticide spraying for West Nile virus control and emergency department asthma visits in New York City, 2000. *Environ Health Perspect.* 2004 Aug;112(11):1183-7.

responses, but there is not evidence that current levels of these chemicals in ambient air in NYC exacerbate the disease or other pulmonary conditions. There is not reliable evidence that ambient concentrations of diesel engine exhaust cause miscarriage. Current ambient concentrations of diesel engine exhaust in New York *City* were included in our analysis of such concentrations within the State as a whole.

52. **Comment:** One speaker wanted to review the Worker's Compensation claims of DSNY workers, as it relates to increased levels of emphysema, asthma and other lung diseases.
Response: An epidemiologic study of this nature is not within the scope of the CEQR process or this EIS. It would be a large, complex, expensive, multi-year effort requiring the invasion of privacy of DSNY workers, and would not necessarily shed light on risks to the public.

53. **Comment:** Several speakers were particularly concerned with the health of the children who live and visit the area near the MTS. The physiology of infants and children is different than adults. They are shorter, and the concentration of toxicants emitted from trucks is greater closer to the ground. The DEIS used a height of 1.8 meters for receptors, but this doesn't take into account people in strollers or little ones walking around. In addition, children breathe faster, and entrain greater quantities of pollutants per body surface area than adults. They also spend more time outdoors, so their exposure to these pollutants is higher. As children they are still growing lungs; between birth and ten years of age, they are adding air sacks, so any damage that is created to developing lungs has a permanent effect on lung function. The DEIS does not discuss the physiology of children, and their exposure to these pollutants. A recent article from the *New England Journal of Medicine* relates to this issue, where an 8 year prospective study of over 1,700 school-aged children was undertaken. These children had measurements of their lung function conducted and correlated with ambient exposures to ozone, acid vapor nitrogen dioxide and particulate matter. The authors concluded that the levels of air pollution had chronic, adverse effects on lung development in children from 10 to 18 years of age. The concentrations of PM_{10} for the 91st Street site were well within this range of concentrations studied in the article.

Response: NAAQS are set by the USEPA to protect sensitive persons, whether they are children or adults. For some pollutants, such as NO_2 and SO_2, the NAAQS are based on adverse pulmonary responses of children since they appear to be particularly sensitive to these pollutants. Evaluations of air impacts in light of NAAQS, then, do indeed incorporate children's responses. Furthermore, the NAAQS established for different averaging times (for example, 1 hour and 8 hours for CO) assume that the sensitive individuals may be outside for the full period. With regard to the receptor height, truck emissions were modeled as coming from *greater* than a 1.8m height, so receptors below 1.8m would encounter smaller pollutant concentrations than receptors at 1.8m. The Gauderman work is discussed below in Comment #54.

54. Comment: The reliance of thresholds is an inadequate method for capturing the effect of air quality deterioration on the public health. The Gauderman study indicates a linear rather than a threshold effect of exposure to air pollution. The effects from the MTSs will place thousands of children for years to come at increased risk of permanent lung damage, and none of these effects are addressed in the current DEIS.

Response: The threshold approach to assessing the health impacts of virtually all non-carcinogenic chemicals is well established in regulatory policy and health risk assessment. The Gauderman *et al*. (2004)[10] study is an observational study of air pollution in Southern California, which has a very different mixture of pollutants than those prevalent in NYC. Half of the air pollutants measured by Gauderman *et al*. were not measured or analyzed in the DEIS or this FEIS. The others, NO_2, PM_{10}, and $PM_{2.5}$, were evaluated by comparing predicted project-related increments and background concentrations (except for $PM_{2.5}$) to the concentrations allowed by U.S. EPA and defined by NAAQS or to incremental concentrations allowed or proposed by New York City or New York State agencies. As described above, current NAAQS for some pollutants of concern are based on effects in children. The NAAQS, which are regularly reviewed,

---

[10] Gauderman WJ, Avol E, Gilliland F, Vora H, Thomas D, Berhane K, McConnell R, Kuenzli N, Lurmann F, Rappaport E, Margolis H, Bates D, Peters J. The effect of air pollution on lung development from 10 to 18 years of age. N Engl J Med. 2004 Sep 9; 351(11):1057-67.

consider data like that in Gauderman *et al*. and, conceivably, may be altered in the future if the weight of the evidence suggests that children or other human populations are insufficiently protected by current standards or that effect thresholds are not apparent. In the meantime, it was felt that a review of literature on traffic's potential effects on health, in addition to analyses of specific air pollutants (which are addressed by existing regulations), is relevant to neighborhood concerns.

55. **Comment:** The Public Health chapter acknowledges that the EPA says that diesel exhaust has the potential to pose a lung caner hazard at anticipated levels of exposure, but the authors of this chapter have disregarded this in the conclusion that the impacts are not of public health significance. At least one of the authors of the chapter has published elsewhere that there is a statistically significant association between mortality and acute exposure to an increase in concentration of $PM_{10.5}$ (sic) in New York City. While an association does not mean cause and effect it is often used as the basis for further investigation, and for justifying issuing protective guidelines, air quality standards and warnings. The CEQR Technical Manual guidelines on Public Health state "Other actions, which might not exceed the preceding thresholds, but might nonetheless result in significant public health concerns, including projects such as….the NYC Comprehensive Solid Waste Management Plan. For some of these actions, there might be published, peer-reviewed scientific literature suggesting an association between an exposure potentially caused by the action and potential health impacts". This indicates that "association" of exposure and health impact is sufficient.

Response: The Public Health chapter indeed acknowledges USEPA's statement that "diesel exhaust has the potential to pose a lung cancer hazard to humans at anticipated levels of environmental exposure." Since neither USEPA nor New York State has published a cancer slope factor for diesel exhaust, however, the potential increase in cancer risk posed by the proposed project's releases of exhaust cannot be evaluated with any confidence. Thus, the cancer hazard of diesel exhaust is not dismissed, but cannot be assessed in a meaningful way for public health impact. (Some components of diesel exhaust, such as benzo(a)pyrene, were included in the HAPs cancer risk assessments.

The potential increases in cancer risk were within commonly accepted limits.) The ultimate conclusions of the Public Health Evaluation are based on the qualitative and quantitative evaluation of health risks.

The potential health impacts of acute or chronic exposure to $PM_{2.5}$ and PM_{10} are considered by USEPA when establishing the NAAQS. Thus, comparison of predicted project-related impacts to the NAAQS, SILs, or STVs (as applicable) is appropriately health protective. It is not within the scope of this FEIS to modify NAAQS based on a review of the literature, particularly since the literature on PM health effects is extremely large and complex; even USEPA's recent evaluation of the recent PM literature took years to complete.

56. **Comment:** (A9) Some of the chapters on the various facility sites acknowledge "some of the pollutants included in the group of non-carcinogenic pollutants, such as anthracene, benzo(a)anthracene and chrysene, may also have carcinogenic effects. As these pollutants do not have established unit risk factors, they were evaluated using the hazard index approach for non-carcinogens" Just because the EPA has not set an acceptably safe level for a pollutant is not justification for ignoring any and all negative effects from that pollutant.

Response: The goal of the public health evaluation is not simply to list or acknowledge the various health hazards that may be posed by the proposed project (such as release of potential carcinogens), but to gauge whether a hazard will be present at levels sufficient to significantly affect public health. That assessment relies heavily on numerical expressions of the hazard's potency. Since accepted cancer slope factors for anthracene and related chemicals do not exist, the potential impact of these chemicals on cancer risk was not quantitatively evaluated. The non-carcinogenic effects of anthracene and the other chemicals mentioned were quantitatively evaluated, however, so it is not accurate to state that any and all negative effects were ignored.

40.3.1.7 Odor

57. **Comment:** The purported sophisticated odor control system will not mitigate serious health consequences from pollution, filth and vermin associated with transfer station operations. What are the contingency plans when negative air pressure exhaust fans break down?

Response: The facilities and equipment are carefully designed and strict procedures will be implemented to minimize problems that may arise as a result of managing solid waste. The environmental controls are considerably more advanced than is the case with the existing MTS design. The primary source of MTS-related air pollution will be the operation of fuel-fired equipment inside the MTS building and trucks queuing on the on-site ramp. New stationary equipment and non-road vehicle engines will be purchased new for the facilities and, therefore, these emissions sources will meet the latest EPA emissions standards applicable to new engines. Adequate truck unloading space inside the building will be provided, thus minimizing on-site queuing time on the ramp and vehicle emissions. Emission of odors and dust will be strictly controlled using a ventilation system that will maintain the MTS at "negative pressure" such that odors, dust and litter will not tend to migrate out of open doors. Odors will be neutralized before the facility air is exhausted from the roof vents. The facility will also be equipped with a dust suppression misting system which will cause dust to settle to the floor to be processed with the waste, washed and/or swept away. Routine cleaning of the entire facility will be performed and daily cleaning of the MTS process area floor will be required as a condition of the MTS's operating permit. For vermin control, licensed exterminators will routinely service the MTS as part of a preventative maintenance cycle, which will include applying spray and placing traps. Any emergency complaints would prompt additional attention as appropriate. NYSDEC and City regulators will periodically inspect the facilities for compliance with applicable rules and permits, as appropriate.

The ventilation system was designed so that the waste tipping and loading areas will have three separate supply and exhaust systems, each sized for up to 12 air changes per hour, the design criterion for the MTSs. These systems provide redundancy for ventilation

equipment failure and maintenance. In the event of a power failure, each of the MTSs will be equipped with an emergency generator to supply power, including to the ventilation and negative air pressure exhaust system.

40.3.1.8 Air Quality

58. **Comment:** The DEIS should contain an analysis of the impacts on a regional basis for particulate matter. It omits any analysis of the impacts of the Proposed Action's nitrogen oxides and VOC emission contributions to ozone pollution in the region, yet claims it is not significant. The region is a non-attainment area for the one-hour and eight-hour ozone standard. As such, it should include a cumulative analysis of air quality effects.

Response: On a regional basis, emissions and impacts of particulate matter, NOx, and VOC will not change significantly due to the Proposed Action. A credible regional emissions analysis to compare waste export alternatives is not feasible at this time. The equipment and routes to be used to transport and dispose of NYC solid waste once it leaves the city are undefined. DSNY cannot predict the associated emissions outside the City. More importantly, the pollutants of primary regional concern, particularly $PM_{2.5}$ and ozone, are strongly affected by precursor pollutant emissions far upwind (outside to the City and State), making it difficult to establish a "domain" over which to conduct such an analysis. However, looking broadly at cumulative regional emissions, it is apparent that such emissions from several large source categories, including power plants, on-road engines, non-road engines, and many types of industrial sources, will continue to decrease dramatically in the next few years due to existing and proposed federal rules. Therefore, one can say with confidence that the City's air quality, to the extent it is impacted by these cumulative upwind regional emissions, will continue to improve in the coming years.

Currently, waste is being exported from the City via semi-truck transfer trailers. DSNY has estimated that the shift from truck-based transfer to barge/rail based for DSNY-managed Waste will reduce waste transfer vehicle traffic by approximately 2.8 million miles per year. (See the response to Comment #42 in Section 40.3.3.1 for more detail on this estimate.) The noise, emissions, and congestion caused by this mode

of waste export would be eliminated by the Proposed Action to move this waste out of the City predominantly by barges or rail. While barge tugboats and locomotives also produce air pollutant emissions, these emissions are less proximate to businesses, residences, and the commuting public, and therefore, the Proposed Action is expected to lessen public exposure to air pollution within the region.

Furthermore, the region's ozone and particulate matter non-attainment issues are largely a function of industrial and power plant emissions occurring far upwind, with a lesser contribution from local transportation-related emissions sources. The EPA has already proposed rules to drastically reduce upwind ozone and particulate matter precursor pollutant (mainly nitrogen oxides and sulfur dioxide) emissions from power plants and from non-road vehicles, and has in place much more stringent on-road emissions standards for diesel trucks, which go into effect in 2007. With or without the Proposed Action, the cumulative effects of these current and pending rules on a regional basis will far outweigh the regional differences in emissions between the current waste export program and the Proposed Action.

59. **Comment:** With the objective of minimizing truck traffic and emissions, the EIS should evaluate truck emissions in all parts of the City from the "no action" alternative, the Proposed Alternative, and an additional scheme whereby truck queuing and idling is minimized and truck route mileage is minimized via changes in operations and optimized locations of garages and waste transfer points. Additionally, dioxin TEQ should be added to the criteria pollutants evaluated since governmental agencies such as the USEPA have determined in past studies that automotive sources produce this carcinogenic substance.

Response: The Proposed Action would certainly minimize truck traffic and associated emissions by essentially eliminating the current export of city waste via transfer trailer. The Proposed Action would minimize truck idling at transfer stations by constructing transfer stations that are designed to have sufficient internal dumping and handling capacity to minimize queues. The transfer stations are designed to contain truck queues within the facility properties.

Dioxin TEQ (total equivalents of 2,3,7,8 tetra chloro dibenzo-p-dioxin, or TCDD) was not analyzed in this study. As stated by EPA, reliable emissions data applicable to US automotive fleets and fuels are not available (see publication EPA-454/R-97-003, "Locating and Estimating Air Emissions from Sources of Dioxins and Furans", Office of Air Quality Planning and Standards, Office of Air and Radiation, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711, May 1997). However, the Proposed Action would eliminate much automotive (transfer trailer truck) travel within and outside the city, thus minimizing any dioxin that may be emitted by diesel trucks transporting solid waste.

60. **Comment:** The New SWMP should develop an overall strategy for monitoring and tracking emissions from the vehicles which are integral to the solid waste program. While the long-term export program reduces the number of miles traveled by DSNY vehicles, and potentially reduces the journeys of some commercial vehicles, there will still be substantial vehicle miles traveled overall. Many currently operating transfer stations experience queuing trucks, with attendant idling emissions, odors, and noise. The proposed program will therefore continue to have truck operations producing significant emissions, including emissions outside the City. Emissions both inside and outside of the City should be quantified as a baseline emissions inventory within the FEIS. At a minimum, it should contain a list of DSNY vehicles with make, model and certification level for regulated pollutants of each vehicle. This can be updated annually, and would allow interested parties to compare the fleet's emissions with emissions from the cleanest refuse trucks available. Estimated costs for CNG and diesel vehicles can also be presented.

Response: DSNY replaces its waste collection vehicles on a seven-year cycle, meaning the average age of DSNY waste collection vehicles at any time is approximately 3.5 years old. Consequently, DSNY operates one of the cleanest large fleets of refuse trucks in the nation/state/region. EPA emissions standards applicable to the diesel engines powering DSNY vehicles are already accessible to the public, as they are published in the Code of Federal Regulations at 40 CFR 86. Therefore, for any given future year, comparisons can be made between the emissions standards applicable for

model years represented in DSNY's fleet to the latest model year EPA emissions standards published at 40 CFR 86. Under these circumstances, the suggested tracking program is an expensive and unnecessary bookkeeping exercise.

As noted in Volume VI of the Commercial Waste Management Study, Waste Vehicle Technology Assessment, included as an Appendix to this FEIS, DSNY has developed and implemented one of the most innovative programs in the country to test new clean fuel technologies for use in its fleet.

61. **Comment:** We are pleased that the SWMP recommendations are consistent with DSNY's commitment to using CNG as a vehicle fuel, which is cleaner and reduces the nation's reliance on foreign oil. However, there needs to be commitment for additional purchases, since CNG trucks only account for one percent of the fleet. In May, 2002, DSNY released a report on particulate matter reductions being achieved with various diesel retrofit technologies. The data at the time showed little NO_X reduction and some fuel economy penalty. No newer data has been released, even though DSNY has expanded its testing program. We believe that DSNY should provide ongoing public reporting on the findings of vehicle testing, but should continue to purchase natural gas vehicles since they are the cleanest and generally quieter commercially-available refuse trucks. Areas with the greatest sensitivity to truck noise should be given priority in utilizing quieter CNG vehicles. DSNY should fully take advantage of the capacity of the new CNG fueling station in Woodside, Greenpoint and Canarsie. These facilities could accommodate up to 200 CNG refuse trucks with no additional infrastructure costs. Government incentives should make expanding the CNG fleet affordable. A discussion of these incentives such as Congestion Mitigation and Air Quality funds should be presented in the FEIS.

Response: Volume VI of the Commercial Waste Management Study, Waste Vehicle Technology Assessment, published in March 2004, reports on the results of numerous test programs that DSNY has and continues to conduct to evaluate the applicability of Clean Fuel technology to its Fleet Operations. As reflected in a prior Response to comment #60, DSNY's fleet of waste collection vehicles is replaced on a 7-year cycle.

Shortly after implementation of the proposed SWMP projects, EPA's new 2007 emissions standards would come into effect for new diesel vehicle engines. The 2007 emissions standards would reduce NOx emissions by more than an order of magnitude below the currently applicable 2004 standards, and 20 times below the 1998 NOx standards. The PM emission standard in 2007 will be an order of magnitude below the standard applicable to DSNY's current fleet. Because a sizeable portion of the DSNY's fleet will be replaced each year, emissions from the entire fleet will drop dramatically each year until the entire fleet is turned over in only 7 years. While experimentation with alternative fuels (e.g., CNG) and technologies is advantageous from an energy dependence standpoint, any air emissions concerns will be greatly minimized as a result of new EPA emissions standards already in place that will become effective in the near future. Moreover, with clean diesel technology and other treatment devices such as filters, truck emissions can be comparable to CNG truck emissions, whereas CNG trucks cost $200,000 compared to $130,000 for a DSNY clean diesel collection truck.

40.3.1.9 Traffic

62. **Comment:** The traffic analyses are shown for each facility independently, and are based on a half-mile radius around each facility. The DEIS does not show the overlay of trips from all facilities and their interactive effects (as was done in the 1991 SWMP/DEIS). This small study area also excludes consideration of traffic being generated by major development just outside a half-mile area.

Response: This statement is incorrect. Traffic study areas were not based upon a half-mile radius around each facility. Rather, intersections were selected for analysis based on convergence points of DSNY collection vehicles traveling to and from the facility, field surveys of intersection operating conditions, input from the New York City Department of Transportation (NYCDOT) on selected intersections, and any potential additional intersections of concern near a facility site. If multiple intersections were projected to be traversed along a congested corridor, several intersections were selected along that corridor for analysis – typically those that have lower (poorer) operating Levels of Service (LOS), based on the average delay at an intersection. The Future No-Build

estimates were obtained from available environmental review documents/traffic studies, and included additional traffic from any planned developments along access/egress routes that would: (i) be implemented by the 2006 Build Year; and (ii) travel through the selected intersections during the same periods analyzed (based on consultation with the New York City Department of City Planning). The traffic analysis properly shows the difference between the No-Build condition, under which DSNY collection vehicles would continue to utilize certain intersections on the way to transfer facilities in and outside the City as at present, and the Build Condition, which would return DSNY vehicles to the four proposed MTS sites, in addition to utilizing four or five private transfer stations in the City.

63. **Comment:** The traffic analysis method that examines each intersection in isolation does not accurately disclose real world operations of a traffic network in which a significant delay from added traffic on a major congested road can cause miles of spillback delay. Many impacts remain unmitigated, with the token efforts to reduce their severity (increasing green time) worsening conditions on adjacent roads.

Response: The 2001 CEQR Technical Manual notes that the key to evaluating urban area traffic conditions is the analysis of its intersections, since the capacity of an urban street is typically controlled by the capacity of its intersections with other streets. As part of the intersection analysis, field studies and traffic counts were obtained to identify current operating conditions. Potential traffic impacts at intersections analyzed in the DEIS and this FEIS were mitigated through signal timing changes, which are among the preferred low-cost, readily implementable mitigation measures identified in the CEQR Technical Manual. The goal of signal timing changes is to shift additional green time from approaches that do not have adequate capacity to approaches or intersections that have clearly sufficient capacity. In addition, NYCDOT reviews all applications submitted for signal timing and/or phasing modifications with consideration given to traffic conditions at nearby intersections prior to implementing changes.

64. **Comment:** There needs to be an analysis of the turnaround time of deliveries at each facility and the queuing potential at the entrances. Additionally, there is no evaluation of the principal initiative to reduce the adverse impacts of commercial transfer stations by utilizing the Converted MTSs for commercial waste. This change would add hundreds of trucks, with enough trucks in the 8 to 9a.m. peak hour to push the facility peaks from 9-10 a.m. back to 8-9 a.m.

Response: The suggested analyses have already been done. For the DEIS and this FEIS, a facility spreadsheet model was developed using conservative assumptions to estimate the travel time of arriving DSNY collection vehicles through the Converted MTSs based on: (1) historical delivery patterns; and (2) operating assumptions such as the amount of time to weigh in, travel up the ramp into the processing building, unload in the processing building, weigh out, and exit the facility. This model was used for the DEIS and this FEIS to predict the number of collection vehicles that might queue on the facility entrance ramp at a given hour. In addition, the facility peak hour is not 8:00 a.m. to 9:00 a.m. It begins after 9:30 - 10:00 a.m. at various facilities. Commercial waste deliveries have no effect on the peak hour, since these arrive during the 8:00 p.m. to 8:00 a.m. period, when DSNY deliveries are at their lowest levels.

In addition, a CEQR-level analysis of potentially significant adverse impacts related to processing Commercial Waste at the Converted MTSs in the Commercial Waste Management Study (CWMS)– Volume III is included as Appendix I to this FEIS. Each Chapter in this FEIS that reviews a Converted MTS has a section summarizing that more detailed CEQR level analysis in the CWMS – Volume III. On-site operations were analyzed assuming 24-hour operation. For example, for the noise analysis, it is assumed that the facility is operating all of its equipment during the quietest background hour, which, given the amount of commercial waste that actually might be processed during this period, is conservative. Off-site traffic, air quality and noise analysis locations were analyzed for potential impacts from DSNY collection vehicles plus commercial waste hauling vehicles. Restrictions will be imposed on some DSNY collection vehicle relays and commercial waste deliveries to certain Converted MTSs during specified hours to mitigate the potential for significant adverse on-site impacts at boundary points or nearby

sensitive receptors, and/or off-site noise impacts at certain sensitive receptors along access/egress routes to the facility. In addition, deliveries of commercial waste to the Converted MTSs will be restricted to the hours of 8:00 p.m. and 8:00 a.m., which does not coincide with the facility peak hour analyzed for the Converted MTSs.

65. **Comment:** The traffic studies were not accurately conducted. While true that the CEQR Technical Manual classifies waste collection vehicles as 1.5 PCEs, this is not appropriate for traffic studies relating to an on-going flow of traffic to and from a site. The CEQR technical manual is merely a set of guidelines. A truck weighing approximately 23 tons cannot be considered a "light truck." The 1.5 factor may perhaps be applied when there is an occasional garbage truck within a stream of cars, or perhaps when empty. According to the USDOT Federal Highway Administration guidelines, a heavy vehicle is equated to 2 Passenger Car Equivalent (PCE). This would change many of the impacts in the analyses.

Response: The traffic analyses were properly prepared in accordance with the 2001 CEQR Technical Manual that specifically designates a PCE ratio of 1.5 for waste collection vehicles, while a PCE of 2.0 is appropriately designated for the longer, larger waste transfer trailer vehicles with an allowable gross vehicle weight of 80,000 pounds (40 tons).

66. **Comment:** While the Federal Highway Capacity Manual was used to evaluate truck traffic, several consultants were used for the traffic studies, and their analyses were not consistent across all the sites evaluated in the DEIS. For example, the evaluation at West. 135th Street treats a DSNY truck as a heavy vehicle. However, for East 91st Street, (and other sites) a DSNY vehicle is not considered to be a heavy vehicle. Additionally trucks owned by commercial waste haulers are heavier and have a greater capacity than DSNY vehicles. Trucks owned by Waste Management indicate that their tonnage is 15 tons empty, and 30 tons full. Therefore traffic studies (and noise and air) need to be adjusted for when the analysis is for DSNY-managed waste versus commercial waste.

Response: There are two ways of evaluating future conditions that are used in the FEIS. Both methods were reviewed and approved by the NYCDOT. In the first method, new

truck trips generated by a facility are entered into the model as Passenger Car Equivalents (PCEs). In the analysis, the percentage of trucks is left unchanged from the No-Build to Build conditions since the change in percent heavy vehicles due to the addition of DSNY collection vehicles is represented as an increase in PCEs (by adding DSNY collection vehicles as a PCE of 1.5, which is the value specified in the 2001 CEQR Technical Manual for waste collection vehicles). Method 1 conservatively estimates the number of new trips generated by a facility because the heavy vehicle percentage between Future No-Build and Future Build Condition decreases because the software program does not recognize that the new truck trips are counted as PCEs.

In the second method, new truck trips generated by a facility are added to Future No-Build volumes on a one for one basis (no PCE factors are used for trucks). The truck percentage is then adjusted (increased) assuming that all new truck trips are heavy vehicles. Under this method, the Highway Capacity Software (HCS) automatically assigns a default PCE value of 2.0 for heavy vehicle trips. By conservatively estimating the number of new trips generated by trucks, Method 2 also conservatively estimates the number of new trips generated by a facility. Although the methods for including new trips differ, both methods conservatively estimate the number of new trips generated by trucks for each facility and NYCDOT approved both methods of analysis. The off-site noise analyses were based on use of PCE noise conversion factors from the 2001 CEQR Technical Manual for heavy trucks (47 PCEs).

67. **Comment:** The DEIS states that a new traffic study would not need to be conducted if one of the sites evaluated is used instead for recyclables. While the number of trucks may be fewer, we don't know that since we don't have information on the number of trucks or their size.

Response: The comment refers to use of the existing West 59th Street MTS for receiving Recyclables. This facility currently receives paper, which is accounted for as an Existing Condition. The use of this facility to receive more or different Recyclables, e.g., MGP, is not an element of the Proposed Action. The Proposed Action designates two sites for recycling, Gansevoort and SBMT, that are completely unrelated to the Proposed Converted MTSs. The DEIS and this FEIS evaluated collection vehicle deliveries to both

Gansevoort and SBMT. As discussed in the response to Comment #99 in Section 40.3.1.10, there are no overlapping effects in traffic patterns to the proposed Converted MTSs and either of the proposed Recycling facilities (Gansevoort and SBMT).

68. **Comment:** The DEIS should present a detailed description of the methodology used to collect the actual truck counts at the commercial waste transfer stations, including when they took place. Additionally, the DEIS should present the total volume of waste traffic for each intersection evaluated in the traffic analyses, and indicate the truck type (DSNY, private collection or waste export). The CWMS reports traffic volumes based upon the number of vehicles, rather than PCE ratios, which are used to assess impacts in the DEIS. What are the PCE totals for the intersections evaluated, and what percentage of that can be attributed to waste management trucks? The DEIS should be updated to provide basic information regarding the collection of traffic impact information and provide the data and methodologies used to arrive at its conclusions as an Appendix. Additionally, information should be included on the volume of waste managed and delivered to various sites by Community District.

Response: See Response to Comment #64 pertaining to the level of analysis presented in the Commercial Waste Management Study for acceptance of commercial waste at the Converted MTSs. The DEIS and this FEIS includes several figures for each facility analyzed, one of which presents the net additional number of DSNY collection vehicles analyzed during the am, facility and pm peak hours. Since any commercial waste deliveries to a Converted MTS would be restricted to between 8:00 p.m. and 8:00 a.m. when background traffic volumes are lower and intersection LOS is higher (better), no additional traffic analyses were conducted for commercial waste deliveries to the Converted MTSs.

The traffic analyses of commercial waste transfer stations located in geographical proximity were not CEQR-level analyses and the methodology and analyses are presented in the Commercial Waste Management Study (CWMS)–Volume I in Appendix I to this FEIS. In addition the Technical Backup for the DEIS and this FEIS, available request, includes supporting detail from which the relative proportions of waste collection vehicles and heavy trucks can be calculated.

69. **Comment:** The DEIS needs to include the hourly distribution and type of truck accessing the facility. There needs to be an explanation as to how DSNY determined the temporal distribution of the commercial waste trucks that would access DSNY's facilities.

Response: Figures that present the hourly deliveries of DSNY-managed waste throughout the day are included in the DEIS and this FEIS and are based on historical delivery patterns. The methodology used to determine the potential temporal distribution of the commercial waste deliveries to the Converted MTSs is included in the Commercial Waste Management Study (CWMS) – Volume III in Appendix I in this FEIS.

40.3.1.10 SWMP Process and Objectives

70. **Comment:** Neither the SWMP or the DEIS provide information as to what will happen to the containerized waste once it leaves the MTS. Failure to address that element is a classic example of segmentation which is prohibited under CEQRA/SEQRA.

Response: DSNY is in the process of negotiating contracts for transport and disposal services to support the Long Term Export Program and has not made final decisions on the intermodal and disposal facilities that will used. Federal law establishes the Surface Transportation Board as the authority with regulatory oversight over railroads in the United States. The role of the Surface Transportation Board preempts state and local environmental review and permitting of railroad-owned facilities. Other types of out-of-state facilities, such as intermodal facilities and disposal facilities that may be used for the Long Term Export Program are subject to environmental review and permitting under the laws of their respective host jurisdictions. Facilities in New York State that are lawfully permitted and will be used for their intended purpose without modification as part of a Proposed Action are not subject to environmental review. The DEIS and this FEIS reviews several in-City intermodal facilities and one, Steel Style, in New York State as facilities that may potentially be used by the Long Term Export program, although none have been designated as an element of the Proposed Action. The DEIS, and this FEIS notes that, in case where the environmental review of these facilities is incomplete, a supplemental environmental review will be prepared, if that facility is selected as a part of the Long Term Export Program.

Section 40.3.5 of this chapter contains a Transfer, Transport and Disposal Plan that describes the intermodal transfer and transport facilities and services that may be employed to support the Converted MTSs.

71. **Comment:** The SWMP is vague and lacking in detail, especially on new programs, like Zero Waste, as well as the means to achieve Zero Waste. Sound alternatives to export should be discussed, as should the long term export costs.

Response: Section 40.3.1.3, Comment #12 addresses DSNY's commitment to waste reduction and reuse, including a discussion of the concept of "zero waste".

72. **Comment:** A number of individuals and groups supported the use of a marine and/or rail system to transport waste, which would take trucks and cars off the streets, and were in support of the key components of the SWMP. Transport of waste by barge can cut the truck traffic to half of the nearly eight million truck miles of traffic per year for solid waste transport on City streets, and can improve the quality of life in all five boroughs.

Response: Comment noted.

73. **Comment:** The SWMP should clearly state that the Fresh Kills Landfill is not a part of this new SWMP, and will not reopen.

Response: The information provided in Attachment X of the SWMP on the Fresh Kills Closure Construction and End Use clearly indicates that it is permanently closed to the acceptance of waste, undergoing closure construction and the subject of a planning effort that will define the phased reuse of the site through the development of a Master Plan.

74. **Comment:** The SWMP proposed facilities were chosen long before the DEIS was undertaken. The DEIS was tailored to justify a preconceived conclusion, and would not be accepted as being complete if submitted by a private developer. The SWMP pitted one neighborhood against another. A "real master plan" for the City should be developed as a collaborative effort with local community groups and leaders.

Response: The Draft New SWMP proposes an equitable distribution of Long Term Export and Recycling facilities among the City' five boroughs. It seeks to minimize the transport of DSNY-managed Waste generated in one borough to another for transfer. It avoids adding transfer capacity in communities, the South Bronx and Brooklyn CD #1 that have the highest relative concentrations of private transfer stations in the City. The SWMP was developed through consultation with affected communities and, as evidenced by the affirmative votes on the Converted MTS ULURP applications of three of the four affected community boards, has broad community support.

The DEIS and this FEIS were prepared to support a City-wide plan for a twenty year planning period. It is not comparable to an EIS prepared by a developer to support the construction of a single project. In July of 2002, Mayor Michael Bloomberg completed a review of the Long Term Export Program. That program, authorized under the 2000 SWMP Modification, had been unanimously adopted by the City Council in November of 2000. It was supported by an FEIS issued in October of 2000 that provide an environmental review of long term export options at some 20 different sites with 25 different facility options across the City. (The October 2004 DEIS and this FEIS, in analytical content and format, parallels the 2000 FEIS.) The Mayor's decision to pursue containerization at the MTSs was based on problems encountered in implementing the Linden EBUF project, which unfortunately could not be overcome, as well as recognition that the Alternatives evaluated in the 2000 SWMP FEIS were not acceptable substitutes for Long Term Export from the Manhattan MTS and North Shore MTS wastesheds, which comprised four of the five MTSs wastesheds that the Linden Project would have served.

The Mayor announced that the City would move in a new direction by redeveloping all eight of MTSs as facilities capable of containerizing waste for intermodal transport by barge or rail to out-of-City disposal facilities. Since that announcement, DSNY has worked diligently with NYCEDC and other City agencies to implement the Mayor's policy directive.

In the course of this work, other Alternatives were considered. DSNY is proposing to implement four Converted MTS projects, not eight. As alternatives to developing Converted MTSs to serving the West 135th and West 59th Street wastesheds in Manhattan and the wastesheds formerly served by the South Bronx and Greenpoint MTSs, other Long Term Export options were found. These options are now part of the Proposed Action, because they can be implemented more quickly, and are more cost effective than developing Alternative Converted MTSs for those wastesheds. Additionally they avoid adding new in-City waste transfer capacity, particularly in the Bronx and Brooklyn. DSNY also investigated alternative rail or barge export sites in Manhattan in the Scope of the Commercial Waste Management Study (CWMS). Three of the four sites investigated, West 140th Street (between the North River Water Pollution Control Plant on the Hudson River and the Henry Hudson Parkway), West 30th Street and Pier 42 on the East River were found to be infeasible. The fourth site, the Gansevoort peninsula is proposed as the site of an Acceptance Facility for Manhattan Recyclables. Section 1.3 of the FEIS provides additional discussion of the history of Alternatives considered to the Proposed Action.

75. **Comment:** One speaker thought that the Converted transfer stations will be inferior to the way garbage is transferred today. It is better to have hundreds of independent facilities.

Response: The development process and expense, the siting issues, lack of economies of scale and the additional truck traffic all argue against this approach.

76. **Comment:** The SWMP fails to address the need for the City to acquire long term landfill or other disposal capacity, which without, the City will be forever dependent on the private landfill market, and its constant escalation in price. Some landfill capacity will always be needed, so the City must control its cost. It would be prudent to develop or acquire capacity within New York; there should be greater consideration to self-sufficiency on a State-wide, if not a City-wide basis.

Response: DSNY has previously investigated the possibility of acquiring out-of-City New York State disposal capacity by issuing an RFEI on February 17, 2004 to solicit

expressions of interest from private and public entities, willing to sell such disposal capacity to the City. That initiative did not produce any promising results. In principal, DSNY remains interested in this idea. As a practical matter, it is unlikely that a party with permitted disposal capacity capable of accepting significant volumes of DSNY Waste would be interested in selling that asset to the City. It is more likely that DSNY would be offered a potential site that requires substantive permit approvals. That scenario would expose the City to significant risks that are beyond its control and is not particularly attractive.

The Long Term Export Program will in effect acquire out-of-City disposal capacity through the vehicle of a 20-year Contract with waste management companies and the Port Authority. DSNY has progressed far enough in its Long Term Export procurements to be confident that it can secure disposal capacity guarantees from private companies for 20 years. The Long Term Contracts will allow DSNY to "lock-in" large volumes of capacity at a time when the remote disposal capacity market is highly competitive. It will fund the contract for this capacity from its expense budget rather than making large up front investments with capital funds to acquire disposal capacity assets.

77. **Comment:** A few speakers though that landfilling of the waste would be the most expensive disposal option, and also the most damaging to the environment and to public health. Waste-to-energy should be considered because it reduces greenhouse gases, and a facility could be developed within the City. The only discussion on waste-to-energy is the Essex County Incinerator; however, this facility is inconsistent with the State's policy that recovered energy be available to the planning unit (NYC) or to the state.

Response: Past efforts to develop waste-to-energy facilities have demonstrated the extreme difficulties of siting such a facility in the City, and DSNY has no plans to do so.

78. **Comment:** Best Available Control Technologies should be used for all of the MTSs to make them accepted within the neighborhoods. GPS systems should be used on trucks to avoid queuing, or deliveries can be staggered. The Converted MTS should utilize an odor capture and control system, not an odor neutralizing system, and a vector and

vermin control system. There must be no standing water which would attract vermin. There should be a hazardous materials detection, segregation and disposal system. Every site must maintain a record keeping system. There should be on-site decontamination at the point of exit from the facility to remove all residues from vehicles leaving the facility. Truck deliveries should be staggered to minimize air quality impacts.

Response: The odor neutralizing systems is an odor control system that achieves better than 90% odor removal efficiencies. The MTSs are also equipped with dust suppression systems to keep dust out of the exhaust air and ventilation systems with sufficient capacity to maintain the building under negative pressure to prevent the escape of odors and litter to the outside environment. "Best Available Control Technology" as used in the context of air pollution regulation is equipment used to control release of criteria pollutants from "major sources" such as power plants. The Converted MTSs are classified as "minor sources". The emission control systems designed for the MTSs are the appropriate level of control for these facilities and are protective of public health.

The d**r**aft Part 360 Permit application, undergoing review by NYSDEC, extensively documents the measures and equipment that will employed at the MTSs to detect and segregate hazardous materials, control vermin through the periodic application of pest control measures, and clean the facility on a daily basis. The tipping floor, from which collection vehicles dumps their loads, is elevated 10 feet above the processing floor. Consequently, there is a very little accumulation of waste on the tipping floor and it is periodically swept with mechanical equipment. The additional ramp and truck queuing capacity at the Converted MTSs will eliminate the problem of on-street truck queuing and is more than sufficient to handle the peak anticipated truck rate at each facility. See the response to Comment #2 in section 40.3.1.1 for additional information about design features of the Converted MTSs.

79. **Comment:** The SWMP needs to include the planned closure of truck-based facilities in conjunction with the reopening of the Converted MTSs. This is not currently addressed in the document. The DEIS needs to examine the impacts of private land-based facilities

as thoroughly as the impacts of the Converted MTSs, and include the impacts of the transfer station siting regulations and operational regulations.

Response: DSNY is committed to reducing permitted putrescible capacity in the communities with the greatest number of transfer stations once the Converted MTSs open. DSNY will work with the industry, the Council and community groups to achieve this reduction in capacity. If DSNY is unable to obtain the cooperation of the industry, DSNY will work with the Council on legislation that will clarify DSNY's authority to reduce permitted capacity at transfer stations.

80. **Comment:** Communities need to be compensated for accepting more than their fair share of waste. Community mitigation programs need to be included, as well as amenities which would benefit the local community where a facility is sited. These might include tree plantings and open space improvements. The City should include this as a requirement for all transfer stations with which it enters into a contract.

Response: The reactivation of the four proposed MTS sites will not generate significant adverse impacts to the community. The three to five private transfer stations under consideration for long-term contracts already exist, and are located in suitable M-3 areas. DSNY does not believe that the DEIS or FEIS analysis supports a need for community mitigation programs for the Proposed Action.

81. **Comment:** DSNY should evaluate the feasibility and environmental impacts of a number of small sites for barging recyclables and waste rather than asking communities to accept truck traffic from several districts many miles away. Truck miles and emissions would be minimized, and smaller facilities would be easier to site.

Response: There is no evidence that smaller facilities are easier to site than larger facilities. The Proposed Action for Recycling includes development of a Materials Processing Facility at the SBMT in Brooklyn and a Recyclables Acceptance Facility at the Gansevoort peninsula for Manhattan. These new facilities would be integrated with existing Recyclable Acceptance facilities in the South Bronx and Long Island City, Queens, and the Visy Paper plant on Staten Island. These facilities in aggregate create a

system in which post-collection shipment of Recyclable materials between boroughs would be by barge.

82. **Comment:** As new DSNY trucks are purchased, alternatively fueled trucks, such as those that utilize biodiesel or natural gas should be considered to reduce pollution from truck emissions. Diesel trucks should be phased out. Non-road equipment within the transfer facilities should also be retrofitted to reduce diesel emissions.

Response: The Waste Vehicle Technology Assessment, Volume VI of the CWMS, published in March of 2004 and included as Appendix I in this FEIS extensively discusses DSNY's noteworthy efforts in reducing emissions from its collection fleet, including: use of low sulfur fuel in all its collection vehicles; fleet replacement on a seven year cycle that results on engine performance upgrades; testing of clean diesel technology; and the planned use of diesel particulate filters.

83. **Comment:** The City needs to vigorously enforce siting and operational regulations at existing facilities, with escalating fines for each violation. The City's new marine facilities also need to follow these stringent standards, and any transfer station that continually disobeys operational health and safety regulations must be fined or closed. This should also apply to other violations as well, such as violation of truck routes.

Response: The Enforcement Effectiveness Study in Appendix K of Volume I of the Commercial Waste Management Study included in Appendix I to this FEIS reports on activity of the Permit and Inspection Unit (PIU), DSNY's enforcement arm that conducts regular inspections of transfer stations for compliance with regulations.

84. **Comment:** Exporting waste will impose environmental burdens in communities where the landfills are located. These communities are most likely poor and minority communities. This is also true for the community in New Jersey where Manhattan waste will be incinerated. Exporting waste is not good for the environment; it is only beneficial to the waste industry, especially to Waste Management.

Response: The City sees no practicable alternative but to export its non-recycled waste. Waste exported by DSNY is disposed of at permitted facilities operating in compliance with local, state and federal law.

85. **Comment:** A few people thought that no waste should be incinerated. Incineration produces some of the most dangerous chemicals on earth, and causes cancer. New York City should not send its waste to an incinerator.

Response: All waste-to-energy facilities in the United States are stringently regulated, use Best Available Control Technology for emission control; and meet air emissions standards that are established as protective of public health.

86. **Comment:** The City needs to commit to a plan that includes establishment of a community advisory group, and a timeline of milestones to develop and implement the redistribution of waste capacity throughout the City. It should plan a phase-in for new technologies, and other environmentally-beneficial initiatives.

Response: DSNY is willing to work with Community Advisory Groups on addressing issues of concern related to Converted MTS construction and operation. See Response to Comment #79 on the issue of reducing private transfer stations in the City.

87. **Comment:** A number of people were critical of the alternatives included in the SWMP. The Solid Waste Management Act (SWMA) places high priority on reducing and reusing waste prior before disposal. The City needs to be more creative with how waste is handled in New York City. The MTS system is said to be a "key component" of the SWMP, but in fact, it is the only program discussed in detail. The City needs a world-class state-of-the-art processing and recycling system that will serve as a model for the world, instead of putting off dealing with the waste by sending it elsewhere. The SWMP should have an overall vision of where the solid waste system should be, and should encompass economic and environmental sustainability as well as social responsibility and equity. The cost increase for interim export of 91% is clearly unsustainable, and solid waste infrastructure must be maintained in municipal hands. Alternatives other than versions of incineration must be explored, and capital resources

should be used to explore and implement technologies such as anaerobic digestion, gasification, and newer means of handling recyclables.

Response: Please refer in the Draft New SWMP to the following sections: Chapter 2, Waste Prevention and Recycling; Attachment III, Waste Characterization Activities; Attachment VI, Recycling; and Appendices A, B, C, and D, all of which describe various aspects of the City's Waste Prevention and Recycling activities and Appendix F (Report on New and Emerging Solid Waste Management Technologies). Also refer to the Section 40.3.1.3 in this Chapter for responses to related comments on recycling.

88. **Comment:** The SWMP states that the transfer station fees will be increased. These revenues should be dedicated to commercial waste prevention and recycling programs.

Response: The transfer station permit fees collected by DSNY are applied in DSNY's budget to support the operations of the Permit and Inspection Unit (PIU). The PIU's principle function is to the regular inspection of private transfer stations for compliance with DSNY rules. The existing transfer station fees are not sufficient to cover the cost of PIU operations, particularly in light of PIU's new responsibilities to inspect for compliance with DSNY's new operational rules. The increase in fees is to help cover the cost of PIU operations.

89. **Comment:** A number of speakers were critical of how the SWMP handled the issue of commercial waste. State law requires that all waste, both residential and commercial, within a planning unit be managed in the SWMP. The New SWMP recognizes the problems associated with the current system for managing solid waste, but includes very few commitments for improving commercial waste management. The SWMP does not provide adequate alternatives for the management of the commercial waste stream, fails to create enough alternative capacity, and fails to provide milestones for its goals, or to prepare for the phasing out of unnecessary private transfer stations.

Response: See the Response to Comment #79.

90. **Comment:** The DEIS fails to analyze the cumulative impacts of the City's entire solid waste management system, including residential and commercial waste. SEQRA requires

that the EIS consider the impacts of the proposed actions in conjunction with the impacts of the current system for handling commercial waste. This should include those future actions that the SWMP envisions, such as moving commercial waste through the West 59th Street MTS and moving recyclables through the facility at Gansevoort. The cumulative analysis should include air pollution impacts from diesel truck and barge exhaust so that alternatives can be developed to reduce increases in air emissions. The DEIS should also analyze the cumulative emissions in all parts of New York from the no action alternative, which is continuing the interim plan on a permanent basis, and compare it to an alternative where truck queuing and idling is minimized at the MTSs. Any environmental review of existing programs related to the 1992 SWMP is too old to be "incorporated by reference" into the SWMP.

Response: The DEIS and this FEIS properly analyzes the impacts associated with the adoption of the New SWMP, which would modify certain aspects of the City's waste management system, and compares such impacts to existing conditions that the New SWMP in part is intended to address. Moreover, an analysis of the combined effects of the existing private transfer stations located in relative proximity in four study areas in the City that is reported in the 2004 Commercial Waste Management Study, included as Appendix I to this FEIS. CEQR requires cumulative impacts to be analyzed when two or more individual effects on the environment, when taken together, are significant or compound or increase other environmental effects. Elements of the Proposed Action for Long Term Export and Recycling include siting of four Converted MTSs (two in Brooklyn, one in Manhattan and one in Queens) and two recycling facilities (one in Brooklyn and one in Manhattan). Each of these facilities serves a discrete wasteshed. The waste flows to these facilities would have no overlapping effects with other facilities that are elements of the Proposed Action.

The Proposed Action for the Bronx wasteshed would involve contacting with either or both of two existing facilities that are permitted and operate at substantially greater capacity than the total of DSNY-managed waste in the Bronx. The DEIS and this FEIS evaluate the off-site impacts (traffic, air quality, and noise) of DSNY waste deliveries to East 132nd Street, assuming that facility received all of DSNY-managed Waste in the

Bronx, and found no potentially significant unmitigatable impacts. A 2003 EAS for expansion of the Harlem River Yard Truck to Rail Transfer Station analyzes an increment of additional collection vehicles that is greater than the increment of sending all DSNY-managed Waste in the Bronx to that site, and also found no potentially significant unmitigable impacts. If DSNY contracted with each facility to receive a portion of the Bronx waste, the waste flows to these facilities would not converge at points that would cause combined effects at a level of significance. A similar situation, involving two facilities, exists in Brooklyn and supports the same conclusion.

Existing businesses that may contribute to air quality, odor, noise and traffic within a given Study Area are included in the analyses for each facility, as applicable, as described in Chapter 3.0 of the DEIS and this FEIS. In essence, existing conditions are identified through collection of current traffic data, ambient noise levels, and air monitoring stations located throughout the City for use in the analyses. Future No-Build conditions are estimated conservatively using NYSDOT-approved growth factors and traffic projections for planned developments for the traffic and off-site air and noise analyses. The interim export actions have been the subject of separate environmental reviews, and are included in the DEIS and this FEIS as Existing Conditions and is accounted for in the Future No-Build Conditions analyses.

As noted in Section 1.2, Purpose and Need, DSNY intends to continue an array of Existing Programs (programs authorized under the existing SWMP), including New Initiatives to improve their effectiveness. These Existing Programs do not require environmental review.

91. **Comment:** One person had suggested the creation of a truck-to-rail facility within the Amtrak right of way, which DSNY had said was "inconsistent" with development plans in the area between West 30th Street and West 38th Street, on the basis that other facilities proposed are also inconsistent with existing plans. It was suggested that innovative architecture could be used by building a facility in part of the area now proposed as underground automobile garage under the proposed raised pedestrian way to be built on a

platform over the Amtrak rails between 10th and 11th Avenues, between 34th and 41st Street.

Response: A transfer station is not compatible with other development plans for this area.

92. **Comment:** A number of people were critical of the environmental review for the SWMP facilities. For all of the MTS sites, the DEIS fails to provide an adequate analysis of the impacts of the MTS site use on the surrounding areas and community facilities, which service vulnerable populations. It is not sufficient to say that the site will be reactivated for a previous use, and therefore will not present any significant adverse impacts. The DEIS must look at what issues previously existed when the MTS was operational, and determine whether these problems are likely to re-emerge with the reactivation of the site. Where are the assumptions and data backing up the determination that no significant, unmitigatible adverse traffic, air quality, odor or noise impacts were found?

Response: Chapter 3, Methodology, in the DEIS and this FEIS describes the methods and assumptions used to conduct all required CEQR analyses, including, but not limited to, reviews of potentially significant impacts in the areas of: Land Use, Zoning and Public Policy; Socioeconomic Conditions; Community Facilities and Services, Open Space; Cultural Resources and Neighborhood Character. As indicated in Chapter 3, additional technical backup documentation is available upon request. All of the required CEQR evaluations were performed for all of the Converted MTS sites, and the results are reported in the site-specific chapters.

Problems related to the operations of the existing MTSs are addressed in the proposed design and plan of operation for the Converted MTSs. Please refer to the response to Comment #2 in Section 40.3.1.1 for a review of the design features of these proposed facilities that represent improvements over the existing facilities and which avoid causing potentially significant adverse impacts.

93. **Comment:** The SWMP and DEIS is lacking basic information, such as the quantification of waste and recyclables generated by individuals, household, type of business or even by borough, and there is no explanation of the relationship to demographic characteristics.

The SWMP is not based on the latest NYMTC forecasts, which are much higher than reported in the document. Additionally, borough residential waste quantities are not provided, and with differing population growth rates, the reader cannot understand the effectiveness and equity of the facility locations.

Response: These subjects are addressed in the Draft New SWMP, Attachment 1, DSNY-managed Waste Quantification and Projections for the Plan Period and Attachment III, Waste Characterization Activities and in Volume II, Commercial Waste Generation and Projections. The latest NYMTC data that was available at the time was used in the employment-based waste forecast of Commercial Waste Generation.

94. **Comment:** A number of people commented on the overall lack of infrastructure to handle waste within the Borough of Manhattan. The Plan's intent is to maximize the use of barge and rail for export of solid waste and recyclables. The current Manhattan system moves all of the Borough's materials out by truck, creating unacceptable air pollution and traffic congestion, and must be phased out. The SWMP does not improve the handling of DSNY-managed solid waste from two-thirds of Manhattan. However, there should be additional capacity south of 59th Street. Additional transfer sites should be developed with the objective of decentralizing waste handling, enabling communities to take more responsibility for their waste. For example a rail site at 30th Street was evaluated and rejected because it did not conform to zoning. This should not bar it from the siting of a station.

Response: As reported in the Manhattan Siting Study, Volume V of the CWMS, included as Appendix I in this FEIS, Manhattan has a very limited potential for siting transfer stations. The Proposed Action included development of a Converted MTS at the East 91st Street MTS site, development of the West 59th Street MTS site for export of commercial waste and development of a Recyclables Acceptance facility at the Gansevoort peninsula. The West 30th Street site was found infeasible as a transfer station site based on technical and engineering considerations as documented in the above referenced report.

95. **Comment:** One commenter urged the creation of an independent planning task force to plan and implement a new SWMP.

Response: See the Response to Comment #74.

96. **Comment:** The SWMP and DEIS do not consider other ways to dispose of garbage other than those described in the SWMP. The goals of the SWMP, to more equitably distribute the burden of solid waste disposal and to make less of an environmental impact are admirable, but the public should have a voice in policy decision. Were rail transport, waste-to-energy in NYC, and other alternatives considered? If so, why were they dismissed?

Response: Please see the response to NYSDEC Comment #18 in Section 40.3.3.1 for an extensive description of DSNY's enhanced public participation program. See comment #77 above on consideration of waste-to-energy technology. Rail and or barge transport is a fundamental premise of the Proposed Action.

97. **Comment:** The SWMP and DEIS must discuss the capacity of the existing intermodal waste export infrastructure required to implement the SWMP, and identify alternative export capacity should there be a lack of rail and/or barge service. The DEIS, SWMP and permit applications must fully document the adequacy of intermodal capacity.

Response: Section 40.3.5 of this Chapter provides a Transfer, Transport and Disposal Plan (TTDP) describing the intermodal facilities and the rail transport facilities that is available to support the operation of the Converted MTS program. The TTDP will also be included as an Appendix in each of the Converted MTS Part 360 permit Applications.

98. **Comment:** Selected findings and recommendations of the CWMS were used as the basis for a number of conclusions in the DEIS. Other important aspects such as the evaluation of regional disposal capacity or the burdens generated by the concentration of private sector waste facilities are not addressed within the DEIS. The relationship between the recommendations and findings of the CWMS and the DEIS need to be clarified, since the CWMS was not subject to SEQRA review, and its findings challenged.

Response: The DEIS and this FEIS addresses the Proposed Actions in the Draft New SWMP. The CWMS is included as Appendix I to this FEIS. The Volume IV report in the CWMS on Landfill Disposal Capacity Potentially Available to the City was developed as information that confirms the direction of the Long Term Export Program. The Volume I report on Private Transfer Station Evaluations has resulted in DSNY regulatory initiatives that are being implemented independently of the Proposed Action in the Draft New SWMP. See the response to Comment #79 on the question of transfer station concentrations in certain communities.

99. Comment: There will likely be an overlap between interim and long-term waste export contracts during the implementation of the SWMP that may result in traffic impacts not previously assessed. The initial interim waste export contracts did not look at cumulative impacts that might arise from the recycling facilities proposed in the SWMP, conversion of the 59th Street MTS, or the decision to rely on truck-based export for the vast majority of commercial waste.

Response: Long term contracts will not overlap with interim export contracts in the same wasteshed. Once service commences under a Long Term Export contract, DSNY will terminate the Interim Export contract in that wasteshed. Truck deliveries of Curbside Recyclables to Recyclables Acceptance Facilities in the Bronx and Long Island City are accounted for as an Existing Condition. Truck deliveries of Curbside Recyclables to the Gansevoort Recyclables Acceptance Facility do not overlap to any significant degree with the routes taken by DSNY collection vehicles delivering DSNY-managed Waste from Manhattan to Long Term Export destinations. As noted in the response to Comment #160 in Section 40.3.2.2.2. Hamilton Avenue, truck deliveries of Curbside Recyclables from Brooklyn Community Districts 9, 14, and 15 to the SBMT Materials Processing Facility would cause no overlapping impacts with deliveries of DSNY-managed Waste to the Hamilton Avenue Converted MTS. Under the Proposed Action, each of the three to five private transfer stations that are proposed to receive DSNY waste would also be required to export waste from their commercial customers by barge or rail, thus reducing outbound commercial transfer trailer traffic.

100. **Comment:** The environmental assessment for interim export of waste from Manhattan was modeled using the hypothetical quantity and temporal distribution of trucks leaving Manhattan for New Jersey. The DEIS should evaluate the impacts based on DSNY's actual operations, proposed actions and current traffic conditions. The traffic patterns around the bridges and tunnels have changed considerably since the environmental review for interim export. For example, no eastbound commercial traffic has been allowed to enter the Holland Tunnel since August 2004.

Response: The Interim Export EAS used actual data on existing operations as the baseline conditions. Future conditions were projected using DSNY data and were based on real numbers. The quantity of waste and trucks analyzed was not hypothetical, but typical peak weekday DSNY volumes. The temporal distribution was based on current DSNY truck patterns, modified for changes in disposal destinations and operations. When commercial traffic restrictions were enacted, it could have had the potential to lighten traffic around the Holland Tunnel while increasing it at other river crossings. DSNY vehicles, however, continued to use the Holland Tunnel. To the extent that these patterns affected traffic at the DEIS/FEIS study locations, they would have been captured in the updated counts. To the extent they do not impact DEIS/FEIS study locations, they are not relevant.

The DEIS and this FEIS looked at past temporal distributions of trips at the 91st Street MTS as a predictor of future trip patterns. Interim Export assessments did not factor in the projections of DSNY truck traffic to the East 91st Street facility. Projected future DSNY truck numbers, by route, were compared to existing DSNY truck numbers, by route, to determine increases or decreases by specific roadway segment. As use of the MTS represents an end to truck export, there were projected decreases in DSNY trucks on links near river crossing portals. Therefore no analysis was needed or performed at intersections most likely to be affected by changes in rules governing use of bridges or tunnels. The greatest net increase in DSNY trucks would be on links near the MTSs which were proposed to be opened. The links with the greatest projected increases were the focus of the analysis.

101. **Comment:** The DEIS should include a technical appendix containing the data and methodologies used to determine the impacts of the proposed action.

Response: As noted in Chapter 3 of the DEIS and this FEIS, a copy of the technical backup for the analyses in the DEIS and this FEIS is available upon request in *.pdf format on compact disk.

40.3.1.11 Project Cost

102. **Comment**: If disposal costs have risen 91 percent since the City started exporting its waste, why does the City intend to give almost 10,000 tpd of waste to these same companies that have increased their fees? This is an unsustainable situation.

Response: Interim Export costs have not increased 91%. Over the period of Interim Export contract awards, 1997-2004, the average annual rate of increase has been in the range of 3.5% to 4%. The City requires out-of-City disposal facilities to dispose of its waste. DSNY is negotiating with companies that have responded to five RFPs for Long Term Export services. No decisions have been made on contract awards. A significant contributor to cost increases for Interim Export is the increase in truck travel distance to the disposal facilities as disposal sites nearer to the City are used up. In shifting to barge/rail export from a truck based export system, DSNY expects those costs to stabilize.

103. **Comment:** In 2000, the City prepared a generic analysis of costs; we are asking for this same analysis now, as well as clarification concerning the long term contracts for disposal. Will they be "put or pay" contracts that will require the delivery of a certain amount of waste and prevent the City from expanding composting and recycling?

Response: The contacts that DSNY is negotiating will not have "put or pay" provisions. DSNY is in the midst of several competitive procurements with multiple companies that will determine the costs of Long Term Export when final contracts are negotiated. The City's procurement rules preclude revealing information that could compromise this competitive process. However, during the City Council's hearing on this matter, DSNY presented information clearly demonstrating the Proposed Action to be a fiscally prudent

alternative for the City's solid waste management needs.

104. **Comment:** The SWMP fails to adequately provide a comparative economic analysis of the present plan, the Proposed Action, and other alternative waste management approaches. The DEIS lacks a comprehensive cost/benefit analysis; there are no projections for the whole project, no construction costs, operating costs, or discussion on who will work at these facilities. Without concrete information about the method of transporting and disposal of the containers, the costs associated with the plan cannot be known, and it can't be determined if it is preferable to, and more cost effective than, the current plan. The overall estimated costs of only two variations are provided (revamping four MTSs and the conversion of all 8 MTSs), and the analysis does not describe the underlying calculations or assumptions. The cost analysis needs to look at the possible inclusion of commercial waste and recycling as well.

Response: See the response to Comment #103, above.

105. **Comment:** The Plan also needs to consider the economic impacts of the MTS for commercial waste at 59th Street, the barge staging area and any incentives used to encourage private carters' usage of the site, in addition to the surplus capacity at the other MTSs.

Response: The use of the existing West 59th Street MTS site for commercial waste will be the subject of a procurement to be initiated by DSNY. Please review the responses to comments in Section 40.3.2.3.2 of this chapter for further information on this issue.

106. **Comment:** The SWMP states that the cost of the proposed action will be about $100 per ton, but doesn't address whether these costs will decrease over the 20-year planning period. It is not clear if the numbers account for potential increases in exporting costs, etc.

Response: See response to Comment #102 and #103, above.

107. **Comment:** The SWMP/DEIS contains none of the analysis that was in the 1992 report of the hidden social costs of transport (traffic delay, accidents, energy usage, air and noise impacts)

Response: See response to Comment #103, above.

108. **Comment:** There should be an analysis of the alternative uses and economic development potential of the proposed MTS sites.

Response: These sites have marine transfer stations that have active permits to process 4,800 tpd of waste. When the New SWMP is approved by the City Council, Long Term Export contracts have been executed, and the permits required to implement the Long Term Export Program have been approved, DSNY will work with interested parties on alternative uses for those MTS sites that are not included in the Plan.

109. **Comment:** There should be a consideration of the cost-effectiveness of promoting increased use of garbage disposals to redirect some of the largest component of the waste stream to sewage.

Response: In 1997, residential garbage grinders became lawful in the City. This issue is within the purview of NYCDEP and is not the subject of the New SWMP. See the response to Comment #13 in Section 40.3.1.3 for more on this issue.

40.3.2 Comments and Responses

40.3.2.1 Bronx

110. **Comment:** The SWMP is a step in the right direction in that it recognizes that the Bronx MTS should not be reopened.

Response: Comment noted.

111. **Comment:** A number of comments stated that the Harlem River Yard and the East 132nd Street sites are preferred locations for handling Bronx waste, but that the DEIS inadequately analyzes these properties. The full environmental impact of these sites is

not provided because they received negative declarations in previous reviews. A facility handling thousands of tons of waste cannot result in no impacts. References are made to previous studies, but there is no analysis of existing impacts on the community, in particular, off-site impacts.

Response: Both the East 132nd Street Transfer Station and the Harlem River Yard Transfer Station currently accept DSNY-managed Waste under Interim Export contracts, and those actions were subject to environmental review for acceptance of up to 1,500 tpd and 1,800 tpd of DSNY-managed Waste respectively. In addition, as discussed in the DEIS and this FEIS, both facilities have permits to process 2999 tpd and 4000 tpd of waste, respectively. These permits were issued based on prior environmental reviews.

At the East 132nd Street Transfer Station, the acceptance of DSNY-managed Waste for export by rail would require the addition of an outdoor lidding operation that would require a minor permit modification from NYSDEC. Accordingly, the potential for on-site impacts related to operating at or below the facility's currently permitted capacity does not require environmental review in this FEIS.

The Proposed Action for the East 132nd Street Transfer Station may involve a change in the quantity of Bronx DSNY-managed Waste from the current average of 1,033 tpd under Interim Export to up to 2,337 tpd, an increment of 1,304 tpd. A contingency factor of 20% was added to this amount for a total of 1,565 tpd to provide a margin of conservatism in the analysis. The DEIS and this FEIS evaluates potential off-site impacts associated with the DSNY collection vehicles that would deliver the increment (1,565 tpd) of DSNY-managed Waste to the facility. The results of this evaluation are reported in Section 12.14 of the DEIS and this FEIS. Additionally, the DEIS and this FEIS assumes that the facility would export all waste received via rail by draying containers between the facility and the Oak Point Yard. This element of the Proposed Action would involve a permit modification and is evaluated in the DEIS and this FEIS. The potential off-site analyses impacts associated with this draying activity are presented in the Oak Point Railyard Section 12.14.3 of the DEIS and this FEIS.

The Harlem River Yard facility is an existing fully permitted 4,000 tpd truck to rail transfer station where no proposed modifications are required. Therefore, no further review of potential on-site impacts associated with processing a lesser quantity of DSNY-managed Waste is required.

The Proposed Action for the Harlem River Yard Transfer Station may involve a change in the quantity of Bronx DSNY-Managed Waste from the current average peak day of 1,381 tpd under Interim Export to up to 2,337 tpd, an increment of 956 tpd. A contingency factor of 20% was added to this increment for a total of 1,147 tpd to provide a margin of conservatism in the analysis. The August 2003 EAS prepared to support the expansion of Harlem River Yard from 3,000 to 4,000 tpd analyzed an additional 117 one-way truck trips (equivalent to 1,170 tpd of waste) per day of potential traffic to the site. The intersections analyzed for traffic (Bruckner Boulevard and Lincoln Avenue, St. Ann's Avenue and Willis Avenue) and for mobile air quality (Lincoln Avenue and Bruckner Boulevard), and noise sensitive receptors along routes (Crack is Wack Playground, Randall's Island and Pulaski Park) are those that would be evaluated for DSNY collection vehicles traveling to and from the Harlem River Yard Transfer Station. Therefore the DEIS and this FEIS does not re-evaluate the potential off-site impacts associated with the increment of DSNY collection vehicles that would deliver DSNY-managed Waste to the facility since the August 2003 EAS provided that analysis and the permit capacity increase was approved by NYSDEC.

112. **Comment:** A number of comments requested a comparative assessment so that the two sites could be compared and a decision could be made on that basis. The DEIS doesn't provide any new information on the HRY site, and the proposed Oak Point intermodal site is also not subject to review. The new truck traffic on Bruckner and down Barry Street is not analyzed. Changing one traffic signal will not mitigate the environmental impact of receiving the entire borough's waste.

Response: See response to Comment #111 for the Harlem River Yard site. The Oak Point Railyard is analyzed for off-site impacts in the DEIS and this FEIS. The site description for the Oak Point Railyard is in Section 2.2.9.3, and results of the off-site

traffic, air quality and noise analyses are presented in Sections 12.14, 12.15 and 12.17, respectively, of the DEIS and this FEIS. The volume of dray trips between the East 132nd Street Transfer Station and the Oak Point Rail Yard is expected to average 8 one-way trips per hour (16 trip ends, or 32 passenger car equivalents [PCEs]), which falls below the traffic analysis screening threshold of 50 PCEs. In addition, the off-site noise analysis showed no potential for doubling of PCEs from these additional trips at the sensitive receptor along the dray route at East 138th Street between Bruckner Boulevard and Walnut Street. Therefore, no traffic or off-site noise analyses were required. Two links that meet the 2001 CEQR Technical Manual screening thresholds were analyzed for off-site air quality impacts (Bruckner Boulevard and East 138th Street, and Locust Avenue and East 138th Street) were analyzed, and there were no unmitigable adverse air quality impacts identified.

113. **Comment:** A number of speakers addressed analyses that they thought were missing from the DEIS. A $PM_{2.5}$ analysis was not undertaken at 132nd Street. Given the high level of asthma in the South Bronx, the highest monitoring standards should be applied. It is just not the case that there are no impacts.

Response: See Response to Comment #111. On-site analyses of the East 132nd Street Transfer Station is not required because it is a fully permitted facility. The addition of the outdoor lidding operation does not add emissions-generating equipment to the facility. Off-site analyses were evaluated for the increment of additional DSNY-managed Waste that could potentially be received at this facility under long term export. See Response to Comment #112. An off-site $PM_{2.5}$ analysis conducted at Bruckner Boulevard and East 138th Street, and Locust Avenue and East 138th Street resulted in no umitigatible significant adverse impacts. The off-site air quality analysis included the additional DSNY-managed Waste collection vehicles plus dray trips associated with transporting containers between the East 132nd Street Transfer Station and the Oak Point Railyard.

114. **Comment:** A number of people agreed with the fair share objectives of the SWMP, but thought that bringing containers of waste from other boroughs to HRY would contradict these objectives. This facility has not been subject to environmental review. There is no

back-up information provided, no discussion of visual impacts to Randalls Island or the odor impacts from containers moving through the site. What is the contingency plan for this site?

Response: A barge to rail intermodal facility at the Harlem River Yard site was evaluated in the DEIS and this FEIS as an Alternative. The 2000 SWMP Modification FEIS had evaluated a much larger Enclosed Barge Unloading Facility (EBUF) at the same location. The 2000 FEIS evaluated odors from the potential processing of an average of 5,000 tpd and a peak of 7,500 tpd of waste in an enclosed processing building and resulted in no significant adverse environmental impacts on Randall's Island. Because the 2000 FEIS did not analyze on-site $PM_{2.5}$ impacts, the DEIS and this FEIS presents the results of this analysis. Because it is a barge to rail facility, no off-site environmental review is warranted. Note that development of Harlem River Yard barge to rail intermodal facility is not an element of the Proposed Action.

115. **Comment:** The DEIS fails to analyze the impact on the proposed mixed use residential and industrial districts adjacent to the Harlem River Yard. It inaccurately states that development related to rezoning in Port Morris is projected to occur by 2014 at the earliest, while this is the year for full build-out. Vigilant regulation of waste operations in HRY is essential, but the DEIS denies impacts beyond the property borders.

Response: NYCDCP's Port Morris Rezoning EAS considers 2014 the build year for that project. The DEIS and this FEIS reflects this fact.

116. **Comment:** Randall's Island is undergoing a major overhaul to become a public recreational area. Impacts to Randall's Island must be addressed.

Response: Under existing conditions, DSNY delivers its Bronx waste to the Harlem River Yard as well as Waste Services at East 132nd Street. Randall's Island was analyzed as a noise-sensitive receptor for the Harlem River Yard Barge to Rail Intermodal Facility and for the minor modification of adding an outdoor lidding station to the East 132nd Street Transfer Station (see Sections 9.17 and 12.17 of the DEIS and this FEIS), and no impacts were predicted. An on-site analysis of the Harlem River Yard Truck to Rail Transfer Station was not required since it is a fully permitted 4,000 tpd transfer station.

117. **Comment:** While the South Bronx MTS is not being proposed, the DEIS states that the South Bronx Converted MTS would be compatible with its industrial surroundings and not have a significant adverse impact on residents. This ignores the truck traffic, accompanying diesel fumes, and garbage odors. Since the old MTS closed, the rodent population in the area has decreased markedly, and the area has improved. The MTS would not be compatible with a major food center, so the facility should not remain as DSNY property. This contradicts the Hunts Point Vision Plan. These changes should be made to the FEIS.

Response: The possible waste transfer use of the South Bronx MTS is referenced in the Hunts Point Vision Plan, but this is not part of the Proposed Action. However, it was analyzed as a reasonable alternative. The disposition of this site, once a Final SWMP is adopted, will be considered by the City.

118. **Comment:** Several comments reflected concern over the vagueness of the SWMP. In addition to not stating where the waste will be disposed, there is no discussion on the rules for selecting a contractor. Will there be an RFP to determine which of the two sites will receive the waste? It seems that only one facility should receive the waste, not both of them.

Response: Please review the Transfer, Transport and Disposal Plan (TTDP) contained in Section 40.3.5 of this FEIS for a discussion of the intermodal transfer and transport facilities that may be used for the movement of containerized waste from the Converted MTSs to out-of-City disposal facilities. DSNY waste from these two facilities currently goes to landfills in Virginia and Ohio. In general, potential disposal locations include landfills in South Carolina, Ohio and Virginia, in addition to the Essex County Resource Recovery facility in Newark NJ. DSNY issued four RFPs in December of 2003 to procure the transfer, transport and disposal services, as appropriate, for long-term export from the wastesheds defined in the Draft New SWMP. These documents define the procedures for and requirements on the selection of contractors.

119. **Comment:** Specific details for developing an intermodal facility in the Bronx should be provided. Since the South Bronx already contains a disproportionate share of the City's

waste facilities, the DEIS should consider the impact of the proposed actions in conjunction with the facilities already in existence in the area. All available mitigative strategies for reducing impacts should be considered, including an analysis of the proposed operational and siting regulations, or other regulations which might serve to mitigate traffic or air impacts.

Response: The Proposed Action does not include development of a new intermodal facility in the Bronx. For Bronx facilities evaluated in the DEIS and this FEIS, Existing Conditions, Future No-Build Conditions and Future Build Conditions were analyzed, as applicable. Existing Conditions account for all current operations in the area and include background traffic, air quality and noise along routes to and from the facilities. These background volumes are escalated and added to any new planned developments in the Study Area that will be constructed by 2006 to represent the Future No-Build Conditions. The increment of DSNY-managed Waste that is analyzed is added to the Future No-Build Conditions and, therefore, takes into account the impact of the Proposed Action in conjunction with existing facilities utilized for interim export, in accordance with the CEQR Technical Manual. Also, see the response to Comment #114.

120. Comment: One comment stated that the DEIS misrepresented the facts concerning the Bronx facilities, stating that it is unfair to state that there is no permit expansion, when in fact, there just was a permit expansion within the past year.

Response: Statements in the DEIS regarding proposed capacity expansions at private transfer stations in the Bronx or the lack of need for same apply as of the time the DEIS was published. Section 2.2.8.2 of the DEIS correctly describes the capacity of the Harlem River Yard Truck to Rail Transfer Station as 4,000 tpd and notes that the August 2003 EAS prepared to support the 1,000 tpd expansion was approved.

121. Comment: Several comments indicated that Waste Management will have control over a significant portion of the waste in New York City, but there are problems with odors and insufficient rail capacity at the Harlem River Yards. This facility should have better environmental controls before receiving a contract for DSNY waste. Additionally, the

company has a history of abuse and discrimination within the Bronx, exposing workers to dangerous working conditions and paying lower salaries than in other communities.

Response: DSNY intends to have diversity among the contractors providing long term export services. The Harlem River Yard Transfer Station uses an odor control system that introduces a misting agent containing a deodorant around the exhaust fans of the processing building, and, at times, applies deodorant near the openings (i.e. doorways). DSNY is not aware of any current odor problems at the Harlem River Yard Transfer Station. If there are complaints, they should be brought to the attention of DSNY's Permit and Inspection Unit.

122. **Comment:** There should be host community benefits for CD1 since all of the Bronx waste will be sent there. A local neighborhood advisory council should be established to monitor operation of the facilities.

Response: DSNY is willing to work with a local advisory council on matters related to its waste export activity and enforcement activities in the Bronx CD1. A community benefit fund was created by Waste Management in connection with receiving approvals for the Harlem River Yard facility currently used for interim export.

123. **Comment:** The Waste Management and Allied properties take up much of the waterfront area. DSNY should pressure these companies to provide community access and resources to the waterfront in space that is not utilized for the facility. The area needs more waterfront access and parks.

Response: This matter is beyond the scope of DSNY's authority.

124. **Comment:** The most important issues for the Bronx are borough self-sufficiency, closure of the land-based stations and the reduction of excess permitted waste capacity in Bronx CD1. There are a total of 15 transfer stations in the Hunts Point area, and these facilities have degraded the area. The total putrescible capacity must be reduced. New facilities should not open until there is a plan for closing the land-based transfer stations in the neighborhood.

Response: The Long Term Export Proposed Action for DSNY-managed Bronx Waste involves neither any expansion of waste transfer capacity in the Bronx above existing permitted levels, nor the transfer of DSNY-managed Waste generated in other boroughs through Bronx transfer stations. The Recycling Proposed Action—development of a Recyclables Acceptance Facility at the Gansevoort peninsula in Manhattan—would result in a reduction DSNY Recyclables now trucked into the Bronx. DSNY is committed to reducing permitted putrescible capacity in the communities with the greatest number of transfer stations once the Converted MTSs open. DSNY will work with the industry, the City Council and community groups to achieve this reduction in capacity. As part of this effort DSNY will work with the Council on legislation that will clarify DSNY's authority to reduce permitted capacity at transfer stations.

125. **Comment:** The South Bronx is willing to accept the waste that the borough creates if standards of operation are dramatically improved to ensure safety and well being of surrounding neighborhoods, including the workers at the facilities.

Response: The issue of enforcement of worker safety regulations is appropriately addressed through the state and federal agencies that have enforcement responsibility in this area, such as the federal Occupational Health and Safety Administration.

126. **Comment:** Several speakers voiced support for the export of Manhattan's commercial waste from the proposed West 59th Street Station to reduce the impact of commercial waste transfer in the Bronx.

Response: Comment noted.

127. **Comment:** There should be a barge option in addition to a rail option for the Bronx. The exclusive reliance on rail for export will be problematic. Any industrial user will attest to the undependable nature of the rail system for moving goods, particularly along the East of Hudson lines.

Response: The existing rail infrastructure in the Bronx is more than adequate for export of Bronx Waste. A barge option is not required. Although presented in the DEIS as an Alternative, development of a Converted South Bronx MTS would entail a significant

capital expenditure of City funds and would add more waste transfer capacity in the Bronx, which many Bronx CD1 residents oppose.

128. **Comment:** The depth of the analyses provided in the DEIS is insufficient. References are made to previous studies in 1994, 1997 and 2000, but there are no updated analyses of the impacts that the existing system has on the community. Significant local projects such as the South Bronx Greenway are not addressed. The analysis in the DEIS for the 132nd Street facility depends on an old analysis that is not included with the document. It does not address the infrastructure needs at Oak Point to support increasing export by rail, and does not discuss the impacts of the dray route traveling through residential areas. There also needs to be a contingency plan if there are problems with the rail line.

Response: See response to Comment #111 for an explanation of the level of environmental review that is required for both transfer stations.

Oak Point is an existing permitted facility owned by CSX. When Waste Management owned the East 132nd Street Transfer Station, containers were drayed to Oak Point for export by rail. Although some track improvements at Oak Point may be required, these are not subject to environmental review or permitting. The traffic, air quality, and impacts of draying containers from East 132nd Street to Oak Point were evaluated in the DEIS and this FEIS and no potentially unmitigable significant adverse impacts were found. The permit issued by NYSDEC for export by rail from East 132nd Street has a contingency plan to address interruptions in rail service. These are anticipated to be infrequent and can be addressed by exporting by transfer trailer over a few days until rail service would be restored.

The proposed Bronx River Greenway will be an 8-mile bicycle/pedestrian waterfront linear park beginning in the south near Lafayette Avenue in Hunts Point. At its southern terminus, it is approximately 1 3/4 miles from the evaluated East 132nd Street site and slightly further from the Harlem River Yard site; therefore, is far outside the study areas (1/2 mile radius) for both sites. It is approximately 1 mile northeast of the South Bronx

MTS site, and is described in the Open Space analysis: Section 19.5.2 (Future No-Build Conditions).

129. **Comment:** Waste facilities not regulated by DSNY were not included in the DEIS for the South Bronx. For example, the sludge processing plant and the sludge dewatering facility are not included.

Response: The New York City Department of Environmental Protection (NYCDEP) owns and operates the water pollution control plants in the City – including the Hunts Point Water Pollution Control Plant. The New York Organic Fertilizer Company (NYOFCo) sludge pelletization facility located in Oak Point is privately owned and operated. DSNY does not regulate these types of facilities; they are subject to regulations by NYSDEC and others. These are not solid waste facilities. Biosolids management is discussed in Attachment V of the Draft New SWMP.

130. **Comment:** The DEIS concludes that by changing the traffic signals at 138th Street and Bruckner Boulevard, the impact of transporting the waste from the entire borough of the Bronx will be mitigated. Many more controls are needed. There needs to be an analysis of the impacts of $PM_{2.5}$ and H_2S. The facility must demonstrate impacts below 1 ppb for H_2S, one-hour average maximum impact at sensitive thresholds, and 10 ppb/ hour ambient air. For $PM_{2.5}$, the analysis must include all vehicular emissions, and have a maximum annual impact of 0.3 $\mu g/m^3$, or a maximum 24-hour impact of 5 $\mu g/m^3$. Alternative particulate/dust migration controls must be installed.

Response: As discussed in the DEIS and this FEIS, the East 132nd Street Transfer Station is an existing, permitted facility, capable of processing 2,999 tpd of putrescible waste, which is greater than the amount generated in the Bronx wasteshed. The facility will require a minor permit modification to add an outdoor container lidding operation a short distance away from the processing building where the containers will be loaded. This container lidding operation will not add emissions-generating equipment. In addition, CEQR generally refers to odor analyses and thresholds pertaining to hydrogen sulfide (H_2S) which is applicable to City Water Pollution Control Plants, but not solid waste operations. The methodology for analyzing odors from the transfer stations, when

applicable, is described in Section 3.18 of the DEIS and this FEIS. No additional on-site air quality or odor analysis is required.

40.3.2.2 Brooklyn

40.3.2.2.1 Greenpoint, Brooklyn

131. Comment: A number of speakers stated that it would be unacceptable for both of the Greenpoint alternatives (Scott Avenue and Scott/Scholes) to remain open for processing waste, especially if a capacity expansion is required; the impact on the community would be too great. Some people were confused about the status of the Greenpoint MTS, and its relationship to the two alternatives. They were willing to handle their fair share of waste, but did not want additional capacity to be made available. They wanted any capacity expansion to be accompanied by an offset of throughput in the same community district. They were willing to accept one alternative, but not two.

Response: The Proposed Action to contract for export from more than one existing transfer station facility in Brooklyn CD 1 would have the benefits of: (i) transporting all DSNY waste from the former Greenpoint- Brooklyn wasteshed by rail or barge; and (ii) per the requirements of DSNY's RFP for export services, transporting all waste processed at either facility by barge or rail. Furthermore, DSNY may contract with more than one facility because this would: (i) maintain a competitive market for export of DSNY waste; (ii) provide the potential redundancy in the export facilities serving the former Greenpoint-Brooklyn CD1 wasteshed; and (iii) require the companies that enter into contracts with DSNY to export all waste received at their respective facilities by barge or rail, and thereby increase the quantity of waste exported by means of rail or barge and decrease transfer trailer truck trips from Brooklyn CD 1.

The Greenpoint Converted MTS is an Alternative that was evaluated, but is not an element of the Proposed Action. After the New SWMP has been approved and export contracts with one or more private transfer stations in Brooklyn have been implemented, including completion of any required supplemental environmental reviews and issuance of required permits, DSNY will consider reuse alternatives for the Greenpoint MTS site.

132. **Comment:** A number of speakers commented on the high volume of traffic in the neighborhood, which has created a major problem, especially on Metropolitan Avenue. There were complaints of the existing conditions of the roads, which have been worsened by heavy truck traffic. If either of the two proposed facilities are chosen, there would need to be clear mitigation measures, such as designated off ramps or truck routes, so that trucks could go straight to the sites without impacting on the residential streets. Suggestions were made for possibly widening the ramps or providing new exits or entrances to the East Williamsburg Industrial Park, to minimize impacts to the community. It was requested that an additional traffic survey be undertaken. Waste vehicle regulations should be strengthened, so that trucks are kept covered, and don't deviate from designated truck routes.

Response: As noted in the Draft New SWMP, DSNY is committed to reducing the impacts on those communities that are along truck routes leading to transfer stations by evaluating alternate routing options. DSNY will work with the New York City Department of Transportation (NYCDOT) and community advisory groups on the conduct of a traffic analysis to study the feasibility of redirecting truck routes leading to transfer stations with the objective of minimizing traffic-related impacts in residential areas to the extent possible.

133. **Comment:** Several speakers urged DSNY to create a Community Advisory Board so that they could work with the community board, elected officials, etc. on local concerns such as truck routes and closure of other existing transfer stations in the neighborhood. The SWMP includes an advisory group to study traffic on Metropolitan Avenue, and similarly they would like a group to effectively monitor implementation of the new SWMP. There requested continued community involvement, through the construction phase and into operations.

Response: Brooklyn Community Board #7 and #11 raised this issue in the ULURP application review process. DSNY has indicated in its written responses that it will work with community advisory groups. DSNY has agreed that DSNY representatives will attend periodic meetings and will address issues raised by the community.

134. **Comment:** Several speakers stated that they were opposed to the opening of any private marine or rail-based transfer station in Community District 1. They wanted a reduction of land-based facilities in CD#1, especially since CD#1 houses other burdens, like the Newtown Creek wastewater treatment plant. They wanted the new facilities to open in other areas of the City. The SWMP must address the concentration of waste transfer stations in Williamsburg, and Greenpoint as well as in the South Bronx. The concentration of these facilities has created negative environmental impacts.

Response: DSNY is committed to reducing permitted putrescible capacity in the communities with the greatest concentration of transfer stations including Brooklyn CD#1, once the New SWMP has been approved and the Converted MTSs are under construction. DSNY will work with the industry, the Council and community groups to achieve this reduction in capacity. As part of its efforts, DSNY will work with the Council on legislation that will clarify DSNY's authority to reduce permitted capacity at transfer stations.

135. **Comment:** Several speakers spoke about how Brooklyn has been shouldering the burden of the City's waste transfer stations for years, and the Greenpoint/Williamsburg area has been the most significantly impacted, handling over 40 percent of the City's waste. They wanted reassurance that Manhattan transfer stations (West 59th Street and East 91st Street) would open, and that Manhattan waste does not come to Brooklyn.

Response: DSNY has proposed developing a Converted MTS at the existing East 91st Street MTS Site. The next steps in implementing this Proposed Action are approval of DSNY's Uniform Land Use Review Applications for the four Converted MTSs and City Council adoption of the New SWMP. DSNY has met with waste companies and haulers to discuss their use of the West 59th Street MTS as a transfer point for Manhattan commercial waste. These discussions will continue later this month and DSNY expects to issue a procurement in the near future to solicit proposals from the waste industry.

136. **Comment:** Several speakers wanted the excess capacity at the MTSs in Brooklyn to be utilized for commercial waste, so that no new land-based facilities would be needed. They wanted the City to utilize various incentives to coax the private haulers to utilize

these facilities. They wanted the MTSs to be opened first, prior to the opening of any private alternatives, to reduce commercial waste processed in CD1.

Response: The Proposed Action provides for containerization and transfer of limited quantities of Commercial Waste from the Converted MTSs at Southwest Brooklyn and Hamilton Avenue. Converting the Greenpoint MTS to containerize Commercial Waste for export would involve a substantial capital investment and, all other things being equal would actually increase the total waste transfer capacity in Brooklyn CD 1. DSNY believes that its proposal to contract with existing already permitted private transfer stations in Brooklyn CD 1 for export of DSNY-managed Waste and requirement that all waste, including commercial waste received at these facilities be exported by barge or rail would better serve the community.

137. Comment: There was concern that neighborhood projects were not accounted for in the DEIS analyses. For example, the rezoning of Greenpoint/ Williamsburg will result in population and traffic impacts. There will be additional impacts from the Kosciusko Bridge Project and the Cross Harbor Project, which proposes the construction of a new bridge over Newtown Creek, and indicates there will be major truck impacts in the community.

Response: The impact analysis considers other projects and proposals within the project study area (properties within 1/2 mile of the site) that would be completed or in effect by the DSNY build year of 2006. These future No- Action Projects are listed in Section 20.2.2 and shown on Figure 20.2-4. The Kosciusko Bridge is located outside the study area about 1 mile southeast of the site and the proposed rezoning of Greenpoint Williamsburg will affect the western side of the peninsula, away from the industrial Newtown Creek vicinity. At its closest, the proposed mixed use (industrial/residential area) west of McGinnis Boulevard, is about 2000 feet away from the Greenpoint MTS. The build years for the Cross-Harbor Project (as described in the Cross-Harbor Freight Movement DEIS, April 2004) identifies 2010 and 2025 as its analysis years, (beyond the DSNY build year of 2006); therefore, the Cross-Harbor Freight Movement EIS must take into consideration DSNY's plans, as appropriate.

138. **Comment:** Brooklyn CD1 handles about 45% of the City's waste, has 16 transfer stations, two DSNY garages, and this overburden on the community results in serious health concerns. How can the DEIS say that there are no negative health concerns from all of these facilities? The EIS needs to examine existing toxin levels, odors, asthma rates, and the number of trucks on neighborhood streets. The EIS also needs to look for ways to mitigate the impacts of the solid waste system including redistribution of transfer stations, as envisioned in the SWMP.

Response: The air quality, traffic and public health analyses in the EIS take into account the existing conditions, which are already affected by the garages and transfer stations mentioned by the commenter and their associated emissions and traffic. Background air quality monitoring data is obtained from those monitoring stations nearest to the study area, as required under CEQR and provided by the NYCDEP which are: (1) MTA at Flatbush Avenue between Tillary Street and Johnson Avenue for CO; (2) the College Point Post Office for NO_2; and (3) Greenpoint (for PM_{10} and SO_2). Despite these multiple facilities, air quality is not markedly different in this area of Brooklyn than in other parts of New York City. The estimated emissions from the proposed facility are added to background for comparison to NAAQs. For the traffic analysis, traffic counts were obtained in the study area in February of 2003 that represent Existing Conditions for the analysis. Existing background traffic data was escalated for background growth using NYCDOT-approved escalation factors, and traffic from any known future developments in the Study Area, determined in consultation with NYCDCP, was added to determine future conditions without the project. DSNY collection vehicles were added to the Future No-Build Conditions to determine potential impacts considering the projected Future Build Conditions.

139. **Comment:** Several speakers had questions concerning the reduction of waste in this community. How would the City be able to bring about the closure of privately-owned businesses? What businesses would the transfer stations be replaced with? What is the timetable for facility closures?

Response: See response to Comment #134

140. **Comment:** A number of people spoke about how health issues are important, in this neighborhood where asthma rates are increasing. They wanted an analysis of the impacts of $PM_{2.5}$ and H_2S separate from what NYS DEC requires in the air permits. The $PM_{2.5}$ analysis must include all vehicular emissions, on-site equipment and truck idling.

Response: The air quality analysis conducted for the DEIS and this FEIS already includes a complete analysis of $PM_{2.5}$ impacts, accounting for emissions from waste collection vehicles moving and idling on-site, on-site equipment, including truck and other engine emissions exhausted through building roof vents, and tugboats. Also, off-site $PM_{2.5}$ impacts were analyzed for waste collection vehicle emissions near affected intersections. With respect to H_2S, the 2000 Solid Waste Management Plan Modification EIS included results from H_2S monitoring performed near older MTS facilities. This monitoring showed that H_2S concentrations were negligible in comparison to thresholds set to protect human health. Because the new MTS facilities would utilize state-of-art emissions controls and operating procedures, any H_2S emissions would be even lower than for the older MTS facilities.

141. **Comment:** Speakers were concerned with the operation of private waste transfer stations, and wanted putrescible, C&D and clean fill transfer stations to be required to install particulate matter and dust control systems. They wanted the facilities to be enclosed, with particulate matter filtered through a baghouse or other device, and activated carbon filtration used to filter out odors. Odor neutralizing systems, unless they remove hazardous substances should not be used, since they may add to breathing problems. Community monitoring of particulate matter should be undertaken.

Response: DSNY is revising its Transfer Station rules to require changes to private putrescible, non-putrescible (C&D), and fill material transfer stations in the City. The goal of these design and operational changes is to improve conditions at and near the private transfer stations. Some of DSNY's requirements include odor neutralizing systems and negative air pressure to prevent the escape of untreated air from putrescible waste transfer stations, and use of dust suppression systems and air emission limits for C&D and fill material transfer stations.

142. **Comment:** Speakers were concerned with the queuing of trucks in the community and requested that DSNY stagger deliveries of waste to alleviate queuing. They also thought it would alleviate workplace accidents, help to keep the facility clean, and minimize air quality impacts. A staggered schedule would be the largest contribution to a smoothly operating facility.

Response: DSNY evaluation of proposals from private companies for Long Term Export services from Brooklyn CD 1 included an assessment of the adequacy of the proposer's plans to limit off-street queuing. DSNY will require that contracts with the selected companies include provisions to ensure compliance with this requirement.

143. **Comment:** Questions were raised about the dredging of Newtown Creek. Would Waste Management need to dredge for their barging operation, how long would that take, and how do the NYSDEC and USACE feel about dredging? Would there be health implications from airborne bacteria and VOCs from dredging? Where would this dredged material be stored? What are the impacts of dredging?

Response: Any required dredging to provide a bulkhead with sufficient water depth to moor barges at any proposed waste barging facility on Newtown Creek would be the subject of an Article 15/25 permit Application to NYSDEC and a Section 10/404 Permit application to the USACE. The permit applications would be required to include information on the results of sampling and testing of the materials to be dredged and on the proposed arrangements on disposition of these materials. NYSDEC and the USACE would review these applications in terms of compliance with applicable regulations.

144. **Comment:** If the BFI site (Scott/Scholes) is selected, and utilizes CSX Rail Transport, how would DSNY minimize congestion in the Harlem River Rail Yards?

Response: Rail service to the site would be provided by New York & Atlantic (NYA) Railroad, the shortline rail freight carrier that services the Bushwick line, passing by the site. NYA would turn over cars to CSX at the Fresh Pond Yard in Queens. CSX would move cars to the Oak Point in the Bronx, where the train would reverse direction to leave the Bronx on the Hudson North line. The train would be dispatched through the Harlem

River Yard using the Oak Point Connector but would not be delayed by train assembly in Harlem River Yard.

145. **Comment:** What is the contingency transportation plan for each alternative? Where can waste be stored in case there is a train strike, or other problem with the movement of waste? A better contingency plan is needed.

Response: The contingency plan for the Converted MTSs is described in the Part 360 Permit. Additionally, Section 40.3.5 of this FEIS contains a Transfer, Transport and Disposal Plan that describes the intermodal and rail facilities in the New York harbor region that would support export operations from these facilities, as well as, barge export operations for those private transfer stations included in the Proposed Action that elect to use this option. Those private transfer stations included in the Proposed Action that use a rail export option would rely upon existing rail facilities in the Bronx Brooklyn and Queens that have the capacity to provide the required service. Short term disruptions in service can be managed by the redundancy in the overall system and short term storage of containerized waste until service recommences.

146. **Comment:** There is concern that any waste transfer facility be well maintained. The floor should be washed, and there should be an automated on-site decontamination system to remove dust, residue and odors from trucks. A log must be kept confirming each truck goes through the system. The facility should operate its own street cleaner to clean up any debris within a 10-block radius of the plant, twice per day.

Response: All of these requirements, but for street sweeping, which is a DSNY activity, are addressed in the draft Part 360 Permit application submitted by DSNY to NYSDEC, which is available for review in the Public Repositories located in the Sunset Park Library, and the New Utrecht Public Library as well as the CB7 and CB11 offices.

147. **Comment:** A number of people raised issues with the private waste transfer stations in the community, particularly with respect to odors. A resident on White Street complains that they can't even open their windows because of odors. Additional waste will only

exacerbate the problem. More effective odor controls should be utilized. Misters are not acceptable; carbon filtration would be more reliable.

Response: The private transfer stations in the Bronx, Brooklyn and Queens that are proposed to handle DSNY-managed waste will be required to have odor neutralizing systems and negative air pressure to prevent the escape of untreated air. This type of odor control system is included in the Staten Island Transfer Station that will be completed in 2005, and is in use at large transfer stations located in Puente Hills, California (a 4000 tpd facility) and Brevard County, Florida (a 1500 tpd facility). Odors from waste hauling vehicles operating/idling on the access ramps and within the processing building are included in the DEIS and this FEIS analysis.

148. Comment: There was concern expressed about the current operation of the Scott/Scholes site. Speakers requested that the facility be improved, and DSNY must ensure that the facility is state-of-the-art.

Response: The proposal by Allied for export from this site proposes a major redesign of the existing separated facilities into a functionally integrated complex. The proposed facility is subject to both NYSDEC Part 360 regulations that govern a solid waste management facility and DSNY permitting rules and regulations.

149. Comment: Some speakers wanted assurances that the existing Greenpoint MTS not be put into operation or be expanded. It is near the largest sewage treatment facility in the City, and the surrounding community could not handle both facilities. DSNY should work with the community to address what will replace the existing facility.

Response: See Response to Comment #131.

150. Comment: The noise from all the traffic in the community affects the children in the schools near the truck routes. Some schools have children in trailers in the front of schoolyards, so they are even closer to the traffic than what was analyzed. These impacts should be examined in the FEIS.

Response: The school referred to is presumed to be PS 132, located at 320 Manhattan Avenue in Greenpoint. DSNY collection vehicles would not travel along Manhattan

Avenue to and from the Greenpoint MTS site, therefore, no off-site traffic, air quality or noise analyses were conducted.

151. **Comment:** This area is an old industrial area, with much nonconforming zoning, specifically on Grattan Street, Thames Street, Seigal Street, and White Street, where impacts from the private facilities are terrible.

Response: Land Uses (including nonconforming uses) were considered in the environmental analyses conducted as part of the EIS. The streets listed (Thames, Grattan, Seigal, and White Streets) are at the edge of (or beyond) the 1/2 mile land use study areas evaluated for the Scott/Scholes and Meserole St. sites (which are currently active waste transfer facilities). (The Greenpoint MTS is approximately two miles to the northwest.) The various EIS studies determined that on-site operations of these potential transfer facilities and projected traffic conditions related to facility truck activity were found to have no significant adverse environmental impacts and would be compatible with the active industrial land uses that exist in the vicinity today.

152. **Comment:** A number of speakers raised the issue of asthma, and the high level of diesel emissions. Asthma rates in this neighborhood are significantly higher than elsewhere in the City, with one out of four children in the neighborhood having asthma. It's the number one reason children go to the emergency room. Almost 25 percent of the asthma deaths in the United States occur in Brooklyn. The diesel particulate emissions are a very powerful trigger for asthmatics; this neighborhood should not have to put up with this level of emissions. Truck traffic needs to decrease.

Response: Asthma among children is indeed an urgent public health problem, in Greenpoint as well as other areas of the City, but the information cited by the commenter regarding the Greenpoint area is at odds with asthma data provided by the New York City Department of Health and Mental Hygiene and presented in the Public Health Evaluation. Those data indicate that asthma among children and adults in the Greenpoint neighborhood is somewhat less frequent than in the City as a whole. It is certainly not the case that "almost 25 percent of the asthma deaths in the United States occur in Brooklyn." The Public Health Evaluation examines the role of diesel engine exhaust as

one of many factors that may cause asthma attacks. The expected increases in particulate matter (PM) due to the project and traffic, do not exceed the acceptable levels set or proposed by the City or State of New York. New national regulations regarding diesel fuel and diesel engines will, it is expected, reduce particulate and gaseous emissions in the future.

153. **Comment:** The SWMP states that waste from Scott Avenue will transfer garbage containers to ocean going barges at Red Hook. Ocean going barges require significantly more tonnage than would be supplied by this facility. How would this be feasible?

Response: Use of Red Hood to receive containerized waste is not contemplated as part of the Proposed Action.

40.3.2.2.2 Hamilton Avenue Converted MTS

154. **Comment:** A number of people were concerned about what would happen if all of the facilities in the SWMP did not get implemented. Specifically, there was concern about where Manhattan's waste would go if the East 91st Street MTS were not implemented and questions about if it would be trucked to Brooklyn or go to New Jersey? A number of people were willing to support the Brooklyn facilities, but only if the Manhattan facilities opened and if there was a reduction in truck-based facilities.

Response: If a New SWMP were not adopted by the City Council and approved by NYSDEC, DSNY would remain dependent on Interim Export. Interim Export contracts are awarded for a three-year term with two 1-year renewal options and are rebid as required. It has been DSNY's practice under Interim Export to not send waste generated in one borough to another borough for transfer to disposal facilities. Five putrescible waste transfer stations in Brooklyn — Waste Management at 485 Scott Avenue, Waste Management at 123 Varick Street, IESI at 110 50th Street, IESI at 577 Court Street, and BFI Waste Services at 598-636 Scholes — receive Brooklyn Waste as the result of an Interim Export contract rebid in November of 2003, while DSNY delivers some Brooklyn waste directly to three other facilities in New Jersey. Manhattan's Interim Export contract was rebid in November 2004. Under it, Manhattan Waste is delivered in

DSNY collection vehicles to facilities in New Jersey. While DSNY does not have blanket legal authority to close existing permitted transfer stations unless substantial violations of DSNY Rules are committed, it is seeking to clarify its authority to limit permitted capacity in specific communities in which transfer stations are relatively concentrated.. The issue of how to mitigate the impacts of waste transfer operations in neighborhoods of the City where such facilities are relatively concentrated will be tackled by DSNY after the SWMP is approved and the Converted MTSs are under construction. DSNY will work with the industry, neighborhood advisory councils and the City Council in this effort.

155. Comment: A number of speakers commented on the 65th Street Intermodal facility and requested more details concerning the use of the site. There were complaints that, at the present time, trains with waste protruding from the containers line up on 5th Avenue and 65th Street. Questions included: whose waste is it, where does it come from, and will this practice be continued under the plan? What types of waste will be in the containers at the site? How many trains and barges will be needed in a day? Is there any potential for the site to be a source of truck traffic? What happens if the trains are not moving due to bad weather conditions? How long will the trains be sitting under the apartment building that straddles the site? What assurances will be provided that all waste will be in sealed containers? How would the containers be moved off the barges given that there are no cranes at the site?

Response: At the Community Board #7 Hearing on the Hamilton Avenue Converted MTS ULURP application, DSNY made a commitment to not use the 65th Street railyard for intermodal transfer/transport operations to support the Long Term Export Program. See Section 40.3.3.2 of this Chapter for DSNY's formal response to Community Board #7 on this issue.

156. Comment: Why is there no need to undertake an environmental study for the 65th Street Intermodal Yard or for the 52nd Street Barge staging area? Both of these facilities are support facilities, but it is not clear if they are part of the proposed action or alternative actions. The intermodal yard sits right near the waterway adjacent to residential housing

and could be a source of environmental impacts. What is the impact of all of the rail traffic on the structural stability of the Bay Ridge Coop building? How can the community be assured that there will not be odors or loud noises in the nighttime? There is concern with the transport of propane and other chemicals on these rail lines. Mitigation strategies should be identified in the final EIS.

Response: Regarding the 65th Street Intermodal Yard, see response to Comment #155). Regarding the 52nd Street Barge Staging Area, based on the Draft New SWMP and the procurement in progress for transport and disposal services to support the MTS Containerization Program, DSNY does not currently anticipate a need to use this facility. Should that change, Article 15/25 and Section 10/404 permits for a replacement-in-kind of the existing pier would be required and any additional environmental review required to support that permitting action would result in a supplemental environmental review.

157. Comment: Several speakers wanted to know the details about the 52nd Street barge staging area, and if it would generate any truck traffic. They wanted to know why the pier is 500 feet long and 60 feet wide, and asked if the reason was so that trucks could turn around.

Response: See response to Comment # 156. Use of the 52nd Street barge staging area is not contemplated.

158. Comment: Why does the Sunset Park area get all of the barges when, for instance, Arthur Kill could be handling some?

Response: See Response to Comment #155 and #156.

159. Comment: A number of people commented on the planned Hugo Neu facility, saying that this firm's other facilities in the City are not well maintained, so dirt and vermin will be issues. Specific questions included: What assurances can be made that the operation in Brooklyn will be clean? How will this maintenance be enforced? When will the facility be open? Comments made were that the facility should be fully enclosed and the barges covered, preferably the Waste should be containerized, and floatables needed to be controlled.

Response: The environmental review of the Hugo Neu facility is specifically limited because the details of its design are not complete. The processing of recyclables at this facility is subject to a Part 360 registration procedure by NYSDEC. This facility will also require Article 15/25 permits from NYSDEC and Section 10/404 permits from the USACE for in-water construction. The permitting actions will be subject to a supplemental environmental review.

160. Comment: There were questions about the conflicting number of trucks going to the Hugo Neu facility and the impacts resulting from this traffic. Commenters were not sure if Manhattan recyclables will be trucked to Hugo Neu, or if only specific CDs in Brooklyn would truck their waste to the facility. Why is a truck weighing station required? It was suggested that two-thirds of Brooklyn recyclables be delivered by barge. Although the community was told that only 25 trucks would be coming to the facility, that number seems too low. The EIS should propose more extensive mitigation strategies for traffic at the Hugo Neu facility.

Response: Manhattan recyclables will not be trucked to the Hugo Neu facility. Only Brooklyn Community Districts 9, 14, and 15 will deliver recyclables to the facility via collection trucks. Manhattan Recyclables will continue to be delivered to the facilities that currently process them until a Manhattan Recyclables Acceptance facility is developed. It is estimated that 25 collection vehicles would deliver Recyclables to the proposed Hugo Neu facility at the SBMT from the districts in Brooklyn. Because the trip generation was sufficiently low during peak facility hours, no further traffic analysis was warranted. All recyclable materials received from collection facilities in Manhattan, Brooklyn and the Bronx will be via barge. Thus there would not be any additional collection vehicles from accepting materials from other areas of the City.

161. Comment: What will happen with the 20 percent of materials going to Hugo Neu, that can't be recycled and would be considered residue?

Response: It is DSNY's expectation that the terms of the 20-year agreement with Hugo Neu for development of the Material Processing facility at SBMT will provide incentives to the company to significantly reduce the historic rates for process residuals that must be

disposed of. It is the company's responsibility to dispose of any materials that cannot be recovered.

162. **Comment:** There was concern about truck traffic along Hamilton Avenue, the elevated highway, and Third Avenue because even though the footprint for the Hamilton Avenue Converted MTS facility is small, the facility services a large wasteshed so numerous trucks are anticipated. Specific questions and comments included: What are the plans for trucks queuing on Hamilton Avenue? Queuing will result in air, noise and traffic problems. How can the community be reassured that trucks will not deviate from designated truck routes? Because truck traffic is such a concern, water-based transport must be used wherever possible.

Response: No collection vehicles will queue on Hamilton Avenue. The Hamilton Avenue Converted MTS is designed with the following features:

- Six tipping bays;
- On-floor waste storage capacity of 634 tons;
- An automated scale system that can complete a weigh-in/weigh-out transaction in 30 seconds; and
- Queuing space to accommodate 10 trucks on the ramp.

Taken together, these features provide the facility with the capability to process 36 collection vehicles per hour with an average truck turnaround time of 10 minutes per vehicle. The maximum peak hour truck arrival rate at the Hamilton Avenue Converted MTS is anticipated to be 29 vehicles per hour on the average peak day. Given the truck turnaround time and the on-ramp queuing space, there will be no on-street queuing of collection vehicles. Under normal operating conditions, no DSNY collection vehicles will use the elevated highway to access the MTS. DSNY will reduce the number of waste related vehicles on City streets by exporting waste via barge, thus eliminating the use of transfer trailers to move waste generated in this area out of the City.

163. **Comment:** A number of people were concerned with the size of the Hamilton Avenue Converted MTS compared to other planned MTSs, the fact that it will service 10 CDs in Brooklyn, and its hours of operation. How will DSNY be able to restrict the number of commercial waste trucks coming to the facility during a certain hour? The facility will

end up taking commercial waste trucks from every borough and all of the impacts must be assessed and mitigated.

Response: One of the basic policies underpinning the Draft New SWMP is to develop all four of the Converted MTSs to serve the same wastesheds as the facilities they replace. Each of the MTSs, assuming they containerize commercial waste, would operate 24 hours per day. The restriction limiting commercial carter access to the 8:00 p.m. to 8:00 a.m. period is consistent with the collection practices of commercial carters who pick up during nighttime hours. DSNY is proposing maximum hourly limits for commercial carter vehicles tipping at the Converted MTS. The arrangements for implementing this program will include means of enforcing this limitation.

164. Comment: There was concern that the four facilities proposed for Community District 7the Hamilton Avenue Converted MTS, Hugo Neu recycling facility, 65th Street Intermodal Yard, and 52nd Street Barge Staging area represented an overburden to the community. Specific questions and comments included: Has the DEIS addressed the cumulative impacts from all of these facilities located in one neighborhood? No other communities are getting four facilities and, in addition, we are housing DSNY's garage for CD7 and CD10l. Other areas of Brooklyn should be taking some of these facilities, such as the Navy Yard or Bushwick, where the areas aren't residential.

Response: See Responses to Comment #155 and #156.

165. Comment: A few people claimed that they could not review the documents because they did not receive the entire SWMP or the appendices. They complained that they did not receive a copy of the ULURP application.

Response: In addition to being available on request and on the DSNY web site, the entire SWMP and Appendices were made available for public review in hard copy form at two public repositories in each affected community, including in the Brooklyn Community Board #7 Office at 4201 4th Avenue, and the Sunset Park Library at 5108 4th Avenue at 51st Street. ULURP hearing notices were issued by the affected Community Boards; DSNY also sent out notices of the ULURP hearings at the

community board level to stakeholders and published display ads in local newspapers to advertise those hearings.

166. **Comment:** The DEIS neglected to discuss a number of neighborhood projects, such as the Gowanus redecking project, cruise ship terminal in Red Hook and reconstruction of the drawbridge at Hamilton Avenue in 2008; and the decade of reconstruction of the Gowanus Expressway. How will the trucks get to the facility during the construction phase for the drawbridge? The EIS failed to develop a plan for the closure of land-based transfer stations, such as the ones on 50th Street and Court Street. There need to be guarantees with respect to tonnage offsets within the community.

Response: The DEIS and this FEIS accounts for developments within the study area that could potentially have overlapping effects upon the community**.** The Gowanus redecking will start in 2007, one year after the 2006 build year, so it is not considered as a background condition in the No-Build scenario. The Red Hook Cruise Ship Terminal is more than 1.5 miles away, which is outside of the project study area radius. The reconstruction of Hamilton Avenue drawbridge will begin in 2008, which is after the 2006 build year. Whatever long-term or even interim alternative is selected for reconstruction of the Gowanus Expressway, it will not be constructed by 2006. Regarding tonnage offsets for the Hamilton Avenue Converted MTS, it is replacing an existing facility with a permit to process 4,800 tpd that is still in effect. Regarding closure of other private transfer stations in Community Board #7, see the response to Comment # 154.

167. **Comment:** The proposed community development project 197A to revitalize the Sunset Park waterfront does not envision garbage barges on the water. The MTS conflicts with the plan. While the waterfront park is being constructed there will be even more traffic in the area, and all of this traffic was not analyzed in the EIS.

Response: According to the DCP, no 197A plan for Sunset Park/CB7 has been adopted by the City planning Commission and the City Council; no draft of such a plan has been submitted to the DCP for review as of February 2005. DCP notes that Community Board 7 has been working for several years on a plan to guide development of the CB7

waterfront; DCP does not have information, however, about the Community Board's plans for park development on the waterfront. As stated in section 4.12 of the FEIS, the Sunset Park waterfront is designated as a Significant Maritime and Industrial Area.

168. **Comment:** Brooklyn will be the centerpiece for the City's waste system, with more facilities than any other borough. Residents need certainty that any facilities will operate with the highest degree of environmental controls. The community should receive host community benefits, especially for taking the burden of the recycling facility.

Response: The Proposed Action for Long Term Export in the Draft New SWMP would containerize all DSNY-managed Waste generated in Brooklyn at Long Term export facilities in Brooklyn. No DSNY-managed Waste generated outside of Brooklyn would be processed in Brooklyn for export. All Recyclables processed at Hugo Neu, except those from Brooklyn CDs 9, 14 and 15, would be delivered by barge, thereby eliminating any significant adverse local truck traffic impacts. The Hugo Neu facility will generate in-City employment, making local jobs available to City residents, a benefit which would otherwise be realized in New Jersey.

The Hamilton Avenue Converted MTS design includes the following state-of-the-art environmental controls:

- An advanced odor control system;
- A ventilation system exceeding building code standards that maintains negative pressure to prevent the escape of odors to the outside under all conditions; and
- A tipping floor capable of accommodating six trucks, an automated scale system and a ramp with increased structural support – all with the objective of eliminating on-street truck queuing.

Separate from the Proposed Action, the Draft New SWMP identifies several regulatory measures that DSNY is proposing to adopt in its Rules applicable to the operations of private transfer stations that would represent upgrades in the environmental design and operation of these facilities.

169. **Comment:** Water-based transport must be utilized wherever possible to reduce truck traffic for any of the planned facilities.

Response: The Draft New SWMP is premised on barge and/or rail export of DSNY-managed Waste. Furthermore, the RFP procurements to solicit proposals for Transfer Transport and Disposal Services for the Bronx, Queens and Brooklyn wastesheds formerly served by the Bronx and Greenpoint MTS require that those private facilities awarded Long Term Export contracts export waste by barge or rail, including all commercial waste processed.

170. **Comment:** Several people commented on the impacts on the waterways, both from dredging and from facility operation. A representative comment is: "Best practices must be utilized in dredging, such as clam shell buckets and silk curtains, and during containerization, to ensure there will be no fugitive debris at the facility."

Response: Chapter 32 of the DEIS has been revised to include a more detailed discussion on dredging procedures that will be implemented at the proposed Converted MTS sites. Each proposed Converted MTS Natural Resources section analyze these potential impacts. In addition, the detailed management of demolition and construction activity at the Converted MTS sites is addressed in applications for Article 15/25 Joint Permits to be submitted to NYSDEC and the USACE. These permit applications are the subject of permit hearings to be conducted by NYSDEC. The impacts from facility operation are discussed in Chapter 4.11 of the DEIS and this FEIS. Refer to response to Comment #176 for additional details on dredging methods.

171. **Comment:** The USEPA or NYCDEP should get involved in monitoring idling vehicles. They should enforce the three-minute idling regulation.

Response: DSNY's Permit and Inspection Unit (PIU) does enforce the three-minute idling restriction. As a practical matter it is a difficult restriction to enforce, however, because trucks queued at a facility move periodically as loads are processed and because drivers of queued trucks will shut off the engines when a PIU inspector appears.

172. **Comment:** The privately-owned facility on Thames Street between Porter and Knickerbocker Avenue is creating a health hazard. The facility is less than 25-feet from a residence where the windows must be kept closed in the summertime due to odors coming from the facility.

Response: DSNY has referred this matter to the DSNY Permitting and Inspection Unit, who will coordinate with NYCDEP and any other City agencies sharing enforcement responsibility for this matter.

40.3.2.2.3 Southwest Brooklyn Converted MTS

173. **Comment:** The DEIS severely underestimates the traffic that will be traveling to the facility. A new traffic analysis should be undertaken that includes a realistic worst-case scenario and explores creative mitigation options. Traffic patterns vary considerably throughout the year; a study on Bay Parkway and Shore Road undertaken in December would show different traffic patterns than if it was undertaken in February. We need to know how traffic will affect the neighborhood. The existing traffic on Bay Parkway near Caesar's Bay is intolerable.

Response: CEQR identifies specific times of the year and days during the week when typical conditions at study intersections can be observed and counted. Generally, holiday weeks and periods are excluded from acceptable counting days, as are Mondays and Fridays during the week. CEQR specifically states that "It is usually preferable to rely on typical day counts rather than seasonally adjusted counts." Traffic counts were collected on typical days for this project.

The goal of the environmental review is to evaluate whether or not the Proposed Action will cause unmitigable significant environmental impacts, not to change existing conditions that are viewed as a problem. The DEIS and this FEIS found that the addition of this facility would not cause significant adverse impacts in the study area. Also see responses to Comments #192 and #198 below.

174. **Comment:** Because the previous MTS only handled residential waste, adding commercial waste will represent a huge increase in the amount of waste handled, especially since there is only a small amount of commercial waste generated in the area. The DEIS claims that only 828 tpd of commercial waste will be delivered, but this is an unrealistic amount, and where will this commercial waste be coming from? How will the City coax the private carters to utilize the facility?

Response: The Proposed Action to process Commercial Waste at the Converted MTSs responds to the requirements for the Commercial Waste Management Study (CWMS) required to be completed by Local Law 74 of 2000. This issue was evaluated in Volume III of the CWMS published in March 2004, and in the New SWMP DEIS and FEIS. The CWMS is included as Appendix I in this FEIS. Based on revisions to the DEIS analyses, and reported in this FEIS, 718 tpd of Commercial Waste, the equivalent of approximately 66 truckloads (conservatively assuming 11 tons per truckload, which is less than what many commercial waste hauling vehicles actually transport), can be processed without causing potential significant adverse impacts at the Southwest Brooklyn Converted MTS by limiting waste deliveries by commercial carters to between the hours of 8:00 p.m. to 8:00 a.m. with specific limits on the number of commercial waste hauling vehicles in the early morning hours.

The Part 360 permit limits that DSNY has proposed to NYSDEC would stipulate 718 tpd as the maximum quantity of Commercial Waste that could be received at the Southwest Brooklyn Converted MTS. (See the discussion of the permit limits Proposed by DSNY in Section 40.3.1.1 Facility Capacity and Design, Comment #1.) Based on processing the Maximum Peak Day limit proposed by DSNY to NYSDEC, Commercial Waste would represent approximately 34% of the total waste processed, with the balance being DSNY-managed Waste from the three Community Districts that constitute the Southwest Brooklyn MTS wasteshed.

175. **Comment:** The community is very concerned with the environmental impact on the marine environment, especially on the marina adjacent to the MTS. It is critical that

neither the marina nor the marine habitat are negatively impacted by the project. What type of seawall is to be constructed? Will water be able to pass through it?

Response: The DEIS includes a Fish Habitat Study conducted over a 12-month period that evaluated marine life at the site of the Southwest Brooklyn MTS. The conclusions of that study were that this MTS supported one of the more biologically productive marine communities. This site is situated on the north shore of Gravesend Bay at the mouth of the estuary and is influenced by Atlantic Ocean water more than the other MTSs.

The Converted MTS will have the same footprint over water and remain in the same location. There will be, however, some minor construction around the existing facility and local dredging, resulting in minor impacts to the marine environment. The existing fender system at SW Brooklyn will be removed and replaced with a new fender system designed for the mooring loads of the deck barges. The existing fender system is a partially submerged timber structure approximately 330 feet long that is comprised of vertical timber piles, timber wales, and timber face sheeting. Construction impacts such as turbidity and siltation will be limited spatially to the immediate area of the transfer station and temporally to the duration of the construction program, approximately 30 months.

Benthic organisms, being immobile (at least in the adult stages), are subject to impacts of construction activities that have the potential to result in temporary disruption. Local dredging of approximately 4,280 cubic yards of material could smother and physically remove the local benthic population. However, benthic communities reestablish themselves quickly after a disturbance. The epibenthic community will experience a temporary negative impact with the removal of the existing fendering system, but will colonize the new fendering system after construction, thereby reversing the impact. Adult finfish impacts are not expected because motile organisms will avoid construction activities that produce less than optimal environmental conditions.

While the construction impacts are limited to the duration of the activities, the operational impacts will persist for the duration of the facility's life span, a time span measured in

decades. Since the existing MTS will remain and there is no new construction over water at this site, there is no difference in impacts between Existing Condition and Build Action. The benthic, epibenthic, and finfish communities are not expected to be significantly altered from their existing state as platform coverage over water will remain the same. In fact, the epibenthic community will colonize the new king pile wall.

The greatest impacts will be temporary destruction of benthic and epibenthic communities and short term avoidance by finfish due to suspended particles and food source reduction. While not amenable to avoidance or reduction, these impacts will be limited and will not last beyond one seasonal cycle for invertebrates. Construction impacts on finfish will not be quantifiable. These impacts, however, are not deemed significant because the benthic communities will reestablish themselves within 6 to 12 months after the construction is completed. Finfish are expected to return after construction is completed also, and once the benthic food sources have returned to the area of disturbance, finfish will begin to feed in the area and establish a more permanent residence.

Also, see responses to comments # 176, #177 and #178 below.

176. Comment: How will dredging (both initial dredging and routine maintenance dredging) affect the water quality surrounding the MTS, and how will it affect the marine environment? To what extent will dredging be necessary? Many people consume the local fish and it may contain higher levels of mercury, arsenic, PCBs and other chemicals. The best available and most environmentally protective dredging method should be used (vacuum dredging). Due to the content of the silt as well as the currents, a closed clamshell dredge will not be sufficient to ensure safety. These waters are well known for both recreational and commercial fishing, and it is well established that toxins from silt can bioaccumulate in finfish, as well as in the people who consume them. In addition, there are harbor seals that frequent the area behind Toys-R-Us which are attracted to the herring present in the water, and Dreier Offerman Park is a major Atlantic flyway for bird migration. Many of these birds also consume these fish. Dispersal of

dredging contaminants to the waters around Dreier Offerman would be impossible to avoid, so protective dredging measures need to be implemented to minimize impacts.

Response: Resumed use of this MTS site would require some dredging to provide sufficient water depths for the use of flat-top barges and tugboats. The volume of dredged materials would be approximately 4,280 cubic yards. DSNY has submitted a draft application for Article 15/25 permits that is now undergoing review by NYSDEC. The application specifically addresses issues related to impacts on marine resources arising from facility construction, including dredging. As NYSDEC proceeds with review of the application, including a local public hearing, it will determine the appropriate mitigative measures to minimize impacts on marine life and the local community.

DSNY has carefully considered various dredging methods, including the vacuum (hydraulic) option, for this site. The basic premise for selecting a dredging method was that it must provide environmental safeguards as necessary and comply with all applicable environmental regulations, without incurring unnecessary expenses for dredging. The mechanical clamshell dredging method using an environmental bucket was selected for this site, and the vacuum dredging method was rejected for the following reasons:

A. Vacuum (Hydraulic) dredging is preferred when dealing with "Hazardous" sediments. DSNY has conducted sediment sampling and testing at this location to characterize the sediments. The testing included Toxicity Characteristic Leaching Procedure (TCLP) as specified by the federal Resource Conservation and Recovery Act (RCRA) regulations, and the New York State regulations for Identification of Hazardous Waste (6 NYCRR Part 371). None of the sediment samples failed these tests, indicating that the sediments at this location are not "Hazardous" as defined by the applicable federal or state regulations.

B. For any dredging operation, re-entrainment of contaminated sediments and its impact on the surrounding biota is a reasonable concern. DSNY has taken this concern into consideration, and will employ the following safeguards to minimize such impacts:

a. Dredging operations will be conducted using an environmental clamshell bucket. The environmental bucket is constructed with sealing gaskets or an overlapping sealed design at the jaws.

- The bucket will be equipped with a signal light in the control station to verify bucket closure and seal.
- Bucket hoist speed will be limited to approximately 2 ft/second.
- The bucket will be lowered to the level of barge gunwales prior to release of load.

b. No barge overflow will be allowed

c. Excessive loss of water, sediment or both from the time the bucket breaks the water surface to the time it crosses the barge gunwale will not be permitted. In other words, the environmental bucket will be kept in good working order throughout the dredging operation.

d. As appropriate, dredging operations may be restricted during spawning seasons that may be identified in the permits issued for the Proposed Action.

C. Neither NYSDEC nor the US Army Corps of Engineers (USACE) has required or recommended the Vacuum (Hydraulic) method in the DSNY maintenance dredge permits for this or other MTS sites. These permits require the use of a mechanical clamshell dredge with an environmental bucket. In other words, NYSDEC and USACE have found that the mechanical clamshell dredging with an environmental bucket provides appropriate environmental safeguards, including protection against potential re-entrainment of sediments in the water column and its impact on the surrounding biota.

177. **Comment:** Where will the dredged material be disposed, given that it may be contaminated with hazardous substances? Additional study is needed.

Response: The Article 15/25 Joint Application referenced in the Response to Comment #176 above identifies several options for disposition of dredge spoils that comply with applicable law and regulations. Specific locations have not been identified at this time. Dredged materials will be analyzed in accordance with applicable regulations and requirements prior to their disposition. Based upon the results of these analyses and in conjunction with discussions with involved agencies, DSNY will manage the materials in accordance with applicable rules and regulations governing the disposal and/or beneficial reuse of dredged material. Initial analysis of sediment samples at the Southwest

Brooklyn site conducted by DSNY indicates that these materials are not a characteristic hazardous waste under federal and state guidelines and regulations. Additional information with regard to these alternatives will be provided within the Joint Application.

178. **Comment:** There were numerous concerns about the impacts on the marina. There is concern that the wake from the barges and tugboats used at the MTS may affect the structure and integrity of the marina. It was requested than an analysis of the impacts to the marina during both the construction and operational phases of the MTS be undertaken. In addition, we would like the City to protect the marina's seawall from barge and tug traffic. If it cannot be protected, the marina will be adversely impacted.

Response: The Southwest Brooklyn MTS is located immediately adjacent to the existing Marine Basin Marina seawall. Based on an engineering review, in order to protect the stability of the existing seawall during construction, maintenance, dredging and facility operations, a "king pile" bulkhead wall and rock apron will need to be provided. The rock apron will be installed between the "king pile" bulkhead wall and the existing seawall. It will consist of 250-pound armor stone with an under layer consisting of 10- to 50-pound stone (provided as a filter between the seabed and the armor stone). The rock apron will be designed to remain stable under the wave action of wind-generated waves with a 50-year significant wave height of 5.9 feet, and it will mitigate the effects of erosion and eliminate the risk of undermining the existing seawall due to wave action of wind generated waves and prop-wash from tugboats maneuvering barges.

An existing "red" buoy marks the approach channel to the facility approximately 150-feet west of the Marina's seawall and 300-feet south of the existing DSNY property's bulkhead wall. All tugboats must approach to the west of the buoy; otherwise, they will run aground. A wall that extends past the buoy is not required to protect the marina from tug movements at the Converted MTS.

179. **Comment:** We would like an analysis of the impacts of the facility on the amusement park adjacent to the MTS, which gets heavy usage during the summer. Were impacts on the two schools across the street taken into account? We are concerned with the traffic impacts on neighborhood children.

Response: Under City Environmental Quality Review (CEQR) procedures, reasonable worst case peak hour traffic conditions must be evaluated in an EIS. The DEIS and this FEIS establish reasonable worst case conditions at intersections where project generated traffic would be most concentrated or most likely to have an impact on traffic flow through the intersection. Traffic counts are not typically obtained during summer months unless high seasonal traffic is anticipated in that area, since typical background traffic volumes are generally lower during the summer months when schools are closed. The Nelly Bly Amusement area is not expected to generate high seasonal traffic in the area of the MTS. Nelly Bly does not open until 11:00 AM daily, which is after DSNY's estimated peak hour arrival rate at the Southwest Brooklyn Converted MTS. A screening analysis performed to determine the study intersections took into account the volume and routing of the project generated traffic. Also, see Responses to Comments #173 above, and #192 below.

The intersection at 26th Avenue and Shore Road was modeled for the DEIS and this FEIS. All intersections within a 1,000 feet of this intersection (including the intersections at Bay 41st and 25th Avenue that straddle the amusement park) were lined with receptors. There were no unmitigable adverse significant impacts found at these intersections. In addition, the impacts of facility operations were added to the off-site impacts to determine whether there would be cumulative impacts. No significant unmitigatible adverse impacts were found. Cropsey Avenue between 26th Avenue and Bay Parkway (which the schools fall within) was analyzed for off-site traffic and air impacts. No significant unmitigatible adverse impacts were found.

180. **Comment:** What will happen when the incoming volume of waste exceeds the facility's capacity. This will create significant odor, noise and traffic problems.

Response: DSNY will not deliver waste in excess of the facility's processing capacity. As noted in the Response to Comment #174, the DEIS and this FEIS evaluate the potential for significant adverse air quality, traffic, odor and noise impacts. The maximum daily permitted capacity proposed by DSNY, except for rare public emergency

situations, is 2,143 tpd. Also see response to Comment 2 in Section 40.3.1.1 for a discussion of design features intended to minimize the potential for impacts.

181. **Comment:** Since the Southwest Brooklyn facility is anticipated to receive less waste than other MTSs, there is concern that more and more waste will be transferred to the Southwest Brooklyn site to "equalize" the amounts of waste sent to each of the sites from other areas.

Response: See Response to Comments # 174 and #180.

182. **Comment:** Commercial waste vehicles are not under the same type of regulation as the City-owned collection vehicles. There is concern in terms of noise and pollution. Will they be traveling down residential streets during the nighttime hours, and how can you assure the community that the quality of life will not be affected? Currently the noise from trucks rumbling down Cropsey Avenue at night is intolerable, and commercial vehicles may make this worse. What routes will these commercial vehicles be taking, and how will they be regulated?

Response: Both DSNY and Commercial vehicles are required to travel along New York City Department of Transportation designated trucks routes to and from their destination. These vehicles may leave designated truck routes only to access their destination (in this instance, the Converted MTS) in the most direct manor possible. DSNY's Permit and Inspection Unit enforces these regulations. Also see Response to Comment # 174.

183. **Comment:** The plans for the Southwest Brooklyn MTS, as submitted to the CB, showed encroachments onto Bay 41st Street and onto the marina property.

Response: The construction of the Southwest Brooklyn Converted MTS occurs entirely within the boundaries of City-owned property dedicated to DSNY use.

184. **Comment:** The Bensonhurst area has poor air quality, many residents have asthma, and any new facilities will make matters worse. The DEIS must analyze the cumulative health effects that the air pollution from the idling vehicles and tug boats will have on a population already exposed to poor air quality.

Response: The DEIS and this FEIS did in fact analyze the effects of tug boat and idling vehicle emissions, as well as truck traffic and facility vents. The DEIS and this FEIS also analyzed the health effects of pollutants from the Converted MTSs. See the General Section 40.3.1.6, which details responses to public health comments.

185. Comment: What types of "state-of-the art" equipment will be utilized to minimize odor emissions from the facility? How will odors attributed to the trucks be minimized, and what restrictions will be placed on air emissions coming from stationary equipment and non-road vehicles. How will the NYCDEP or NYSDEC ensure that regulations are being met under various weather conditions and that no odors will impact the neighborhood?

Response: The facilities will be designed with ventilation systems to maintain the facility at "negative pressure" such that odors will not migrate out of open doors. The ventilation system will include a mist system to apply odor neutralizing chemicals to air as it passes through the ductwork before it is exhausted to the open atmosphere through facility roof vents. Rapid roll-up access doors will be kept closed when waste collection vehicles and/or containers are not entering/exiting the building. There will be a requirement that all waste processing areas be cleaned daily to ensure that all waste is processed within 24 hours and that the floors are washed to eliminate buildup of waste residue. Truck odors will be minimized by keeping the trucks as clean as practical, and by allowing adequate unloading space inside the building, thus minimizing on-site queuing time outside of the buildings. Stationary equipment and non-road vehicle engines will be purchased new for the facilities, and therefore, these emissions sources will meet the latest EPA emissions standards applicable to new engines. NYSDEC, NYCDEP and other City regulators will periodically inspect the facilities for compliance with applicable rules and permits, as appropriate. Because residential garbage cans and dumpsters, residential garbage collection vehicles, and other sources emit odors that are often detectable in close proximity to residences, a goal of zero odor is not feasible. However, based on dispersion modeling of the proposed MTS facility design and operation, predicted odor impacts in the surrounding neighborhood are less than detection thresholds.

186. **Comment:** A number of comments addressed concerns about local waterways. The coastal ecosystem has been on the road to recovery. How will the runoff from the site, possible leakages, discharges, and accidental garbage spills be managed and treated before entering the waterway?

Response: DSNY has devoted a great deal of attention during the facility design process to ensuring that the facility's environmental control system prevents waste processing operations from affecting the outside environment, including the escape of litter into the adjacent waterbody. A comparison of the Converted MTS with the existing MTS facility highlights these design features, for example:

- The Converted MTS will be located upland on the old incinerator site, not over water like the existing MTS.
- The Converted MTS will process waste into lidded, sealed containers in contrast to the use of open hopper barges in the existing MTSs.
- Waste processing operations in the Converted MTS will be entirely enclosed within the building in contrast to the old MTS, which is open at the entrance to the barge slip.
- The Converted MTS will be equipped with a ventilation system capable of 12 air changes per hour, twice the applicable code standard, to maintain negative air pressure in the building and thereby prevent the escape of odors and litter to the outside environment. The existing MTSs do not have this type of ventilation system.
- The Converted MTS is equipped with an odor neutralizing system that neutralizes odors from exhaust air as it leaves the building.

187. **Comment:** Given that the MTS will be operating 24 hours per day and that there are residences nearby, how will the noise from movement of containers to the barges be mitigated?

188. **Response:** The on-site noise analysis assessed noise levels from the gantry crane including the movement of the containers on to the barges. The number of: (1) relayed DSNY collection vehicles delivering waste to the facility will be restricted during the 2:00 a.m. to 3:00 a.m. period to mitigate the potential for on-site noise impacts at two off-site noise sensitive receptors during this period; and (2) commercial waste vehicles delivering waste to the facility will be restricted during certain hours to mitigate estimated off-site noise impacts at receptors along the routes to these facilities between

8:00 p.m. and 8:00 a.m.

189. **Comment:** When the incinerator operated at the site, it operated without a permit, and there were plenty of negative impacts. How can the residents be assured that similar impacts won't arise with the MTS? The City should not be building a waste facility in a residential area or near a recreational area, such as Coney Island.

Response: Unlike an incinerator or other waste disposal facility, the MTS is designed to facilitate the movement of waste out of the neighborhood as reliably and quickly as possible. The existing MTS operated for over fifty years at this site. It was and continues to be permitted to operate. The DEIS and this FEIS is a comprehensive assessment of the potential for significant adverse unmitigatible impacts from construction and operation of the Converted MTS: none were found.

190. **Comment:** It appears that Brooklyn will be the centerpiece of the City's SWMP, so there need to be assurances that the facilities will operate with the highest levels of environmental controls and have the least impact on the affected communities. DSNY needs to work with the community to ensure that impacts to the community are minimized. There should not be any floatables or debris in the vicinity of the MTS, and truck emissions need to be minimized.

Response: See Responses to Comments #175, 180 and 186.

191. **Comment:** There is concern that trucks will idle along Shore Parkway, affecting air quality and noise. How will this be addressed?

Response: The DEIS and this FEIS evaluated the potential for significant adverse noise and air quality impacts on the truck routes and approach roads that waste hauling vehicles would take to and from the facility and found none. Collection vehicles bringing waste to the facility will not idle off site.

192. **Comment:** Gravesend Bay is already polluted with sewage; will it also be further degraded by the accidental dumping of garbage into the water?

Response: See Response to Comment #186.

193. **Comment:** Truck traffic was a major concern of the residents. There are numerous discrepancies in the DEIS in truck traffic along Cropsey Avenue and along Shore Parkway. Four different sets of figures (average trucks/hour, total tonnage, etc.) are used, and these numbers are different from what was presented during the DEIS presentation. There will be major disruptions to Bay Parkway, Cropsey Avenue and Shore Parkway. The traffic analysis must take into account existing problems and conditions. The DEIS failed to consider the impacts of the traffic on the large number of senior citizen homes, nursing homes and other facilities along Cropsey Avenue.

Response: Under City Environmental Quality Review (CEQR) procedures, reasonable worst case peak hour traffic conditions must be evaluated in an EIS. Three peak time periods were analyzed in the DEIS and this FEIS, the AM peak hour (7:45 a.m. to 8:45 a.m.) and PM peak hour (5:00 p.m. and 6:00 p.m.) when background traffic volumes are highest, and the facility peak hour (10:00 a.m. and 11:00 a.m.) when facility-generated traffic volumes are the highest. The facility peak hour occurs during the late morning hours after the AM peak hour. The analysis in the New SWMP DEIS and this FEIS of the potential for project induced significant traffic impacts used a conservative assumption for the facility peak hour by: (1) using the average peak daily DSNY collection vehicle arrival profiles – that is, the typical highest day of each week (i.e. every Tuesday) when collection vehicle delivery profiles are between approximately 15% and 20% higher than the average day; and (2) increasing the average peak day hourly DSNY collection vehicle volumes by 20% above the DSNY-reported collection truck delivery profile to account for potential fluctuations. By using the facility peak day as a basis for analysis and adding a 20% contingency factor for collection vehicle traffic, the DEIS and this FEIS overstates the volumes of facility traffic that will occur on both average and peak days and, therefore, constitutes a reasonable worst case scenario. The trip generation data used in the DEIS and this FEIS for this facility was derived from a sample of peak days during Fiscal Year 1998, when DSNY-managed loads and tons were relatively high compared to the historical averages that are used in the permit application. This, combined with the 20% contingency factor applied to the average peak day, means that the traffic data used in the DEIS and this FEIS is comparable to the holiday week peak tons and loads based on historical data for the Southwest Brooklyn MTS wasteshed. The

DEIS and this FEIS traffic analysis under these reasonably conservative conditions found that the development of the Converted MTS would not cause any potentially significant adverse traffic impacts.

194. **Comment:** The DEIS failed to anticipate increases in rodent and mosquito populations and the effects of increased pesticide use on the neighborhood. What vector control measures will be used and what will their impact be?

Response: The barges serving the Converted MTSs will be flat-deck barges. This avoids the problems associated with vector control in the old hopper barges, which could have standing water and a layer of refuse in the bottom of empty barges that when full, attracted vermin. Additionally, the MTS facility will be serviced by licensed DSNY pest technicians on a periodic basis, approximately every 45 days or on a more frequent basis, as necessary. The technicians will implement and maintain a pest control program, involving the application of spray and the placement of traps. These design measures in the new facility and operational practices will prevent conditions that can support the growth of vectors.

195. **Comment:** The DEIS failed to examine the increase in toxic burden in the area (from the bus depot, Belt Parkway, pesticide use, and from oil refineries in New Jersey). The cumulative effects from all of these projects will have a severe socioeconomic impact on the community as a whole, and the project will further degrade the area.

Response: Under the NYSDEC air toxics assessment policy, the health risk associated with any project is to be evaluated on an incremental, not a cumulative basis. For permitting of facilities, the acceptable limit from NYSDEC policy with respect to carcinogenic air emissions is either a 1/1,000,000 or 1/100,000 inhalation risk of cancer, with the latter value applying if a project facility has applied "Best Available Control Technology. To evaluate health risk (e.g., cancer risk) on a cumulative basis, one would need to assess the total impact of all causes of cancer. In that case, the total risk would be very large (because of the cumulative risk posed by factors such as diet, cigarette smoke, etc.,) in comparison to the relatively small risk of the project. The NYSDEC policy, similar to that used in many other states and derived from federal policy, assesses

potential health impacts of air toxics emissions from a project only on an incremental basis.

196. **Comment:** The DEIS has not adequately explored other industrial sites where an MTS could be located without affecting a densely populated area, such as Bensonhurst/Bath Beach/ Gravesend Bay.

Response: See response in Section 40.3.1.2, Alternatives, Comment #7 and additional discussion of Alternatives in Section 1.3 of this FEIS.

197. **Comment:** As to the recycling operation at the SBMT, very few details about the materials to be recycled were provided. What are the sources of the recyclable materials, and what will the impacts on traffic, noise, and air pollution be? What will be the hours of operation, and what health and safety protocols will be utilized?

Response: See responses in Section 40.3.2.2 (Hamilton Avenue) on Proposed Action for Recycling at the SBMT.

198. **Comment:** The Notice of Completion maintains that the DEIS will comply with SEQRA, so both long and short-term impacts must be examined. For the "no-build" alternative, the Year 2006 would qualify for the short term analysis. However, the Future "No-Build" condition must analyze to a forecasted future year, associated with the life cycle of the facility. This time frame would be the estimated time of completion plus 20 years (ETC+20). The Demographic Characteristics and Economic Conditions and Potential Impact analysis should be undertaken for this time period. NYMTC has developed new Socio-economic data (SED) and forecasts to the year 2030 based upon updated information. The 2025 SED was not approved due to the uncertainties related to the 9-11 disaster and recovery. All future impacts under the "no-build" scenario must be undertaken at ETC+20. NYMTC's demand modeling tools should be used to forecast traffic.

Response: CEQR requires an evaluation of impacts considering Existing Conditions and comparing No-Build Conditions for the specified Build year with Build Conditions for that year. It does not require an evaluation of impacts over a 20-year time horizon, which cannot be done with any degree of accuracy. The referenced ETC+20 is an analysis that

the New York State Department of Transportation (NYSDOT) requires for design under their Design Procedures Manual and that is typically analyzed for New York State transportation projects that follow the NYSDOT's Environmental Procedures Manual under SEQRA, but not for CEQR projects. In accordance with CEQR protocols, the analyses presented in the DEIS and this FEIS do account for the cumulative effect of additional projects in the area. For example, Existing Conditions reflect current (late 2003/2004) traffic volumes. The project Build Year is 2006. Build Year conditions are estimated by applying an NYCDOT-approved traffic annual growth factor of 1%. Additionally, through consultation with DCP and other agencies, it was determined that no new projects are in development in the study area that would be complete by the Build Year and add traffic to the future background volumes. This information was then used to re-evaluate traffic levels of service at intersections affected by the project in 2006 under a Future No-Build scenario. The Future No-Build scenario estimates what levels of service would be in 2006, accounting for anticipated growth without the Converted MTS. The effect of the Converted MTS is then evaluated by adding its traffic as an increment to the forecasted No-Build scenario, and assessing whether it has any significant adverse unmitigatible impacts. These results are reported in the DEIS and this FEIS and were found to have no unmitigatible significant adverse impacts.

199. **Comment:** In the DEIS, under existing traffic operations, there is no mention if and when vehicle classification counts were conducted. Since the area has pronounced summer recreational activities, winter traffic may be significantly lower than traffic in other seasons. This must be taken into account before the analysis is conducted. In addition, this seasonality would affect pedestrian activity.

Response: In accordance with the 2001 CEQR Technical Manual, traffic counts are not typically obtained during summer months unless **high** seasonal traffic is anticipated in that area. Generally, traffic volumes are higher during months when school is in session as opposed to summer months when school-related traffic is not a factor. In addition, NYSDOT generally classifies roadways in the vicinity of the Southwest Brooklyn Converted MTS site as FC30 (low seasonal variation).

Pedestrian counts were taken in the field at the time of the traffic counts. These pedestrian counts were incorporated in the traffic analyses of intersections in the area. At the intersection of Bay Parkway and Shore Road southbound Exit 5 from Shore Parkway, there is a protected signal phase for pedestrian crossing only. This phase provides a time solely dedicated for safe pedestrian movements at this intersection. The traffic analyses take the signal phase into account. Also see Response to Comment #173 above.

200. **Comment:** All figures showing traffic volumes depict ambiguous traffic approach diagrams. The traffic approach diagrams should be turned so that the traffic flow coincides with the street grid.

Response: Traffic figures were updated for the FEIS to clarify approach directions while maintaining readability.

201. **Comment:** In Section 5.14.2.4, Sentence 2, "However, DSNY and other agency collection vehicles pass through the traffic study area on truck routes from Queens CDs 11 and 13 to the commercial vendor, IESI, located at 110 50th Street in Brooklyn". We cannot relate the meaning of this sentence to the context of the DEIS, section 5.

Response: This statement indicates that there are existing DSNY generated trips that are currently traveling through study intersections in the study area. Because these trips are already within the study area under Existing Conditions, they are excluded from the net increase of traffic trips generated by the Southwest Brooklyn Converted MTS in the future. Further information on the calculation of net project generated trips can be found in Section 3.16, which describes the methodology used for traffic analysis.

202. **Comment:** In Section 5.14.4.1, the statement beginning with "The need for Saturday analysis was considered…" is too vague, as there is no weekend traffic data shown. Weekend traffic has different characteristics than weekday traffic, as trips are made for different purposes. The shopping area at the southern end of Bay Parkway generates traffic trips; new establishments have located there. The amusement park and other seasonal activities within the primary and secondary study area generate many trips during summer weekends. Traffic must be adjusted for seasonal variations.

Response: Section 15.14.4.1 describes weekend traffic volumes in terms of both background volumes and project generated volumes. Table 5.14-3 illustrates the differences between weekday and weekend background and project generated volumes. Also see Response to Comment #173, above.

203. **Comment:** The effects of constructing a 300-foot steel sheet pile and rock breakwater should be evaluated in conjunction with other rock structures planned for the area. Currently, there is severe shoaling within Gravesend Bay as a result of a groin constructed on the ocean side of the Coney Island peninsula. There are plans for the construction of five t-groins off the nearby community of Sea Gate as well as tentative plans in the Harbor Deepening Project (DEC No. 2-6500-00053/00001) for the creation of rock reefs within Gravesend Bay. The continued destruction of bottom habitat needs to be addressed in terms of the cumulative effects of all these projects.

Response: See Response to Comment #178.

204. **Comment:** The DEIS notes that containers will be transported via flat bottom barges, but does not indicate if or how the containers will be secured to those barges. Containers can and do fall off ships and into the water, where they remain submerged, and can be hit by unsuspecting boaters. This impact can result in a huge quantity of floatable debris reaching local shorelines.

Response: All barges will be fitted with "cell guides," structural steel frame compartments that will extend to the height of the middle of the topmost container on the barge. The cell guide will serve to secure the containers.

205. **Comment:** Exactly what mitigation is proposed for environmental impacts to the waterways and when will such mitigation occur? Page 5-62 (Waterfront Revitalization Program) states that “mitigation for potential impacts would be proposed during the environmental review and permitting, if required.” At least ten acres of wetlands should be replenished for every acre of bottom habitat destroyed. There should be solid time frames and substantial penalties for delays.

Response: DSNY has submitted a draft application for Article 15/25 permits that is now undergoing review by NYSDEC. The application specifically addresses issues related to potential effects on marine resources arising from facility construction including effects upon designated littoral zone. As NYSDEC proceeds with review of the application, including a local public hearing, DSNY in coordination with NYSDEC and other involved agencies will determine the appropriate measures to address potential effects from the development of the proposed facility.

206. **Comment:** The Southwest Brooklyn MTS should not be reopened. The community does not want additional cases of cancer or leukemia.

Response: Please see responses to Public Health comments in Section 40.3.1.6.

40.3.2.3 Manhattan

40.3.2.3.1 East 91st Street Converted MTS

206. **Comment:** Numerous speakers were opposed to the reopening of the East 91st Street MTS, and were concerned with what sites were examined as alternatives to the site. They wanted to know why this site, located in a residential area, and adjacent to Asphalt Green was determined to be the preferred Manhattan site, given that it is the only MTS planned for a heavily residential neighborhood. They thought that the facility should be sited in a commercial area, not a residential one, as it will have significant adverse impacts on local air quality, traffic, pediatric health, open space and public health within the community.

Response: The zoning of the site, M-1-4, allows for the proposed waste transfer use and, for over 50 years, the site was used as a marine transfer station (MTS). The MTS site use was included in the 2001 SWMP Modification approved by the City Council and DSNY continues to hold a New York State Department of Environmental Conservation (NYSDEC) permit to handle 4,800 tons per day (tpd) of waste at the existing facility. Site conditions, including proximity (of the existing MTS and the Converted MTS) to residential buildings and parks used by residents were thoroughly considered in the DEIS and this FEIS analysis of potentially adverse impacts. No potential significant

unmitigatable adverse impacts were identified. Access into the facility will be gated and guarded. DSNY enforcement personnel will manage and direct truck traffic at the entrance on York Avenue at 91st Street to protect pedestrians. Waste processing operations occur on the east side of the FDR Drive over the East River and are completely isolated from pedestrian and non-DSNY vehicular traffic. The past problem with DSNY collection vehicles queuing on York Avenue will be eliminated through a combination of the facility's design features and the limitations that DSNY proposes for the facility's permitted capacity at this facility. Accident records were researched for the intersection of York Avenue and 91st Street at the MTS entrance. When the MTS operated previously, this intersection was not a high accident location. The annual average number of reportable accidents was just over 4 per year for the years 1997, 1998 and 1999, and none involved DSNY collection vehicles. During that period, only one accident involved a pedestrian. In the year immediately after closure (2000), there were 8 reportable accidents, 2 of which involved pedestrians. In the future, DSNY enforcement personnel will manage truck and pedestrian traffic at the entrance on York Avenue at 91st Street to ensure that it continues to operate safely.

The response to Comment # 2 in Section 40.3.1.1, Facility Capacity and Design, provides additional information on the design features of the facility that are improvements on the existing MTS design and which avoid the potential for significant adverse impacts on the community, as documented in this FEIS.

207. Comment: Several speakers stated that the 91st Street Converted MTS would receive far more vehicles than the 130 projected, which would result in each truck requiring more than 3.5 minutes turn around time. As these trucks will take longer to unload, there will be queuing of trucks on the east-west streets as well as on York Avenue, which will create problems which will have no adequate mitigation. There was concern that the additional truck trips would make York Avenue impassable and potentially unsafe, and would increase noise, odors and air pollution. The corner of East 91st Street is already extremely congested, and additional waste vehicles will bring this block to a complete standstill.

Response: As noted in the response to the preceding Comment #206, traffic conditions have been fully evaluated. The DEIS and this FEIS reasonably and conservatively used

the historical and higher than current expected average peak weekly deliveries (i.e. Tuesday of each week) when deliveries of waste are 15-20% higher than the average during the week. A 20% contingency was then added to the average peak day value. To add further conservatism to the analysis, approximately nine (9) tons per truck load was assumed as compared to the expected load of 10 to 11 tons, thereby increasing truck volumes. These assumptions result in 130 peak day loads for DSNY collection vehicles (since CEQR requires examination of trips in and out, this translates to 260 truck trips), and 28 peak hour loads (56 truck trips) for DSNY-managed Waste. By comparison, DSNY's expected average tpd from the East 91st Street wasteshed is approximately 720 tons, which translates into 75 loads per day (150 truck trips) with a peak hour of 21 loads (42 truck trips).

The DEIS and this FEIS analysis is actually based on the assumption that the East 91st Street Converted MTS would generate a total 259 net inbound waste hauling vehicles per average peak day, which includes both DSNY and commercial vehicles.

Traffic operations and potential impacts were projected in accordance with City environmental review guidelines and nationally accepted methodologies. The 2*001 CEQR Technical Manual* guidelines were used to determine study intersections and, in accordance with these guidelines, the Highway Capacity Manual methodologies were used to assess traffic operations. Based on that analysis, it was projected that the level of service (LOS) under the 2006 build conditions would be the same as under the 2003 existing condition (with a nominal increment in delays) at the intersections along York Avenue, and at the lane groups at all study intersections with the exception of the eastbound approach at the intersection of York Avenue and East 86th Street. The analysis of travel time and delay runs also projected that the overall build run speed (estimated for air quality analysis) along the northbound York Avenue between East 82nd Street and East 92nd Street would not reduce significantly. The overall run speed was projected to reduce:

- From 23.0 mph under the 2003 existing condition to 22.8 mph under the 2006 build condition during the AM peak hours
- From 23.9 mph under the 2003 existing condition to 23.6 mph under the 2003

build condition during the Facility peak hour
- From 19.0 mph under the 2003 existing condition to 17.9 mph under the 2006 build condition during the PM peak hours

Similarly the overall build run speed along the southbound York Avenue between 92nd Street and 82nd Street was projected to reduce:

- From 20.3 mph under the 2003 existing condition to 19.8 mph under the 2006 build condition during the AM peak hours
- From 20.2 mph under the 2003 existing condition to 20.0 mph under the 2006 build condition during the Facility peak hour
- From 21.0 mph under the 2003 existing condition to 20.8 mph under the 2006 build condition during the PM peak hours

Therefore, based on the LOS and speed run analyses, it is projected that the proposed MTS would not have significant adverse traffic impact at the study intersections.

The response to Comment # 2 in Section 40.3.1.1, Facility Capacity and Design provides additional information on the design and operational features that will avoid collection vehicles queuing on local streets.

208. **Comment:** There was concern that the residents of the Holmes and Isaacs Development, between First Avenue and the East River, and from 92nd to 96th Streets, would be directly and negatively impacted by the MTS. Specifically, they thought that the facility would impact community facilities and services, pedestrian traffic, open space, health and aesthetic values of the community. The waste vehicles on York Avenue will pose a safety hazard to pedestrians.

Response: See the responses to Comments #206 and #207.

209. **Comment:** Several speakers noted that when the MTS was previously open, there were rats, noise, and odors, especially in the summer months. At that time, the neighborhood was primarily manufacturing, but now it is residential, with no commercial buffer. There is concern that these previous impacts will return at an increased rate due to the increased capacity of the proposed Converted MTS. Rats and other vermin are already a problem in the neighborhood, and children are frequently exposed to exterminating poisons when

playing in the parks. The old facility received about 900 tpd of residential waste, but now it will receive two to four times what it used to, and operate around the clock. It was stated that this is not a simple retrofitting of a facility but the construction of a totally new, much larger facility. How can this increase create no environmental impact?

Response: See Response to Comment #206. The response to Comment #2 in Section 40.3.1.1, Facility Capacity and Design, provides additional information on the design features of the facility that are improvements on the existing MTS design, and which avoid the potential for significant adverse impacts on the community, as documented in this FEIS.

The facility will not receive 3,600 tpd of waste. Please refer to the response to Comment #1 in Section 40.3.1.1, Facility Design and Operations, for information on the capacity that DSNY has proposed to permit at this site.

210. **Comment:** The original Solid Waste Management Plan, as described in the Draft Scoping document was to have 8 MTSs, but four were eliminated. However the East 91st Street site is located in a residential community. What are the financial, environmental, technical or legal data which support this choice of site over other sites in Manhattan, particularly over the West 135th Street site? The CWMS provides clear screening criteria for eliminating four Manhattan sites which were examined for private waste transfer stations. Yet for the same reasons that these sites were eliminated from consideration, inexplicably, the East 91st Street site, which shares the same attributes, remains as an alternative.

Response: Please see the response to Comment #7 in Section 40.3.1.2, Alternatives Analysis, for a discussion on the Alternatives that were considered in formulating the Draft New SWMP.

211. **Comment:** A number of speakers commented that the DEIS fails to address the negative impacts of the MTS on local parks such as Carl Schurz and particularly Asphalt Green. DSNY's own siting rules would not permit a private transfer station within 400 feet of a park, so how could this facility be located adjacent to two parks? They were concerned

with the fact that the document fails to analyze traffic on a Saturday, which is the biggest traffic day for Asphalt Green, and wanted DSNY to provide the traffic count data to support the statement that Saturday traffic levels are lower than weekday traffic. They claimed that there is no analysis of the impact of odors on the park, or mitigation, except for "prison-like" walls on the ramp. There was concern that the facility would have other impacts on the park, such as casting a shadow for up to five hours a day on the recreational area, and the impacts from truck exhaust. There was a general concern that the facility would impact on the economic viability of Asphalt Green, especially during construction, which might result in closing of the Park's entrance. There were comments made that when the MTS had been previously open, parents withdrew their children from the day camps located within the park. The facility would have an economic impact on other neighborhood businesses as well, by hindering deliveries and reducing customers.

Response: See Response to Comment # 206. Approximately 140,000 cars drive by this site every day on the FDR Drive and over 20,000 vehicles pass through the York Avenue and East 91st Street intersection each day under existing conditions. There are 50,000 tpd of solid waste generated in the City, and multiple facilities are needed to handle this waste. The regulations for private transfer stations take into account this fact, and to ensure that all waste in the City is not directed to one or two communities, the regulations allow already permitted facilities less than four hundred feet from sensitive receptors to operate. Additionally, the facility will have the following state-of-the-art environmental controls:

- An advanced odor control system;
- A ventilation system exceeding building code standards that maintains negative pressure to prevent the escape of untreated odors to the outside under all conditions; and
- a tipping floor capable of accommodating six trucks, an automated scale system and a ramp with increased structural support – all with the objective of eliminating on-street truck queuing.

The estimated time for demolition and construction of the Converted MTSs in the Proposed Action is 30 to 32 months, which is considered short term. Under CEQR, short-term construction impacts are not considered significant, and do not require a detailed analysis. In addition, at the time the DEIS was prepared, the design of the Converted MTSs was still in

progress. Additional available information on construction related to the Converted MTSs and mitigation measures for potential temporary impacts on Asphalt Green is included in Chapter 32.0 of this FEIS.

The combination of reduced weekend traffic volumes and the lower volume of DSNY-managed Waste collection vehicles that would arrive at the Converted MTSs on a Saturday (Sunday they will be closed except for emergencies) did not warrant a weekend traffic analysis. In fact, based on historical higher tonnages, Saturday volumes of DSNY-managed Waste collection vehicles for the East 91st Street Converted MTS are approximately 64% of the conservative average peak daily totals plus 20% contingency used for the weekday analysis in the DEIS and this FEIS. Background traffic volumes Northbound and southbound on York Avenue are 14,433 average vehicles per day during the weekend versus 20,674 vehicles per day during the week, which is approximately 70% of the weekday traffic. The DEIS presents results of the odor analysis at the property boundary and at the nearest sensitive receptor for the Converted MTSs, with no unmitigable significant adverse odor impacts identified. Odor results at the additional sensitive receptors included in the noise analysis are presented in the FEIS, and are lower than that predicted at the property boundary. Other applicable CEQR analyses, including air quality, shadows, were completed and are presented in Section 6.0 of the DEIS and this FEIS.

212. **Comment:** A speaker noted that there are more appropriate and sensible alternatives to deal with Manhattan's waste. Reference was made to studies which have been undertaken at Columbia University which identify alternatives that are less destructive and less disruptive.

Response: Please review the Chapter 2, Waste Prevention and Recycling, and Attachment VI, Recycling, of the Draft New SWMP and the comments and responses in Section 40.3.1.3 Waste Reduction and Recycling that describe the City's extensive support of and experience with recycling and waste prevention programs.

213. **Comment:** A number of people claimed that the DEIS contains significant flaws characterized by inadequate studies, false statements and harmful conclusions, and

reflects heavy deference to political rather than policy concerns. The Plan is lacking in specifics, and details presented to the public have varied and been inconsistent. The DEIS does not support its conclusions of no significant impacts. Underlying assumptions are not documented and in many cases analysis methodologies are changed to provide the desired conclusion.

Response: This statement is incorrect. The DEIS and this FEIS was prepared in accordance with the Methodologies developed in accordance with the 2001 CEQR Technical Manual, and in consultation with NYCDEP, NYCDOT and other City agencies. As with any environmental review, certain analyses will be prepared based on the most conservative assumptions, and then refined, if the most conservative analysis shows unreasonable results, applying methods that are reasonable and prudent. For example, the first level of an off-site air quality analysis assumes that the peak hour number of project-generated traffic occurs 24 hours per day. If results are below standards, no further analysis is required, though predicted emissions from that traffic would be higher than actually experienced. If results of the initial rough screening are above standards, a more refined Tier II analysis is completed using actual projected hourly volumes. As noted in the DEIS and this FEIS, Technical Backup for the analyses is available on request in a compact disk format from DSNY.

214. **Comment:** A number of speakers were concerned that the rates of asthma and other respiratory ailments are among the highest in the United States within a few blocks of the MTS. It was felt that the facility and diesel emissions from increased traffic would have a significant impact on the health and safety of the people in this vicinity, with new cases and exacerbations of asthma, chronic obstructive pulmonary disease. They were concerned that the facility's venting system would also increase the area's emissions. Additionally, they believed that the new facility will attract pests such as insects, rats and rodents, which can be powerful allergens, triggering asthma symptoms. Since garbage can be moist, it provides a fertile breeding ground for mold, which can also trigger allergies and asthma.

Response: Section 40.3.1.6, Public Health, in this Chapter addresses comments on public health and supplements the information contained in Chapter 33, Public Health of

the FEIS. The off-site air quality analysis presents emissions from the additional DSNY collection vehicles at congested intersections near the Converted MTS. The on-site air quality analysis in the DEIS and this FEIS includes all mobile and stationary on-site emissions-generating equipment, including emissions from the processing building that will exit the processing building through the facility exhaust fans. DSNY collection vehicles all use emissions much cleaner than was the case when the existing MTS operated. The draft Part 360 Solid Waste Facility Permit Application submitted by DSNY to NYSDEC and available for public review at the Community Board #8 Office, 550 Park Avenue and the 96th Street Public Library, 112 East 96th Street, describes the operational measures, including, among others, daily cleaning of the processing floor and periodic application of pest control measures by licensed technicians that will be followed to eliminate disease-bearing vectors.

215. **Comment:** A number of speakers commented on the capacity of the facility, and their belief that the environmental impacts are underestimated. SEQR mandates analyses be performed at full capacity, 4,290 tpd, yet this DEIS only considers the impact of 1,700 to 1,800 tpd of waste. Moreover, the facility is being permitted to receive up to 5,280 tons per day, a five-fold increase over its previous operation. Why was the analysis not done on the full capacity, and why is such a large facility necessary, if this is only designed to handle local waste? Please explain the tonnage numbers which vary from the Part 360 application.

Response: The CEQR Technical Manual states that an analysis of impacts should consider a reasonable worst case condition. For traffic analyses, this condition is represented through evaluating: (1) potential impacts during peak hour traffic volumes - in this case, an am peak period; a facility peak period when the majority of DSNY collection vehicles are expected at the facility, even though background traffic levels are lower than the am peak period; and a pm peak period to determine the potential for the highest impact; (2) the average peak day deliveries of DNSY-managed Waste (the peak day that occurs each week – i.e. Tuesday) based on historical tonnage data that is higher than the current tonnage managed and would be experienced on average no more than 40 to 45 times per year; (3) an average weight per DSNY truck of 9 tons at the East 91st Street Converted MTS, when DSNY collection vehicles now average about 11 tons per truck, resulting in a greater number of estimated DSNY collection vehicles; and (4) an

additional conservative 20% contingency factor to allow for daily and seasonal variability in DSNY's weekly collections as well as the potential growth in waste generated over time, as a function of future population growth.

The DEIS and this FEIS evaluated the potential for significant adverse on-site air quality, odor, and noise impacts with the facility operating at its nominal design capacity of 4,290 tpd, found no impacts and, therefore no further analysis was required. See Response to Comment #213 for an explanation of modeling approaches and use of conservative assumptions. The results of the on-site air, noise and odor emissions reported for these analyses accounted for the facility's waste processing equipment, collection trucks within the building and on the ramp, and tugs servicing barges. The DEIS and this FEIS evaluated the potential for significant adverse off-site (collection vehicles traveling to/from the facility) air quality, odor, noise and traffic impacts, assuming it was operating at an equivalent peak day capacity of 2,892 tpd and found no unmitigable significant adverse impacts. The response to Comment # 1 in Section 40.3.1.1, Facility Capacity and Design states that DSNY is seeking a Maximum Peak Day Permit Limit of 1,860 tpd, which is only 64% of the throughput assumed in the off-site impact analyses. Comment # 1 in Section 40.3.1.1, presents a complete discussion of the permit limits that DSNY is proposing for all the Converted MTSs. It should be noted that, of the four proposed Converted MTSs, the East 91st Street Converted MTS has the lowest proposed tonnage limits.

216. **Comment:** Several individuals commented that the DEIS provides only vague descriptions of the dimension and appearance of the new MTS. Given that it will be twice the height of the old facility, what will the visual impacts be? Drawings and illustrations are needed within the document to get an idea of the actual visual impact will be on users of Asphalt Green and nearby residences. How will the noise barriers or covering of the ramp affect the visual impact?

Response: The visual impacts of the East 91st Street Converted MTS were assessed based on: (1) the design drawings which provided the height of the proposed Converted MTS in relation to the borough datum; (2) the presence of a potential visual/noise barrier along the ramp at the height of the louvered screen that is now part of the design along

the southern side of the ramp; and (3) aerial photos with the proposed facility superimposed on the existing facility footprint. The DEIS presented the information available at the time of publication. Subsequently, additional design documents and renderings have been prepared for the Converted MTSs and are included in Chapter 2, Site Descriptions, of this FEIS.

217. **Comment:** Since commercial waste vehicles emit more pollution than the DSNY vehicles, the EIS must examine air quality and noise impacts from these commercial vehicles on the surrounding neighborhood.

Response: The DEIS and this FEIS analysis assumed a City metro area-specific mix of ages for diesel powered waste collection vehicles, which would include commercial waste hauling vehicles. Because DSNY's fleet of waste collection vehicles is newer than the average for the City area, the DEIS and this FEIS air quality analysis is already quite conservative in this respect, because DSNY's newer diesel engines are subject to lower emissions standards than the existing metro area fleet average. Additionally, the on-site and off-site air quality analyses were revised for this FEIS using the most current approved New York State Department of Transportation (NYSDOT) Mobile 6.2 emission factors, which accounts for the even lower emissions produced by DSNY's newer fleet. Also, it should be emphasized that new diesel powered vehicles purchased today are subject to emissions standards far lower than engines manufactured 20 years ago, and that starting in 2007, new diesel engine emission standards for particulate matter and nitrogen oxides will drop by at least an order of magnitude from today's emissions standards and commercial diesel trucks will begin to use ultra low sulfur diesel fuel. Thus, fleet-wide diesel engine emissions are dropping and will continue to drop even more dramatically with time. In terms of noise, for the Proposed Action Facilities, the noise levels emitted from the trucks used in the DEIS and this FEIS analysis were compared to the noise levels that would be emitted from a mixture of DSNY and Commercial Waste hauling vehicles. The resultant noise level was higher for the projected combination of DSNY and Commercial Waste hauling vehicles for the Hamilton Avenue Converted MTS, Southwest Brooklyn Converted MTS and North

Shore Converted MTS, so the modified noise level was used and is presented in this FEIS for these three facilities.

218. **Comment:** A number of people commented on the lack of sites examined for a Manhattan facility. There needs to be a better explanation of which sites were examined, which were found suitable, and what criteria were used to select the 91st Street site. In addition there are 300 properties in Manhattan alone which are City-owned or City-leased waterfront properties, and these were not reviewed. Several sites were suggested including an industrial site at the cement plant north of the northern end of 1st Avenue, the rail yard on the West side of Manhattan, Pier 42, and Randall and Wards Island. There should be reasonable minimum criteria for identifying multiple possible locations, along with a discussion of the problems and constraints for each site.

Response: Please refer to the response to Comment #7 in Section 40.3.1.2, Alternatives Analysis for a discussion on the Alternatives that were considered in formulating the Draft new SWMP. The 300 sites referred to are found in an inventory of City-owned or leased waterfront site in Manhattan. This inventory contains sites that are mostly in beneficial use already. For example, Battery Park, Castle Clinton and piers that are part of South Street Seaport and the Hudson River Park are listed, along with many tiny parcels that cannot be combined. DSNY's Real Estate Unit has reviewed the list of these sites.

219. **Comment:** There were questions concerning the traffic model, which used 2003 data. Did the model consider the construction of the Second Avenue Subway? Did it take into account the articulated buses? The streets from 87th to 91st Street are very narrow, and there is no practical way to have garbage trucks go down 90th Street without causing gridlock. Traffic through the neighborhood already takes too long, and the additional DSNY trucks will only make it worse. In addition, strict enforcement guidelines are needed to ensure that queuing trucks do not block access to available bus stops.

Response: An analysis of the traffic operations with and without the proposed Converted MTS was performed for York Avenue using the federally accepted Highway

Capacity Manual and data collected in February 2003. These are nationally recognized methodologies and are used universally in City impact assessments in accordance with the requirements of the City's *2001 CEQR Technical Manual*. The purpose of the analysis was to assess if placing a Converted MTS at this location would cause an unmitigable significant adverse impact on traffic operations. The traffic analysis presented in the DEIS and this FEIS included projects that would be implemented by the 2006 Build Year, as discussed below:

- The Second Avenue Subway will not be completed and in operation by the project's 2006 build year. Therefore, following the *2001 CEQR Technical Manual* guidelines, the Second Avenue Subway was not included in the 2006 no-build condition analysis.

- All the buses (including regular and articulated MTA buses) were counted as part of the vehicle classification counts. Level of service analysis took into account all the buses counted at the study intersections.

- As per NYCDOT Title 34 of the Rules of the City of New York, truck trips to and from the site are restricted to travel along local truck routes directly to the site of the intersection closest to the site if the streets adjacent to the site are not designated truck routes. Practically, this means that trucks should use First and Second Avenues to the maximum extent possible, only turning onto cross streets which are non-truck routes at the closest point, typically East 90th, East 91st or East 92nd Streets. Therefore other cross streets should not experience truck traffic except as part of normal collection operations.

- Traffic operations and potential impacts were projected in accordance with New York City Environmental review guidelines and nationally accepted methodologies. The *2001 CEQR Technical Manual* guidelines were used to determine study intersections and, in accordance with these guidelines, the Highway Capacity Manual methodologies were used to assess traffic operations and determine Level of Service (LOS) for each study intersection.

Based on the LOS and Travel time and delay analyses, the analysis showed that any potential for significant impacts from the MTS could easily be mitigated by minor adjustments to signal timing. Signal timing changes at two intersections on York Avenue are the only mitigation required.

220. Comment: Odors were not adequately addressed. There is no mention in the DEIS of the potential for odor impacts from Sanitation trucks which are not kept neat and clean.

No matter how good the technology, the trucks will leak and produce odors. Moreover, there will be a large quantity of solid waste sitting on the loading floor of the facility, and this decaying waste along with the diesel exhaust will pose a hazard to workers on the loading floor.

Response: The DEIS and this FEIS address potential odor impacts from trucks. Some trucks will be more odorous than others. The level of odor emissions from a given DSNY collection vehicle will depend on the state of cleanliness of exposed surfaces, and also on the particular load of waste being transported in the vehicle. To develop input into the DEIS and FEIS odor analysis, a representative group of DSNY collection vehicles was sampled in an enclosed, indoor environment, including some of the most odorous DSNY collection vehicles available. The measured composite odor emissions were included in the on site odor analysis. Regarding the exposure to solid waste-related emissions and diesel exhaust by workers in the Converted MTS facilities, this is an indoor air quality issue regulated by OSHA. However, the Converted MTSs are being designed to allow for up to 12 air changes per hour in the processing building which far exceeds the minimum of six required under the Building Code, thus resulting in an exchange of fresh air into the processing building on a more frequent basis. A copy of the DSNY collection vehicles odor sampling and analysis report is included in Appendix J to this FEIS.

221. **Comment:** While there have been discussions of fair share, in terms of commercial waste, the restaurants and businesses in CD#8 are used by people from all over the City and world, it is not just generated by the residents of CD#8, so having commercial waste go to the MTS would not be fair. Where will the residential and commercial waste be coming from? Will it be transported from lower Manhattan?

Response: The portion of Manhattan waste that may be disposed of at the East 91st Street Converted MTS, 780 tpd, is approximately 26% of the total 2,970 tpd of estimated commercial waste generated in Manhattan. The residential waste that would be disposed of at the East 91st Street Converted MTS is generated in the former East 91st Street wasteshed, comprised of Community Districts #5, #6, #8, and #11.

222. **Comment:** A number of speakers stated that the area is one of the quietest

neighborhoods in the City, and the MTS, with its heavy equipment will create more noise, especially at night. Limitations on the number of trucks transporting commercial waste would not provide any comfort. The mere suggestion of the mitigation measures, such as replacement windows, guarantees there will be much greater noise than indicated in the DEIS. The noise will be a serious threat to the auditory health of those who live and work in the neighborhood, and will make it difficult for students to concentrate.

Response: The on-site noise analysis presented in the DEIS and this FEIS included all noise generating equipment (indoor and outdoor) operating on site, including waste hauling vehicles moving and queuing on the ramp. Under the CEQR Technical Manual, the noise analysis is a worst-case analysis, in that it assumes all equipment is operating on site during the period of time when the background noise levels are quietest, when, in fact, this might not be the case. The off-site noise analysis also evaluated the potential 24-hour delivery of waste to the Converted MTS site (DSNY-managed Waste during the day and commercial waste between 8:00 p.m. and 8:00 a.m.) and, as a result, determined that restrictions on deliveries would be required during certain hours to mitigate potential significant adverse impacts at specific receptors along the routes. The typical kinds of physical mitigation measures, such as sound insulating barriers on equipment or facilities, noise barriers and replacement windows are not required or proposed in this case.

223. Comment: DSNY's siting rules are being changed by measuring the distance from the building, not from the property line, to determine the distance allowed for siting a waste transfer facility. Yet, the East 91st Street Converted MTS is only one-foot between the boundary and the park, how does the siting of this facility comply with the siting rules?

Response: See response to Comment #211 above. The existing MTS is located in a manufacturing zone (M 1-4) adjacent to the FDR Drive. Approximately 140,000 cars drive by this site every day. The site has been used as a solid waste facility for over 50 years and while DSNY is currently not operating the facility, it continues to hold a permit to operate a transfer station at this site. The existing permit issued by NYSDEC allows it to process 4,800 tons per day. There are 50,000 tpd of solid waste generated in the City, and multiple facilities are needed to handle this waste. The regulations for private transfer stations take into account this fact, and to ensure that all waste in the City

is not directed to one or two communities, the regulations allow already permitted facilities less than four hundred feet from sensitive receptors to operate.

224. **Comment:** I do not understand which zoning resolution is going to be utilized, May 2004, or the regulations of the build year, 2006? I am confused about the zoning in the vicinity of the MTS.

Response: As indicated in Chapter 3 of the DEIS and this FEIS, zoning on the site and in the primary and secondary study areas are characterized, then assessed to determine whether the Proposed Action would be compatible with and/or could affect these conditions. No changes to the zoning resolution, as applicable to the site/action, are anticipated, and therefore, it is assumed that the zoning regulations in place at the time of the FEIS will be the same as those in place during the proposed build year.

225. **Comment:** The area surrounding the MTS has seven major hospitals and therefore many ambulances on local streets. What is the impact of the waste vehicles on these ambulances which will be trying to quickly get to the hospitals?

Response: Since the proposed East 91st Street Converted MTS (based on traffic analysis) is not projected to have significant adverse traffic impacts in the peak hours, the effect on traffic operations during the majority of the day with off-peak operations would be even less. Therefore, the MTS operation would be also be unlikely to have any significant adverse impacts on emergency vehicles, including ambulances. Refer to FDNY correspondence in Appendix A of the FEIS. In addition, DSNY's driver operational regulations require that its drivers immediately move to the right side of the road to allow passage of emergency vehicles. The facility design and operation will preclude the queuing of DSNY or commercial vehicles on public streets.

226. **Comment:** Several speakers indicated that they didn't want all of the residential or commercial waste in Manhattan to be delivered to one location. They were willing to take their district's fair share, but not all of the waste. They supported expanded recycling, exploring other technologies, and using barge and rail transportation. They did not advocate sending Manhattan' garbage to other boroughs, but did not want a facility sited in a residential neighborhood.

Response: DSNY believes that building the converted MTS at the same East 91st St. location where an MTS has operated for over 50 years and that was approved by the City Council in the 2000 SWMP Modification is reasonable and fair. See Responses to Comments #206, #212, #221 and #223.

227. Comment: The population of the study area for the East 91st Street facility is three times as densely populated as the next most populated study area in the DEIS. The CEQR Technical Manual guidelines advise that EISs consider the "number of people potentially affected" when assessing the significance of potential impacts. This would include the influx of people coming into the neighborhood daily to use schools, parks and facilities such as Asphalt Green, as well as additional census tracts that will be affected by increased traffic. Additionally, it is illogical to study the economic impacts of the MTS up to a half-mile radius of the site, but only study the effects on population within a quarter-mile of the site. There are seven additional census tracts within a half-mile of the site which includes 52,796 more people., so the grand total of people affected within a half-mile radius is 113,263, almost 100,000 more than proposed in the DEIS. Recently completed buildings on First Avenue at 90th and 91st Streets have added several thousand more people, and the neighborhood will continue to grow.

Response: While the population of the study area for the proposed East 91st Street Converted MTS is greater than that of the other study areas in the DEIS and this FEIS, impact analyses were conducted in study areas that encompassed the most sensitive land uses (i.e. residences or parks) or streets most likely to be affected by the project-related changes. No significant adverse impacts were ultimately identified after all relevant analyses conducted in accordance with the CEQR Technical Manual.

228. Comment: The data in the DEIS are given as percentages, whether pertaining to poverty rates or to asthma prevalence. When the population is disproportionately large, as in the East 91st Street study area, it is essential to consider the actual number of people affected. Focusing on percentages masks the real disparity and actual numbers.

Response: As shown on Table 6.3-1 on p 6-13, the 2000 census reported 13,417 people living in the two census tracts (50% or more) within 1/4 mile of the 91st Street MTS.

Further demographic data for all sites is provided in Appendix B of the DEIS and this FEIS. As noted, the analysis shows that the facilities would not cause any unmitigatible significant adverse impacts.

229. **Comment:** One speaker noted that Manhattan's residential waste stream is trucked directly to New Jersey. Therefore, they felt that no other borough or community is directly affected by Manhattan's disposal needs, so the fair share argument is incorrect. Another speaker requested that the impacts from the continuation of the present system of trucking waste to facilities in New Jersey be examined to determine its impacts.

Response: The Essex County Resource Recovery Facility that is proposed as the facility to receive waste from the former West 135th Street and West 59th Street MTS wastesheds does not have sufficient capacity available to dispose of waste from the East 91st Street wasteshed. The continuation of the Interim Export contracts has been addressed in environmental reviews to support those contracts which found no significant impacts from each round of contracting. The Long Term Export Program is predicated on policy objectives that seek to shift waste transport from a largely truck-based system to a rail/barge based system and to secure disposal capacity with long-term contracts. The Proposed Action would also alleviate impacts associated with the transfer and long-haul trucking of commercial waste from areas such as East Williamsburg in Brooklyn.

230. **Comment:** A number of speakers were concerned with the ramp leading to the facility. How can the ramp that goes through Asphalt Green be widened? The Aquatic Center is on one side, and the field is on the other, therefore there is no practical way of widening the ramp. Would children share the field with the new ramp? The portion of the park that the ramp will go through is designed for use by small children, so the impacts from idling trucks and emissions will be greater than indicated.

Response: The design of the Converted MTS does not involve widening the existing ramp. It will be rebuilt to provide the structural support to queue collection vehicles. The impacts of trucks idling on the ramp have been evaluated on a conservative basis, depending on the analysis, assuming up to 19 vehicles would be queuing/moving on the

ramp. Based on the "Transportation and Traffic Engineering Handbook, Second Edition" chapter on queuing analysis, actual peak hour deliveries are not anticipated to cause a queue longer than a single truck.

231. **Comment:** Some speakers spoke in favor of the East 91st Street MTS, claiming that it will bring a significant environmental and economic benefit to the City by reducing the number of truck miles traveled, thereby reducing pollution.

Response: Transferring waste at the East 91st Street MTS site from the four community districts that historically sent waste to this location will end the current practice of delivering waste from this wasteshed by collection truck to facilities in New Jersey reducing transportation and labor costs and reducing vehicle miles traveled.

232. **Comment:** The large number of waste vehicles will impact the "walkability" factor of the neighborhood. This will impact some of the special needs children of the neighborhood, who find the situation already challenging.

Response: The traffic analysis accounted for pedestrians crossing at intersections and found no potentially significant unmitigatable adverse impacts. It is standard practice to include pedestrian movements, counted at intersections analyzed for traffic, in using the federally approved Highway Capacity Software (HCS). In addition, accident analyses were conducted for the study areas evaluated in accordance with the 2001 CEQR Technical Manual procedures. See Response to Comment #206 regarding the DSNY's on-site pedestrian safety attendant.

233. **Comment:** Several people were concerned with the increased traffic on the river which might create a hazard to navigation. What would happen if a tanker blocked the river, what would happen to the containerized units? Is there a contingency plan should such a situation arise?

Response: The East 91st Street site would only need to process one or two barges per day. The Harbor Operations Steering Committee (consisting of the Coast Guard, Port Authority and Harbor Operators) was briefed on the Converted MTS program in April 2004, and saw no impact from the barge operations on harbor navigation. If a

tanker or other ship is blocking the river downstream from the 91st Street MTS, barges already at the MTS would be prevented from moving downriver, so they would need to remain at one of the three berths located at the MTS. Waste processing operations could continue so long as empty containers are available, either containers stored on the pier or containers from a barge. If empty barges could not reach the station, waste processing would stop when the supply of empty containers is exhausted, and collection vehicles would be re-directed. Full barges would remain at the MTS until the blockage is cleared.

234. **Comment:** Several people wanted to stop the trucking of waste to a waste-to-energy facility in New Jersey, since the emissions from the facility would affect New York City, and it is located in a low-income community of color.

Response: The Essex County Resource Recovery Facility is a lawfully permitted facility, regulated by the New Jersey Department of Environmental Protection. It is equipped with state-of-the-art emissions control technology and must operate in compliance with federal and state air quality regulations.

235. **Comment:** Some speakers thought that the East 91st Street MTS could be redesigned to become an amenity to the community. There could be natural landscaping and concealment of the ramp. With thoughtful design and the latest environmental technology, the MTS could be accepted by the neighborhood. It was suggested that DSNY work with the local community to come up with a ramp design that is aesthetically acceptable and also addresses their concerns. In addition, the facility should be outfitted with the best available emission controls. To minimize impacts, limits should be set on the tonnage that private carter trucks can carry. DSNY's promise of no queuing must be enforced. The logistical details that assure efficient and safe movement of trucks onto and off the ramp and in and out of the facility must be provided. There should be a policeman as well as DSNY employee to keep order at the site, and staggered work shifts for collection or use of GPS systems should be employed to eliminate potential queuing. There must be protection of the neighborhood from noise, odors and toxic emissions. An educational center and viewing facility could also be incorporated into the design. Use of the facility should be subject to daily average and

annual tonnage caps. Permit conditions should specify an enforceable average daily tonnage for both residential and commercial waste as well as peak day use limits. The facility should be closed after a prescribed hour to reduce impacts to the local residential community. Commercial carter use should be linked to compliance with state-of-the-art emission, odor control and noise standards. In addition there should be funding to the Gracie Point Community to monitor what is going on at the facility, and compliance with regulations. DSNY must commit to change the way that the MTSs had previously operated, even if it means confronting established work practices and difficult personnel issues. These new facilities must set a benchmark for the rest of the City's transfer stations.

Response: DSNY presented concepts for enhancing the MTS design, including a proposal to provide pedestrian recreational access to the waterfront at the Community Board #8 Hearing on the ULURP application, which were not endorsed by the Community Board. Because there is no means of pedestrian access to the facility, an educational center and viewing facility is precluded. The DEIS and this FEIS reports that there are no unmitigable significant adverse impacts on the community and new USEPA mandated engine performance and low sulfur fuel standards that will become effective by 2007 will significantly reduce particulate emissions from new collection vehicles. DSNY is willing to work with the Community Board on addressing issues that arise during operation of the facility. The remaining comments have been addressed in the above responses.

236. **Comment:** Any mitigation measures discussed in the DEIS are either inadequate, impractical or unenforceable.

Response: DSNY disagrees with this statement. The proposed mitigation measures: traffic signal changes and limit on commercial waste deliveries at night, are both practical and easily enforceable and are adequate to fully mitigate potentially significant adverse impacts. DSNY is committed to ensure that mitigation measures are implemented and compliance as necessary is monitored.

237. **Comment:** Several people disputed the air quality analyses. The DEIS states that the

Proposed Plan facilities analyzed would add less than 1 µg DPM/m^3, as measured by $PM_{2.5}$, on an annual basis. They believe that this is based upon several false assumptions:

- The maximum number of sources analyzed is not based upon the analyzed truck arrival rates. Therefore the trucks that arrive and are queuing are not accounted for.

- The analysis of the air quality of trucks outside of the 91st Street MTS was limited to 6. Based upon the analysis "the 3-hour value should be no less than one-third of the peak 1-hours value (18)" So the analysis should be of at least 18 trucks. Queuing of trucks on the street, which will occur, was ignored.

- "For the $PM_{2.5}$ analyses, the incremental concentrations contributed by traffic related to the Proposed Plan Facilities were modeled, but not added to existing background levels". This distorts the impact of particulate matter. The annual average last year for NYC was 14µg/m^3. Any additional particulate matter will put NYC into a level above the USEPA regulation of 15µg/m^3. The MTS will place NYC in violation of the USEPA regulations.

- The cumulative effect of particulates is what should be looked at.

Response: Specific responses to bulleted items are noted below:

- The number of trucks queuing at any one time is not the same as the number of trucks arriving in an hour. The numbers of queuing trucks were set specific to each averaging period and represent reasonable values. For example, on an annual basis, the analysis assumes there would be an average of three trucks in the inbound queue and one truck at the outbound queue.

- The conservative assumption of six (6) trucks in queue for a 3-hour impact period (needed for SO_2 impact analysis) is appropriate based on expected truck arrival rates. The proposed transfer stations are designed to allow for maximum queuing of trucks on-site so that no street queuing will be needed. Also, DSNY policy will be to not allow queuing of trucks on streets outside of the DSNY property.

- The air quality analysis did in fact assume that the NYC area would become "non-attainment" with respect to $PM_{2.5}$, and as expected, USEPA did make this determination in December 2004, after publication of the DEIS. In non-attainment areas, federal rules require that "major" emitters of air pollutants demonstrate that their incremental impacts (not their impacts plus the existing concentrations) are below established significance thresholds. Rules relating to new source impacts in non-attainment areas do not actually apply to the proposed DSNY facilities, because their emissions are much too low (i.e., they are not "major"). For example, a "major" new source must have the potential to emit at least 100 tons per year of $PM_{2.5}$. By comparison, the East 91st St. MTS would emit only about one ton per year of $PM_{2.5}$. However, for the air quality analysis

for the DEIS and this FEIS, the $PM_{2.5}$ incremental impacts were analyzed nonetheless, with respect to conservatively low interim significance thresholds developed by the NYCDEP. The NYCDEP's thresholds were used because the USEPA has not yet developed $PM_{2.5}$ significance thresholds. The finding of the DEIS and this FEIS air quality analysis is that the impacts of the proposed transfer station emissions (total from point sources, tugs, and waste hauling trucks) will not exceed the NYCDEP's interim significance thresholds for $PM_{2.5}$.

- Combined off-site and on-site air quality analysis results for the Converted MTSs are presented in the FEIS in Section 6.15.

238. **Comment:** Several individuals commented on the number of trucks arriving at the facility. Over a one-hour period at 9am, 56 trucks are arriving, and speakers were concerned with queuing on local streets. Recently DSNY committed to sending any extra trucks to a garage. Where will this garage be located, and how will the trucks get there and return?

Response: Regarding the hourly truck arrival, please refer to Comment #207. Each of the four Collection Districts that would send waste to the East 91st Street Converted MTS has a garage located in the following locations:

- Manhattan CD #5 540 East 74th Street
- Manhattan CD #6 606 West 30th Street
- Manhattan CD #8 423 West 215th Street
- Manhattan CD #11 343 East 99th Street

During the next five years, it is expected that the E. 74th Street garage will be rebuilt and will house both CD #6 and #8. CD #5's garage will move to 606 West 30th Street, and CD #11 will move to 110 East 131st Street.

239. **Comment:** Several people complained that the hearing was scheduled at an inconvenient time, during the week of Christmas, when the community is very busy. They felt that there was a concerted effort to manipulate the process, and not let the community voice its concerns.

Response: Community Board #8 requested the specific date for hearing. In addition, DSNY conducted extensive public notice and outreach about the hearing which was well attended.

240. **Comment:** Several individuals complained that the facts in the handouts were misleading. The architectural drawing on the back cover failed to identify that the ramp to the facility divides Asphalt Green. The bus stop across the street from the facility entrance is missing, etc.

Response: DSNY had no intention to mislead: it intended to provide a graphic that depicts the effect of the MTS on the surrounding environment.

241. **Comment:** Would you let your children or grandchildren play within 20 feet of a garbage dump:

Response: Re-establishing the MTS use at the site at which it operated for over 50 years and that was reaffirmed for this use by the City Council in 2000, with significantly enhanced environmental controls and clean diesel technology, has been shown by the DEIS and this FEIS to result in no unmitigable significant adverse impacts.

242. **Comment:** There is an EJ community within the East 91st Street primary study area, which is of a size equal to that of other EJ communities at other proposed sites. Therefore outreach to this population should be conducted as aggressively, thoroughly and promptly as for other neighborhoods.

Response: The East 91st Street project area does not meet the numerical criteria established by NYSDEC in its Environmental Policy Guidance for an Environmental Justice community. However, DSNY has conducted the same public outreach program as conducted in project areas that meet such EJ criteria. See Section 40.3.1.4, Enhanced Public Participation for further discussion on this topic.

243. **Comment:** No buses appear to have been counted on 1st, 2nd, or York Avenues or on East 86th Street except for 6 buses turning right off of East 86th and onto East End Avenue. These 6 buses are the 3% heavy vehicles for that intersection and are presumably school buses. Therefore it appears that MTA buses are not considered to be a bus. Perhaps buses are considered part of the heavy vehicle percents, but then what PCEs are used for an articulated bus versus a standard bus making stops after almost every

intersection. Also, no intersections were evaluated north of the site. The PCE issue is important because LOS at many intersections may fall below the acceptable threshold.

Response: Buses were a significant part of the count program and data collected. Two types of classification counts were performed:

- Three-way classification counts included autos, trucks, and buses
- Six-way classification counts for air quality analysis included autos, SUVs, taxis, light trucks, heavy trucks, and buses.

Classification counts showed large numbers of buses at each of the study intersections during the analysis peak hours. For example, during the AM peak hour, the data presented showed approximately:

- 180 buses at the intersection of 1st Avenue/86th Street (about 55 buses on eastbound 86th Street, 55 buses on westbound 86th Street, and 70 buses on northbound 1st Avenue).
- 160 buses at the intersection of 2nd Avenue/86th Street (about 35 buses on eastbound 86th Street, 45 buses on westbound 86th Street, and 80 buses on northbound 2nd Avenue).
- 135 buses at the intersection of York Avenue/86th Street (about 40 buses on eastbound 86th Street, 20 buses on westbound 86th Street, 15 buses on northbound York Avenue, and 60 buses on southbound York Avenue).

For the level of service analysis performed at intersections, buses were considered as heavy vehicles. If there was a bus stop within 250 feet upstream or down stream of the study intersection, then the number of buses stopping at bus stops was also used in the HCS analysis to account the affect of bus blockages on travel lane.

HCS uses a factor of 2.0 to convert the heavy vehicles into PCEs. The CEQR Technical Manual also suggests using a PCE factor of 2.0 for buses and trucks with 3 or more axles, waste transfer vehicles, and large school buses.

Since no site generated traffic was assigned on York Avenue north of 92nd Street, no intersection north of 92nd Street was selected for level of service analysis.

244. Comment: Counts of pedestrians and bicycles seem inadequately estimated for some

neighborhoods. It seems odd that the number of people on Lexington and East 86th Street, the major subway entrance for most of the study area's commuting population, is considered to be 500 people, while a less traveled intersection such as East 85th and York, has 350 people in the morning hour.

Response: For the proposed East 91st Street Converted MTS analysis, pedestrian and bicycle counts were not performed at the study intersections. However, during the data collection efforts, pedestrian activities were observed at the study intersections as is standard practice. The pedestrian numbers cited above were used in level of service analysis to determine the impact of pedestrians on turning vehicles. The Highway Capacity Manual suggests using the following default values for pedestrian flows:

- 400 pedestrians per hour for Central Business District (CBD)
- 50 pedestrians per hour for other area.

However, based on our field observation, the more realistic estimated pedestrian numbers were used in level of service analysis.

245. Comment: The number and temporal distribution of trucks in the permit application for the conversion of the 91st Street MTS issued in November 2004 is significantly different than the number of trucks and their temporal distribution used in the October 2004 DEIS. Why is this the case?

Response: There are several reasons that the number and temporal distributions of trucks shown in the figures for the permit application and DEIS and this FEIS differ, while both are correct for their intended use. The DEIS and this FEIS figure 6.14-9_only depicts the number and temporal distribution of DSNY-managed collection vehicles analyzed, and includes a 20% contingency factor on the expected number of DSNY collection vehicles making deliveries. The DEIS and this FEIS also depicts both incoming and outgoing vehicles as well as the total number of trips generated (incoming plus outgoing) for each hour. Finally, in the DEIS and this FEIS figure the x-axis, which shows the time of day, begins at hour 0:00 (midnight). However, the DEIS and this FEIS also incorporated analysis done for the Commercial Waste Management Study showing the potential numbers of commercial waste vehicles that the facility could accommodate without causing significant adverse impacts.

The permit application figure depicts both DSNY collection vehicles without the 20% contingency, and potential commercial deliveries to the facility, without the contingencies analyzed in the DEIS and this FEIS. The permit application figure depicts only incoming vehicles to the facility. Finally, in the permit application figure the x-axis, which shows the time of day, begins at hour 8:00 (8 a.m.).

246. Comment: The SWMP must establish detailed monitoring, data collection, assessment, reporting and enforcement procedures that provide assurance that truck operation and facility performance standards will be met once the facility becomes operational. Funds should be provided for a technical expert to review and assess data for compliance with permit conditions and standards.

Response: DSNY will develop detailed procedures on truck operation and facility performance standards that will be required to be met once the facility is in operation. DSNY has technical experts on staff that will assess compliance with permit conditions and standards.

247. Comment: The community was asked to consider the environmental impacts for the 91st Street site, for a single daytime shift operation, but DSNY is really planning for a round-the-clock operation handling commercial waste. This change is not being honest with the community.

Response: The DEIS and this FEIS analysis shows both the impacts from handling only DSNY-managed waste, and the impacts from handling limited amounts of commercial waste at times when there is capacity as required by the City Council. For the on-site noise, air quality and odor analyses, facility operations were modeled at design capacity using the conservative approach as a starting point (See Response to Comment #209). When no unmitigable significant adverse environmental impacts were identified, a more refined analysis was not completed. While the DEIS and this FEIS supports use of the facility at design capacity, please refer to the response to Comment #1 in Section 40.3.1.1, Facility Capacity and Design, for information on the capacity that DSNY has proposed to permit at this site.

248. **Comment:** The facility's footprint extends beyond the City' property line. Who owns the property being taken for the facility?

Response: The property proposed to be taken for the facility is owned by the State of New York. DSNY is preparing an application and detailed map for a riverbed grant that will be filed with the New York State Office of General Services.

249. **Comment:** In several chapters of the document, different assumptions and methodologies are used, which suggest that if one approach to the analysis resulted in the "wrong" answer, modifications were made to the analysis to achieve the desired outcome. For example, values for vehicle noise were arbitrarily changed in the noise analysis from the widely accepted Federal standard to a replacement input derived from allegedly measuring DSNY-specific vehicle noise. Special methods can be used to reduce truck noise when it is desirable to do so, and it is no surprise that DSNY found the predicted noise levels higher than the "measured" levels. While the normal modeling resulted in noise impacts, using the "measured" levels resulted in no noise impacts. Just as DSNY trucks are allegedly cleaner, they are purportedly quieter too. This ignores the fact that the Proposed Action, which is supposed to be studied in this DEIS, includes commercial waste, carried by non-DSNY vehicles.

Response: The noise analysis properly took into account actual noise measurements in assessing potential noise impacts. A noise simulation was conducted for DSNY collection vehicles because the Traffic Noise Model (TNM) used in CEQR analyses generally overpredicts the potential for off-site impacts. The CEQR Technical Manual also notes that, while calculated values using the TNM model can be used directly, it is preferable to verify the accuracy of the model for the particular condition being analyzed. Based on these measurements, adjustment factors can be developed to account for site-specific differences between measured and model-predicted values. In consultation with NYCDEP, since: (1) noise measurements were obtained during appropriate times at sensitive receptors along routes that DSNY collection vehicles would travel to and from the Converted MTS site; and (2) these measurements take into account actual background noise levels, these noise values were used for the impact assessment. A copy of the

DSNY collection vehicles noise simulation report is included in Appendix K to this FEIS. The allowable commercial waste hauling vehicles to the Converted MTSs was based on second level screening results that identified the sensitive receptor locations where there is the potential to double PCEs. Normally, TNM analyses are conducted at these locations and often result in a finding of no potential impacts. Therefore, the method used to determine the potential allowable commercial waste deliveries to the Converted MTSs was conservative.

250. **Comment:** Development of enclosed barge unloading facilities (EBUFs) is an essential component of the Solid Waste Management Plan, yet locations for these facilities have not been determined. Deferring the review of the environmental impacts of these facilities is segmentation, and violates CEQR and SEQR.

Response: This is incorrect. Enclosed Barge Unloading Facilities are not required to implement the Proposed Action. Waste containers can be transloaded at conventional terminals in the harbor without special facilities or equipment.

251. **Comment:** The discussion of construction impacts is totally deficient, as it only addresses impacts to benthic organisms and finfish in the river, ignoring significant adverse human impacts of traffic, noise, dust and rodents caused by the complete demolition of the existing MTS and construction of a new facility. Demolition and construction of a new ramp over FDR Drive will have significant adverse impacts upon traffic on the Drive, which is not addressed in the DEIS. Nor are the impacts to Asphalt Green arising from the demolition and reconstruction of the ramp to the facility.

Response: The estimated time for demolition and construction of the Converted MTSs in the Proposed Action is approximately 28 to 30 months, considered temporary under CEQR and therefore, not significant. DSNY will nonetheless utilize good engineering practices throughout the construction phase to ensure that any potential impacts are minimized to the maximum extent practicable.

Please refer to Chapter 32 of the FEIS, which has been revised to provide a more extensive discussion of potential temporary construction impacts for the Converted MTSs

that are elements of the Proposed Action, including measures that will be employed to minimize their effects. Construction activities related to modification of privately owned and operated transfer stations evaluated in the DEIS and this FEIS are currently unavailable, but are also expected to be temporary in nature.

252. **Comment:** The DEIS found significant adverse noise impacts at sensitive receptors caused by the delivery of commercial waste between the hours of 8:00 p.m. and 8:00 a.m. (page 6-154). The DEIS offers no mechanism to assure the neighborhood that the limits to commercial waste would be enforced. Won't trucks just idle on residential streets while waiting to get into the MTS?

Response: The arrangements that DSNY would enter into with private carters for delivering waste to a Converted MTS would include a dump ticket procedure that includes contractual recourse against the carter for failure to follow the agreed upon procedure. For example, the contract could stipulate that a carter who arrives before or after his appointed hour on a given night would forfeit his dumping privileges for that evening. Clearly, in time, such a stipulation could cause carters to adhere to schedules set.

253. **Comment:** The waste proposed to be sent to the East 91st Street MTS currently travels through Manhattan to sites in New Jersey. The DEIS does not consider any alternatives to the MTS "conversion" for this wasteshed, including the most obvious one, transfer to rail at the HRY transfer Station in the Bronx. It is located in an industrially-zoned area, would transfer solid waste by rail, and capacity exists to accept the East 91st Street wasteshed. There is no reason not to use this facility.

Response: An important premise of the Draft New SWMP is reliance upon the existing MTS wastesheds to identify facilities to receive waste that does not shift waste transfer operations to another wasteshed. The existing MTS wastesheds served the Bronx Brooklyn, Manhattan and Queens for over 50 years and reflect an equitable allocation of essential waste management functions among communities in the City. Please review the response to Comment #7 in Section 40.3.1.2 for an explanation of the Alternatives to the Proposed Action that DSNY considered, as well as section 1.3 of the FEIS for additional

discussion on the Alternatives considered.

254. **Comment:** Page 1-1, section 1.1, paragraph 2, line 7: It is incorrect to describe the demolition of the existing, unused Marine Transfer Station at East 91st Street and construction of a larger, entirely new facility as being "converted". This is an entirely new facility that is being proposed.

Response: The term "Converted" refers to Mayor's decision to convert the existing MTSs to waste containerization facilities. DSNY has been very clear that the Converted MTSs are new facilities that replace the existing facilities.

255. **Comment:** Page 1-5, section 1.3.2, paragraph 2, line 2: Scoping comments, dated July 9, 2004, noted that the Project is not properly defined. The Purpose and Need does not support the construction of a new MTS at East 91st Street. The Purpose and Need states that the new Proposed Action for Long Term export in the SWMP includes "an expedited timeframe, a lower cost, and reduced reliance on complex MTS conversions". The DEIS does not contain any data or analysis that forms a basis for the conclusion that construction of a new MTS at East 91st Street meets any of these criteria.

Response: The existing SWMP, as modified in November 2000, acknowledged that Interim Export was a temporary measure of "independent utility" that enabled the City to phase down delivery of waste to Fresh Kills landfill and achieve its closure and provided a means to replace waste disposal capacity until a long-term waste infrastructure could be implemented. Interim Export was never intended to be a permanent solution for the City's waste disposal needs. The Mayor has cited the necessity of transitioning to a Long-Term program that relies on export by barge or rail, to the greatest degree practical, as a fundamental policy objective of the SWMP. Chapter 3 of the Draft New SWMP clearly states the reasons for and advantages of the Proposed Action. The Purpose and Need Section of this FEIS clearly refers to these as the basis for the Proposed Action. The Proposed Action would require the construction of four converted MTSs rather than eight as previously contemplated.

CEQR does not require that a Proposed Action be supported by a detailed economic

analysis. DSNY is in the midst of several competitive procurements with multiple companies that will determine the costs of Long Term Export when final contracts are negotiated. DSNY is sensitive to the need to protect specific cost information that could compromise this competitive process. DSNY has made the case for the Proposed Action on economic grounds and presented that information, including the range of projected costs, at a recent City Council hearing devoted to a discussion of this issue.

256. **Comment:** Page 1-9, section 1.3.2, paragraph 8, line 13: Considerations which guided the formation of the Long Term Export Program included "developing a long-term solution that is equitable". Transferring a third of Manhattan's residential waste and commercial waste from throughout the City through a single facility in a densely populated residential neighborhood is simply not equitable.

Response: See Response to Comment #253 in this section.

257. **Comment:** Page 1-20, section 1.4.4, paragraph 1, line 6: There is no analysis of using the East 91st Street MTS for recyclables, or support for the statement that there would be a lower number of DSNY collection vehicles for recyclables. Moreover, the analysis of waste volume assumes that the City will maintain a recycling program. We have already seen the City's recycling program interrupted due to economic considerations. The analysis of facility waste volume should consider the "worst case" scenario, which would include recyclables in the waste stream.

Response: No Curbside Recyclables will be delivered to the East 91st Street Converted MTS. The Converted MTSs are not proposed as facilities that will receive or process Recyclables. The Draft New SWMP describes the facilities that DSNY will use to support the Curbside Recycling Program, including two that are elements of the Proposed Action. Please see the response to Comment #12 in Section 40.3.1.3, Waste Prevention and Recycling for additional information on this matter.

258. **Comment:** Page 1-22, section 1.5.1, paragraph 2, line 7: If truck traffic is an overriding concern, why has no analysis of vehicle miles traveled been performed? The current

proposed action does not reduce VMT in Manhattan, nor would it eliminate any VMT of long haul tractor trailers.

Response: Analytical methodologies presented in Chapter 3.0 of the DEIS and this FEIS were based on CEQR requirements and consultation with NYCDEP, NYCDOT and other City agencies that require site specific analyses (including traffic) for facilities analyzed. Under the current Interim Export contracts, DSNY collection vehicles travel from collection districts in Manhattan directly to out of City disposal locations. Under the Proposed Action, DSNY collection vehicles would travel from Manhattan CDs 5, 6, 8 and 11 to the nearby East 91st Street Converted MTS, thus reducing the number of VMTs traveled in Manhattan. Furthermore, the Draft New SWMP is a City-wide plan and, on a City-wide basis, DSNY estimates in will reduce VMT annually by 2.8 million miles. See table 40.3-4 in response to Comment #42 in Section 40.3.3.1.7 for the derivation of this estimate.

259. **Comment:** Page 1-22, section 1.5.2, paragraph 1, line 9: The DEIS provides no justification for DSNY to begin managing commercial waste. The DEIS proposes to "encourage private carters to deliver commercial waste during the 8:00 p.m. to 8:00 a.m. time period". This new nighttime industrial activity will greatly increase noise exposure in a residential area. This Proposed Action has significant impacts that are not adequately justified and are not adequately studied. To merely say that the action would "facilitate the City's transition" to rail- and barge-based export system is not sufficient justification.

Response: The Proposed Action is the result of planning efforts set forth in detail in the City's 2000 SWMP Modification and the recommendations of the Commercial Waste Management Study issued in March 2004 (CWMS). The Study was conducted in compliance with Local Law 74 (LL74) enacted in 2000 in tandem with the City Council's adoption of the 2000 SWMP Modification. LL74, among other things, required DSNY to evaluate the issue of using the MTSs to transfer Commercial Waste. A CEQR-level analysis of potentially significant adverse impacts related to processing Commercial Waste at the Converted MTSs is included in the CWMS, Volume III, is included as Appendix I to this FEIS, and was also included in the Draft New SWMP.

Each Chapter in the DEIS and this FEIS that reviews a Converted MTS has a section summarizing that more detailed CEQR level analysis in the CWMS – Volume III (see Section X.18 of each Converted MTS chapter). On-site operations were analyzed assuming 24-hour operation. For example, for the noise analysis, it is assumed that the facility is operating all of its equipment during the quietest background hour, which, given the amount of commercial waste that might be processed during this period, is conservative. Neighborhood character is assessed based upon, among other things, a compilation of all of the on and off-site analyses in the DEIS and this FEIS, which analyze the acceptance of commercial waste at certain levels between 8:00 p.m. and 8:00 a.m. As discussed in this FEIS, a restriction on the number of Commercial Waste vehicles delivering waste to the Southwest Brooklyn, Hamilton Avenue, East 91st Street and North Shore Converted MTSs during certain hours will mitigate estimated off-site noise impacts at receptors along the routes to these facilities between 8:00 p.m. and 8:00 a.m. The limits on commercial waste can be found on Table 40.3-1of the Response to Comment # 1. See also Response to Comment #252.

260. **Comment:** Page 2-8, section 2.1.2.1, paragraph 5, line 3: The statement "this environmental review concludes that varying quantities of commercial waste that can also be processed at each of the converted MTSs without significant adverse impacts" is totally unsupported by this document.

Response: See Response to Comment #259.

261. **Comment:** Page 2-32, section 2.2.3.1, paragraph 3, line 4: The DEIS acknowledges that the East 91st Street MTS site is located in a "high-density residential" neighborhood, but doesn't address the extraordinary incompatibility of a large industrial facility with noise, odors, and truck traffic.

Response: The zoning of the site allows for the proposed waste transfer use and for over 50 years the site was used as a marine transfer station. The City Council reaffirmed the MTS use at this site in 2000. DSNY continues to hold a New York State Department of Environmental Conservation (NYSDEC) permit to handle 4,800 tons per day (tpd) of waste at the existing facility. Site conditions, including proximity to residential buildings and parks used by residents, were thoroughly considered in the DEIS and this FEIS

analysis of potentially adverse impacts. No potential significant unmitigatable adverse impacts were identified. Access into the facility will be gated and guarded. DSNY enforcement personnel will manage and direct truck traffic at the entrance on York Avenue at 91st Street to protect pedestrians. Waste processing operations occur on the other side of the FDR Drive over the East River and are completely isolated from pedestrian and non-DSNY vehicular traffic. Unlike the Plan approved in 2000, the past occurrence of DSNY collection vehicles queuing on York Avenue will be eliminated through a combination of the facility's design features and the limitations that DSNY proposes for the facility's permitted capacity at this facility. Accident records were researched for the intersection of York Avenue and 91st Street at the MTS entrance. When the MTS operated previously, this intersection was not a high accident location. The annual average number of reportable accidents was just over 4 per year for the years 1997, 1998 and 1999 and none involved DSNY vehicles. During that period only one accident involved a pedestrian. In the year immediately after closure (2000), there were 8 reportable accidents, two of which involved pedestrians. In the future, DSNY enforcement personnel will manage truck and pedestrian traffic at the entrance on York Avenue at 91st Street to ensure that it continues to operate safely.

The design features of the facility that minimize the potential for impacts include the following:

- The Converted MTS is designed to receive and process up to 36 collection vehicles an hour, well more than is anticipated in the peak hour. Trucks queuing outside the old MTS buildings were a frequent source of complaints. Accordingly, the new tipping floor for the Converted MTS is designed with a large maneuvering area and six tipping bays to unload six trucks at a time. The anticipated peak hourly arrival rate for DSNY trucks at this facility is 21. Over a 24 hour period, an average of 147 DSNY and commercial carter collection vehicles would be able to use the facility.
- The tipping floor is 12 feet above the loading floor which accelerates the unloading process by eliminating potential interference between collection vehicles and waste processing equipment. Truck turnaround time is also improved through the use of automated scales in contrast to the manual weigh-in – weigh-out system at the old MTSs. Finally, should the arrival rate ever exceed the 36 trucks per hour design criteria, the ramp is structurally strong enough to hold 19 queuing trucks. Although the peak arrival rate occurs during only one

hour a day, the need to accommodate this peak rate, maintain the efficiency of DSNY collection operations and avoid on-street queuing problems were all important considerations in the design of the building.

- The loading floor is designed to process up to 220 tons per hour into containers, using three of four processing lines with one held in reserve as a spare. The floor can also provide approximately 760 tons of on-floor storage in the event of a delivery surge or a delay in barge arrival. These design criteria enable the facility to manage maximum expected arrival rates, without excessive queuing or turning away trucks. The fourth processing line provides redundancy in the event of mechanical problems affecting one of the other processing lines.
- Container loading and lidding operations occur on the level below the loading floor and are within the enclosed building to prevent the escape of litter and odors to the outside environment. The through-the-floor loading system is a simple, fast, gravity-based process to assure a high degree of reliability.
- The building's ventilation system is designed to maintain negative pressure in the building at all times, even when doors are open with the capability to provide 12 air changes per hour (acph), compared to the code standard of 6 acph. It is also equipped with an odor neutralizing system that treats air as it is exhausted from the building to remove 90% to 99% of the odors from the building's exhaust air. The odor control system uses a natural neutralizing agent that is made from a plant compound.

262. **Comment:** Page 2-34, section 2.2.3.1, paragraph 2, line 1: Although the DEIS states that "No archeologically significant resources exist on the site" there is no data to support this conclusion. Excavation of footings for the enlargement of the ramp and new building may reveal unanticipated resources, but the DEIS does not study the potential for the existence of such resources or describe a methodology for dealing with these issues during construction, as is standard CEQR methodology.

Response: Consultation with LPC and the SHPO conclude that there is no potential for impact to archaeological resources. The design of the Converted MTS does not involve widening the existing ramp. It will be rebuilt to provide the structural support to queue collection vehicles.

263. **Comment:** Page 2-34, section 2.2.3.2, paragraph 1, line 8: In the Proposed Action, the ramp which crosses Asphalt Green and FDR Drive will be demolished and replaced. The short term and long term impacts of this action are not sufficiently described, such as

construction impacts, and increased shading on public parkland due to the wider ramp and noise barriers. The noise barriers are not described.

Response: See Response to Comment #251. The DEIS and this FEIS presents an analysis of shadows (see Section 6.7) of the proposed East 91st Street Converted MTS on neighboring areas. The shadows analysis includes what was once described as noise barriers, but is now the currently designed louvered screens that will be constructed along the southern side of the ramp. The FEIS is corrected to note that, although the purpose of the screen on the ramp is primarily visual, it also makes a contribution to noise mitigation.

264. Comment: Table 3.16-1: This table shows 130 net loads of DSNY collection vehicles for this facility for an average peak day. Does this correspond to a typical Monday or Tuesday when tonnage is 10 to 15 percent higher than the remaining days of the week? At two trips per load (entering and exiting) the daily number of vehicle trips is 260. There is no data provided in this section or in the site specific analysis for the East 91st Street Converted MTS documenting how the number of trips generated by this facility was determined. The section preceding trip generation presented generalized discussions of existing and future DSNY operations but there is no documentation of how these assumptions factored into the calculation of the number of 130 loads for the East 91st Street Converted MTS. A footnote on the entry for this facility in Table 3.16-1 indicates that the total number of loads from DSNY collection vehicles is the same for the converted MTSs and the existing MTSs. The column giving the number of loads for the facility is headed, "Total Number of New Loads…" These are not consistent, creating a potential conflict in the analysis.

Response: DSNY collection vehicle deliveries analyzed in the DEIS and this FEIS were based on historical average peak daily totals of DSNY-managed Waste (i.e. Tuesday of every week), which are: (1) higher than current estimated tonnages; (2) the highest number of DSNY collection vehicles expected on average each week, and (3) include a 20% contingency to allow for daily and seasonal variability in DSNY's weekly collections as well as the potential growth waste generated over time, as a function of future population growth. The referenced footnote in Table 3.16-1 pertains to the numbers used in the analysis of the Converted MTSs and Existing MTS presented in the

DEIS and this FEIS, assuming the wastesheds for these facilities would be the same. The Existing MTSs, as analyzed, are not included in the Proposed Action. As noted in the DEIS and this FEIS, technical backup containing supporting documentation (including trip generation estimates) is available upon request.

265. **Comment:** Page 3-81, section 3.17.4.3, paragraph 7, line 9: The DEIS provided no justification for the assumption that there would be a 50 percent reduction in emission factor for speeds of 5 mph and does not describe the operational controls that will assure that speeds will be maintained at 5 mph or less.

Response: The 50% reduction refers to fugitive PM_{10} emissions estimated according to the USEPA's publication AP-42, Section 13.2.1, dated December 2003. The emissions equation from AP-42 was developed based on emission measurements for traffic speeds ranging from 10 to 55 mph. At lower vehicle speeds (e.g., 5 mph), there is serious doubt as to whether there is any significant fugitive dust emitted, since the re-suspension of fugitive dust on paved roads likely requires some threshold vehicle speed before the vehicle wake is moving fast enough to "sweep" dust from the surface. USEPA experts responsible for developing this section of AP-42 have stated that, for vehicle speeds of 5 mph, an assumption of 50% of the emissions produced at speeds in the 10-55 mph range would yield conservative (high) estimates of emissions. This has more recently been supported by studies at large facilities with truck traffic moving at speeds up to 10 mph, which have shown measured PM_{10} emissions several times lower than yielded by the AP-42 equation (Reference: Midwest Research Institute, "Emission Tests of Paved Road Traffic at Minnesota Corn Processors, Marshall, Minnesota, Facility", MRI Project No. 310212.1.001, July 6, 2001). Additional operational controls on speed are not required at the Converted MTSs due to the relatively short distances of on-site travel and the location of the scales, which will effectively limit on-site vehicle speeds.

266. **Comment:** Page 3-85, section 3.17.4.5, paragraph 2, line 1: There is a discrepancy in assumptions of the number of shift operations. For the purposes of the air quality analysis, the operating assumption is two shifts per day. Pages 2-9 and 6-87 describe a

three-shift operation. The traffic and noise analyses assume three shifts per day. The assumptions must be consistent and the incorrect analysis redone.

Response: The on-site air quality and noise analyses use two different methodologies and models that evaluate impacts over different periods of time, both of which are appropriate. The on-site air quality analysis estimates emissions for specific pollutants with both short term (24 hour, 8 hour, 3 hour and 1 hour averages) and long term (annual average) standards for two scenarios: acceptance of DSNY-managed Waste only and acceptance of DSNY-managed Waste plus commercial waste. For purposes of modeling pollutants with annual average standards for the DSNY-managed Waste scenario, the facility was assumed to operate on a two-shift basis, which is reasonable for estimating emissions on an annual basis under this scenario. For pollutants with 24 hour, 8 hour, 3 hour and 1 hour average standards, all equipment is assumed to be operating during that period. For the DSNY-managed Waste plus commercial waste scenario (results of which are presented in Appendix D of the DEIS and this FEIS), the annual average standards were modeled using a three-shift operation. The on-site noise analysis is an L_{eq} (1 hour) or L_{max} (instantaneous) analysis, depending on the standard, so it assumes that all of the equipment is operating during these periods. For CEQR analysis, the facility is assumed to be operating during the hour when the background noise levels are quietest. Off-site traffic, mobile noise and mobile air quality analyses evaluate the potential for 24 hour deliveries of waste to the Converted MTSs.

267. Comment: Page 6-6, section 6.2.1.3.1: Scoping comments dated July 9, 2004, asked that the background and history of the current zoning for the site and adjoining properties be provided and the existing underlying and overlay zones applicable to the site be summarized. The DEIS does not summarize provisions of the M1-4 zoning district. The Proposed Action is not consistent with the regulations governing a M1-4 district. There is no analysis of how the facility will meet performance standards necessary for this type of use in an M1-4 district, as required by the NYC Zoning Resolution.

Response: Table 3.4-1 of the DEIS and this FEIS provides information from the City Zoning Resolution summarizing the characteristics of the types of zoning districts that are found at the sites analyzed, including M1-4 zoning districts. As described in Section

3.19.3.2, and presented in the noise section of each applicable Chapter, the DEIS and this FEIS provides an analysis of the Converted MTSs for conformance with the New York City Zoning Regulation maximum permitted sound pressure levels. New York City Zoning Resolution requirements for odors and air quality are general and CEQR analyses conducted for odor and air quality presented in the DEIS and this FEIS demonstrate the requisite compliance.

268. **Comment:** Page 6-8, section 6.2.2, paragraph 1: The DEIS does not describe in detail the residential development initiatives within the primary and secondary study areas.

Response: The information describing buildings was obtained from the NYCDCP. This level of detail is adequate for the analyses, particularly as the developments will be located on First Avenue, approximately two blocks (nearly ¼ mile) west of the site. No additional information has been provided as a comment to this FEIS.

269. **Comment:** Page 6-10, section 6.2.3.1, paragraph 1, line 6: There is a discrepancy that has significant adverse impacts. Under Potential Impacts, this section indicates that "the ramped entrance to the site would remain unchanged" while Page 2-34 states that the ramp which crosses Asphalt Green and FDR Drive will be demolished and replaced with a wider, steeper structure.

Response: The text has been revised to clarify the point that the new ramp will be constructed with the same footprint as the old ramp, thus resulting in no taking of land or changes in access between the northern and southern portions of the site

270. **Comment:** Page 6-10, section 6.2.3.1, paragraph 2: The Proposed Action will re-introduce a disruptive land use which is no longer suitable or compatible with the residential/institutional neighborhood character, resulting in undesirable land use impacts. There is no data to support a conclusion of land use compatibility with surrounding high density residential development, community facilities, parks and open space.

Response: Many of the residential and institutional uses surrounding the site were developed while the former MTS at East 91st Street was in operation, including such sensitive uses as the waterfront esplanade adjacent to the existing MTS and the Asphalt green complex, which is located on the grounds of the former Municipal Asphalt Plant. Continuation of the long-standing MTS use at the site was approved by the City Council

in 2000. Technical analyses predict no significant adverse impacts would result from the East 91st street Converted MTS, and no changes in land use patterns would be attributable to the reactivation of this site for a similar operation.

271. **Comment:** Page 6-10, section 6.2.3.2: The DEIS does not demonstrate how the East 91st Street facility would be consistent with applicable policies and plans, including the Comprehensive Manhattan Waterfront Plan (CMWP), and recommendations of the Plan for Reach 1, which notes that the East River water is "an important fish migration route". The DEIS should contain substantive examination of local and regional land use plans for consistency with the Proposed Action and Alternatives.

Response: Refer to Section 6.2.1.4 for a summary of CMWP policies and recommendations for Reach 1 as they relate to the site; no policies preclude or recommend against the East 91st street Converted MTS. No impacts to natural resources were predicted (See Section 6.9.3 of the FEIS).

272. **Comment:** Page 6-11, section 6.3.1.1, paragraph 1, line 4, and Page 6-12, Figure 6.3-1: The Study Area is mischaracterized by eliminating portions of four additional Census Tracts: 144.01, 154, 156.01, and 156.02. This affects the analysis of socioeconomic conditions and environmental justice issues. The significant growth in residents of Hispanic origin and the potential impact on that population should be addressed.

Response: Refer to Chapter 3, Methodology for the number of people "affected". The Environmental Justice assessment was undertaken as a discrete task, separate from analysis of socioeconomic impacts, as described in Section 40.3.1.4, Enhanced Public Participation. As no technical analyses predict impacts, it is reasonable to conclude that none of the residents would endure adverse effects, regardless of socioeconomic characteristics.

273. **Comment:** Page 6-18, section 6.3.3: In our July 9, 2004 scoping comments, we noted that the reopening of the East 91st Street MTS has the potential to adversely affect neighborhood character, and thus will likely have a significant negative impact on property values in the area. As such, we asked that DSNY provide an overview of the

current residential real estate market, including a detailed discussion of the impacts on property values and resultant reduction to the tax base. We also asked that a qualitative assessment of impacts on surrounding uses, including commercial uses be provided, based upon an analysis of increase or decrease in property values. Those comments were not responded to in the final scope and these analyses are not included in the DEIS.

Response: The SWMP Modification approved by the City Council in 2000 included the continued use of this site as an MTS. Under the Proposed action, the facility will have a more environmentally protective design than is the case with the existing facility. The *"Douglas Elliman Manhattan Market Report 1994-2003, Ten Year Trend Analysis"* prepared by Miller Samuel, Inc. presents, among other things, a summary of the trends in the Manhattan housing market, apartment inventories and price per square foot from 1994 through 2003. Borough-wide, condominium and co-operative apartment sale prices were generally flat from 1994 through 1997, then began an upward trend from 1998 through 2003. For the area bounded by East 90th Street on the north, East 79th Street on the south along East End Avenue (including Gracie Square and Gracie Terrace), from 1994 and 1997 the average price per square foot for co-ops remained relatively flat, increased dramatically in 1998 (55% from 1997), and again in 2000 and 2003 (though not at a slower pace—22% and 16% respectively). In Yorkville (the area bounded by E. 86th St., E 96th St., York and Lexington Avenues) the average price per square foot for co-ops increased each year from 1995 through 2003.

The East 91st Street MTS closed in October 2000. The market data suggests that proximity to the MTS while it was fully operational, had no adverse effect on property values. Based on the methodology described in Chapter 3 of the DEIS and this FEIS, the study found that re-opening the East 91st Street MTS would have no significant adverse impacts to neighborhood character.

274. **Comment:** Page 6-20, section 6.4.3, The DEIS does not substantiate the assertion that community facilities and services will not be impacted; no method of assessment of emergency service response times is provided.

Response: Technical analyses predict no significant adverse impacts to the environs,

including traffic conditions, and so the East 91st Street Converted MTS would not affect emergency response times. Refer to FDNY correspondence in Appendix A.

275. **Comment:** Page 6-27, section 6.5.3, paragraph 1, Line 4: The analysis of open space impacts relies on the odor analysis to conclude that there are no significant open space impacts. However, the odor analysis did not assess any receptors outside but only examined impacts to nearby residences. There will be odor impacts to parks and recreational facilities which are not honestly presented.

Response: The DEIS presents results of the odor analysis at the property boundary and at the nearest sensitive receptor for the Converted MTSs, with no unmitigable significant adverse odor impacts identified. Odor results at the additional sensitive receptors included in the noise analysis are presented in the FEIS, and are lower than that predicted at the property boundary.

276. **Comment:** Page 6-27, section 6.5.3: The DEIS does not assess either direct or indirect impacts upon Asphalt Green, Carl Schurz Park and the East River Esplanade, caused by noise and air pollutant emissions and odors. The new MTS structure, the larger ramp the queuing of trucks, and the operations of the MTS will reduce the aesthetic value and as a result, intensity of use of these valuable open spaces and parklands. The conflicts between school buses dropping off children and queued trucks, and the challenge for pedestrians to navigate around large odor emitting trucks will interfere with public access to this significant recreational facility.

Response: The text in the DEIS has been revised in this FEIS to note the new ramp will be constructed in the same footprint as the existing ramp.

Traffic patterns at the York Avenue and East 91st Street entrance were observed during typical midweek days between 7:00 a.m. and 7:00 p.m. Bus activities were observed on a typical weekday in the summer of 2004, and on a typical weekday in the spring of 2005. On the summer weekday, no more than four school buses were observed during any given hour dropping off/picking up children at Asphalt Green and typically there were only 1 to 2 school buses. The average layover time of a school bus waiting to pick up students was observed to be 54 minutes.

On the spring weekday, six occurrences of school buses picking up children were observed in the morning between 7:00 a.m. and 9:00 a.m. on York Avenue at four different locations between 88th and 91st Streets. Two of these pickups were on the northbound side, and four were on the southbound side. The dwell time for each occurrence was less than one minute. Between 10:00 a.m. and 2:00 p.m., one school bus was observed dropping off children on York Avenue at the northeast corner of 91st Street. The bus stood there for about one hour, then picked up the children. Between 2:00 p.m. and 4:00 p.m., five occurrences of school buses dropping off children were observed on York Avenue between 88th and 91st Streets. Two of these pickups were on the northbound side, and three were on the southbound side. The dwell time for each occurrence was less than 30 seconds. None of the school bus activity described above caused any unusual conflicts with the rest of the traffic stream.

On a typical weekday during the summer of 2004, the peak number of City buses was 63 in a given hour, of which, approximately 50 percent were articulated buses. Background volumes were counted over the same period. Overall, the existing number of buses and background traffic volumes observed were lower than those analyzed in the DEIS and this FEIS, which would indicate that the traffic analyses presented in the DEIS and this FEIS are conservative.

277. **Comment:** Page 6-32, section 6.6.3: The DEIS does not assess potential impacts on historic resources resulting from incompatible visual, audible and atmospheric elements, including construction-related impacts, which have the potential to affect neighborhood character. While the DEIS includes discussion of the Landmarks and Historic Districts, etc, it does not identify whether any properties in the study area are eligible for listing.

Response: No "eligible" properties were identified via secondary sources (refer to Appendix A), field surveys, LPC or SHPO correspondence (See Appendix A), or as part of public comment on the DEIS. SHPO and LPC concur that no impacts to historic (architectural) resources would result.

278. **Comment:** Page 6-33, section 6.7.1.3: The DEIS does not describe the exterior or the interior layout of the proposed facility, nor does it describe the proposed ramp walls. The larger facility and ramp has the potential to affect neighborhood character. Without a detailed design, including streetscape elements, the DEIS cannot properly and adequately analyze the operations of the facility of the impacts on visual resources, shadows, traffic, air, noise and odor.

Response: The text in Section 6.7, Urban Design, Visual Resources, and Shadows has been revised and additional illustrations have been provided in Chapter 2.0 of the FEIS to clearly present current design information for the Converted MTS.

279. **Comment:** Page 6-46, section 6.8.1.2, paragraph 1, line 1: The DEIS accurately describes the existing neighborhood character as being pleasant, well-maintained and conducive to pedestrians, yet on Page 6-48 the study concludes that the MTS "is not expected to result in significant impacts on neighborhood character" even though the "reintroduction of trucks into the neighborhood would be noticeable" and that the "MTS potentially could result in impacts to neighborhood character due to potential odor conditions". How can this not create significant adverse impacts to neighborhood character?

Response: Please refer to the responses to Comments #269 through #278, above.

280. **Comment:** Page 6-46, section 6.8.3: The DEIS states that "unlike other sites studied, this site is within fairly close proximity to both residential and open space resources, which are the two major factors contributing to the neighborhood character of the area" . The DEIS acknowledges that the site is high-density residential, but does not conclude that this is a poor location for a large solid waste transfer station. The DEIS acknowledges that the MTS facility encompasses "most of the Asphalt Green Recreational Center" which is a City-owned park and a City-wide resource serving many people outside the Gracie Point Community. It is also a historic resource. Gracie Mansion is also adjacent to the site but the impacts are trivialized. The conclusion that the impacts are not significant has no supporting basis.

Response: Please refer to the responses to Comments #269 through #278, above.

281. **Comment:** Page 6-58, section 6.10.1, paragraph 2, line 6: An Environmental Site Assessment is not properly performed according to ASTM E-1527 and DSNY's own stated methodology for assessing impacts relating to Hazardous Materials without a site visit. Claiming inability to access a facility owned by DSNY to conduct a site visit is inexcusable. The assertion of no adverse impacts is completely without support, because an Environmental Site Assessment was not performed to any reasonable standard of care.

Response: The Phase I inspectors initially were denied entry due to a locked gate, but the site visit was rescheduled and the site investigation was conducted on April 25, 2003. The statement has been corrected in section 6.10.1 of the FEIS.

282. **Comment:** Page 6-59, section 6.10.3, paragraph 1, line 1: There is no discussion of how receipt of oil or hazardous, explosive, infectious, or radioactive material would be handled at the facility. DSNY has no control over what materials are thrown into the trash, and the risk to the neighborhood could be significant. There needs to be a detailed plan for the management of hazardous materials at the facility and evacuation procedures in the event of a fire, explosion or toxic substance release.

Response: The d**r**aft Part 360 Permit application, undergoing review by NYSDEC, extensively documents the measures and equipment that will employed at the MTSs to inspect incoming loads of waste, detect and segregate hazardous and unacceptable materials, control vermin through the periodic application of pest control measures, and clean the facility on a daily basis. See the response to Comment #2 in section 40.3.1.1 for additional information about design features of the Converted MTSs.

283. **Comment:** Page 6-60, figure 6.10-1: This figure is incorrect. The Toxics Targeting Environmental Report identifies 33 toxic sites within 1,000 feet of the MTS site, including several active hazardous spills.

Response: The figure is correct. The site specific radius map indicates only those sites which may create a significant impact to redevelopment or reuse through on-site or off-site pathways. None of these sites were identified at the East 91st street Converted MTS site. The hazardous materials methodology in Chapter 3.0 of this FEIS has been revised

to include this explanation.

284. **Comment:** The MTS redevelopment is subject to review under the 10 policies of the City's Waterfront Revitalization Program. Policy 1 supports commercial and residential development, but the MTS is incompatible with residential development. Policy 2 supports water-dependent and industrial uses in NYC's coastal areas that are well suited to their continued operation, and this site is not well suited since it is surrounded by parks and residential areas. The MTS development does not appear to support Policy 3, which promotes boating, nor does it appear to support Policy 8, to provide public access to and along the City's coastal waters. The DEIS does not address impacts to the adjacent Commuter Ferry. It does not support Policy 9, to protect scenic resources, nor Policy 10, to protect, preserve, and enhance resources significant to the historical, archaeological and cultural legacy of the NYC coastal area. The DEIS should discuss enforcement measures of this program, and how DSNY can be required to abide with these policies.

Response:

Responses to each of the policy-related comments are noted below.

1. *Policy 1 supports commercial and residential development in areas well suited to such development, and the Upper East Side is ideal for that. However, an MTS is incompatible with residential development.*

The East 91st Street Converted MTS would be an expansion of an existing site and would not preclude the development of commercial or residential development in the area. In addition, the proposed facility would replace an existing over-water facility and would not occupy a significant amount of upland space.

2. *Policy 2 supports water-dependent and industrial uses in New York City's coastal area that are well suited to their continued operation. This site would not be considered well suited for industrial uses as it is surrounded by parks and residential areas.*

The proposed action would involve the revitalization of an existing water-dependent, industrial use at the site. Although parks and residential areas surround the site, the Proposed East 91st Street Converted MTS represents a reactivation of industrial use,

around which the adjacent waterfront esplanade, Asphalt Green complex, and nearby residential towers developed. Development of a ferry terminal at East 90th Street and the waterfront promenade in the area near the site has already occurred as per the recommendation of the Comprehensive Manhattan Waterfront Plan. As demonstrated in the FEIS, the proposed action would not cause unmitigable significant adverse impacts to the surrounding environs, including commercial and residential uses; therefore the site is well suited to this continued water-dependent industrial use.

3. The MTS redevelopment does not appear to support Policy 3, which promotes boating and water transportation.

The "Plan for the Manhattan Waterfront" recommends renovating the existing 90th Street Pier, located south of the existing MTS, for commuter service. Development of a ferry terminal at East 90th Street and the waterfront promenade in the area near the site has already occurred as per the recommendation of the Comprehensive Manhattan Waterfront Plan. The proposed MTS is consistent with the "Plan for the Manhattan Waterfront" which specifically states that the MTS should be taken into account when siting the ferry landing at this location. Development of the Converted MTS would not preclude the development of additional boating and water transportation uses along the East River.

a. The MTS redevelopment does not support Policy 8 to provide public access to and along New York City's coastal waters. The DEIS does not address potential impacts to the adjacent Commuter Ferry.

As stated in the DEIS and this FEIS, public access would generally not be compatible with the East 91st Street Converted MTS. However, there are numerous points of public access located north and south of the proposed MTS, specifically along the East River Esplanade.

Text has been incorporated under Policy 3 of the Waterfront Revitalization Program section to clarify the point that the proposed MTS is consistent with the "Plan for the Manhattan Waterfront," which specifically states that the MTS should be taken into account when siting the ferry landing at this location.

4. *The redevelopment does not support Policy 9 to protect scenic resources that contribute to visual quality.*

Existing views of the water are obstructed to some extent by the existing facility. The proposed MTS would resemble the existing MTS in terms of its building typology, massing and position and elevated access. The larger scale and overall appearance of the proposed facility would not likely contribute to a substantial change of views toward the waterfront from inland areas. Therefore, the new facility and reactivation of the former ramp would result in no significant impact to the visual quality of the area, and the urban design of the area would remain virtually unchanged.

5. *The MTS does not support Policy 10 to protect, preserve, and enhance resources significant to the historical, archaeological and cultural legacy of the New York City's coastal waters.*

As stated in the DEIS and this FEIS, the SHPO and LPC concur that there would be no impacts to archaeological or historic architectural resources; therefore, the proposed MTS would be consistent with this Policy. Although the access ramp leading to the MTS is currently located near the Municipal Asphalt Plant, which is listed as a City landmark on the National Register, the proposed replacement ramp would be located within the same footprint and would, therefore, not pose any impacts to this resource.

Given that DSNY's proposed use of the site for a Converted MTS is not inconsistent with the above-referenced Policies, enforcement measures are not necessary.

285. **Comment:** Page 6-95, section 6.14.2.3.1, line 1: The worksheets for the intersection level of service analyses should be provided so that the geometry, signal phasing and timing, and other parameters used in the analysis can be reviewed.

Response: As indicated in Chapter 3.0 of the DEIS and this FEIS, Technical Backup for the analyses is available upon request. This technical backup includes supporting documentation such as spreadsheets, trip generation figures, Highway Capacity Software (HCS) input/output files, intersection geometries, and signal timing and phasing used in the traffic analysis.

286. **Comment:** Page 6-99, section 6.14.2.6, line 2: This sentence suggests that the high level of pedestrian activity at the analysis locations is not expected to affect the capacity analysis significantly. A high volume of pedestrians will interfere with turning vehicles or will require a pedestrian phase. Either of these could have a substantial impact on traffic operations. The level of service analyses should be reviewed to verify that pedestrian volumes and pedestrian signal phasing are properly factored in the analysis. Please address.

Response: The pedestrian volumes at the study intersections do indeed affect level of service and capacity of turning vehicles. Accordingly, pedestrian volumes and pedestrian phasing were properly factored in the capacity analysis. However, it should be noted that the proposed 91st Street MTS is not projected to increase any pedestrian volumes.

In addition there will be a DSNY employee who will monitor pedestrian activity. See Response to Comment #206 for more information on the proposed employee and their responsibilities.

287. **Comment:** Pages 6-108-113, Figures 6.14-13 through 6.14-15: The morning peak hour volume exiting the site is 39 and the entering volume is 45 for a total 84. The entering and exiting volumes for the peak hour are 28 each, for a total of 56. Why is the facility peak hour volume lower than the morning commuter peak hour volume? The text in the last paragraph on page 6-105 indicates that 56 is the peak hourly volume of traffic. Why is the morning commuter peak hour trip generation higher? Moreover, what are the volumes at peak capacity? There is no documentation of how the net trips were calculated for each analysis hour from the 130 daily truck loads reported in Trip Generation, Section 3.16.4. There is no documentation of how the following factors were incorporated in the calculation of hourly volumes: (1) truck volumes should be increased by 50% to obtain Paces; (2) volumes were increased by 20% to account for daily and seasonal variation; (3) There will be 40 trips by employees for each shift change. Please reconcile, and provide assumptions and calculation work sheets.

Response: The facility peak hour is the hour where the highest number of DSNY collection vehicles will arrive at the facility. All 56 trips projected to be generated during

the facility peak hour are trucks. During the a.m. background peak hour, 41 of the 84 projected trips are trucks. The remaining 43 trips are employee automobile trips. To be conservative, employee automobile trips were added to the truck trips during the a.m. background peak hour. Both the a.m. and facility peak hours were analyzed to determine the impact of the proposed East 91st Street Converted MTS at the study intersections.

The calculation of hourly volumes is based on historical data. See Response to Comment #245 for more information on how these hourly volumes were estimated.

As part of the level of service analysis, the truck trips were increased by 50 percent to obtain PCEs (Passenger Car Equivalent).

288. **Comment:** Page 6-116, section 6.14.4.2, paragraph 1, line 3: The proposed mitigation for the York Avenue/ East 91st Street intersection is a one second increase in the green time for the northbound left turn. Could there be an additional increase in northbound left turn green time to restore delay and level of service to the levels for existing conditions without significantly negatively impacting other moves? Delay at that intersection is expected to increase to 97.3 seconds in the Build Condition from the existing delay of 41.6 seconds for a decline in level of service from D to F. Since traffic impacts were studied with an unrealistically low number of net loads based on DSNY-managed waste only, impacts of maximum permitted capacity of 5,280 tpd can only increase the amount of reduction of LOS for the intersections studied. In our analysis significant impacts would have been found at the highest peak hour for permitted capacity. Our projections show two movements that decline from LOS C to LOS D.

Response: The Future No-Build condition is used as a baseline to determine the Build Condition that includes any projected impacts of the Proposed Action. The projected delay for the northbound de-facto left turn is 86.9 seconds per vehicle under the 2006 Future No-build condition during the PM peak hour. Following the 2001 *CEQR Technical Manual* guidelines, the signal timing adjustment described above was proposed to mitigate projected Future Build Conditions back to what they would be if the proposed action were not in place (No-Build Condition).

The proposed East 91st Street Converted MTS is not projected to generate any truck trips during the p.m. peak analysis hour. All projected vehicle trips during this peak hour are employee auto trips.

289. **Comment:** The DEIS traffic analysis is deficient because the traffic impacts to East 96th Street were not evaluated. Trucks leaving the MTS and heading north will significantly add to the existing congestion. The analysis is further flowed in that it deals in average vehicle counts, whereas the reality is that trucks come in groups. The MTS will create a dense clump of garbage trucks queuing at signalized intersections on York Avenue, jockeying for position with school buses. Additionally, congestion on the side streets must be addressed.

Response: There are projected to be seven and 13 trucks leaving the proposed East 91st Street Converted MTS and heading north during the a.m. peak and facility peak hours, respectively. These trucks are projected to proceed northbound on First Avenue at 96th Street. Therefore, the intersections along 96th Street were not selected for level of service analysis because of the relatively small number of trips to be added to the northbound through volumes.

The HCS methodology considers the worst 15 minutes peak within the peak hour analyzed. Thus, the level of service for the peak 15 minute volume (also referred to as peak flow rate) is analyzed and this peak hour factor was incorporated in the level of service analysis for all the turning movements.

290. **Comment:** The DEIS does not address the cumulative impacts of the project on air quality. The results of the off-site analysis imply that only the site-generated traffic was used to evaluate traffic emissions at the off-site intersections. The NAAQS demonstration should be based upon the total traffic volumes at each intersection under Future Build Conditions. This analysis should be conducted for both CO and PM.

Response: For pollutants not currently meeting the NAAQS, an incremental analysis (not cumulative) was performed in accordance with federal air quality impact analysis guidance. The purpose of an incremental analysis in this context is to demonstrate whether the incremental facility impacts would be insignificant, and therefore, by

definition, not worthy of mitigation. Any "significant" incremental impacts, in a NAAQS nonattainment context, would be grounds for requiring mitigation measures. For pollutants that are not in a nonattainment status with respect to NAAQS, a cumulative analysis of total concentrations (existing plus action-related) was performed for the DEIS and this FEIS, in accordance with appropriate guidance. Cumulative analyses, for the "attainment" pollutants, were conducted for both on-site (facility) air quality impacts and for off-site (intersection) air quality impacts.

291. **Comment:** Page 6-120, figure 6.15-1: Insufficient analysis is provided to determine the number of queuing collection vehicles expected at any time, and the real impacts of noise, odor and diesel exhaust. DSNY must address the issue of truck queuing in the neighborhood, and how the City's anti-idling law will be enforced. How will arriving trucks be accommodated, to prevent queuing on York Avenue? During the Public Hearing, it was stated that on-street queuing will not be allowed, without any indication as to how this will be enforced. It was also stated that if necessary, collection vehicles will be diverted to the garage, and a DSNY employee will be stationed at the ramp entrance to ensure pedestrian safety. Diverting trucks elsewhere will increase traffic. What garage will they go to, and what are the environmental impacts of storing waste in the garage? The commercial vehicles won't have a garage to go to, so won't they idle nearby? This management technique must be explained and impacts analyzed. What are the risks to pedestrian safety which require that an employee be stationed at the ramp entrance full time to ameliorate? Will this address significant safety impacts?

Response: The historical peak hour arrival rate assumed in the DEIS and this FEIS, which includes a 20% contingency factor, is significantly higher than the expected peak hour arrival rate, based on current East 91st Street wasteshed volumes. Depending upon the analysis, the DEIS and this FEIS assumes space for up to 19 queuing/moving vehicles on the ramp. The City's idling law only applies if a truck is idling (not moving) for more than 3 minutes. The likelihood of a delay of this duration on the ramp is insignificant. Garages for the collection vehicles serving the CDs in the East 91st Street wasteshed are located at 540 E. 74th St. (CD#5), 606 West 30th St. (CD#6), 423 W. 215th St. (CD#8) and 343 East 99th St. (CD#11). DSNY's operating procedure for many years has been to send

some collection vehicles to the garage with full loads, and then relay those collection vehicles to unload during non-priority times. Commercial vehicles would arrive during the 8:00 p.m. to 8:00 a.m. period, the non-peak period. Based upon the total number of DSNY and Commercial vehicles that are expected at this time, there will be no queue. Please see the response to Comment #206, regarding historical data on accidents at the location of the East 91st Street ramp. A DSNY employee will be stationed at the foot of the ramp as an extra safety measure, and to allay neighborhood concerns about safety.

292. **Comment:** Page 6-129, section 6.16.1, paragraph 1, line: The DEIS does not include the worst-case receptor locations. The locations for sensitive receptors in the odor analysis should be the same as those used in the noise analysis. Page 6-132 five sensate receptor locations are identified that are closer to the site than the one apartment building on 90th Street, east of York. City Zoning Regulations require that odors not be detectable at any point along or beyond lot lines. Please address.

Response: See Responses to Comments #267 and #275 .

293. **Comment:** Page 6-129, table 6.16-1: The information presented here is inconsistent with the number of moving and queuing collection vehicles identified in the air quality analysis (page 6-119). Which is correct?

Response: Both are correct. The noise analysis is an "instantaneous" model that includes the maximum number of collection vehicles that could be present on the ramp within a given hour, with assigned utilization factors to represent the average amount of time over that hour that the collection vehicle would be in that position on the ramp. For the annual average pollutants, the air quality analysis model includes the average number of idling and moving collection vehicles that would travel along the ramp to and from the facility over the period analyzed (i.e. 24-hours).

294. **Comment:** Page 6-131, table 6.16-2: Please provide copies of the modeling assumptions and modeling runs. By DSNY's own numbers, the collection vehicles emit 3.2 OU/sec and 19 are queued on the ramp, yet only 0.31 OU are modeled immediately adjacent to the ramp. Hundreds of comments were made about the odors at the MTS

when it previously operated, but the modeling predicts that odors will not be detected at the site boundary? Additionally, DSNY-owned trucks were measured, not commercial trucks. Address these inconsistencies.

Response: As indicated in the DEIS and this FEIS, technical backup (including air quality model input and output files) are available upon request. With respect to the per truck emission rate of 3.2 odor units (OU) per second, this is a relatively low emission rate, and not likely to be detected unless one is very near the point of emission (e.g., standing on a sidewalk when a garbage truck is at the curb). Once the emissions are dispersed over even a few meters, odor concentrations will drop off very rapidly. A common means of simple estimation of the initial concentration near an object, such as a building or in this case, a truck, is to use a "box model" approach. The projected area on a vertical plane through the object, together with wind speed, can be used to perform a simple box model calculation. For example, assuming a truck is approximately 10 feet high by 27 feet long, this would give a vertical cross-sectional area of 270 square feet (10 x 27). At a very low wind speed of only 1.0 meter/second, each 3.2 odor units/second of emissions would be diluted within a volume of approximately 270 square feet, or 24 cubic meters of air, (24 square meters x 1.0 meters/sec), immediately downwind of the truck. As the plume continues downwind, further horizontal and vertical dispersion due to turbulence would rapidly reduce concentrations even further. The initial "box model" concentration in this case would be only 0.13 odor units. This example demonstrates that, by putting multiple trucks in close proximity, concentrations could approach the 0.31 OU level in the very near vicinity of the trucks, with decreasing concentrations farther downwind.

295. **Comment:** Page 6-142, table 6.17-6, footnote (5): How is it that the closest East 90th Street apartment building is assumed to only be in use during daytime hours? The occupants are noise-sensitive receptors at night, too.

Response: The reference to footnote 5 for the East 90th Street apartment building in Table 6.17-6 is incorrect and is corrected in the FEIS.

296. **Comment:** Page 6-147, section 6.17.3.5, paragraph 3, line 3: The DEIS utilizes noise monitoring data collected during a site-specific DSNY collection vehicle simulation to demonstrate compliance with the CEQR threshold. These data are used to replace the FHWA TMN model which demonstrated values over-predicted the CEQR threshold. The CEQR Manual requires the use of the TNM. Results of this modeling must be provided. FHA's TNM model has the added capability of modeling sound levels accounting for complex terrain and buildings. It is not clear that noise monitoring for vehicle simulations is more valid than the use of TNM. Additionally, the DEIS appears to utilize two different assumptions for calculating the reduction in sound levels due to distance In Section 3.19.5.1, the On-Site Source Screening Analysis uses a -6 dBA drop-off rate, which is typically used for hard ground from point sources. In section 3.19.7.1.1, the CEQR and Part 360 Noise Code Analysis uses a -4.5 dBA drop-off rate. The urban environment is typically hard ground. The mobile source drop-off rate should be revised. Similarly, this difference in drop-off is a conflict in Section 3.19.1.7.2 in the Current Noise Code. Please address.

Response: As indicated in the DEIS and this FEIS, technical backup (including Traffic Noise Model (TNM) input and output files) are available upon request. A noise simulation was conducted for DSNY collection vehicles and illustrates that the Traffic Noise Model (TNM) used in CEQR analyses generally overpredicts the potential for off-site impacts when additional background noise sources are present at the modeled location. CEQR also notes that, while calculated values using the TNM model can be used directly, it is preferable to verify the accuracy of the model for the particular condition being analyzed. Based on these measurements, adjustment factors can be developed to account for site-specific differences between measured and model-predicted values. In consultation with NYCDEP, since noise measurements were obtained during appropriate times at sensitive receptors along routes that DSNY collection vehicles would travel to and from the Converted MTS site, and these measurements take into account actual background noise levels, these noise values were used for the impact assessment. A truck noise simulation letter report that provides information on the noise simulations that were conducted was prepared and is included in Appendix K to the FEIS.

A -6 dBA drop-off rate was used for all on-site sources to generate the 55 dBA contours around the proposed facilities. Since the configuration of the on-site trucks queuing on the ramp more closely represents a line source than individual point sources, the drop off rate for on-site trucks was adjusted to a -4.5 dBA, which is more appropriate and more conservative than a -6 dBA drop-off rate.

297. **Comment:** The DEIS ignores potential impacts of vibration from trucks on the ramp, or the impact of dropping containers in the MTS. The FTA has vibration criteria that can be used to determine potential impacts. A vibration impact analysis must be performed using the sensitive receptors as defined for noise.

Response: Impact or impulsive noise levels are defined by the City Performance Standards as those noise levels that are of short-duration (i.e. two seconds or less in duration as defined under the current proposed NYC Noise Code) and are not required to be included in the noise analysis for compliance with Performance Standards. For the Converted MTSs, based on spectral noise level measurements of container loading operations at a similar type of facility in the City, and operational estimates for container lidding operations within the processing building, these noise levels are considered impact noise levels and not included in the noise analysis for conformance with Performance Standards.

Typical equipment-induced vibration levels at the Converted MTSs are below the threshold of human perception for vibration at a distance of 50 feet. Therefore, equipment-induced vibrations at these facilities are not expected to be perceived as problematic by nearby residents or other vibration-sensitive receptors if they exist nearby a DSNY facility. A summary of the vibration analysis determination is included as Appendix L to this FEIS.

298. **Comment:** Page 6-153, section 6.18.3.2, paragraph 2: The DEIS provides no reasonable justification for DSNY to begin managing commercial waste. This will greatly increase noise in a residential area.

Response: See response to Comment #259.

299. **Comment:** Page 34-1, line 1: The statement "Any impacts that would result at in-City sites (designated in the Proposed Plan) where new construction would likely occur are capable of being mitigated" is refuted by the analysis of noise and odor impacts. Please address.

Response: As stated in this FEIS and presented in the analyses therein, there are no unmitigatible significant adverse environmental impacts, including noise and odor. Therefore, the statement is correct.

300. **Comment:** Page 34-2, paragraph 1, line 3: The statement "Furthermore, by utilizing existing facilities and sites (in heavily industrial areas) the Plan substantially minimizes or eliminates any potential impacts to neighborhood character" does not apply to the East 91st Street site, which is in a densely populated area, and the impact to neighborhood character and open space will be very significant and unmitigatible. Please reconcile.

Response: See response to comment #261, #279, #280 and #299.

301. **Comment:** Page 34-2, paragraph 2, line 4: There is no analysis in the DEIS which supports the statement that "This would reduce the number of trucks from what is currently required to provide waste collection and transfer services" for the wasteshed in Manhattan. Please provide this analysis.

Response: See response to comment #258.

302. **Comment:** Page 34-2, paragraph 2, line 6: The DEIS states that "traffic and air quality conditions on City streets would likely improve overall within the City with the implementation of the Proposed Plan" The DEIS contains no evidence that the East 91st Street MTS would serve to improve traffic and air quality conditions on City streets. Please provide this evidence.

Response: Since the adoption of the 2000 SWMP Plan Modification, approved by NYSDEC in 2001, the City has been committed to a transition from a truck-based system of waste export to a rail-based system. In July of 2002 Mayor Bloomberg reaffirmed the Administration's commitment to this objective. The Draft New SWMP cites several critical factors in support of this objective. See Section 3.3.1 of the Draft New SWMP and Response to #258.

303. **Comment:** No commercial waste company would site a transfer station at East 91st Street due to the potential risks involved, or the congestion in the area. A private firm would be interested in siting a facility where they can quickly get their trucks into and out of a facility, not a highly congested area. Moreover, there is only once access to the street; what would happen if a truck breaks down on the sole access ramp during peak rush hour?

Response: Commercial carters do not service the City's residences. The reliability and cost of service is affected by the proximity of the location where waste is tipped to the centroid of the wasteshed served. For more than 50 years the City's MTSs were important factors in maintaining the efficiency and productivity of DSNY's workforce.

304. **Comment:** The DEIS does not discuss the fact that DSNY will seek a land grant from New York State to enable DSNY to extend the new MTS an additional 40 feet into the East River. There is no discussion in the DEIS regarding the potential impacts to the East River arising from this land grant.

Response: Development of the East 91st Street Converted MTS would require the acquisition of a River Bed Easement or Grant from the New York State Office of General Services (OGS). At the time that the DEIS was published, DSNY was initially looking to pursue an easement, which was discussed within the DEIS. Based upon design consideration which emerged after the DEIS was published, as well as further investigation of obtaining an easement versus a grant, DSNY decided to pursue a River Bed Grant. The description of the proposed grant is included in the new site plan drawing, Figure 2.2.3-4 in Section 2.2.3 of the FEIS. The land grant itself has no impact upon the East River; the impacts of the Converted MTS, inclusive of the area that would encompass the proposed grant, were discussed in relevant sections of the FEIS. Additionally, the OGS was listed as an Interested Agency in the Executive Summary and on page 1-28 of the DEIS.

40.3.2.3.2 West 59th Street MTS

305. **Comment:** One speaker voiced support for the use of the 59th Street MTS by commercial carters during the nighttime hours, but thought that the facility should containerize the waste. The Plan fails to identify clear steps as to how and when the 59th Street MTS will be brought on line for commercial waste. The plan for the usage of this facility should optimize its use and minimize negative impacts.

Response: The West 59th Street MTS site is proposed to be made available for the transfer of commercial waste, either as the facility currently exists or in another form to be determined. Once the details of this proposal have been further defined, a supplemental environmental review would occur. The facility is currently permitted for the transfer of putrescible waste without containers and is utilized for the transfer of waste paper for recycling. As an Alternative to the Proposed Action of sending waste from this facility's historic wasteshed to the Essex County Resource Recovery facility, the DEIS and this FEIS analyzes the impacts from constructing a Converted MTS to containerize waste at this site, using a design similar to that proposed for the four MTS sites in the Proposed Action, that could accept DSNY waste and a certain amount of commercial waste. DSNY will likely issue an RFP to define the specifics of a plan for developing a Commercial Waste export facility at the site of the West 59th Street MTS. DSNY may issue a Request for Expressions of Interest (RFEI) prior to this procurement. Section 4.3.2.1 of the Draft New SWMP provides a summary description of the approach DSNY would take. DSNY will perform a supplemental environmental review once it has a specific proposal for this site. Note that the DEIS and this FEIS evaluates a West 59th Street Converted MTS for use as a long term export facility for DSNY-managed Waste, and includes analysis from the Commercial Waste Management Study concerning potential transfer of some commercial waste as well; however, this Alternative is not part of the Proposed Action in the Draft New SWMP (see Section 3.3). Accordingly, an environmental review of this site as a commercial waste export facility will be required.

306. **Comment:** If the West 59th Street facility is part of the final SWMP, DSNY must work with the State Department of Transportation, Hudson River Park Trust and other appropriate government agencies and community groups to make an access plan that puts the safety of Greenway users ahead of the movement of traffic entering and exiting the transfer station, and create and enforce policies to ensure that the Greenway path is not

blocked by vehicles. The fly-over ramp and tunnel to the transfer station should be carefully studied and analyzed as alternatives.

Response: DSNY will coordinate with involved agencies as the concept for reuse of this site is better defined. In addition, these issues will be assessed in a future environmental review referenced in the response to Comment #305.

307. **Comment:** The Draft Scoping Document identified the zoning in the area north of the West 59th Street MTS as M2-3. The DEIS identifies the zoning as R-10, and shows this on Figure 22.2-3. This area is in fact mapped parkland, which has no zone.

Response: Figure 22.2-3, Zoning, and Section 22.2.1.3.1 have been revised to reflect the extent of mapped parkland.

308. **Comment:** The chapter discussing the existing West 59th Street MTS states that both the south and north sides of the pier are used for barge tie-ups. The water north of the pier is parkland, so any use of this area for tie-up or any other use is an illegal alienation of parkland. In addition, the small boating uses of Riverside Park South Phase IV will conflict with barge tie-up on the north side. Therefore the environmental review for the "no action" alternative must study how the existing West 59th Street MTS will operate legally with only the south side of the pier for barge tie-up.

Response: DSNY is aware of these potential constraints at this MTS and would so inform the potential respondents to the procurement for this site. The Hudson River Park Act allows for continuation of current DSNY operations at this pier. The supplemental environmental review to be performed for the proposed commercial waste transfer use will analyze potential impacts on parkland of the proposal, and further discussions between Hudson River Park Trust and DSNY are expected once the proposal is better defined.

309. **Comment:** Chapter 22.5.3 and Chapter 35 conclude that additional truck traffic to and from the West 59th Street MTS "could potentially worsen the safety conditions on the bike path" and then go on to state that "appropriate measures developed in coordination

with the NYCDPR would likely resolve this conflict." Such measures must be disclosed in the FEIS for public comment and their potential effects analyzed.

Response: See response to Comment #305 and #306.

310. Comment: Any action affecting the West 59th Street MTS or the Gansevoort Peninsula must be determined by the Hudson River Park Trust to be consistent with the Hudson River Park Act or the act amended (Chapter 1.7.2.1). The Existing conditions section of the DEIS should be amended to include mention that the 59th Street Transfer Station is located within the Hudson River Park. It should also acknowledge the fact that the waters surrounding Pier 99 are legally part of the Hudson River Park Estuarine Sanctuary. The supplemental environmental review described on page 4-4 of the DEIS should mention the Act and its restrictions, and describe how any physical or operational changes required to accommodate the new facility would be consistent with the Act. The supplemental review for West 59th Street should include an analysis of any potential expansion of the existing operations at the site, including a description of any increase in traffic or expansion of use in either the surrounding water of the plant area located to the east of the pier. Any new road configurations should be assessed with respect to their possible effects on users of Hudson River Park. The review should also detail the plans created between DSNY and the Department of Parks and Recreation to resolve conflicts and safety issues created on the bikeway by increased trucking. Additionally, the Trust and the NYSDOT should be involved in such planning. Moreover, DSNY should consider the fact that the operational hours identified on page 4-2 of the DEIS of 8:00 a.m. to 8:00 p.m. are the hours during which Hudson River Park and the bikeway are most heavily used. To the extent possible, operations should be planned to avoid or minimize weekend use as well as use during weekday afternoons and early evenings. The DEIS should acknowledge that the entire bulkhead within Hudson River Park including that bordering Pier 99 is eligible for the State and National Registers of Historic Places, and that any construction on it is subject to the terms of a Programmatic Agreement executed by the USACE, the Advisory Council on Historic Preservation, the NYSHPO and the Hudson River Park Trust. The natural resources assessment should analyze any potential changes to the

Hudson River habitat resulting from any expansion of operations or construction at the pier including those related to emissions from tug boats.

Response: Comments noted. The DEIS has been revised and this FEIS indicates that the site is located with the boundaries of the Hudson River Park (see Sections 22.2.1.4, Plans and Policies, and 22.5.1.2, Open Space of this FEIS.) The estuarine sanctuary status is already acknowledged in the DEIS and this FEIS in Section 22.5.1.2. The LPC and SHPO have reviewed the site and concur that there would be no impact to archaeological or architectural resources. However, Section 22.6.1.3, Cultural Resources on the Site, and Section 22.6.2 (Future No-Build Conditions) has been revised to indicate that the bulkhead in the vicinity of the site may be eligible for listing on the State and National Registers. Additional consultation with the SHPO, LPC, and the Hudson River Park Trust may be appropriate as development of this site as a waste export facility proceeds.

311. **Comment:** Given that both the West 59th Street and Gansevoort facilities lie within Hudson River Park, the Trust requests that it be listed as an involved agency, as it must hold hearings and perform other functions.

Response: DSNY agrees that the Trust would be listed as an involved agency in connection with the supplemental environmental review of the proposed commercial waste export facility at the West 59th Street MTS site and the Gansevoort former MTS site proposed for a recyclables acceptance facility.

312. **Comment:** How will the plan finance Hudson River Park's operating costs and capital improvements? No dollar amounts were given. Who would receive the income if commercial contractors utilize the facility at night? The park should be completed with existing funds.

Response: Comment noted. Issues regarding the Hudson River Park will be raised during the negotiations DSNY is conducting with commercial waste industry representatives regarding the proposed use of the site. The development of more definitive plans as to future facility use and cost and financing issues will be better defined in the future.

313. **Comment:** The use of the West 59th Street MTS evaluated by the DEIS is not the use contemplated by the SWMP. While the DEIS found no unmitigatible adverse impacts, that finding is moot because it was evaluated for a different usage. As a commercial waste transfer station it will involve a different type of waste, increase the volume of traffic, require a larger or a non-containerized facility, alter the mix of trucks and hours of operation, decrease the ability of the city to manage facility operation, and continue the use of truck export of residential garbage from Manhattan CDs 1, 2, 3, 4, 7, 9, 10 and 12. The DEIS does not study the impacts of keeping paper recycling at West 59th Street until Gansevoort is available. The risk is too great that by the time a supplemental review is conducted, no meaningful options for the transfer of Manhattan's commercial waste will remain.

Response: Comments noted. As indicated in the response to Comment #305, a supplemental environmental review will be required to evaluate a proposed action to reuse this site for export of Commercial Waste when the procurement processes that DSNY will initiate define what that reuse plan would be.

314. **Comment:** The DEIS should provide information on the impacts caused by a different use at 59th Street, should East 91st Street MTS not get approved, or the Hudson River Park Act does not get amended.

Response: Comment Noted. See responses to Comments #305 and #313.

315. **Comment:** Section 22 of the DEIS does not reflect the current and near-future neighborhood character of the area and needs to be updated. The DEIS must estimate the future impact on the future character of the neighborhood, which is defined by Riverside South, the new Hudson River Park, Riverside Park South, rezoning between Amsterdam Avenue and West End Avenue to permit more than 1,000 new residential units, westward expansion of John Jay College, and other changes. While the area may have been industrial in the past, it will not be in the future, when it will be predominantly residential. The Artkraft Strauss sign factory referred to is in fact vacant and soon to be redeveloped. The Foundry, a residential building at 505 West 54th Street is not listed, and the Nicole at 400 West 55th Street is just outside the half mile radius, but is across the

street from Alvin Ailey. In addition the study zone should be widened to a ¾ mile radius to asses the potential impact of truck traffic. Additionally, in the land use section the document erroneously states that a 197-a Plan is in development for South Hell's Kitchen. No such plan is being developed, although there are massive rezonings in the ULURP process that must be included.

Response: See response to Comments #305 and #313.

316. Comment: Con Ed's use of Pier 98 for fuel transfer operations is cited as a mitigating factor because it will screen the visual impact of the new loading activity at West 59th Street. This statement should be changed since we don't know what the loading activity will look like, and what would happen when the lease for this Pier has expired? It may have a negative impact. The visual impacts need to be studied in greater detail.

Response: See response to Comments #305 and #313.

317. Comment: The DEIS for West 59th Street contemplates not just the continued, but expanded transfer activity at the site. The details of what exactly was shown by the studies undertaken should be shown. It acknowledges that the safety conditions on the bike path could be worsened, but doesn't state how this problem could be corrected. Additionally, in the neighborhood character section, it states that "no destination in the immediate area…would attract anyone but workers" is simply untrue when the immediate area includes two popular parks. The DEIS must be amended to reflect the fact that there will be more trucks and more sanitation activity in a newly populated, greened place. Data is needed on the number of vehicles that are intended to utilize the West 59th Street MTS site. The DEIS should include data on District 7's collection and relay trucks, recycling trucks, and snow operations.

Response: See response to Comments #305 and #313.

318. Comment: Page 22-20 of the DEIS indicates that regional projections indicate that the population of Manhattan CDs 4 and 7 will remain about the same as current conditions. This is incorrect. New developments for the area will substantially increase the

residential population. The DEIS needs to be amended to reflect these new numbers and address the implications of this growth.

Response: The NYMTC population projections (which were calculated by the consortium of metropolitan planning/transportation agencies to account for births, deaths, and in- and out-migration) are referenced in the DEIS and this FEIS to provide a general view of conditions throughout the community boards. The NYMTC-projected total net change for the two Community Districts is an increase of about 3,500 people (about 1.20 percent) between 2003 and 2006. Section 22.3.2.2 has been revised to reflect this information and to refer to the planned developments in the vicinity of the site. The planned developments were considered in all analyses, both as potential sensitive receptors and as potential generators of transit and traffic; no impacts were found to result assuming these planned developments as part of the Future No-Build Condition.

319. Comment: The DEIS for West 59th Street needs to include the following, including the impacts on traffic during the morning rush hour:

- Riverside South mitigations on West End Avenue that have changed the traffic flow from West 59th to West 70th Streets.
- Analyses of the implications of the anticipated connection of Riverside Boulevard and Route 9A at West 59th Street.
- Condition of increased traffic in and around Columbus Circle resulting from the new Time Warner building.
- Use of West 59th Street west of 11th Avenue as a commercial bus layover and a staging area for vehicles that serve the cruise ship lines to the south.
- The potential for vermin and sea gull infestations in the parklands.
- A study of asthma rates in Amsterdam Houses and Amsterdam Addition, and include this development in the EJ Plan
- Add to the secondary study area: Lincoln Square Neighborhood Center, 250 West 65th Street, Mabel Barrett Fitzgerald Day Care Center, and 243 West 64th Street.
- Clinton Cove Park is actually between Piers 94 and 97 and includes development of Pier 97.
- The Future No-Build conditions need to include the Encore Senior Residence at 755-765 10th Avenue, Clinton Green (CURA sites 8 and 9C0, and Flats/Old School at 552 and 554 West 53rd Street.

Response: See response to Comments #305 and #313.

320. **Comment:** Section 22.13.1.2. should analyze the MTS sanitary sewage and stormwater impacts on North River WPCP with data that include the new Hudson Yards rezoning.

Response: The Hudson Yards proposed rezoning is not included in the DEIS or FEIS Future No-Build analysis because it would not take effect until after 2007. Planning and environmental review for the proposed rezoning efforts must consider all existing uses nearby, including the West 59th Street site. See response to Comments #305 and #313.

321. **Comment:** The build years for West 59th Street and Gansevoort will be later than those for the other planned facilities. Therefore, these two facilities must be analyzed with a later build year and should be studied anticipating additions to parkland and residential growth in the areas, particularly given the anticipated rezonings of the far west side that will encourage development at greater densities. The effects on traffic are also likely to be considerably different at this later date.

Response: See response to Comments # 305 and #313.

322. **Comment:** There is concern with noise impacts at these two sites, since many large trucks will be traveling down residential streets at night. The DEIS only considers this to be an impact if the PCEs are doubled. Residents however, will experience an impact at a lower threshold, since one heavy noisy truck bouncing over uneven streets at 3 a.m. will be more of a nuisance than 47 light cars humming by. A noise analysis of off-site noise impacts is therefore required.

Response: See response to Comments #305 and #313.

323. **Comment:** The DEIS appears to contradict itself in recognizing that Pier 99 is between two major park areas, but characterizes the surrounding area as "largely industrial." This is misleading. Table 22.5-1 must include Hudson River Park.

Response: See response to Comments #305 and #313. Existing land uses surrounding the site consist of large transportation, utility and industrial uses (in addition to vacant lots), though much of the vacant area over water is mapped parkland. As noted in Section 22.2, major land uses in the immediate area include the elevated Miller Highway,

the Con Edison generating plant, which comprises an entire block inland, a large parking lot, and the Con Edison operations on Pier 98, which is used for barge delivery of fuel oil. The parkland, as mapped, and adjacent greenway is described within the revised Section 22.5.

324. **Comment:** In developing the design for the West 59th street facility, DSNY should consider design that is not only efficient and environmentally responsible, but one that promotes public interest and involvement.

Response: Comment noted. See response to Comments # 305 and #313.

325. **Comment:** The EIS states that the impacts from dredging will be temporary, but it will probably have to be done repeatedly. How often will dredging be necessary, and what will be the effect on natural resources?

Response: See response to Comments #305 and #313.

326. **Comment:** How will queuing be provided for on site? How will staggering truck arrivals be implemented and enforced with commercial operators? How will the truck routes affect traffic going down 9th Avenue, and how will this problem be addressed? Will enforcement be stepped up, to keep trucks on their designated routes?

Response: See response to Comments #305 and #313.

327. **Comment:** The EIS predicts no change in pedestrian and cyclist conditions. However, the study must consider the increased use of the bikeway/walkway related to the pending completion of the neighborhood parks. Additionally, a Saturday traffic analysis must be completed because pedestrian and cyclist traffic will increase on Saturdays. The analysis should be done to assess the true impacts of the facility on park users and the surrounding community.

Response: See response to Comments #305 and #313.

328. **Comment:** Why are the nearest sensitive receptors for odor at 11th Avenue and 61st Street? Noise, odor must be studied in the park abutting the facility and at the nearest

major development sites. Although the odor methodology is described, nowhere does the EIS state what the assumed odor output would be both with and without partial commercial use, or how those figures were arrived at.

Response: See response to Comments #305 and #313.

329. Comment: Section 22.17.3.6 states that a combined on-site and off-site noise analysis was not required because no sensitive receptor was found. However there was indeed a sensitive receptor found, so it must be performed. Given the odd reference to Figure 4.17.1, perhaps this was a misprint? Is it also an error that the quietest hour is the afternoon rush hour? This seems impossible. How would the analysis be affected if it was repeated during the nighttime?

Response: See response to Comments #305 and #313.

330. Comment: Given the differing odor levels sampled at municipal and commercial waste facilities, a more sensitive odor analysis should be performed for this option rather than assume that both types of waste have the same odor impact. Moreover, the air quality analysis for commercial vehicles cannot assume that they use the same fuel as municipal vehicles, nor that the fleet is of the same age.

Response: See response to Comments #305 and #313.

331. Comment: The traffic analysis for West 59th Street is speculative. None of the details are known concerning where the commercial waste would come from, how it would reach the facility, how much would arrive, and at what times. A worst case analysis should be undertaken.

Response: See response to Comments #305 and #313.

40.3.2.3.3 Gansevoort Recyclables Acceptance Facility

332. Comment: The DEIS identifies only one alternative to the new Manhattan Recyclables acceptance facility at the Gansevoort Peninsula. Other sites should be considered as alternatives, including Pier 76 on the Hudson River. The NYPD tow pound that currently

occupies Pier 76 is scheduled to move to a new facility that received site selection approval by the City Council on January 19, 2005.

Response: In the Draft New SWMP, the Gansevoort Recyclables Acceptance facility is the Proposed Action. Refer to Section 1.4.4 of this FEIS for a discussion of the Alternatives considered to this element of the Proposed Action.

333. **Comment:** Regarding the recycling facility at Pier 52 on the Gansevoort Peninsula, it is vital that if a recycling facility were to be located on this site then the surrounding park area be protected. We believe that DSNY's planning efforts have been a good faith attempt to do this, but the Hudson River Park Act would still have to be amended to permit a recycling facility, and the Trust will need to continue to work closely to successfully address issues related to traffic, natural resources, noise, odors, open space and other environmental concerns. A timetable for design of the facility must be developed as well as for the environmental review for the site.

Response: As noted in Section 2.3.2.2 of the DEIS and this FEIS, NYCEDC is in the process of developing a design for this facility. As the design is developed, it will be reviewed with the Hudson River Park Trust and Manhattan Community Board #2. When NYCEDC is prepared to move forward with the project, the design and operation of this facility will be subject to environmental review. The environmental review will necessarily define the proposed construction and operation of the facility, including the type and source of materials proposed to be accepted and the assumed number of trucks that would deliver materials to the facility; determine the range and permits and approvals required to be obtained; and perform analyses required to determine whether there are potential significant adverse impacts related to traffic, natural resources, noise, odors, open space and other environmental concerns.

334. **Comment:** A number of people commented that the proposed recyclables acceptance facility at the Gansevoort Peninsula will create noise and odor impacts within the park from a potential 190 truck trips each day. The trucks will create a safety hazard to joggers, cyclists and skaters and create traffic flow problems. Odors will be a problem with park users because the materials will be uncontainerized within the barges, and

would be aggravated by the tugboats burning the most polluting diesel fuel. The strong winds will also carry the odors of waste into the West Village and the new Gansevoort Market Historic District, which is a thriving cultural and commercial center.

Response: See response to Comment #333.

335. Comment: The City has not been open about the number of trucks that will be using the Gansevoort facility. It will include materials not only from residents, but from City, state and federal agencies, and the amount of material will continue to grow. Even more waste will be delivered if commercial recyclables are delivered to the site.

Response: See response to Comment #333.

336. Comment: It has been indicated that the recycling transfer station would be of educational value, but it is unclear what the learning value would actually be. Materials won't be separated and processed at the site.

Response: The scope of the recycling educational activities planned for this site would be substantially broader than the transfer of Recyclables going on within the building.

337. Comment: The City should explore moving the recyclables facility away from one of the few green space sections of Hudson River Park or use more than one site for recyclable materials so that not all of the burden would be placed on Gansevoort.

Response: See response to Comments #332 and #333.

338. Comment: The "Waterfront Revitalization Program" identifies several sub-policies as inapplicable, which is incorrect. Sub-policy 8.1: "Preserve, protect and maintain existing physical, visual and recreational access to the waterfront" has a response "access would not be compatible with the principal use of the site, therefore this sub-policy is not applicable." Public use certainly could be compatible with the use of the site (see public access proposed for Pier 52 facility). Sub-policy 9.1: "Protect scenic values associated with natural resources" has a response that the facility would pose no impact to scenic values associated with natural resources. It would have a very real impact to the views of the Hudson River.

Response: Once a facility design and its relationship to barges, bikeways, the esplanade and street access are defined and proposed by NYCEDC, it will be the subject of discussions with the Trust and other interested parties and an environmental review will be conducted on the proposed facility to evaluate and disclose potential impacts to scenic values and other natural resources issues articulated in the policies of the Waterfront Revitalization Program. See response to Comments #332 and #333.

339. Comment: What other sites were examined for a Manhattan acceptance facility for recyclables? The DEIS needs to study other locations for such a facility, including Pier 76. A single site for transferring recyclables in each borough would produce excessive mileage, waste fuel and create pollution. The City could save considerable mileage by using three or four simple well-placed rail transfer sidings in each borough, which would have the added advantage of providing connections for exporting recyclables to a broader range of markets.

Response: The recyclable materials collected require processing before they can be marketed. The Hugo Neu facility in Brooklyn is proposed to process and market this material. It is accessible by barge or truck, not rail. The proposed Gansevoort site and Manhattan alternatives considered were evaluated as facilities that would accept materials that have been collected by truck and transfer them for barge transport to Hugo Neu. See response to Comment #332.

340. Comment: NYCEDC has not presented any concrete proposal for financially supporting the Hudson River Park development, so it is unclear what benefit the SWMP has to the park or the community, especially given that DSNY has stated that accommodating the recycling facility would not accelerate the removal of DSNY uses on the pier, hence accelerating park construction.

Response: Concrete economic proposals are not typically addressed in the environmental review of proposed facilities; no proposal is available. Decreased truck congestion and a point of destination for Hudson River Park visitors interested to take in the exhibits in the

recycling education center that is central to this proposal are among the general benefits that would accrue from this project. See response to Comments #332 and #333.

341. **Comment:** The text throughout the document refers to a future environmental review of the facility at Gansevoort, yet the footnote states that a full environmental review will not be conducted. A waste management facility in the middle or parkland is likely to have environmental impacts, so this must be analyzed, especially the effect of trucks on users of the park and bikeway/walkway. The Peninsula will be developed entirely as parkland with no industrial uses on it, and this must be acknowledged in the EIS.
Response: See responses to Comments #332, #333 and #338.

342. **Comment:** Noise analyses were only done on Route 9A and West 14th Streets between Washington Street and Route 9A. These analyses must be done farther east on the residential streets most likely to be affected by the truck traffic.
Response: See responses to Comments #332 and #333.

343. **Comment:** There are a number of errors with the figures for the Gansevoort facility. The plan needs to be corrected to show the bikeway and esplanade and the existing highway curve, which would make adding an exit lane for trucks to leave the highway impossible. There are a number of issues with the current plan that would dramatically affect traffic flows, accessibility to the facility, and create hazards to park users. How many trucks per hour were anticipated with the two-lane ramps shown on the figure?
Response: See responses to Comments #332, #333 and #338.

344. **Comment:** What are the specific details for the Gansevoort facility? What is the layout and footprint of the facility? How much space will be taken up by the barges? Will the barges be smaller than the ones are the MTSs? Will there always be 2 barges on site?
Response: See responses to Comments #332, #333 and #338.

40.3.2.4 Queens

40.3.2.4.1 North Shore Converted MTS

345. **Comment:** Community District 7 already has a number of borough-wide Sanitation facilities, such as the MTS and the garage for another CD's Sanitation vehicles. Placing all of these facilities in this CD must end.

Response: DSNY has been working with the Department of City Administrative Services and the Office of the Queens Borough President to relocate the existing CD 11 garage that is currently located in CD 7. To date, no site has been found that is appropriate for a garage. DSNY is continuing to search and will seriously examine any sites that are proposed or become available.

346. **Comment:** The MTS is sited right across from LaGuardia Airport, and there are concerns about what height the Port Authority will allow. If the height of the MTS will have an impact on the airport, it must be redesigned.

Response: DSNY is currently working with the Federal Aviation Administration and will work with the Port Authority of New York and New Jersey to define and resolve issues associated with the height of the Converted MTS. DSNY has submitted Form 7460-1 to the Federal Aviation Administration (FAA) and the FAA has issued a "Determination of Presumed Hazard."

DSNY's design team has been in consultation with aviation industry experts who have reviewed the FAA's initial determination and believe that our proposed building does not pose a significant impact on airport operations and that ultimately we will receive a favorable ruling from the FAA on this. Consequently, DSNY will coordinate these activities with the Port Authority of New York and New Jersey.

347. **Comment:** Since the MTS was last open, the Whitestone/College Point area has changed drastically. There is much more traffic. There are changes being made to the Whitestone Expressway and to the Grand Central exit at Linden Place, and there is increased traffic at 20th Avenue. At times, that exit is backed up almost to the Linden Place exit. On Friday nights the traffic is still heavy because of traffic generated by the movie theater. The MTS may bring 10 to 15 DSNY trucks at the peak hour, and serious

problems will result at Linden Place. There are only so many trucks that can make a left under the expressway and make another left onto the service road to get to 31st Avenue. People sit at this intersection sometimes for 2 to 3 light changes. The situation needs to improve, not get worse. This will create a total standstill at this intersection, block traffic through the Corporate Park, and affect DSNY's schedule. An alternative route should be considered.

Response: When work on the DEIS began, the New York City Department of Transportation (NYCDOT) was consulted to determine if there were any known problem areas from a traffic standpoint in the vicinity of the North Shore Converted MTS. NYCDOT indicated there were existing congestion problems at Linden Place and requested an alternate route be found for DSNY collection vehicles. DSNY altered routes for five of six CDs that were originally routed through the intersection of the Whitestone Expressway Service Roads and Linden Place. Only Queens CD 9 will continue to be routed through this intersection. CD 9 is not expected to generate more than four truck trips to the North Shore Converted MTS in any given hour.

348. **Comment:** College Point Boulevard should be avoided as a DSNY truck route. The Department of City Planning has pinpointed portions of it as part of the expansion of downtown Flushing. Any DSNY trucks on College Point Boulevard in downtown Flushing will be detrimental to the development of the area and hazardous to pedestrians

Response: College Point Boulevard is a NYCDOT designated truck route that provides access to and from both the Long Island Expressway and Van Wyck Expressway, both of which are vital to the collection network for DSNY in this area. In order to avoid existing congestion identified at the Linden Place exit and its surrounding area, DSNY must route collection vehicles along College Point Boulevard in order to access the major expressways in the area. The traffic analysis indicated that the North Shore Converted MTS would cause no significant adverse impacts at intersections along College Point Boulevard between the MTS and entrances to the two major expressways.

349. **Comment:** Please review current traffic studies because the area has changed quite a bit in recent years. 20th Avenue will be widened, and Linden Place will be next. DOT is

considering computerized signals at all College Point Corporate Park arterials. There is a lot of traffic, including CD 11's sanitation trucks traveling through Northern Boulevard.

Response: CEQR guidelines state that traffic data used for traffic analysis must be collected within the past three years. Existing traffic counts were performed at study intersections in November of 2002. Additionally, study intersections did not include intersections at Linden Place because these locations screened out of further analysis due to low volumes of project related traffic flowing through these areas. 20th Avenue is not expected to be used as a major route for DSNY collection vehicles to access the North Shore Converted MTS.

350. Comment: Will the truck routes for the Converted MTS be the same as they were when the MTS was previously open?

Response: DSNY collection vehicle routes to and from the Converted MTS will generally be the same as when the MTS was previously operated except for the route changes noted in the response to #347 above. Generally, collection vehicles will make their way to major expressways along local truck routes in their local collection districts to travel towards the North Shore Converted MTS. Once near the Converted MTS, the collection vehicles will exit the expressways and use local truck routes to make their way to the Converted MTS. Collection vehicles will follow a return path to their respective CDs similar to the ones use to access the MTS.

351. Comment: Southeast Queens hosts a cluster of land-based commercial waste transfer stations located adjacent to residences. The DEIS did not assess these transfer stations, nor any other proposed commercial waste facilities and initiatives. To the extent that the CWMS was used to assess the existing stations, the assessment is flawed since the CWMS analyzed theoretical stations instead of real ones. The trucks used to haul waste, which is not generated locally, to these commercial transfer stations, creates adverse impacts that were not assessed or mitigated in the CWMS or DEIS.

Response: Although an assessment of transfer stations in Queens CD 12 was done as part of the CWMS, none of these facilities are part of the Proposed Action for Long Term Export and, therefore, were not re-evaluated in the DEIS and this FEIS. However,

subsequent to the issuance of the CWMS, DSNY proposed major revisions in its Rules governing transfer station operation that require design and operational modifications to reduce odors and emissions, as well as improve control of stormwater runoff.

40.3.2.4.2 Greenpoint Review Avenue

352. **Comment:** A number of comments state that the neighborhood is a great place to live, but traffic problems are a major concern in the area. The streets are overwhelmed by cars and trucks and are more crowded than they have ever been. Please closely analyze the effects of more car and truck traffic before enacting the final plan. Truck traffic on 48th Street, which Sanitation and other waste vehicles use, is a particular problem at night. 43rd Street, 48th Street, 39th Street and Review Avenue cannot handle any additional traffic. The three transfer stations in such close proximity to one another (Review Ave, 485 Scott and 72 Scott Ave.) have created a major truck traffic problem.
Response: Five of the six Queens CDs that would be assigned to the Review Avenue Transfer Station under the Draft New SWMP are currently making deliveries to this facility under Interim Export contracts. Under the Draft New SWMP, this facility would export all waste received by barge or rail, including any commercial waste received. Export by rail would involve draying waste by truck in sealed containers from the facility to the Maspeth rail yard.

In addition to this initiative, the Draft New SWMP notes that the majority (68%) of the Commercial Waste transfer stations in the City are located in areas zoned for the heaviest industry (M3 zones) and therefore well buffered from any conforming residential use. However, trucks traveling to and from the transfer stations use designated truck routes that pass through residential areas. Metropolitan Avenue in Greenpoint, Brooklyn is an example of such a thoroughfare.

The CWMS (Appendix I) analyzed 58 key intersections in areas leading up to transfer stations and determined that the percentage of waste hauling vehicles was no more than 7% of the total number of vehicles traveling through any of the intersections. While the

number of waste hauling trucks is technically small in comparison with all vehicles, DSNY will work with the New York City Department of Transportation (NYCDOT) to conduct a traffic analysis to study the feasibility of redirecting truck routes leading to transfer stations with the objective of minimizing traffic-related impacts in residential areas to the extent possible. Based on the data gathered in the CWMS (Appendix I), DSNY will select potentially sensitive truck routes. Community advisory committees will then be formed in each of the respective areas identified. These groups will review and approve the truck routes selected or recommend others to be analyzed. The community advisory committees will also review the methodology employed by the analysis and evaluate the alternative routes to ensure that the redistribution of truck routes is equitable. DSNY will also work with the City Council and industry representatives to formulate this study.

353. **Comment:** There will be too many waste vehicles coming from many districts, traveling down Review Avenue and causing traffic jams. There are children and schools on Grand Avenue, an MTA project, and now with a rail station, it will create too much havoc. The traffic is excessive and the trucks always queue, resulting in odor and noise impacts. We urge DSNY to transport waste by rail.

Response: The use of the Review Avenue Transfer Station as either a truck-to-barge or truck-to-rail transfer station for export of DSNY-managed Waste at a capacity of 1,200 tpd was evaluated in the 2000 SWMP FEIS and found to have no potentially significant unmitigatible adverse impacts. The proposed on-site transfer operations at this facility are the same in the Draft New SWMP as previously proposed and, therefore, no further analysis of on-site impacts is required. However, rail export would entail draying (trucking) containers between the facility and the Maspeth Rail Yard on Rust Street. This transport option was not considered in the 2000 FEIS and is evaluated in the DEIS and this FEIS. The analysis showed no potentially significant unmitigatable adverse impacts. Also, see Response to Comment #352.

354. **Comment:** Several people were concerned with the waterfront area, recapturing wasted industrial land along the waterfront and revitalizing it so that in the future it can become a

recreational area for the neighborhood. The barges conveying waste may adversely affect this revitalization effort. We are concerned that Newtown Creek may become further degraded, and that growth for new development will be hindered.

Response: The Review Avenue Facility is currently an active transfer station located within the Newtown Creek Significant Maritime Industrial Area (SMIA). The goal of the SMIA is to protect and facilitate working waterfront uses and to accommodate future growth of these uses, including water-dependent activities. The existing facility and the proposed future use of barge operations with sealed containers at this site are consistent with the SMIA goals. The continued operation of this facility would not preclude future development at other locations along the waterfront.

355. Comment: Long Island City has one of the worst air pollution problems in the City according to data from the new air monitors. All of the truck emissions have caused this area to be called "asthma alley." This will be exacerbated by all of the traffic resulting from the Plan. Currently, trucks don't stay on the truck routes due to the traffic jams and go onto undesignated routes. The Cross Harbor Tunnel project will result in thousands of trucks entering and leaving the area every day. What assurances will be made that trucks will stay on designated routes and not invade residential neighborhoods?

Response: DSNY workers have standing orders to follow certain routes to their destinations, which include, as required by NYCDOT Title 34 regulations, following NYCDOT designated truck routes until they must exit that route to directly access a facility or a collection route. If DSNY workers violate these route requirements, they are subject to discipline. DSNY's Permit and Inspection Unit would continue to be responsible for policing private carters in addition to concurrent NYPD efforts to enforce truck route restrictions.

356. Comment: The streets are not designed to handle the heavy traffic flows, and this frequently results in the rupture of underground pipes, which the homeowner is then

responsible for. The City needs to address these problems, before moving forward with selected facilities.

Response: The streets are designed in accordance with NYCDOT specifications, which take into account the expected usage. Also, see Response to Comment #355.

357. Comment: There is a serious concern with the possible plan for a truck-to truck-to-rail transfer plan. Under the plan, the LIRR tracks along Rust Street at and adjacent to Maspeth Avenue would be a location where trucks would load containers onto rail cars for export. This would mean even more trucks going into and out of the congested West Maspeth Industrial Area. The congestion and air pollution will be serious, and must be evaluated in the EIS.

Response: As noted in the Response to Comment #353, the traffic, air quality and noise impacts of draying containers from the Review Avenue Transfer Station to the Maspeth Rail Yard were evaluated in the DEIS and this FEIS and found to have no potentially significant adverse impacts.

358. Comment: The following issues require study within the EIS: spill mitigation plans at Newtown Creek, waterfront traffic as it may affect the planned Greenpoint/Williamsburg waterfront sports facility, and water traffic as it affects the proposed 2012 Olympic venues.

Response: The Williamsburg waterfront sports facilities proposed as part of the 2012 Olympics plan are not included in the DEIS and this FEIS Future No-Build analysis because they would not be operational by 2007. Planning and environmental review for these proposed waterfront sports venues (including associated water traffic) must consider all existing uses nearby, including the Review Avenue Transfer Station.

Solid waste transfer stations must have a Part 360 permit from the New York State Department of Environmental Conservation (NYSDEC). As part of these permits, the general operations of the facility are discussed in detail, including the handling of spills. Therefore, spill mitigation is part of the operation of the facility not the environmental review process.

359. **Comment:** The SWMP mentions that a new off-site intermodal railyard may be required for the Review Avenue Transfer Station, but there are no details on this facility or what its impact would be. Please provide these details.

Response: The railyard in question is not new; Maspeth Rail Yard on Rust Street exists and no permitting actions are required for its proposed use as an intermodal transfer point for truck to rail transfer of containerized waste drayed from the Review Avenue Transfer Station. The Maspeth Rail Yard site is described in Chapter 2, Section 2.2.12.4, of the DEIS and this FEIS. Chapter 15 of the DEIS and this FEIS, summarizing the results of the environmental review, reports that there were no potentially significant adverse impacts associated with the use of the Maspeth Rail Yard.

40.3.2.5 Staten Island

360. **Comment:** Since the Staten Island transfer station will be the first long-term export facility on line, there is a concern that it accepts only Staten Island waste. Any permit, even if under the name of a private entity, should state that it may only receive Staten Island waste.

Response: The Part 360 permit for DSNY's Staten Island Transfer Station does state that only DSNY-managed Waste from Richmond County can be accepted at this facility. A private vendor would operate under the same permit conditions.

361. **Comment:** We would like the trucks to use the streets of Travis to get back to their destination after using the transfer station instead of narrow Victory Boulevard, and to utilize internal roads within the landfill to access the garage. Highways should be used instead of local roads wherever feasible.

Response: The 2000 FEIS for the 2000 SWMP Modification evaluated the traffic impacts of waste hauling vehicles entering and leaving DSNY's Staten Island Transfer Station and found no potentially significant adverse impacts would result. Notwithstanding, DSNY continues to agree that DSNY collection vehicles entering and leaving the facility will use internal landfill roads and Route 440 where feasible.

362. **Comment:** What is the status of the rail line, and when will Staten Island waste be hauled out by rail?

Response: The Port Authority of New York and New Jersey has awarded a contract for the Chemical Coast connector, and construction is anticipated to be complete in early 2006. The NYCEDC is responsible for the construction of the Travis Branch Extension that will interconnect the rail line with the facility. NYCEDC's current schedule calls for completion of construction in 2006.

363. **Comment:** It would be a mistake for a private entity to operate the Staten Island Transfer Station. The facility should be operated by the City.

Response: Operation of the facility by DSNY personnel is under consideration but a final decision has not been made.

364. **Comment:** The Staten Island transfer station should accommodate state-of-the-art composting tunnels or other high tech options for processing waste.

Response: The transfer station will containerize waste for transfer to rail using well accepted technology. A summary of DSNY's recent evaluation of alternative processing and waste conversion technology for the City can be found in the Draft New SWMP and in other DSNY composting reports located on the DSNY Web site. A DSNY facility for composting yard waste is adjacent to the Staten Island Transfer Station.

40.3.3 Involved Agency Comments

40.3.3.1 NYSDEC Comments on the DEIS For the New York City Comprehensive SWMP

These comments are provided consistent with the notice, DEIS Hearing and Extension of Comment Period, dated November 16, 2004. The comments are specific to NYSDEC regulatory authority and are intended to provide clarity in the assessment of various environmental impacts that may result from the Proposed Action.

40.3.3.1.1 General

1. **Comment:** The DEIS relies heavily on studies and reports prepared earlier that are not significantly summarized, including documents such as the Commercial Waste Study, Manhattan Transfer Siting Report, as well as the 2001 CEQR Technical Manual (see references on page 11 of the final scoping document and throughout the DEIS text). The reference to documents generated outside of the DEIS provides some difficulty in reviewing the appropriate sections for adequacy.

Response: Note that Appendix E of the Draft New SWMP, which the DEIS was prepared to support, includes the entire Commercial Waste Management Study (CWMS) as an appendix in compact disk format. That appendix includes an executive summary of each volume of the study, including the one referenced above. A copy of the CWMS Executive Summary in compact disk format is also included in Appendix I of this FEIS.

2. **Comment:** The DEIS provides reference to and cursory information on the use of private transfer stations for the management of residential waste in boroughs where there is not a converted marine transfer station. The discussion regarding the potential impacts for the use of these facilities is underdeveloped. The DEIS relies heavily on previous and future decisions by the DEC as part of the environmental review of permit applications. The DEIS should fully discuss any likely impacts that result from use of commercial waste management facilities.

Response: Five private transfer stations located in the Bronx, Queens and Brooklyn are designated in the Draft New SWMP as potential long-term export facilities. Four of these are existing facilities currently being used by DSNY for Interim Export. The fifth, Scott-Meserole, which is now the site of several contiguous facilities, would require substantial modification, so was subject to detailed environmental review in the DEIS and this FEIS.

For the four remaining facilities, the DEIS and this FEIS evaluated the potential for significant adverse impacts associated with any proposed expansion or other potentially significant physical modifications to each facility or its operation. These analyses

considered the incremental effects associated with the proposed change and is consistent with CEQR requirements. These evaluations included the following:

- For Review Avenue in Queens (with a proposed expansion of existing permitted capacity of 242 tpd (from 958 tpd to 1200 tpd), the off-site traffic, air quality and noise impacts, as applicable, associated with processing the potential maximum increment of DSNY-managed Waste during Long Term Export for Queens Community Districts 1 through 6 above the average peak daily tons delivered during current Interim Export operations, and the draying of waste containers from the facility to the Maspeth Railyard;

- For Harlem River Yard in the Bronx (permitted for processing 4,000 tpd), the traffic impacts associated with processing potential maximum increment of DSNY-managed Waste during Long Term Export above the average peak daily tons delivered during current Interim Export operations;

- For East 132nd Street in the Bronx (permitted for processing 2,999 tpd), the draying of waste containers from the facility to the Maspeth Railyard at a volume equivalent to the facility's maximum processing capacity and the traffic impacts associated with processing potential maximum increment of DSNY-managed Waste during Long Term Export above the average peak daily tons delivered during current Interim Export operations; and

- For 485 Scott Avenue in Brooklyn, no incremental changes were evaluated, because (i) the volume of DSNY collection vehicle traffic is consistent with levels handled in Interim Export Operations and (ii) the barge-out option was evaluated in the 2000 SWMP FEIS.

Agency review of applications that may be submitted for permit modifications may result in a determination that additional environmental review is required.

3. **Comment:** The DEIS should consider the likely consequences and probable impacts that develop from the use of the existing 59th Street Marine Transfer Station (MTS) and the use of the converted MTS during non peaking hours.

Response: At the present time there is no specific proposal in hand that would be the basis for such an evaluation. As indicated in the Draft New SWMP, DSNY intends to undertake a process of information gathering that would then proceed to a procurement of proposals for using this site for the export of commercial waste. When a decision is made to select a proposal for development of this site for commercial waste, an environmental review will be initiated.

4. **Comment:** The DEIS should discuss the impacts of NYC municipal garbage containing significant quantities of household hazardous waste and its potential impacts on remote landfills and emissions at Waste to Energy (WTE) plants.

Response: Based on the Waste Composition Sorting Program that is now in progress, DSNY does not have any evidence that household hazardous waste (HHW) is present at detectable levels in its Waste picked up at curbside and in Waste that has been containerized. In addition, DSNY plans to release a Request for Proposals (RFP) for a Household Hazardous/Special Waste Collection Program Vendor. Finally, unless specifically permitted otherwise, applicable regulations for remote disposal locations that receive DSNY-managed Waste (i.e., landfills, waste-to-energy facilities) prohibit the acceptance of hazardous wastes. Those disposal facilities are required to have plans in place for screening and managing the receipt of waste and for removal of any inadvertently accepted hazardous waste.

5. **Comment:** NYC proposes a solid waste management plan totally dependant on out-of-city facilities. Absent from the discussion is detailed analysis of potential impacts resulting from unanticipated facility closures and transportation problems.

Response: The DEIS and this FEIS is a review of the Draft New SWMP. The type of information referenced in this comment is available in the Part 360 Solid Waste Facility Permit Applications that have been filed with NYSDEC. Based on comments from NYSDEC during review of these applications, it is DSNY's understanding that the Contingency Plans, as submitted and revised, and other relevant information on this issue comply with NYSDEC regulations. In addition, at NYSDEC's request DSNY has prepared a Transfer Transport and Disposal Plan (TTDP) incorporated as Appendix I to the Part 360 Permit Applications. The TTDP provides a more complete description of how the contracts that DSNY is in the process of negotiating for intermodal transfer, barge and/or rail transport and disposal will provide the resources and assurances to address these types of contingencies with specific reference to terminal and rail facilities with available capacity to serve DSNY's needs. The TTDP is included in the FEIS as Section 40.3.5, of this chapter.

6. **Comment:** The DEIS Plan fails to explore any in-city disposal alternatives including WTE, yet disposal at three out of City WTE plants is proposed. The discussion should explain why no in-City disposal alternatives are presented and why the City continues transporting waste to out-of-City WTE facilities, while not considering WTE plant construction within its borders.

Response: Please refer to the response to comment #7 in Section 40.3.1.2, Alternatives Analysis, that discusses Alternatives considered during Plan development. Also refer to Section 1.3 of this FEIS for more information on the scope of Alternatives considered.

7. **Comment:** The DEIS omits traffic, noise, and air pollution impacts along out of city waste routes.

Response: The Converted MTSs will reduce the number of outbound out-of-City transfer trailer trips that occur, thus reducing this mode of transport on out-of-City truck routes. The out-of-City routes that will serve the Converted MTSs and that will be used to transport waste by rail or barge are existing routes, are located outside of New York State, and can be used for the purpose of moving freight (containerized waste) in compliance with applicable law. Any significant modifications to these routes by their owners/operators would be subject to environmental review in accordance with the laws and regulations applicable to the host jurisdictions, except where federal law preempts local and state jurisdiction, as is the case with railroads. Accordingly, there is no requirement in SEQRA or CEQR to evaluate impacts associated with the use of this existing out-of-state infrastructure.

8. **Comment:** Provide an analysis of waste route construction impacts, both in-city and out of city.

Response: The in-City routes that will be used to support waste transport are the harbor or active rail freight lines. Any in-City construction that is required will be addressed in permit applications where necessary, including any requirements for supplemental environmental review. See Response to Comment #7 regarding out-of-City routes.

9. **Comment:** The DEIS omits significant discussion on the disposal of large amounts of

dredge waste. Details of dredge disposal and a list of destination facilities for this material should be included in the discussion.

Response: The Joint Application for Article 15/25 Permits for the Converted MTSs that was submitted to NYSDEC addresses this matter. No environmental review in the DEIS or FEIS for the Draft New SWMP is required. If NYSDEC deems that the management of dredge spoils, as described in the permit application, requires additional review, a supplemental environmental review will be prepared.

10. **Comment:** The DEIS emphasizes sorting and pro-manufacturing activity without any discussion of possible in-city reuse or manufacturing alternatives. The discussion should include why the City has been unable to attract additional recycled content goods manufacturers and any probable impacts.

Response: The Visy Plant on Staten Island, which has been in operation since 1997, is the result of a major City-State development program to create a manufacturing facility within the City to process recycled paper from the City Curbside Program into finished product. Currently, Visy Paper receives and processes approximately 180,000 tons per year of DSNY's recycled paper. The Draft New SWMP provides an extensive discussion of the Proposed Action for recycling—the development of a Materials Processing Facility at the South Brooklyn Marine Terminal that will process the MGP collected by the Curbside Program. Among the reasons mentioned for developing this facility is the potential to increase the net recovery rate for materials collected by the Curbside Program and to improve the beneficiation of these MGP materials. If this potential is realized, it could also stimulate the growth of reuse industries within the City that would rely of this supply of beneficiated materials.

11. **Comment:** Section 1-2 Purpose and Need - Page 1-3: The last sentence states "These Existing Programs and New Initiatives approved pursuant to the Existing SWMP are therefore not part of the Proposed Action that is subject to environmental review in this DEIS." What specific existing programs and new initiatives are being referred to? If the statement is referring to biosolids, medical waste, dredge spoils and Fresh Kills construction and closure, please provide an updated reference for discussion of these issues.

Response: The definition of the terms, Existing Programs and New Initiatives, appears on page 1-2 of the Draft New SWMP. Page 1-3 lists twelve Attachments to the Draft New SWMP with brief descriptions of the information contained in Attachments V, VI, VII, IX and X where these Existing Programs and New Initiatives are described.

12. **Comment:** Section 2.1.2 General Information, Plan Policies and Key Assumptions - Proposed Plan Long Term Export Facilities - Page 2-6: Please clarify *who* were the independent utilities that approved the environmental reviews for the demolition. Also, please describe the environmental remedial program for each of the individual MTS facilities such as page 3-23 for Southwest Brooklyn.

Response: "Independent utility" is a term used in environmental law review to indicate that a proposed action has value in and of itself and does not commit the decision-maker to a course of other actions Therefore, environmental review of the individual action as part of a larger action is not necessary or necessarily appropriate. This finding, pertaining to the demolition of the Greenpoint and Hamilton Avenue incinerators, was made by the DSNY in connection with the proposed demolition project.

13. **Comment:** All solid waste facilities must be designed to be in compliance with the requirements of Part 360-1.7(a)(2)(ii), which prohibits siting on flood plains unless specific provisions are made as explained therein. Please correct throughout the document.

Response: As documented in the Part 360 Permit Applications and the Joint Application for the Article 15/25 Permits for the Converted MTSs submitted to NYSDEC, these facilities are designed in compliance with Part 360-1.7(a)(2)(ii) by incorporating "provisions…to prevent the encroachment of flood waters upon those facilities." The Converted MTSs are designed to elevate the pier level of the over-water facilities, which is the lowest level where waste processing occurs, six inches above the level of the 100-year flood plain. The upland Converted MTSs are also designed so that the bulkhead or pier level is above the 100-year flood plain

40.3.3.1.2 Rail/Barge Issues

14. **Comment:** The DEIS discussion relies primarily on barge transport with a lesser

emphasis on rail. Inherent in a barge system is the loss of waterfront access; however, rail provides greater flexibility and would require improvements that may attract other industry and possibly trigger additional upgrades to the rail system. Provide an analysis exploring whether the City would be better served by either a barge /or rail-focused system. The DEIS should provide a comparison of the negative environmental impact of the additional rail/barge traffic versus the reduction of vehicle traffic.

Response: The four Converted MTSs that are elements of the Proposed Action for Long Term Export have no rail access and are designed to load barges with containerized waste that will then be transported to intermodal terminals in the New York harbor region. As described in the TTDP (see response to Comment #5, above), the available terminal facilities in the New York Harbor region provide options for both barge or rail transport to disposal destinations.

Four of the five private transfer stations in the Bronx, Queens and Brooklyn that are designated in the Draft New SWMP have rail access, either on-site (Harlem River Yard in the Bronx and Scott-Scholes Street in Brooklyn) or by draying containers to rail yards in the project service area. The traffic and off-site air quality impacts of draying containers to the railyards that would serve the East 132nd Street facility in the Bronx and the Review Avenue facility in Queens have been evaluated in the DEIS and this FEIS and found to have no potentially significant unmitigatable adverse impacts. Scott Avenue in Brooklyn is an existing facility that would transport containers by barge and would use the same terminal facilities that are available to the Converted MTSs.

The point of the Proposed waste management system as advanced in the Draft New SWMP is to provide the City with the flexibility to use both barge and rail while, at the same time, balancing other important considerations so that the Proposed waste management system in the Draft New SWMP is both equitable and efficient.

Since the adoption of the 2000 Plan Modification, which was approved by NYSDEC, the City has been committed to a transition from a truck-based system of waste export to a rail-based system. In July of 2000 Mayor Bloomberg reaffirmed the Administration's

commitment to this objective. The Draft New SWMP cites several critical factors in support of this objective. See Section 3.3.1 of the Draft New SWMP. Finally the Proposed Action is comprised of a set of discrete facilities without overlapping impacts and therefore no cumulative analysis of impacts is required.

15. **Comment:** The DEIS should incorporate a discussion regarding the feasibility and need of improving the rail infrastructure in NYC and along potential out-of-City waste routes, and include an analysis of the additional track and yard capacity that may be required.

Response: The Final Scoping Document for the DEIS, which was developed in consultation with NYSDEC, clearly states that the one objective of the Draft New SWMP is to develop a Long Term Export program. If the City's rail infrastructure is improved incidental to accomplishing that objective (as may be the case), that is a benefit of implementing the SWMP, not the primary objective of the SWMP. Note that the TTDP referred to in the response to Comment #5 addresses the facility requirements for supporting barge/rail export from the Converted MTSs.

16. **Comment:** The DEIS should include a detailed discussion of the rail and barge systems, currently and proposed, and how the proposed SWMP changes are viable within these systems. Included in this assessment should be the possibility of using float barges from 65th Street or New York Cross Harbor and the possible container unloading facilities in the New York City Harbor.

Response: See Response to Comment #5. DSNY does not intend to use the 65th Street railyard in Brooklyn or the related float bridge facility for any form of containerized waste transfer or transport operation that is part of the Long Term Export Program.

40.3.3.1.3 Environmental Justice (Chapter 1)

17. **Comment:** The environmental justice section contains no assessment of the potential burden the proposed action(s) may have on identified environmental justice communities. Mapping neighborhood facilities as noted in the scoping document and coupling that with the statement "As such, they are not intended to depict the type or extent of any

environmental burden in the EJ community," does not assess any potential impacts or provide an evaluation of the burden to those neighborhoods.

Response: Section 1.9, Proposed Outreach Process - Environmental Justice, of the Final Scoping Document for the DEIS was developed through extensive consultation with NYSDEC with the intent of applying NYSDEC's Environmental Justice and Permitting Guidance of March 2003 to the development of the DEIS and this FEIS. Although the Guidance applies only to NYSDEC acting in the role of lead agency, DSNY, as lead agency for the DEIS and this FEIS, determined that implementation of the policy would have benefits in enhancing public participation. The referenced section of the Scoping Document includes the statement: "The project area maps also identify facilities in the project area that would be included in the environmental burden analysis in the event that significant impacts from the project are found." The intent of the statement is clear: a burden analysis will be performed if there is an impact and the analysis will include the assessment of related facilities that may contribute a similar burden. The analyses in the DEIS and this FEIS have determined that there are no potentially unmitigable significant adverse impacts associated with the Proposed Action. Accordingly, no burden analysis is required.

18. Comment: The DEIS provides a discussion of how DSNY will conduct Enhanced Outreach, utilizing the DEIS hearing process. The DEIS further suggests the existing outreach complies with DEC's policy on Environmental Justice and Permitting. The DEIS, however, does not provide in draft the required Enhanced Public Outreach Plan, nor does it provide a schedule for such compliance.

Response: Section 1.9.2 of the Final Scoping Document presents the proposed enhanced public outreach program. In a November 8, 2004 transmittal to NYSDEC, DSNY provided an Interim Implementation Report describing the enhanced public outreach activities that were undertaken during the Scoping process and described the activities that would be undertaken during the DEIS hearing phase. After publication of the DEIS in October 2004, DSNY has implemented additional enhanced public outreach activities consistent with program as proposed. By email on December 26, 2004, DSNY provided NYSDEC with additional materials on its enhanced public outreach program, including

notice of DSNY's intention to mail out notices to stakeholders on the Community Board ULURP hearings on the four Converted ULURP actions scheduled during January. These notices specifically responded to NYSDEC's desire that stakeholders be provided with information on the permit hearing process. This topic was addressed during the Community Board ULURP meetings. A report on the results of DSNY's enhanced public outreach process during the ULURP hearings was transmitted to DSNY in March. When the FEIS is published with a responsiveness summary Chapter 40 addressing the numerous public comments received as a result of DSNY's enhanced public outreach activities on the Draft New SWMP, this chapter will also summarize the extent of DSNY's enhanced public outreach activities though publication of the FEIS and certify that DSNY has complied with its enhanced public outreach plan. Additionally, Section 40.3.6 of this Chapter provides an interim implementation report on the enhanced public participation program.

The following summarizes relevant statistics on implementation of the enhanced public outreach program during the DEIS Scoping, DEIS Hearing and ULURP Hearings Phases.

Pre-Scoping Outreach Meetings at Potentially Affected Communities: - 9

A. Meetings with eight district managers or their representatives, plus a meeting with the Hunt's Point Economic Development Corporation.

B. Repository Locations for New SWMP Project Materials: 22 - *(two locations in each district – 11 districts, in total)*

C. Toll Free Hotline Inquiries: 26 - (*Hotline calls received starting June 2, 2004 through February 9, 2005*)

D. Follow-up Inquiries Logged and Addressed during Scoping/DEIS Comment & Interim Periods: 60 -*(Scoping Meetings, DEIS Hearings, Community Board ULURP Hearings)*

DEIS Scoping Meetings - 10

A. Outreach Activity

- 2,200 stakeholder invitational color tri-fold mailings and project updates.
- 12 main-stream and community based newspaper notices, plus the City Record notice.

B. Meeting Services

- Consecutive and/or simultaneous Spanish interpreters' service available at 8 of 10 meetings.
- List of public information materials available at Scoping meetings:

  - 3 Large Table Top Display Boards_that summarized the Proposed Action, typical EIS topics, and the public involvement process.

C. Meeting Handouts/Fact sheets***:**

- Welcome Sheet
- Opening Statement for Public Scoping Meeting
- PowerPoint Presentation
- Fact sheet #1 – City Environmental Quality Review (CEQR) FAQs
- Fact sheet #2 – CEQR Process Flowchart for the New SWMP EIS
- Fact sheet #3 – Proposed Action
- Comment Sheet

  *****<*Translated into other languages for comprehension by non-English speaking stakeholders*>

DEIS Hearings - 8

A. Pre-Meeting_Outreach Activity

- 3,000 stakeholder invitational color tri-fold mailings with project updates and targeted Spanish translated invitational color tri-fold mailings *(~100*) with project updates.
- 3 main-stream and community based newspaper notices, plus City Record and ENB notices

B. Meeting Services

- Consecutive and/or simultaneous Spanish interpreters' service available at 5 of 8 hearings
- List of public information materials available at DEIS hearings

  - 2 Large Table Top Display Boards_that summarized the proposed action/

impacts & mitigation measures and the public involvement process

C. Meeting Handouts/Fact sheets*****:

- Welcome Sheet
- Opening Statement for DEIS Hearings
- PowerPoint Presentation
- Fact sheet #1 – DSNY Public Involvement
- Fact sheet #2 – Proposed Action / Impacts & Mitigation
- Fact sheet #3 – State Permit Review Process
- Comment Sheet

*****<*Translated into other languages for comprehension by non-English speaking stakeholders*>

Community Board ULURP Hearings - 4

A. Pre-Meeting Outreach Activity

- 1,300 stakeholder invitational tri-fold mailings with project updates
- List of public information materials available at ULURP hearings

B. Meeting Handouts/Fact sheets:

- Fact sheet #1 – DSNY Public Involvement
- Fact sheet #3 – State Permit Review Process

19. **Comment:** Examples of public outreach documents should be added to the appendix as attachments.

Response: These materials are included as Appendix H to this FEIS.

20. **Comment:** Reference to joint hearings with the DEC should be removed. The reference to DEC's commitment to issue Notices of Complete Applications should be deleted from the discussion.

Response: Comment noted. The change is in the FEIS.

40.3.3.1.4 Overview of Study Methodologies for Site-Specific Analyses (Chapter 3)

21. **Comment:** Table 3.16-1 (p. 3-48) is the "Average Peak Day Facility Load Allocation," how is the average peak day defined? Peak generally refers to a maximum. How is an average computed?

Response: Average peak day is defined as the peak day that occurs once a week, typically on a Tuesday, when then number of loads delivered to an MTS is typically higher than the other days of the week. It is an average peak day because load allocations were developed based on the average number of loads delivered on the peak day of the week over the entire Fiscal Year (1997 or 1998, depending on the facility)..

22. **Comment:** On p. 3-71, in the second sentence, the phrase "… comparison with the $PM_{2.5}$ NAAQS is not feasible (*emphasis added*)" should be changed to "... is not attempted" as a more accurate representation.

Response: We concur with this comment.

23. **Comment:** The document is sometimes confusing with regard to the differing requirements of NYSDEC as contrasted with those of NYC DEP. For instance, on p. 3-71 the PM_{10} emissions of 15 tons/year is a state threshold, and not a City DEP requirement, but that is not clearly stated. Elsewhere distinctions between city and state thresholds could be better made. The discussion should clarify the separate city and state requirements.

Response: We agree this could be clarified. To do so, on page 3-71, the second bullet will be edited to include the introductory phrase, "Per NYSDEC and NYCDEP policy, results…". The third bullet on this page will be edited to include the introductory phrase, "Per NYSDEC policy, if primary…" The fourth bullet on this page will be edited to include the introductory phrase "Per NYCDEP policy, the potential incremental….". The fifth bullet in this list, which is on Page 3-72, will be preceded by the introductory phrase, "Per NYCDEP policy the maximum incremental….".

24. **Comment:** Because some aspects of the analysis were begun prior to the general availability of Mobile6.2 in February 2004, Mobile5b was used for some portions of the

analysis. In some cases, Mobile6.2 was also apparently used (see p. 3-81). While there are representations made that the most current state and city approved input parameters were used ..." (p. 3-89), this is contradicted elsewhere by reference to the NYCDEP's Report #34 (Jan. 1982). See p. 3-91 & 3-92. When Mobile6.2 was used, was it consistently applied? The technical backup for the site specific analyses should be included in the appendix.

Response: The initial roadway air quality analysis of all prospective waste transfer station sites utilized MOBILE5b emission factors, because agencies had not yet developed the necessary inputs for the recently released MOBILE6.2 model. As the SWMP was completed, the Proposed Action sites were identified. As the inputs needed to run MOBILE6.2 became available from agencies, the Proposed Action sites were analyzed using MOBILE6.2 emission factors. If Alternative sites were to be substituted for these sites in the future, these sites can be evaluated using MOBILE6.2 emission factors in a supplemental environmental review. For the Proposed Plan Sites Mobile6.2 with the current input parameters was used. The DEIS and this FEIS notes that the Technical Backup for the analysis is available upon request. (See page 3-1.) A copy of the Technical Backup was sent to NYSDEC prior to the publication of the FEIS.

25. **Comment:** The waste handling (transfer) operations are modeled using AP-42 § 13.2.4 Aggregate Handling and Storage Piles, but the DEIS appears to be in error on two counts. This AP-42 method (i.e. § 13.2.4) was not revised on 12/0.3 nor does it contain a correction factor C (see p. 3-83 of the DEIS). The discussion should be revised to correct the errors.

Response: We agree with this comment and will make the correction, as appropriate.

26. **Comment:** Load factors and activity data are not provided to verify the tugboat emission factors presented in Table 3.17-5.

Response: The load factors and activity data are in the Technical Backup that was sent to NYSDEC prior to the publication of the FEIS.

27. **Comment:** For PM_{10} road dust calculations, the latest AP-42 Chapter 13 2.1 (12/0.3) guidance was not used. The DEIS discussion does not estimate $PM_{2.5}$ road dust.

Response: The DEIS and this FEIS did use the latest version of AP-42, Chapter 13.2.1. The date of that version (12.03) will be added to the text where this reference is provided.

The NYSDEC's policy on $PM_{2.5}$ analysis does not apply to the proposed action or to facilities included in the proposed action, but $PM_{2.5}$ analysis was undertaken nevertheless. The DEIS and this FEIS does include $PM_{2.5}$ road dust emissions in the impact analysis at off-site microscale (roadside) receptors, but not at neighborhood-scale receptors for the off-site analysis, per NYCDEP guidance. The on-site analysis does not include $PM_{2.5}$ from road dust in the impact analysis, due to the very low on-site vehicle speeds. The primary source of on-site $PM_{2.5}$ emissions is expected to be vehicle exhaust, and these emissions were included in the $PM_{2.5}$ analysis.

40.3.3.1.5 Descriptions of Facility Sites

59th Street MTS

28. **Comment:** The 59th Street MTS is mentioned as a possible commercial waste transfer point. Describe improvements that would be required for the facility to accommodate the commercial waste sector. Describe the impacts that are expected to occur if this facility is used in this manner.

Response: See Response to Comment #3.

29. **Comment:** Describe the Hudson River Greenway trail at the point of intersection with the 59th Street MTS. Is the trail diverted in a manner that is safe and does not detract significantly from the trail's aesthetics?

Response: This segment of the Hudson River Greenway (Route 9A bikeway) is particularly narrow and surrounded by active industrial operations and transportation

facilities, resulting in a generally low-quality visual environment. In the vicinity of the West 59th Street MTS, the path is adjacent to the elevated Miller Highway columns to the east and the Consolidated Edison pier (at 58th Street) and the existing MTS to the west along the water. There is a stop sign on the path at the West 59th St. intersection and a sharp westward turn as one travels north toward 60th Street, where the waterfront opens up to view and the southernmost portion of Riverside Park South is under construction. (See Sections 22.2: Land Use and 22.5: Open Space.) As noted in the response to Comment #3, any Commercial Waste export facility that might be developed at the site as a result of the investigation and procurement processes that DSNY initiates in the future would be subject to environmental review at a later date. When there is a specific proposal for development of this site, DSNY will consult and coordinate with NYCDPR and the Hudson River Park Trust on the interface between the bike path and the proposed facility.

South Brooklyn Marine Terminal (SBMT)

30. **Comment:** It is expected that *85%* of the inbound recyclables to the South Brooklyn Marine Terminal (SBMT) will be delivered by barge. Where will the material originate and where will it be loaded onto barges? The DEIS discussion should include a description of the recycling support facilities. Provide the names of destination points for processed recyclables.

Response: The facilities that will supply Recyclables by barge to the Materials Processing Facility at the SBMT are described in Chapter 2, Table 2-3.1 of the SWMP and include: (i) the existing Hugo Neu Recyclables Acceptance facilities in the Bronx and Long Island City; and (ii) the proposed Gansevoort Recyclables Acceptance Facility in Manhattan, all of which are or would be capable of shipping materials by barge. These Acceptance Facilities would receive Curbside Program collections from the respective boroughs in which they are located, except the Long Island City and Bronx facility, which currently receive materials from northern Brooklyn and northern Manhattan, respectively.

The destination of processed recyclables from the Materials Processing Facility at the SBMT will depend upon the marketing arrangements made by the operator after the facility is constructed and in operation.

31. **Comment:** Were any alternatives to the SBMT available with both barge and rail capability? Is the SBMT rail-accessible? Discuss the potential for shipping recyclables from the SBMT via rail.

Response: The answer to both questions is no, and there is no potential for shipping recyclables from the SBMT via rail.

32. **Comment:** On p. 17-4 the section entitled "Environmental Review: Manhattan Curbside Recyclables to 30th Street Pier at South Brooklyn Marine Terminal," states that borings taken close to the SBMT show that the area contains 10-25 feet of fill material. Is an investigation planned to determine if contamination is present at the proposed SBMT site?

Response: Yes an investigation is planned. As the plans for this facility are developed, a more detailed supplemental environmental review will be prepared, and a Phase II subsurface site investigation may be required.

33. **Comment:** Please clarify whether all materials from the proposed Gansevoort recyclables transfer facility will be sent to the SBMT. If not, provide a list of destination facilities.

Response: Yes, all of the Recyclables delivered to the Gansevoort Acceptance facility would be shipped to the Materials Processing Facility at the SBMT by barge.

34. **Comment:** The 30th Street Pier, Brooklyn is included in the list of SWMP Facilities and potential contractors as a recyclables processing facility. The footnote states "As a recycling facility, it is not subject to regulation as a solid waste facility." Please correct this statement to reflect that it is regulated under NYSDEC regulation 6 NYCRR Part 360. Correction should be made to page 2-116 for the Gansevoort facility and in Table 2.5-1.

Response: Correction noted. The statement was intended to mean that these facilities are authorized by registration pursuant to Part 360 regulations.

Review Avenue and 485 Scott Avenue

35. **Comment:** It is unclear whether the proposed either or both the Review Avenue and 485 Scott Avenue transfer station will be a truck-to-barge or truck-to-truck-rail facilities. Different parts of the document state different scenarios. Please correct.

Response: Both options at either facility are possible, depending on the outcome of a procurement and contract negotiation that that is now in progress.

36. **Comment:** If both scenarios are options, individual environmental reviews should be done for both possibilities. Section 2.1.2.2 Capacities of Private Transfer Stations. Table 2.1-3 Private Transfer Station Capacities. Please explain why the analysis for 485 Scott Ave. capacity analyzed for on-site impacts is "deferred" while Review Avenue is not.

Response: Chapters 13 and 15 of the DEIS and this FEIS contain a summary of the permitted capacities and environmental reviews of the Scott Avenue and Review Avenue Transfer Stations, respectively. Those explanations provide the basis for the level of analysis presented in the DEIS and this FEIS. Where there is more than one potential option at a given facility, the environmental reviews of all options are presented in the Site/Facility Chapter of the DEIS and this FEIS to avoid repeating redundant information. The analysis of Scott Avenue was deferred because there was insufficient design information on the barge loadout available at the time the DEIS was published. When available, the design details will be subject to review by NYSDEC in an application for a permit modification. If NYSDEC were to determine that these changes merit additional review, a supplemental environmental review would be undertaken.

East 132nd Street Transfer Station

37. **Comment:** Section 2.2.9 East 132nd Street Transfer Station - Page 2-70: Please explain why there is no direct rail connection to this facility.

Response: The lease between Waste Management and the developer of the Harlem River Yard complex prohibits the developer from providing rail access to the Yard to a competing waste transfer station.

Hamilton Avenue MTS

38. **Comment**: Section 4.10.2 Delineation of Area of Concern - Page 4-53: In this section it states that the November 2003 work plan is NYSDEC approved. NYSDEC has not approved the work plan. Please correct.

Response: This is correct. Comments provided by NYSDEC on the draft work plan were incorporated into the final work plan. On May 28, 2003, a Draft Site Investigation Work Plan for the Hamilton Avenue Site was submitted to the NYSDEC for review. On September 9, 2003, NYSDEC provided comments on the draft submittal. All comments were addressed, and on October 23, 2003, a Final Site Investigation Work Plan and Response to Comments letter was submitted to the NYSDEC. These corrections are made in the FEIS.

39. **Comment:** Section 4.10.3 Potential Impacts with Hamilton Avenue Converted MTS - Page 4-54:

Please contact NYSDEC for guidance for disposal or reuse of urban fill and the necessary cover layer over exposed urban fill areas at least 90 days before implementation of plan regarding these materials. This applies to potential demolition/construction plans for all of possible facilities.

Response: Comment noted.

40.3.3.1.6 Construction Impacts (Chapter 32 and various sections)

40. **Comment:** The DEIS limits its discussion to short term construction impacts and long term operational impacts. It also refers to proposed construction at eight converted MTSs. The discussion should be augmented to reveal impacts to the local community and any probable impacts from staging of equipment and machinery, road diversions and

closures, both upland and to the waterway. The discussion should be revised to focus on those facilities determined to be included under the proposed action.

Response: Please refer to Chapter 32 of the FEIS, which has been revised to provide a more extensive discussion of potential construction impacts for the four Converted MTSs that are elements of the Proposed Action, including measures that will be employed to minimize their effects.

41. **Comment:** Section 32.2 Construction Impacts Page 32-2: Please discuss potential construction impacts such as construction traffic, noise, vibration and disruption of services impacts. Also discuss if the construction will impact the use of any off-site properties.

Response: See response to comment #40.

40.3.3.1.7. Evaluation of the Proposed Plan (Chapter 34)

42. **Comment**: The DEIS discussion states "… as a result, traffic and air quality conditions on City streets would likely improve overall within the City with the implementation of the Proposed Plan." The statement is unsupported by environmental analysis and discussion within the DEIS. The discussion further omits a comparative analysis to derive at this conclusion, particularly with the exclusion of commercial waste truck traffic analysis.

Response: The DEIS and this FEIS demonstrates that there are no potential unmitigatable significant adverse environmental impacts from the Proposed Action. The statement that traffic and air quality conditions on City streets would likely improve overall within the City with the implementation of the Proposed Plan is supported by the Proposed Plan's objective of exporting waste out of the City by barge or rail, which reduces the outbound truck/transfer trailer traffic (and resultant noise and air quality) that would otherwise exist on the City streets. DSNY has estimated that the shift from truck-based transfer to barge/rail based for DSNY-managed Waste will reduce waste transfer vehicle traffic by approximately 2.8 million miles per year. This reduction has obvious benefits in terms of reduced congestion and air quality. This reduction is documented in

the following Table 40.3-4, which shows the reduction in transfer trailer vehicle miles traveled within the City to and from the private transfer stations now used for Interim Export that will occur by shifting to a rail/barge based system.

A credible regional emissions analysis to compare waste export alternatives is not feasible at this time. The equipment and routes to be used to transport and dispose of NYC solid waste once it leaves the city are undefined. DSNY cannot predict the associated emissions outside the City. More importantly, the pollutants of primary regional concern, particularly $PM_{2.5}$ and ozone, are strongly affected by precursor pollutant emissions far upwind (outside to the City and State), making it difficult to establish a "domain" over which to conduct such an analysis.

However, looking broadly at cumulative regional emissions, it is apparent that such emissions from several large source categories, including power plants, on-road engines, non-road engines, and many types of industrial sources, will continue to decrease dramatically in the next few years due to existing and proposed federal rules. Therefore, one can say with confidence that the City's air quality, to the extent it is impacted by these cumulative upwind regional emissions, will continue to improve in the coming years.

40.3.3.1.8 Unavoidable and Adverse Impacts (Chapter 35)

43. **Comment:** The discussion concludes that "site specific analysis predicts that any impacts identified are capable of being mitigated." The DEIS should provide a comprehensive comparative chart of unavoidable impacts and corresponding mitigation to allow an adequate assessment of this statement.

Response: The Executive Summary in the DEIS and this FEIS presents the overall findings of the DEIS and FEIS analyses (see Section 4.0, Tables ES-3 and ES-4) and a summary of those potential impacts identified and the mitigation applied to those potential impacts. As noted, no unavoidable impacts were identified.

Table 40.3-4
Private Vendor Round Trip Transfer Stations
Tractor Trailer Mileage to Portal of Egress

Facility	Average Tons per Day	Departing Tractor Trailers	Returning Tractor Trailers	Mileage to NYC Limits	Daily Mileage
Waste Services 920 E 132 St Bronx, NY	743	37.2	37.2	4.73	352
Waste Management 215 Varick St Brooklyn, NY	1,363	68.2	68.2	21.03	2,868
Waste Management 485 Scott Avenue Brooklyn	1,012	50.6	50.6	21.62	2,188

BFI Waste Services 598-636 Scholes St Brooklyn, NY	81	4.1	4.1	21.31	175
TOTAL	**6,346**	**317.6**			**9,264**
				YEARLY TOTAL	**2,797,728**

40.3.3.1.9 Irreversible and Irretrievable Commitment of Resources (Chapter 36)

44. **Comment:** As stated the in the DEIS, "…the soil, shoreline and natural waterway … already committed to industrial use as a result of prior industrial activities ...." implies the waterways are abandoned and non-productive, when in fact the littoral zones, tidal wetlands and open water and habitat existing at the shoreline structures, are beneficial and protected for their natural resources benefits. The loss of marine resources habitat and open water should be further detailed and discussed.

Response: The comment "already committed to industrial use as a result of prior industrial activities" was a comment that referred to the land, its zoning, and the City's Waterfront Revitalization Program. The waterways, themselves are not abandoned and unproductive. The year-long field assessment indicated that the waters were rich in benthic, epibenthic, adult, larval, and juvenile finfish. The loss of marine habitat and communities due to construction and dredging will only be temporary. The benthic and epibenthic communities will reestablish themselves with the following year's recruitment and the adult finfish will return after the environmental disturbance has stopped. The operational impact of the Converted MTSs that are elements of the Proposed Action is small, the increase in the over-water shaded area is only 1.36 acres. It should be noted that, as discussed in the DEIS and this FEIS, construction of additional platforms does not cause a cessation of biological activity underneath and there is not an irreversible and irretrievable commitment of natural resources. The impacts, if any, of new platforms will be difficult to quantify.

40.3.3.1.10 Alternatives

45. **Comment:** Although a component of each facility site assessment description provides alternatives, identifying alternatives to the proposed plan and each MTS should be developed for the benefit of public disclosure and impact assessment.

Response: A discussion on Alternatives is provided in Section 40.3.1.2 of this Chapter, and Section 1.3 of this FEIS provides additional discussion of the scope of Alternatives considered.

40.3.3.2 City Planning Commission

The following correspondence in this section is the responses by DSNY to questions raised during Community Board Hearings on the pending ULURP applications for the Converted MTSs.

hand insert of ULURP letters

40.3.3.3 New York City Department of Transportation

1. **Comment:** There are several bridges and highways scheduled for reconstruction in the New York City area, including the Bruckner/Sheridan Expressway, the Willis Avenue Bridge and the Kosciusko Bridge. The proposed reconstruction of the Willis Avenue Bridge may be worth mentioning since it is located immediately adjacent to the Harlem River Yards. Similarly, the proposed reconstruction o the Bruckner/Sheridan Expressway may affect the East 132nd Street Transfer Station. Recently, NYSDOT requested NYCDOT to implement the westbound Bruckner Expressway interim ramp over the Eastern Boulevard Bridge. The proposed reconstruction of the Kosciusko Bridge (although the preferred alternative has not been selected) will result in potential modifications to the local street network which may affect the proposed Scott Avenue Transfer Station.

Response: Comment noted. In consultation with the NYCDOT, traffic data was collected and analyses conducted in the Bronx considering the construction activities in the study areas, including the Willis Avenue Bridge construction and the Sheridan/Bruckner Expressway. Since reconstruction of the Kosciusko Bridge is not scheduled to begin until 2009 (two to three years after the 2006 Build Year analyzed in the DEIS and this FEIS), and the preferred alternative is not yet chosen, it is not included in the analysis.

2. **Comment:** NYCEDC in conjunction with NYCDOT is examining geometric improvements to Food Center Drive that should be evaluated in relation to the South Bronx Converted MTS.

Response: The South Bronx Converted MTS is not part of the Proposed Action. If this facility were selected as part of the New SWMP and the new geometric improvements to Food Center Drive implemented, they will be assessed in accordance with CEQR as required.

3. **Comment:** The left-turn from southbound Bruckner Boulevard onto Longwood Avenue was not implemented by NYCDOT. Please have the consultant make the necessary adjustments to the traffic analysis conducted for the South Bronx Converted MTS.

Response: Page 19-89 of the DEIS and this FEIS acknowledges the NYCDOT's change to the July 21, 2004 Updated Truck Routes in Hunts Point that no longer de-designated the segment of Tiffany Street from Bruckner Boulevard to Longwood Avenue, after the analysis was completed. The South Bronx Converted MTS is not part of the Proposed Action. If this facility were selected as part of the Draft New SWMP, these changes would be evaluated in a supplemental environmental review, as required.

4. **Comment:** Bush Terminal Open Space is scheduled for completion by 2006 and its northern boundary is the southern boundary of the South Brooklyn Marine Terminal. Please have the consultant include the project in the no build for the South Brooklyn Marine Terminal although it was included in the 52nd Street Barging Staging Area.

Response: The 52nd Street Barge Staging Area is not part of the Proposed Action, but was originally contemplated as a barge staging area. Therefore, no off-site analyses were required. No detailed traffic analysis was necessary for the South Brooklyn Marine Terminal since the trip generation during the peak hours was 21 PCEs, which is below the 50 PCE screening threshold for a traffic analysis.

5. **Comment:** Please have the consultant provide the ATRs, turning movement counts, physical inventories and official signal timing for all analyzed intersections. The proposed mitigation measures will be reviewed upon receipt of the requested information.

Response: Comment noted. ATR counts, turning movement counts, physical inventories, and official signal timing for all analyzed intersections with mitigation were provided to NYCDOT for final approval of mitigation measures.

6. **Comment:** Please have the consultant include the following proposed projects in the no-build condition for the North Shore converted MTS (see attached):

- Tully Environmental, Inc. has recently issued an EAS for expansion of its Queens facility;

- Crystal Windows and Doors Systems, Inc. located at 31-10 Whitestone Expressway.
- NYC DOT network improvement: Linden Place widening and U-Turn

Response: Please see the following regarding the addition of projects to the North Shore Converted MTS analysis:

- The projected traffic generated from the proposed Tully Environmental, Inc. facility expansion will not travel through intersections analyzed for the North Shore Converted MTS and therefore, is not included in the analysis.
- The Crystal Windows and Doors Systems, Inc project build year is 2007, which is beyond the build year of 2006 analyzed in the DEIS and this FEIS, and was therefore, not included in the analysis. Additionally, the Crystal Windows and Door system pm peak analysis hour does not coincide with the North Shore Converted MTS pm peak analysis hour, and the am peak analysis hours partially overlap. Finally, the growth factor used in the DEIS and this FEIS to escalate existing volumes to future no-build volumes would account for relatively low number of projected new trips in the study area.
- The NYCDOT widening and U-Turn improvements at Linden Place do not directly affect the study area intersections for the North Shore Converted MTS. After consultation with NYCDOT, to minimize the potential for impacts from DSNY collection vehicles at Linden Place, only one of the Collection Districts would be accessing the North Shore Converted MTS through the Linden Place exit, which equates to four or five trucks during the facility peak hour of 10:00 a.m. to 11:00 a.m. Traffic volumes at study area intersections analyzed are not expected to change as a result of the Linden Place improvements.

7. **Comment:** Please provide detailed existing and proposed schematics for the intersection control device and parking modification recommended for College Point Avenue at 31st Avenue in the North Shore Converted MTS build with Mitigation condition.

Response: There are no proposed changes to the signal control devices and parking for mitigation purposes at the intersection of College Point Boulevard and 31st Avenue.

8. **Comment:** Please have the consultant provide the No build assignment maps for the soft sites identified at the following Converted MTS:

- Southwest Brooklyn;
- Hamilton Avenue;
- East 91st Street;
- West 59th Street, and
- East 132nd Street.

Response: There are no soft sites that affect traffic at the study intersections for the Southwest Brooklyn Converted MTS or East132nd Street Transfer Station. The consultant has provided NYCDOT with soft site no-build maps for the Hamilton Avenue, East 91st Street, and West 59th Street Converted MTSs.

9. **Comment:** Please have the consultant confirm the status of the American Stevedoring project and its scheduling relationship to the Solid Waste Management project.

Response: The American Stevedoring project is a privately undertaken project and is not directly related to the Draft New SWMP.

10. **Comment:** Please have the consultant present the traffic analysis for the Review Avenue Truck to Rail Transfer Station. The justification presented for not conducting the analysis is not acceptable since the CEQR screening of 50 vehicles per hour is related to the project-generated trips and no on intersection vehicular thresholds.

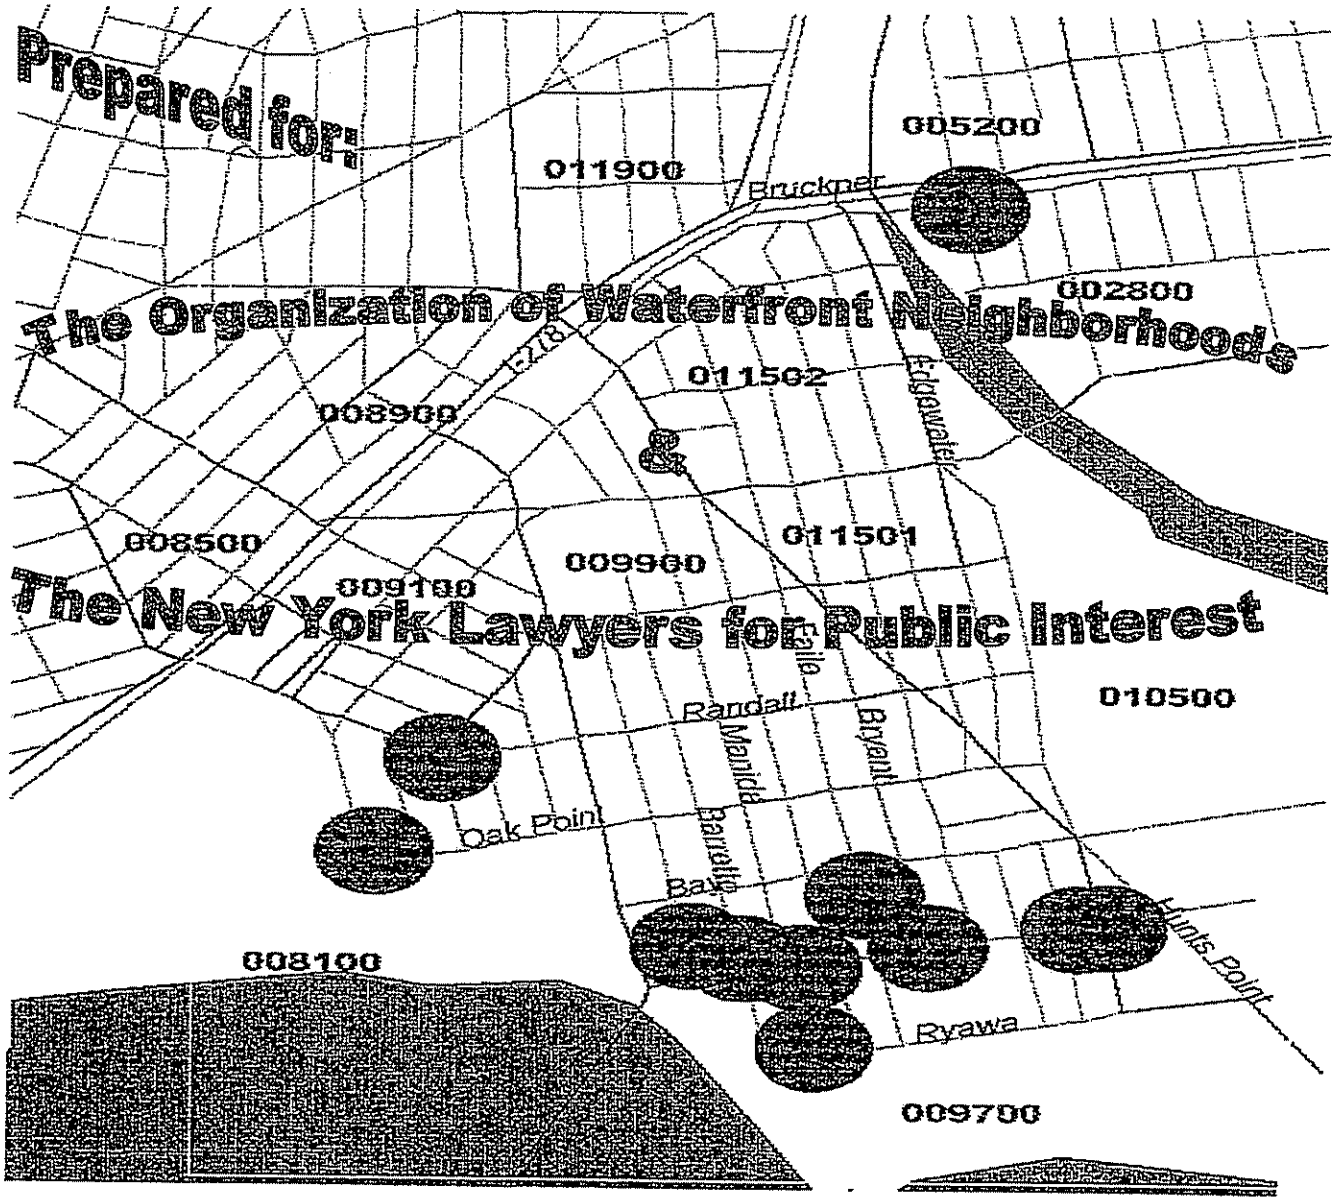
Response: The project-generated PCEs are 54, slightly above the 50 PCE screening threshold. A traffic analysis has been completed for the Review Avenue Transfer Station site and will be provided to the NYCDOT, and included in the FEIS. There are no umitigatable significant adverse traffic impacts from this facility.

11. **Comment:** Please have the consultant provide additional information regarding the "safety conditions on the bike path…" with regard to the West 59th Street Converted MTS. If the bike path is physically located within parkland, then the reference is correct, if it is located on a city street the consultant should reference NYCDOT and NYC Department of City Planning. If the responsible agency includes NYCDOT, please provide detailed drawings for the existing condition and the proposed improvement.

Response: This segment of the Hudson River Greenway (Route 9A bikeway) is particularly narrow and surrounded by active industrial operations and transportation facilities, resulting in a generally low-quality visual environment. In the vicinity of the West 59th Street MTS, the path is adjacent to the elevated Miller Highway columns to the east and the Consolidated Edison pier (at 58th Street) and the existing MTS to the west along the water. There is a stop sign on the path at the West 59th St. intersection

and a sharp westward turn as one travels north toward 60th Street, where the waterfront opens up to view and the southernmost portion of Riverside Park South is under construction. (See Sections 22.2: Land Use and 22.5: Open Space.) Any Commercial Waste export facility that might be developed at the site as a result of the investigation and procurement processes that DSNY initiates in the future would be subject to environmental review at a later date. When DSNY receives specific proposals for development of this site, DSNY will consult with NYCDOT, and NYCDPR, as applicable, on the interface between the bike path and the proposed facility.

12. **Comment:** Please have the consultant provide a Signal Warrant Analysis for the intersections of Metropolitan Avenue at Scott Avenue. If the proposed signalization is not feasible, the consultant should present the traffic analysis for the rerouting of trucks to the alternate route.



Response: This intersection pertains to the Meserole Street Truck to Rail Transfer Station that is not part of the Proposed Action. If it is selected as part of the New SWMP, a Signal Warrant Analysis or the analysis of an alternate route will be included in a supplemental environmental review, as required.

40.3.4 Comments on Commercial Waste Study

40.3.4.1 Analysis of Department of Sanitation Commercial Waste Management Study by Organization of Waterfront Neighborhoods (OWN) and New York Lawyers for the Public Interest (NYPI)

The report that follows in this section was prepared by the Organization of Waterfront Neighborhoods (OWN) after the release of the Commercial Waste Management Study (Study) in March of 2005. It critiques the methodology and findings in Volume I of the Study, Private Transfer Evaluations: Four Study Areas with Transfer Stations in Geographical Proximity. Section 40.3.4.2 provides a response to the OWN critique.

Analysis of the Department of Sanitation of New York Commercial Waste Study

I. BACKGROUND AND APPROACH

This Report sets forth the findings of a focused review of the New York City Department of Sanitation (DSNY) Commercial Waste Management Study (hereinafter, the "CW Study"), issued April 12, 2004. The CW Study was undertaken to implement Local Law 74. As set forth in an April 12, 2004 transmittal letter from DSNY Commissioner Doherty to City Council Speaker Gifford E. Miller and Councilman Michael E. McMahon, Chair of the Committee on Sanitation and Solid Waste Management, the goals of the CW Study were to:

(1) assess potential environmental and public health impacts on communities in which a number of privately-owned, solid waste transfer stations (hereinafter, "Transfer Stations") are located.

(2) provide a foundation for the Department's efforts to develop a new Comprehensive Solid Waste Management Plan (SWMP) for the next 20 years. The findings of the Study will also help inform the Department's new transfer station siting regulations.

The CW Study was performed by a team of consultants hired and overseen by DSNY. The primary consultant was Henningson, Durham & Richardson Architecture and Engineering, P.C., a firm frequently used by DSNY.

This review was commissioned by the New York Lawyers for the Public Interest (NYLPI) and the Organization of Waterfront Neighborhoods (OWN). OWN is a citywide coalition of community-based groups from low-income communities and communities of color, formed in 1996 to address environmental and health concerns associated with the City's handling and disposal of solid waste. Many of the communities represented by

OWN have been inundated with Transfer Stations for the last decade. As such, OWN has consistently urged the City Council and the Administration to adopt an environmentally sound, fiscally responsible, and equitable solid waste management strategy for the City of New York.

The purpose of this review is to analyze key areas of DSNY's analysis of the impacts of Transfer Stations contained in Volume I of the CW Study, and identify and assess any deficiencies in its analysis. There are two major components to this review: (1) an evaluation of the environmental study methodologies used in the CW Study; and (2) an evaluation of certain impact analyses carried out in the CW Study.

The primary foundation for the review and analysis contained in this Report are the guidelines and requirements set out in the New York City Environmental Quality Review Technical Manual, (CEQR TM), October 2001. The New York City Environmental Quality Review (CEQR) process is the City's process for implementing the New York State Environmental Quality Review Act (SEQRA). SEQRA requires that all state and local governments assess environmental effects of all discretionary actions. As set forth in the CEQR TM: "New York is a diverse and complex city with a rich and, in some cases, fragile environment. Both to protect the environment and to ensure a predictable and efficient process for participants in the CEQR process, the City developed the CEQR Technical Manual." See, Forward, CEQR TM.

Thus, the CEQR TM is New York City's official guidance manual for City agencies, project sponsors, and the public regarding the procedures and substance of the City's Environmental Quality Review process. It must be noted that DSNY has indicated that the CW Study will inform the Solid Waste Management Plan - Environmental Impact Statement (SWMP EIS) and, the SWMP EIS must comply with the CEQR TM.

II. EXECUTIVE SUMMARY

DSNY's analysis of Transfer Stations, as set forth in Volume I of the CW Study, is fundamentally flawed. Volume I analysis relied on methodologies that conflict with the CEQR TM, and regulatory standards. Volume I analysis is also internally inconsistent with the analysis of the conversion of Marine Transfer Stations contained in Volume III of the CW Study.

Specifically, the methodologies used by DSNY were designed to limit analysis and undercount the severity of impacts from the clustering of Transfer Stations in the four areas studied by DSNY (hereinafter, "Study Areas"). Consequently, the DSNY conclusion in Volume I of the CW Study that there are no significant and adverse impacts from the clustering of Transfer Stations in the four Study Areas is wrong. Moreover, even DSNY's limited analysis leads to the conclusion that there are clearly significant and adverse impacts from the clustering of Transfer Stations in each of the four Study Areas.

Below is a summary of the major findings of this report, which are fully discussed in Section III – Detailed Evaluation of the CW Study.

I. DSNY's Methodology inappropriately understated the Adverse Impacts associated with the Clustering of Transfer Stations

DSNY's methodology inappropriately understated impacts by: 1) creating "no study zones" around each transfer station rather than assessing the aggregate effects of

clustering, 2) using arbitrary and overly narrow Study Areas to exclude sensitive receptors, 3) applying incorrect impact criteria to exclude negative impacts, 4) taking credit for hypothetical future modifications at the Transfer Stations, and 5) assuming that if Transfer Stations were replaced, they would be replaced by equally or more burdensome uses.

No Study Zones

i. **DSNY created "No Study Zones" around each Transfer Station, which eliminated the analysis of the Aggregate Impacts from Clustering of Transfer Stations as required by Local Law 74**

DSNY failed to study the aggregate impacts of the Transfer Stations as required by Local Law 74. DSNY arbitrarily created a "no study zone" around each transfer station, which eliminated the first 100 meters from its analysis of the impacts of Transfer Stations, as well as aggregate impacts of clustered Transfer Stations. Instead, DSNY only analyzed impacts in a narrow band distance away from each Transfer Station that it deemed to be "overlapping." This understates the impacts of clustering because it excluded the severe impacts immediately adjacent to each of the Transfer Stations and the total cumulative contribution of all the Transfer Stations in each of the Study Areas.

ii. **DSNY's decision to create several "No Study Areas" to limit its Analysis to only "Overlapping Effects," rather than examining the Aggregate or Cumulative Impacts of Clustering, conflicts with the CEQR Technical Manual and Planning and Engineering Criteria**

DSNY's decision to create several "no Study Areas" to limit its analysis to "overlapping effects," rather than examining aggregate or cumulative impacts of clustering,

conflicts with the CEQR TM and planning and engineering criteria. The CEQR TM defines cumulative impacts as "two or more effects on the environment that, when taken together, are significant". There is no basis in the CEQR TM or in planning or engineering criteria that supports the subtraction of impacts – as was done by DSNY in creating its "no Study Areas" and "overlapping effects" theory – in analyzing the impacts of individual or multiple facilities.

iii. The Study Areas for Air Quality Analysis deliberately excluded the Areas of Greatest Impact

DSNY deliberately excluded the areas immediately adjacent to the Transfer Stations from its assessment of impacts. This exclusion removes the areas of highest air quality impact for its study. This ignores the clear requirements under the CEQR TM and all regulatory and engineering standards to begin all air quality analyses at the areas immediately adjacent to the project being analyzed.

Arbitrary and Overly Narrow Study Areas

iv. The DSNY-defined Study Areas are too small and are inconsistent with the CEQR Technical Manual

The areas used by DSNY (hereinafter, the "DSNY Study Areas") to study impacts were drawn arbitrarily small in violation of the CEQR TM. The consequence of the narrow DSNY Study Areas is that they exclude the majority of residences and community facilities from its study of impacts. Thus, the CW Study did not analyze the impact on these critical

community receptors and leads to a gross understatement of the impacts of clustering of Transfer Stations.

Incorrect Impact Criteria

v. The analysis of the Environmental Impacts of Transfer Stations incorrectly omitted numerous Impacts

DSNY arbitrarily and in clear conflict with the CEQR TM excluded numerous impacts from its analysis of the Transfer Stations. Among the impacts DSNY excluded from its study are the impacts to land use, community facilities, and socioeconomic impacts.

vi. The analysis of the Environmental Impacts of Transfer Stations did not analyze worst-case conditions as required by the CEQR

DSNY's study was not based on examining the worst-case operating conditions of the Transfer Stations as required by the CEQR TM. First, DSNY inappropriately used averaging techniques. Second, DSNY failed to demonstrate that the estimate of emissions of on-site equipment represent worst-case conditions. Third, DSNY failed to account for fugitive dust that migrates through the numerous openings at Transfer Stations.

vii. The analysis of the Environmental Impacts of Transfer Stations incorrectly omitted actual impacts of the Transfer Stations and failed to demonstrate that its "Prototypical Stations" reflect real-world Impacts

Rather than use actual conditions and data from Transfer Stations in its study, DSNY created "prototypical stations" – despite the fact that DSNY permits each of these facilities. Moreover, the CW Study does not demonstrate that these prototypical stations accurately represent the true impacts of each of the Transfer Stations operating in the DSNY Study Areas.

viii. DSNY's claimed credit for hypothetical future Modifications at Transfer Stations in its analysis in Violation of CEQR TM

The CEQR TM requires an analysis of the impacts of the "project" as it exists or is proposed. DSNY's methodology for analysis assumed a reduction of impacts will take place through future hypothetical modifications at Transfer Stations. This approach diminishes the true level of impacts in clear contravention of the CEQR TM guidance. Moreover, even if such operational or design modifications are called for, there is no mention in the study as to whether DOS would have the legal authority to impose such changes on the Transfer Stations. DSNY's draft scope for the forthcoming solid waste management plan explicitly states that DSNY believes it has the authority only to implement "some" of the changes recommended in the CW Study.

ix. DSNY incorrectly assumed that Transfer Stations would be Replaced by equally or more Burdensome Uses

In DSNY, where impact criteria were exceeded, even after the implementation of hypothetical reduction measures noted above, DSNY analyzed the impact based on speculative uses on the site of the Transfer Stations. The presumed purpose of this analysis was to compare the impacts on the neighborhood if the properties on which the Transfer Stations are located were replaced by another use.

Under the CEQR TM, there must be a demonstration that the replacement uses chosen for the analysis can be reasonably expected on each of the Transfer Station properties and in each of the DSNY Study Areas, based on such factors as land use and market conditions. Instead, DSNY simply made the assumption that the Transfer Stations would be replaced by truck intensive uses such as printing plants and laboratories without any justification that such uses could reasonably be located in each of the DSNY Study Areas.

II. DSNY's limited analysis demonstrates that Significant and Adverse Impacts exist as a result of the Clustering of Transfer Stations in each of the four DSNY Study Areas

x. The Air Quality Impacts of PM 2.5 found in the CW Study are Significant and Adverse

Even under the limited air quality analysis performed by DSNY, the PM 2.5 impacts – fine air particles that have recently been regulated - exceed the regulatory

thresholds established by both New York State and New York City environmental agencies - New York State Department of Environmental Conservation (NYSDEC) and New York City Department of Environmental Protection (NYCDEP).

Exposure to PM 2.5 is associated with numerous adverse health effects including heart and lung disease. Moreover, each of the neighborhoods that house the Transfer Stations studied by DSNY had levels that are at, or greater than the health standard for PM 2.5 established by the United States Environmental Protection Agency. DSNY chose to ignore the impacts of PM 2.5 with respect to the Transfer Stations, yet it applied the regulatory standards in its analysis of the conversion of Marine Transfer Stations.

xi. The Air Quality Impacts of the NAAQS Pollutants are Severe and should have been deemed Significant and Adverse

The impacts of the National Air Quality Standards (NAAQS) air pollutants from the Transfer Stations were extremely high. NAAQS air pollutants are six of the most commonly occurring air pollutants. In some cases, the impacts from Transfer Stations ranged from 26% to 88% of background conditions. These impacts exceed the thresholds for significant impact established under the Federal Clean Air Act.

Separately, DSNY did not analyze the impacts of any toxic air pollutants from the Transfer Stations even though it acknowledged that diesel equipment used for Transfer Station operations emit 15 toxic compounds – including six cancer causing compounds.

DSNY did analyze the impacts of such in its analysis of the conversion of Marine Transfer Stations in Volume III of the CW Study.

III. Significant flaws with DSNY's Review of Critical Environmental Impacts such as Air Quality, Neighborhood Character and Odors

xii. The DSNY Study Areas excluded the majority of Residences from its Air Analysis

In eliminating the first 100 meters from its analysis of the impacts of NAAQS air pollutants, the CW Study failed to analyze the impacts on residences and other sensitive receptors within that radius. Separately, because the DSNY Study Areas were drawn narrowly, the CW Study excluded the majority of the residential areas adjacent to the DSNY Study Areas. Moreover, communities were not contacted to identify residences and community facilities that should be included in the analysis of environmental impacts.

xiii. DSNY failed to account for Cumulative Sources, artificially reducing levels of Background Pollution

The effect of DSNY's failure to include all receptors impacted by the clustering of the Transfer Stations is compounded by the effect of its failure to correctly account for *existing* local sources. By failing to include any local sources of pollution in its study, the CW Study artificially reduced the level of background pollution. The consequence of this is that their assessment of the severity of the impacts of the Transfer Stations was artificially reduced.

xiv. The analysis of the Odor Impacts of Transfer Stations was Incomplete and did not fully account for Odor Impacts

The odor analysis suffers from many of the basis deficiencies of the air quality analysis. The methods used to study the impacts were incomplete and did not fully account for odor impacts.

xv. An analysis of the Health Impacts of the Clustering of Transfer Stations, as required by Local Law 74, was not performed

DSNY failed to conduct a health analysis of the clustering of Transfer Stations in the four DSNY Study Areas as required under Local Law 74. Instead, DSNY simply referred to the air quality and odor analyses found elsewhere in the CW Study. An authentic health analysis should, at a minimum, have included the development of a health profile of populations surrounding the Transfer Stations with a particular focus on subpopulations vulnerable to the air pollution and should have analyzed the health impacts from the exposure to PM 2.5 and toxic air pollutants exposure.

xvi. DSNY's analysis of Neighborhood Character excluded the majority of Residential Areas and Community Facilities

The CW Study's exclusion of the majority of residential areas and community facilities adjacent to each of the DSNY Study Areas resulted in the failure to examine the impact of the clustering of Transfer Stations on neighborhood character. DSNY's analysis of neighborhood character impacts for Transfer Stations is in sharp contrast to the manner

that DSNY analyzed the neighborhood character in its analysis of the conversion of Marine Transfer Stations where DSNY followed the CEQR TM and used an appropriately sized Study Area that included residences and community facilities adjacent to the Marine Transfer Stations.

III. DETAILED EVALUATION OF THE CW STUDY

Section 1: Evaluation of the CW Study Methodologies

The conclusions and results of any technical study are only as valid as the methods used and assumptions relied upon to conduct the analyses. As set forth in detail below, the study methodologies and assumptions utilized by DSNY in the analysis of Transfer Stations contained in Volume I of the CW Study are significantly flawed, resulting in an inadequate and deficient analysis that understated the magnitude and severity of the environmental impacts of New York City's Transfer Stations. Most notable is DSNY's failure to comply with the requirements of CEQR TM in its analysis of impacts from the clustering of Transfer Stations. Consequently, the DSNY conclusion in the CW Study that there are no significant and adverse impacts from the clustering of Transfer Stations is wrong. Moreover, the failure to abide by requirements of the CEQR TM in the CW Study prevents the use of the results of Volume I of the CW Study in Solid Waste Management Plan (SWMP) Environmental Impact Statement (EIS) and Transfer Station siting regulations because such actions must strictly comply with CEQR and the CEQR TM.

i. The Basic Methodology used by DSNY inappropriately minimized the study of Environmental Impacts

The basic methodology for the conduct of the environmental analyses in the CW Study, entitled *Study Area Environmental Analyses* and described in Section 4.0, Volume I – Private Transfer Station Evaluations is:

(1) Evaluate current conditions in each of the Study Areas;

(2) Evaluate conditions as if the Transfer Stations were not situated in the Study Areas; and

(3) Evaluate conditions without the Transfer Stations, but with "assumed other industrial uses" occupying the same sites . . . assuming the Transfer Stations were replaced by as-of-right general light industrial land uses, e.g., printing plants, laboratories. This land use replacement scenario assumed that the Transfer Station land uses would be occupied by other M-zone land uses typical of current conditions in the Study Areas.

See, Pg. 21, Volume I, CW Study.

The CW Study states that three steps were used in applying the above evaluation methodology. As set forth below, each step was substantially flawed and produced inadequate and inaccurate results.

Step 1

If the evaluation of current conditions, inclusive of the combined effects of multiple Transfer Stations in the Study Areas (i.e., areas of potential overlapping effects) met a set of specified criteria, then the potential effects of the Transfer Stations on the surrounding community were not evaluated any further. See, Pg. 22, Volume I, CW Study for a detailed description of these criteria; the criteria applied for analyzing air quality impacts are discussed below.

This approach is improper for two primary reasons. First, as discussed below in subsection ii, this method fails to include the areas of greatest impacts and, therefore, does not allow for a true evaluation of actual conditions. Second, as discussed more fully in

Section II, the criteria selected by DSNY are unduly restrictive and do not allow for a determination as to whether significant and adverse environmental impacts exist as a result of the clustering of Transfer Stations in the four Study Areas.

Step 2

If the evaluation of current conditions exceeded these specified criteria, then measures to reduce air quality, odor and noise effects were examined to determine whether existing impacts could be reduced through design or operational changes at the Transfer Stations.

This approach is simply inappropriate for an assessment of environmental impacts. The CEQR TM requires an analysis of the actual or projected impacts of the "project" under review. By assuming a reduction of impacts will take place through future hypothetical modifications at Transfer Stations, DSNY has diminished the true level of impacts in clear contravention of the CEQR TM guidance. Moreover, even if such operational or design modifications are called for, there is no mention in the CW Study as to whether DOS would have the legal authority to impose such changes on the Transfer Stations. DSNY's draft scope for the forthcoming solid waste management plan explicitly states that DSNY believes it has the authority only to implement "some" of the changes recommended in the CW Study.

Step 3

If the evaluation of current conditions for traffic, off-site air quality and off-site noise levels still exceeded the applicable criteria even after the implementation of suggested reduction measures, a replacement trip generation ("RTG") analysis was performed. This analysis assumed that the Transfer Stations would be replaced by as-of-right general light industrial land uses such as printing plants and laboratories (i.e., other M-zone land uses typical of current conditions). The effects of these replacement land uses were calculated using trip generation rates published by the Institute of Transportation Engineers (ITE). See, Pg. 23, Summary of reduction measure and replacement scenario analyses, CW Study, Vol. I.

To assess the accuracy of the RTG analysis used in the CW Study, one needs to determine whether DSNY used valid replacement land uses. The CEQR TM states that in order to examine the future conditions without the proposed project (i.e., an assessment of "no action conditions"), one must "compile a list of all the proposals that can reasonably be expected to be completed given market conditions, existing trends, and other constraints and incentives (including zoning and public policy), ...by the build year." See, Pg. 3A-10, CEQR TM.

Therefore, pursuant to the CEQR TM, there must be a demonstration that the replacement uses chosen for the analysis meet this "reasonably expected" test. The CW Study does not make such a demonstration. Instead, it simply makes the assumption --

without justification – that the areas are zoned for manufacturing and that, therefore, future uses will be manufacturing ones.[1] Moreover, the CW Study erroneously assumes that replacement use would be as truck intensive as Transfer Stations.

ii. DSNY failed to study the Aggregate Impacts of Transfer Stations

Local Law 74 requires, in part, that DSNY undertake a study of the "effectiveness of the criteria applied by the department to the siting of putrescible and non-putrescible Transfer Stations, including the **aggregate effect** of the geographic proximity of Transfer Stations to each other. . ." (emphasis added). DSNY's interpretation of the term "aggregate effect" is critical to the validity of the findings and conclusions contained in the CW Study. Regrettably, DSNY construed this term narrowly to avoid the inclusion of the most severe impacts from the clustering of Transfer Stations, resulting in a flawed analysis that contributes to the erroneous conclusion that there are no significant and adverse impacts from the cluster of Transfer Stations.

The common definition of the word "aggregate" is the sum total. Thus, pursuant to requirements of Local Law 74, DSNY should have studied the *sum effects* of the "geographic proximity of Transfer Stations to each other." Instead, DSNY inappropriately limited the scope of its study to "potential areas of **overlapping effects** from multiple Transfer Stations in the Study Areas." See, Final Scope of Work for the Commercial Waste Management Study, dated July 31, 2003. DSNY did not address or analyze the impacts from each of the individual Transfer Stations, rather DSNY created a "no study

[1] As discussed further in the neighborhood character discussion in Section II, this assumption of exclusively manufacturing uses is also flawed because this is based on drawing the Study Area too narrowly and on excluding all residential areas from the Study Area.

zone" around each transfer station and only studied impacts at the periphery of each transfer station that it considered to overlap with those of other Transfer Stations.

In addition, contrary to DSNY's claim that it applied "reasonable criteria adapted from the CEQR and planning and engineering criteria," See, Pg. ES-10, CW Study. DSNY's methodology conflicts with the CEQR TM and planning and engineering criteria. The CEQR TM's guidance regarding cumulative impact analysis is analogous to the requirement of Local Law 74 to assess the aggregate effects of the Transfer Stations. DSNY implies that the terms "overlapping" and "cumulative" are equivalent by using such interchangeably in the CW Study. See, Pg. ES-10, CW Study. The CEQR TM defines cumulative impacts as "two or more effects on the environment that, when taken together are significant." See, Pgs. 2-7, 2-8, CEQR TM. The CEQR TM makes clear that the term, "cumulative impacts" refers to the sum of all impacts. See, Pgs. 1-6, 2-7, 2-8, 3Q-16, 3Q-25, 3Q-26, and 3Q-36, CEQR TM. Nothing in the CEQR TM, or in other planning or engineering criteria supports the *subtraction* of impacts – as was done by DSNY in creating its "overlapping effects" theory – when analyzing the impacts of individual or multiple facilities.

DSNY's decision to limit its study to only "overlapping effects" excludes the most severe impacts of the clustering of Transfer Stations. This allows them to falsely conclude that the "overall results of the Study Area analyses show that the geographical proximity of the existing Transfer Stations in these Study Areas does not cause adverse combined or cumulative effects..... " See, Pg. 10, CW Study, Executive Summary (ES).

The most dramatic consequence of DSNY limiting its evaluation to only overlapping impacts is found in the air quality impact analyses of NAAQS Pollutants[2]. In the conduct of air impact of the NAAQS Pollutants, the CW Study states that all "receptors within 100 meters of any individual Transfer Station within each Study Area were eliminated from the model input so that results would be representative of the collective contributions of all Transfer Stations within the Study Area rather than those of an individual transfer station." See, Pg. 13, Appendix C, Volume I, CW Study. Similarly, when analyzing the on-site and off-site impacts of PM 2.5[3], DSNY eliminated receptors within 15 meters of the Transfer Stations. In creating this "no study zone" the CW Study disregarded the receptors receiving the severest impacts. See, 40 CFR Part 51, App.W.

The appropriate method, pursuant to the CEQR TM, of assessing the aggregate impacts is to plot the radii of the impacts from each facility in each of the four Study Areas and determine the impact upon all of the receptors. In performing the analysis in this way, the actual impacts of each facility on receptors would be analyzed, and the impacts on receptors from individual Transfer Stations *and* from the cumulative impact of Transfer Stations would be included. This stands in sharp contrast to DSNY's contention that the impacts closest to each transfer should be ignored. A more detailed discussion of the consequences of DSNY's flawed methodology in its analysis of air quality impacts is presented in Section 2.A below.

---

[2] NAAQS Pollutants are the most commonly occurring air pollutants and USEPA has established standards know as National Ambient Air Quality Standards. These standards regulate the following pollutants: carbon monoxide (CO), nitrogen dioxide (CO_2), ozone (O_3), particulate matter (PM), sulfur dioxide (SO_2), and Lead (Pb).

[3] PM 2.5 refers to particulate matter less than 2.5 microns in size. It is the subject of recent USEPA and New York State regulation because of its impacts on health, including asthma, and heart illness. NYC has levels of PM 2.5 that exceed USEPA health-based thresholds and the communities within DSNY Study Areas have some of the highest levels of PM 2.5 detected in NYC. See http://www.dec.state.ny.us/website/dar/baqs/pm25datasum.pdf

iii. DSNY defined an overly-small study in Violation of the CEQR Technical Manual

The DSNY identified four areas – the Study Areas - where Transfer Stations are in relatively close geographical proximity to each other, i.e. where Transfer Stations are clustered. The four Study Areas selected by DSNY are as follows: (1) Port Morris, The Bronx; (2) Hunts Points, The Bronx; (3) Jamaica, Queens, and (4) Greenpoint-Williamsburg, Brooklyn. These four areas contain 43 of the 69 Transfer Stations operating in New York City. See, Attachment 1 of this Report for a listing of the DSNY Study Areas by census tract.

In selecting these areas, the DSNY apparently merged the delineation of Study Areas for purposes of analyzing environmental impacts, as set forth in the CEQR TM, with the simple identification of the areas where the clustered Transfer Stations are located. Under the CEQR TM, a Study Area for analyzing environmental impacts is determined by two basic factors: 1) the type of action being reviewed and 2) the type of impact being analyzed. The CEQR TM sets forth two types of actions that relate to localized impact: site-specific actions and regulatory changes affecting small areas. See, Pg. 2-1, CEQR TM. Site-specific actions are those that occur at one specific location. The second type of action relates to changes in regulatory controls for a "site or small group of specific sites . . . such as the (re)zoning of a block or several blocks)" Id.

Evaluating impacts to the area in which the Transfer Stations are clustered is directly analogous to analyzing the impacts of rezoning to a group of sites in a particular

area. The purpose in both cases is to evaluate the environmental impacts of a particular use at multiple local properties. This approach is particularly appropriate here, where the purpose of the CW Study was to examine the environmental impacts of the use of multiple sites for waste processing. For this type of analysis, the DSNY Study Areas should have been only the beginning point in determining the appropriate Study Area.

The second basic factor in determining a Study Area is the specific type of impact being evaluated. The CEQR TM provides:

> For each technical area in which an impact may occur, whether land use, traffic and transportation, or natural resources, a Study Area must be defined for analysis. This is the geographic area likely to be affected by the proposed action for a given technical area, or the area in which impacts of that type could occur. Appropriate Study Areas differ depending on the type of impact being analyzed.

See, Pg. 2-5, CEQR TM.

Accordingly, DSNY should have identified specific and distinct Study Areas for each and every type of environmental impact analyzed. One approach for defining the Study Areas would be to draw radii of impacts from the area where the Transfer Stations are located, in the same way that the impact of a change of use at multiple local sites in a localized regulatory action would be analyzed under the CEQR TM. DSNY, however, simply selected a single Study Area for each of the four neighborhoods studied – the DSNY Study Areas - and analyzed each of the identified impacts based on that single Study Area. This approach conflicts with both the CEQR TM and the basic environmental and engineering principles that underlie the CEQR TM. Specifically, the analysis of

environmental impacts should be based on the projected distance of the impact from the project. DSNY's Study Areas bear no relation to the impacts it analyzes and, therefore, its analysis excluded the impacts to numerous receptors, including schools, homes and parks. Consequently, the overall finding of the CW Study that there are no significant and adverse impacts is unsupported and wrong.

Even if DSNY's analysis was based on equating the study of each of the Transfer Stations in each of the DSNY Study Areas as individual projects, its approach still conflicts with the CEQR TM. The CEQR TM instructs that DSNY should have identified Study Areas for each of the Transfer Stations within each of the DSNY Study Areas based on the radius of each impact analyzed. For example, the CEQR TM provides that the consideration of the Study Area for air quality analysis should begin at 1000 feet and for consideration of land use and socio-economic impacts the analysis should begin at ¼- to ½-mile. In other words, if DSNY analyzed each of the Transfer Stations as an individual action, it should have drawn radii of impacts for each Transfer Station and analyzed the impacts within each radii.

This is precisely the approach that DSNY applied in analyzing the conversion of Marine Transfer Stations. For example, in its analysis of the impacts to land use, zoning, community facilities, open space, and historic resources, the Study Areas were "delineated in a conventional manner according to a radial distance measured from the boundaries of each site." See, Pg. 3-3, Volume 3, Chapter 3, CW Study. For land use, zoning and public policy, and community facilities, a primary Study Area of ¼-mile radius and secondary

Study Area between ¼ and ½ miles were established. Open space, parklands and historic resources were analyzed based on a ½-mile radius Study Area. A ¼-mile radius was used to study socioeconomic impacts. See, Pg. 3-11, Volume III, Chapter 3, CW Study.

Finally, DSNY should have defined two Study Areas for each type of impact: a primary Study Area to analyze *direct* impacts and a secondary Study Area to analyze *indirect* impacts from the clustering of Transfer Stations.. As discussed more fully in Section 2 (below), the major consequence of DSNY selecting a single, small Study Area is that its analysis failed to consider the impacts on numerous receptors, i.e., uses immediately adjacent to the DSNY Study Areas.

iv. DSNY's analysis of the Environmental Impacts of Transfer Stations omitted numerous Impacts.

While the CW Study stated that a range of environmental impacts were examined, it failed to evaluate a number of potentially critical environmental impacts. DSNY limited the analysis of impacts to certain impacts without any justification, contrary to the requirements of the CEQR TM which prescribes that all potentially significant adverse impacts be analyzed. See, Pg. 2-8, CEQR TM. It is interesting to note that in the analysis of the conversion of Marine Transfer Stations in Volume III of the CW Study, DSNY followed the CEQR TM process and analyzed numerous impacts that were not analyzed for the clustering of Transfer Stations in Volume I.

On-Site Impacts

In Volume I, DSNY looked at air quality, odor, noise, neighborhood character, public health and water quality impacts resulting from the presence of the Transfer Stations within each Study Area. Notwithstanding the flaws in the analysis of these included impacts, the CW Study, *at a minimum*, should have also included an analysis of socio-economic, community facility and land use impacts. Key to the examination of the effects of Transfer Station clustering is whether they lead to, or have led to, a pattern of land uses that negatively impact the Study Area. Indeed, the clustering of the Transfer Stations in the first place demonstrates a land use pattern that needs to be analyzed as to its socio-economic and land use impacts because a key aspect of such analysis is whether a pattern of land uses would result in a negative socio-economic consequence, such as indirect displacement. As required by the CEQR TM, DSNY should have analyzed whether the land use pattern of the clustering of Transfer Stations has resulted in indirect displacement of residents, or businesses. See, Pg. 3B-2, CEQR TM. Such analysis is particularly relevant in the case of the clustering of Transfer Stations because of anecdotal evidence of the displacement of commercial establishments in communities in the DSNY Study Areas due to the presence of Transfer Stations.

Off-site Impacts

The CW Study looked at traffic, off-site air quality and off-site noise at "key intersections along major corridors/locations leading to and from the Study Areas." See,

Pg. 21, CW Study. Again, the scope of this evaluation was too narrow. To fully understand potential off-site impacts, socio-economic and community facility impacts should also have been included. Moreover, the CW Study should have looked at the impacts of the truck traffic associated with the Transfer Stations upon residents and commercial establishments. This is one area where DSNY artificially reduced the impact of truck traffic by assuming that Transfer Stations would be replaced by uses that would have equal or worse levels of truck traffic. See, Appendix H, Volume I, CW Study.

Section 2: Review of Key Impact Analyses in the CW Study

This Section consists of a review of three critical environmental impacts analyzed by DSNY: air quality, neighborhood character and odors. These impacts were identified by the OWN member organizations based in the areas where Transfer Stations are clustered, as being of particular concern and importance.

A. Air Quality

In the CW Study, DSNY analyzed air quality in two areas: (1) the impact of on-site emissions from the Transfer Stations and (2) off-site impacts resulting from the trucks going to and from Transfer Stations.

On-Site Analysis

i. The DSNY Study Area excluded the areas of greatest Air Quality Impact

As noted in Section 1, DSNY's study of impacts removed the area of greatest impact from the environmental analysis. Specifically, DSNY eliminated the first 100 meters from its analysis of the impacts of NAAQS pollutants and the first 15 meters from its analysis of PM 2.5 impacts. See, Pg, 13, Appendix C, Volume I, CW Study. DSNY's use of the 100-meter "No Study Zone" is based on a flawed concept. It is a basic principle of engineering, incorporated into federal and New York State regulatory requirements and the CEQR TM, that the area *closest* to an emission source represents one of the areas of *greatest air pollution impact*. This is because, typically, building downwash effects, coupled with fugitive source emissions,[4] result in the greatest impact in these locations. Therefore, it is always critical that air modeling is performed from the property fence line outwards with no region(s) excluded from the analysis.

This is particularly the case with Transfer Stations because the buildings tend to be one-story facilities with vents at a very short height. In eliminating the first 100 meters from its analysis, the CW Study failed to analyze the impacts on residences and community facilities within that radius. See, for example, the Hunts Point Land Use map contained in the enclosed Maps CD, the residential units that are located within the 100 meters of

[4] Downwash is essentially when air pollution gets trapped in close proximity to the facility from which it is being emitted because the height of the air pollution is too short in comparison to adjacent structures. Fugitive emissions are essentially pollution that does not get emitted from a defined point such as a stack. In the case of the Transfer Station, fugitive emissions are emitted from opened doors, and in the case of some facilities, from the processing of waste in an unenclosed area.

Transfer Stations in the Hunts Point Map. Table 1 contains some of the residences and community facilities that were excluded from DSNY's Study Areas and consequently its analysis of impacts:

Table 1 – Receptors Excluded From the Commercial Waste Study

Study Area	Excluded Receptors		
JAMAICA	Residences	• All residences east of 171st Street, between Hillside Avenue and Hollis Avenue • The majority of residences in Hillcrest north of Hillside Avenue • The majority of residences in Jamaica Hills north of Highland Avenue and west of • Upland Avenue and the majority of residences southwest of York College	
	Community Facilities	• PS 95 Eastward School, • The Mary Louis Academy, • PS 82 - The Hammond School, • PS 35 – Nathaniel Woodhull School • Thomas A. Edison Vocational and Technical High School • Jamaica Day School of St. Demetrios • Jamaica Assess/Recreational Center	• AIDS Center/Queens County #2 • Queens Village Health Center • United House of Prayer • Faith Tabernacle Baptist Church • South Jamaica Senior Center • Jamaica Day Nursery • Queens Gateway To Health Center
BROOKLYN GREENPOINT WILLIAMSBURG	Residences	• Most residences west of McGuiness Boulevard in Greenpoint • Residences south and east of the Brooklyn DSNY Study Area in Ridgewood • Residences south and west of Brooklyn DSNY Study Area in Williamsburg	
	Community Facilities	• St. John Lutheran School • PS 18 Edward Bush School • IS 49 – W. J. Gaynor Intermediate School • PS. 132 – The Conselyea • PS 196 – The Ten Eyeck School • PS. 147 Issac Remsen ES • Fennel Day Care Center • PS 145 Andrew Jackson School • Bushwick United Head Start • Junior High School 162 Willoughby • St. Aloysius School • Ridgewood Dialysis Center • St. Cyril & Methodikus School • Builders for Family & Youth • Mercy Home for Children • SS Anthony & Alphonsus School	• PS 34, St. Stanislaus Kostka School • PS 110 Monitor School, • Junior High School 1126 J. Ericsson JHS • Automotive High School • St. Vincent De Paul School • Northside Senior Citizen Center • Heart Share Human Services of New York • PS 84 Jose De Diego School • JHS 50 J.D. Wells JHS • Los Sures Senior Center • El Puente Academy for Peace and Justice • PS 19 Roberto Clemente School • Nuestros Ninos Child Development School
THE BRONX PORT MORRIS & HUNTS POINT	Residences	• All residences to the east, north and west of the Port Morris and Hunts Point Study Areas were excluded including East Side Settlement House, Powers Family Residences, UCC EHRLICH Residence	
	Community Facilities	• Cardinal Hayes High School • PS 1 The Courtland School • Alfred E. Smith High School • Immaculate Conception School • JHS 149 E. D Clark JHS • Dominican Sisters Family Life • PS 49 Willis Ave. School	• PS 30 Wilton School • South Bronx High School Program • PS 754 School for Career Development • PS 161 Ponce DeLeon School • St. Anselm's School • Hunts Point Multi Services Center • United Bronx Day Program, Bronx Regional High School

The CEQR TM provides that:

> For actions that would result in potentially significant odors, including, but not limited to, **solid waste management facilities** . . . the Study Area should include at least a 1,000-foot radius. . . . For actions that would create 'non-point' sources, such as fugitive dust, the effects on the nearest locations to which the public has general access are typically considered. . . . Generally, a preliminary analysis is performed for the locations chosen using the above criteria. If significant impacts are predicted at all or most of the chosen locations, it may be appropriate to expand the Study Area so that more distant locations are included where potential significant impacts may also occur.

See, Pg. 3Q-16, CEQR TM. (Emphasis added).

DSNY failed to apply these CEQR TM requirements when it created the DSNY Study Areas. DSNY should have begun with a 1000-foot radius around each Transfer Station and expanded the radius based upon common impacts from multiple facilities, and upon the significance of the impacts on the receptors. Given the numerous receptors that are located immediately adjacent to the DSNY Study Areas, a 1,000 *meter* radius is a reasonable Study Area to fully study the impacts of the Transfer Stations. Examination of the enclosed Maps CD shows that the numerous receptors that would be included within a 1,000 meter radius.

The net effect of eliminating the first 100/15 meters from DSNY's analysis and the small DSNY Study Areas is that the CW Study failed to analyze numerous receptors impacted by the clustering of Transfer Stations. The CEQR TM provides that:

> Numerous receptors [be] analyzed at each of the locations to be studied in the assessment of stationary sources. These are located where the maximum total pollutant concentrations or incremental pollutant concentrations resulting from the action are likely to occur and where people are likely to have continuous access. . . . Examples of reasonable receptor sites include . . . air intakes to sensitive interior uses, such as residences, hospitals, nursing homes, schools, and community facilities.
>
> See, Pgs.16 –17, CEQR TM.

The identification and analysis of sensitive receptors is the heart of CEQR. Only by including all receptors potentially impacted and analyzing all impacts on such receptors can a project's impacts be legitimately examined. In an absolute rejection of this critical CEQR requirement, the DSNY Study Areas excluded the majority of residences and community facilities impacted by the Transfer Stations from its analysis.

In sharp contrast to the narrow process DSNY used to analyze the impact of the clustering of Transfer Stations, its air quality analysis of the conversion of Marine Transfer Stations followed the methodologies set forth in the CEQR TM. For example, its air quality Study Area consisted of a radius of 500 meters from the site property line in all directions with an examination of receptors at 50-meter increments; discrete elevated receptors (i.e., window, balconies, or air intakes); and sensitive land uses such as playgrounds, schools and residential areas. See, Pgs. 3-55, Chapter 3, Volume III, CW Study.

ii. The CW Study failed to account for Cumulative Sources, artificially reducing levels of Background Pollution

The effect of the failure of DSNY to include all receptors impacted by the clustering of Transfer Stations is compounded by the effect of its failure to correctly account *existing* local sources. By so doing, the CW Study artificially reduced the background levels for each of the pollutants analyzed in the study. The CW Study indicates that it did not include any other sources of emissions in the air quality analysis because it limited the review to only "major sources." See, Pg. 30, Volume I, CW Study.

"Major sources" are facilities that emit large quantities of pollution, at least 10 tons of pollutants per year. Even if we assume that no "major sources" impact the DSNY Study Areas, DSNY still failed to include the emissions from medium and small facilities. Including other local sources in the analysis of background conditions is critical to accurately assessing the air quality in the local Study Areas. By failing to do so, the CW Study underestimates the levels of air pollution in each of the DSNY Study Areas and minimizes the severity of the air quality impacts from Transfer Stations in the DSNY Study Areas.

Contrary to DSNY's overly simplistic approach, the CEQR TM prescribes that emissions from large, mid-size and small facilities beginning at minimum radius of 1,000 feet be included in the air quality analysis. The CEQR TM refers to such analysis as a cumulative impact analysis. See, Pgs. 3Q-36, 3Q-37, CEQR TM.

A recently completed Environmental Impact Study by the New York City Department of Environmental Protection (NYCDEP) – the lead agency for interpreting the CEQR TM - provides an illustration of how sources of pollution in proximity to a project should be analyzed and included in background local air quality conditions. In that matter, NYCDEP noted:

Based on NYCDEP and the CEQR Technical Manual guidance for the inclusion of potential sources to include in such types of cumulative impact analyses, the inventory for the cumulative impact analysis was prepared as follows:

- Primary Study Area Sources – These sources include all NYCDEP permitted combustion sources with heat inputs greater than 2.8 million Btu/hr that were located within a radius of 1000 feet [of the facility] ...
- Secondary Study Area Sources – These sources were defined as the areas between 1000 feet and two kilometer (km) from [the facility]. ... All permitted sources with heat inputs greater than 50 million Btu/hr that were located within these areas were included...
- Tertiary Study Area Sources – The tertiary study area was defined as the combined area between two km and 10 km from [the facility]. . . . Within this study area, current and proposed **"major"** combustion-related facilities as proposed non-major electrical generating facilities were considered. . . .

See. Final Supplemental Environmental Impact Statement, Newtown Creek Water Pollution Control Plant Track 3 Upgrade, June 6, 2003. [Emphasis added][5]

[5] DSNY is specifically aware of this Environmental Impact Statement, as evidenced by its cite to such study in Volume III of the Commercial Waste Study See Pg. 3-65, Chapter 3, Volume III, CW Study.

Essentially, this EIS included all the air emissions from all facilities including smaller facilities (2.8 million Btu/hr) within 1,000 feet of the project, mid-size facilities (50 million Btu/hr) between 1,000 feet and two kilometers and major facilities at a radius between two km and 10 km. In other words, the methodology examines all sources in the immediate area of the project being analyzed and only limits the type of source to larger sources as distance increases. This is done because only the emissions of larger facilities located at a significant distance from the area being studied are likely to migrate and impact the immediate area of the project being analyzed. DSNY's failure to comply with the CEQR TM essentially removed the effect of degraded air quality due to the numerous other polluting facilities located in and adjacent to each of the DSNY Study Areas from the air quality analysis. Lastly, in addition to ignoring existing sources of pollution in its analysis, the DSNY failed to account for the air impact of planned future development as required by CEQR TM.[6] See, Pg. 3Q-24 CEQR TM.

iii. DSNY did not analyze worst-case conditions as required by the CEQR Technical Manual

The CEQR Technical Manual requires that the analysis of air quality impacts from a project be based upon the worst-case conditions of the project's operations. See, Pg. 3Q-33, CEQR TM. DSNY failed to use the worst-case conditions in its analysis. This failure can be seen in three distinct aspects of the analysis..

[6] It should be noted that DSNY did include planned future development in its analysis of the conversion of Marine Transfer Stations. See pg. 3-32, Chapter 3, Volume III, CW Study.

First, DSNY analysis inappropriately used averaging techniques and assumptions to estimate air quality impacts instead of worst-case conditions. There are several areas in the CW Study where this is evident:

- "Assumptions were made for each category (of prototypical Transfer Stations) when determining the types and quantities of equipment that were ***typically*** used in the operations." See, Pg. 7, Volume I, CW Study (emphasis added).
- "An ***average*** number of idling waste hauling vehicles in front of the Transfer Stations were included in the analysis based on observations of stations in the Study Areas." Id. (emphasis added).
- "Long-term estimates were based on annual ***average*** activity levels for each prototypical transfer station. For 24-hour and annual average estimates, hourly distributions or period average estimates of emissions were developed to represent more realistic emission levels. Assumptions on the number of hours that each piece of equipment was in operation were based on observations and on the operating permits of Transfer Stations assigned to each prototype category." Id. (emphasis added).

Second, the CW Study failed to set forth whether the emissions estimates from on-site equipment represent worst-case conditions. See, Table 3.2-1, Pg. 7, Appendix C, Volume I, CW Study. Specifically, the CW Study does not demonstrate that the following factors were applied to its analysis:

- maximum number of vehicles on sites
- vehicles operating with diesel
- simultaneous operation of on-site equipment
- simultaneous operation of each transfer station in each TS clustered area.

Lastly, DSNY assumed that all fugitive dust created by the processing of solid waste within processing buildings was vented from stacks. This assumption is flawed because it is well known – particularly to residents living adjacent to Transfer Stations - that all Transfer Station operations have fugitive dust emissions from processing buildings when doors or other entryways are opened during loading and unloading operations.

iv. The CW Study failed to study the Actual Impacts of the Transfer Stations and failed to demonstrate that "Prototypical Stations" adequately reflect Actual Impacts

Rather than analyze the actual impacts from the 43 Transfer Stations in the four Study Areas, "prototypical Transfer Stations" were created by DSNY to analyze environmental impacts. The CW Study failed to demonstrate that such use accurately reflects the actual impacts of the actual Transfer Stations in the DSNY Study Areas.

While the CEQR TM does allow for the use of "prototypical" sources, it does so only where a facility does not yet exist. Under such circumstances, the CEQR TM requires the analysis of "prototypical worst-case scenarios." See, Pg., 3Q-16, CEQR TM. Not only did the CW Study fail to demonstrate the validity of using prototypical stations, it failed to show that its analysis of "prototypical stations" was based on worst-case scenarios for such stations. As discussed earlier, there is good reason to believe that it is not.

In order to assess worst-case conditions, the CW Study analysis should have included the following scenarios:

- the maximum number of equipment on site
- all equipment operating simultaneously and at highest emission levels
- each transfer station in each TS Clustered Area operating simultaneously at peak conditions, and
- the maximum number of trucks idling for the maximum idling period

There is no evidence in the CW Study that the prototypical stations were based on such factors.

Given that there are only 43 sites under review and all of them are permitted by DSNY, it is unclear why DSNY did not simply use all available information from existing permits and augment any necessary information rather than resorting to a "prototypical" facility. Indeed, use of real data for conducting an analysis is preferred under CEQR.

Utilizing actual information is particularly important in evaluating impacts from Transfer Stations because the majority of Transfer Stations are retrofitted from other uses and do not employ best practices for design or operation. For this same reason, it is nearly impossible to estimate or model the impacts of Transfer Stations in the Study Areas because the impact of each transfer station is driven by facility-specific factors such as the

type and size of the structure, the presence and effectiveness of ventilation systems, proximity to adjacent properties and roads, and the size and number of equipment on-site.

v. Under DSNY's Insufficient Analysis, the Air Quality Impacts of PM 2.5 are Significant and Adverse

PM 2.5 is one the most important public health issues in the United States, New York City and, in particular, for each of the neighborhoods in the DSNY Study Areas that have clustering of Transfer Stations. USEPA describes its negative effects as follows:

> When breathed, particles can accumulate in the respiratory system and are associated with numerous health effects. . . .Fine particles [PM 2.5] are most closely associated with such health effects as increased hospital admissions and emergency room visits for heart and lung disease, increased respiratory disease and symptoms such as asthma, decreased lung function, and even premature death.

See, http://www.epa.gov/oar/oaqps/pm25/general.html.

USEPA Region 2 and New York State Department of Environmental Conservation have recommended, based on three years of monitoring data, that the counties of New York City be designated as "non-attainment".

See, http://www.epa.gov/pmdesignations/regions/region2t.htm.

The designation of non-attainment means that the level of PM 2.5 is above the health-based standard. "By law, non-attainment areas are subject to a number of requirements to reduce particles and the pollutants that form them."

See, http://www.epa.gov/pmdesignations/documents/120/factsheet.htm.

DSNY's analysis – despite all of its limitations - demonstrates that the impact of clustering of Transfer Stations is clearly significant and adverse. Even under the limited air quality analysis performed by DSNY, the PM 2.5 impacts exceed the regulatory thresholds established by NYSDEC and NYCDEP.[7] See, Tables 2 and 3 below.

Table 2
Summary of Air Quality Analysis
PM 2.5 Annual Neighborhood Average

Study Area	Annual Average Monitored Concentration	Annual Neighborhood Concentration	NYSDEP Significance Impact Threshold Level (3)
Brooklyn	16.3	0.88	0.1 ug/m3
Jamaica	13.1	0.29	0.1 ug/m3
Hunts Point	18	1.05	0.1 ug/m3
Port Morris	18	0.22	0.1 ug/m3

(1) NAAQS for PM 2.5 is 15 ug/m3
(2) All information in this table is taken from Table 5.2.2-5 which is found in Pg. 37, Volume I, CW Study.

[7] DEC thresholds for PM 2.5 impacts are set forth in "CP-33/ Assessing and Mitigating Impacts of Fine Particulate Matter Emissions," dated 12/29/03 These thresholds a 0.3 ug/m_3 for the highest annual concentration at any receptor and 5 ug/m_3 for receptor having the highest 24-hour impact; NYCDEP has adopted the DEC thresholds and has required an additional threshold of 1 ug/m_3 and applied such in conduct of environmental impact statements – See New Final Supplemental Environmental Impact Statement, Newtown Creek Water Pollution Control Plant Track 3 Upgrade, June 6, 2003

Table 3
Summary of Air Quality Analysis
PM 2.5 24-Hour Average

Study Area	24-hr Monitored Concentration	24-hour Concentration	NYSDEC/NYSDEP Significance Impact Threshold
Brooklyn Study Area	41.7 ug/m3	11.2 ug/m3	5 ug/m3
Jamaica Study Area	38.6 ug/m3	5.7 ug/m3	5 ug/m3
Hunts Point Study Area	41.1 ug/m3	12 ug/m3	5 ug/m3
Port Morris Study Area	41.1 ug/m3	4.8 ug/m3	5 ug/m3

(1) NAAQS for PM 2.5 is 65 ug/m3

(2) All information in this table is taken from Table 5.2.2-6 which is found in Pg. 37, Volume I, CW Study.

It must be noted that these tables – which contain information exclusively obtained from the CW Study - significantly undercount PM 2.5 impacts because DSNY separated PM 10 from PM 2.5 impacts with a reasonable basis for doing so as required by the NYSDEC[8].

As demonstrated in Tables 2 and 3, the PM 2.5 values in two of the DSNY Study Areas – all the Study Areas exceed the annual neighborhood average impact threshold and all except the Study Areas in Port Morris, the Bronx, exceed the 24-hour threshold with Port Morris marginally below the 24-hour threshold. It should be noted that DSNY did

[8] "The Department staff shall require that applicants for a permit hereunder quantify emissions of PM10 from a proposed project and ***assume that all measured or estimated PM10 emissions are PM2.5.*** Where an applicant demonstrates that a reasonably accurate measure of the PM2.5 fraction of a source's particulate matter emissions is available, Department staff may, in its reasonable discretion, assess potential impacts using the PM2.5 fraction. **"See CP-33/Assessing and Mitigating Impacts of Fine Particulate Matter Emissions, 12/29/03 (hereinafter, the "DEC PM 2.5 Policy")**

not present any analysis of the highest annual PM 2.5 impact in the CW Study. This is a major concern because each of the DSNY Study Areas exceed the USEPA PM 2.5 health standard and, therefore, identifying the highest annual PM 2.5 impact is critical to identifying health consequences from the Transfer Stations.

The exceedances of the PM 2.5 thresholds are bases for concluding that the impacts from the clustering of Transfer Stations in the DSNY Study Areas are significant and adverse. It must be noted that DSNY ignored the DEC and DEP PM 2.5 thresholds when analyzing the Transfer Stations, but correctly applied these thresholds when analyzing the impacts of the conversion of Marine Transfer Stations. See, Attachment 4, "On- and Off-Site Air Quality Analysis Results DSNY-Managed Waste Plus Commercial Waste Collection Vehicles," Volume III, CW Study. Moreover, DSNY also acknowledges the applicability of the PM 2.5 standard in the Draft SWMP EIS Scope. See, Pg. 76, Draft SWMP EIS Scope.

Quite simply the impacts of PM 2.5 from the clustering of Transfer Stations in the neighborhoods studied in DSNY Study Areas are significant and adverse. Given the health consequences of the exposure to PM 2.5[9] - especially because the background levels of PM 2.5 exceed the USEPA health based standards – DSNY's decision to ignore the impacts is indefensible.

vi. The Air Quality Impacts of the NAAQS Pollutants are Severe and should have been judged Significant and Adverse.

As mentioned above, the CW Study concludes that the air quality impacts of the clustered Transfer Stations are not significant and adverse. As is the case with PM 2.5 impacts, Table 4 shows that the air quality impacts of NAAQS pollutants from the Transfer Stations -- even with the limited approach used by DSNY -- are also significant and adverse. Table 4 below sets forth the impact of each NAAQS pollutant analyzed in the CW Study. The Column entitled "Percent of Impact Range" shows a range of impact – the higher end of the range compares the impact of the Transfer Stations against the background conditions without including the existing contribution to the background from Transfer Stations.

Table 4 Summary of Air Quality Analysis
Criteria Pollutants
Hunts Point, Bronx CDs #2 and #9 Study Area

Pollutant	Time Period	Percent of Impact Range (1)	Percent of NAAQS	SILs as a Percentage of NAAQS
Carbon Monoxide (CO)	1-hr	25% to 34%	3.20%	5.00%
	8-hr	20% to 26%	6.75%	5.00%
Nitrogen Dioxide (NO2)	Annual	21% to 26%	18.00%	1.00%
Particulate Matter (PM 10)	24-hr	47% to 88%	44.00%	3.33%
	Annual	23% to 29%	14.00%	2.00%
Sulfur Dioxide (SO2)	3-hr	19% to 24%	4.00%	1.92%
	24-hr	7% to 8%	2.47%	1.37%
	Annual	3 to 4 %	1.25%	1.25%

(1) The range of impact was established by using the ratio of highest estimated pollutant concentration to maximum contribution from on-site emission sources, as set forth in Tables 5.2.2-1 through 5.2.2-4, Volume I of CWS Study, and by using the ratio of maximum contribution from on-site emission sources to the background pollutant concentration.

A more appropriate standard for assessing whether the air quality impacts are significant and adverse is the Significant Impact Levels (SILs) established pursuant to the Clean Air Act to assess the significance of impacts of a facility's proposed air permit.[10] To provide some comparison of the impacts, the last column of the table, entitled "SILs as a Percentage of NAAQS," shows the percentage of impact that is deemed significant under the federal Clean Air Act.[11]

[10] See USEPA New Source Review Workshop Manual - Prevention of Significant Deterioration and Nonattainment Area Permitting. USEPA, OAQPS. October 1990

As can be seen from Table 4, the impacts from the Transfer Stations – as calculated by DSNY - are many times higher than the percentage that is deemed significant under the Clean Air Act. For example, the impact of PM 10 under the 24-hour standard could be as high as 88%, as compared to the SILs impact percentage of 3.3 %, which is deemed significant under the Clean Air Act. Despite the magnitude of the impacts calculated by DSNY, it concluded none of the impacts are significant and adverse.

DSNY arrived at this conclusion by evaluating whether the results of its analysis caused background pollution levels to exceed federal air quality standards (i.e., the NAAQS). DSNY examined whether there would be an exceedance of the standard for each pollutant analyzed, rather than assess the significance of the incremental impact from the Transfer Stations. See, Pgs. 33 – 36, Volume I, CW Study.

While CEQR TM does allow for such comparison, such comparison is inconsistent with the overall methodology of the CEQR TM, the federal Clean Air Act and basic engineering methods which prescribe that impacts be assessed based on the magnitude of impact from the project being analyzed. Merely examining whether the standards would be exceeded ignores the magnitude of the incremental impact of project being analyzed.

Under DSNY's approach, a project could impact 99% of an air quality standard and not be deemed significant and adverse, but another project seeking a permit shortly thereafter whose impacts are 2 % of the standard would be deemed significant and adverse. The proper approach would have been to assess the magnitude of the incremental impact of

Transfer Stations, in and adjacent to the DSNY Study Areas, on background pollution levels. If DSNY had used this approach, it would have concluded that the impacts were clearly significant and adverse.

In addition to drawing incorrect conclusions in its analysis of PM 2.5 and NAAQS pollutants, DSNY chose not to analyze the impacts of any of the toxic air pollutants associated with Transfer Station operations.[12] Again, this is in contrast with DSNY's air quality analysis of the conversion of Maine Transfer Stations, which analyzed the impacts of 15 toxic compounds identified as emissions from diesel equipment. See, Pg. 3-44, Chapter 3, Volume III, CW Study.

These 15 toxic compounds include six toxic compounds that are carcinogenic. DSNY appropriately analyzed the impact of each of these compounds from the conversion of the Marine Transfer Stations to determine whether they exceeded the regulatory thresholds. Id. Despite the use of numerous diesel equipment at land-based Transfer Stations, DSNY simply ignored the emissions and the impacts of toxic compounds in its analysis of the impacts of clustering.

[12] Toxic air pollutants are a category of pollutants that are generally referred to as non-criteria pollutants. Toxic air pollutants are regulated by the NYSDEC by examining the incremental impact of toxic air pollutants from sources of such pollutants. These incremental impact standards are set forth in the NYSDEC *Guidelines for the Control of Toxic Ambient Air Contaminants*.

Off-Site Air Quality Analysis

The CW Study analysis of off-site air quality impacts is also highly flawed, particularly with respect to the analysis of PM 2.5 impacts. As noted earlier, the CW Study excludes *all* receptors within 15 meters of the curb at the intersections analyzed for the analysis of PM 2.5 impacts. DSNY's approach conflicts with the CEQR TM and excludes the areas of significant and adverse impacts.

The CEQR TM states that "receptors should be placed at mid-sidewalk, generally 6 to 7 ½ feet from the curb-line of the sidewalk (for wider sidewalks, no more that 7 ½ feet from the curb)." See, Pgs. 3Q-14, 3Q-15, CEQR TM. The purpose of doing so is to locate receptors "where the maximum total pollutant concentrations with the action or incremental pollutant concentrations resulting from the action are likely to occur and where people are likely to have continuous access. This usually means that receptors are located near those approaches of the intersection where traffic is likely to be the greatest or the most congested . . . [such as] sidewalks near roadways; edge of right-of-way for roadways without sidewalks, if publicly accessible; property lines of all residences, hospitals, schools, playgrounds, and the entrances and air intakes to all other buildings." See, Pg. 3Q-14, CEQR TM. Contrary to the explicit direction of the CEQR TM, DSNY's "no study zone" of the first 15 meters excludes receptors such as sidewalks, property lines of residences, and playgrounds.

B. The study of Neighborhood Character excluded the majority of Residential Areas and Community Facilities

Neighborhood character impact essentially is an evaluation of how impacts on such issues as use, socio-economics, traffic and noise collectively impact the neighborhood as a whole. See, Pg. 3H-1, CEQR TM. Contrary to the manner prescribed by the CEQR TM, DSNY did not establish a specific Study Area for neighborhood character. DSNY simply created a single area for the environmental impacts that were analyzed. Moreover, the DSNY Study Areas are significantly smaller than prescribed by the CEQR TM.

The CEQR TM advises that the Study Area for assessing neighborhood character impacts should minimally begin at 400 feet, and should be expanded to ¼ and ½ mile for larger projects. See, Pg. 3A-7, CEQR TM. Given the intended purpose of CW Study to study the impact of the clustering of Transfer Stations in each of the DSNY Study Areas, DSNY should have used a radius of at least ¼ mile for all primary impacts and ½ mile for secondary impacts. The consequence of the narrow DSNY Study Areas is that a legitimate analysis of neighborhood character was not performed because the very factors for conducting such analysis - residential areas and community facilities - were excluded from the DSNY's analysis.

DSNY's analysis of neighborhood character impacts for land-based Transfer Stations is in sharp contrast to DSNY's analysis of neighborhood character impacts for the conversion of Marine Transfer Stations. In analyzing neighborhood character impacts for conversion of Marine Transfer Stations, DSNY followed the directive of the CEQR TM.

DSNY assessed the neighborhood character impacts based on an appropriately-defined Study Area and environmental impacts that affect neighborhood character, such as land use, traffic, socioeconomic and open space impacts, generally based on a ¼- to ½-mile radius Study Area. See, Pg. 3-19, Chapter 3, Volume III, CW Study.

Indeed, to truly evaluate neighborhood character impacts, it is critical that one begin to identify a much larger Study Area based on community observations of the impacts from Transfer Stations. For example, the Study Area should include the following: roads used by Transfer Station trucks, including non-truck routes within the communities, significant areas of residences, and community facilities (e.g., hospitals, schools, child care facilities, and even small commercial facilities).

C. The analysis of Odor Impacts was incomplete and did not fully account for Odor Impacts

The odor analysis suffers from many of the basic deficiencies noted for the air quality analysis and did not fully account for odor impacts. DSNY limited the analysis of odor impacts from the clustering of Transfer Stations in each of the DSNY Study Areas to those that it deemed to be "overlapping." See, Pg. 45, Volume I, CW Study. It further limited the analysis to only those "overlapping" impacts that were near unidentified "sensitive receptors." In other words rather that analyze all of the odors from all of the Transfer Stations in each of the neighborhoods, DSNY examined only odors at locations that it deemed to be impacted from more than one transfer facility. This approach

essentially excludes the worst odor impacts, those immediately adjacent to Transfer Stations.

As noted above in the air quality discussion, this approach conflicts with the CEQR TM. DSNY should have examined the total odor emissions from each of the Transfer Stations in each of the DSNY Study Areas and assessed their collective impact at all sensitive receptors. As also noted above, because of the narrow Study Area, DSNY failed to account for impacts at numerous residences and community facilities in each of the DSNY Study Areas. In contrast to its limited odor analysis of the Transfer Stations, in its analysis of the odor impacts due to the conversion of Marine Transfer Stations, DSNY appropriately assessed odor impacts at 50-meter intervals for a total radius of 500 meters around the site boundary in all directions.

Separate from DSNY flawed "overlapping" approach, the methodology for conducting estimated odor impacts suffers from numerous flaws. Rather than study the actual odors from the Transfer Stations, it created "odor emission factors" based on four putrescible Transfer Stations. See, Pg.2, Appendix E, Volume I, CW Study. Given the wide variation of Transfer Station design and operation, this approach fails to account for the worst-case odor conditions as required by the CEQR TM.

DSNY also derived a novel "odor per unit mass stored" as the basis for estimating emissions from any transfer station. See, Pg. 6, Appendix E, Volume I, CW Study. This approach is not based on any industry or regulatory approach. Moreover, it does not

account for wide variations of odors due to the varying constituents and age of the putrescible waste, and the varying designs and operations of each of the Transfer Stations. DSNY also failed to account for any fugitive odors - it assumed that all odors were vented from the exhaust vents despite the fact that fugitive odors are a major issue at Transfer Stations due to their numerous openings.

In assessing odor impacts from the Transfer Stations, DSNY did not distinguish between odors from Transfer Stations and odors from other facilities. See, Pg. 46, Volume I, CW Study. In other words, it assumed that all odors in the neighborhoods surrounding Transfer Stations are equal in its detection and impact on residents. This is a critically important issue because residents in and adjacent to the DSNY Study Areas consistently detect the unique odors associated with Transfer Stations in their neighborhoods.

There was no accounting for the unique combination of odors from putrescible waste and various masking agents used in Transfer Stations. This is in sharp contrast to the approach DSNY used to analyze odor impacts from the Marine Transfer Stations. In analyzing the odor impacts from Marine Transfer Stations, DSNY examined odor concentration, odor intensity (i.e., relative strength of an odor) and odor persistence - the three key factors that would uniquely identify putrescible waste odors. See, Pgs. 3- 71, 3-72, Chapter 3, Volume III, CW Study.

DSNY also analyzed hydrogen sulfide (H_2S) emissions from Marine Transfer Stations, but failed to do so for the Transfer Stations. See, Pgs. 3-72, 3-73, Chapter 3, Volume III, CW Study. Hydrogen sulfide is the one odorous compound for which New

York State and New York City have issued regulatory standards. While DSNY appropriately compared the H_2S impacts from Marine Transfer Stations against these regulatory standards, it ignored it in its analysis of the impacts of Transfer Stations.

D. DSNY did not analyze Health Impacts

DSNY failed to conduct any form of health analysis. Its purported health analysis consisted of nothing more than referring to its air quality and odor analyses. See, Appendix I, Public Health Evaluation, Volume I, CW Study. As noted above, even with the major flaws in the CW Study with respect to the air quality analysis, the air quality impacts are significant and adverse. Based on the impacts of PM 2.5 alone, DSNY should have specifically analyzed the asthma and related respiratory and heart consequences of such impacts. As DSNY acknowledges, certain communities have a much higher susceptibility to asthma and respiratory illness. See, Pg. 16, Appendix I, Public Health Evaluation, Volume I, CW Study.

Based on this acknowledgement, the fact that each of the communities in and adjacent to the DSNY Study Areas consist of residents whose asthma rates are among the highest in New York City, and the documented asthma and respiratory risk due to exposure to PM 2.5, DSNY should have performed a detailed health impact analysis to assess the health risks to community residents from the exposure to PM 2.5. Such health analysis should have included a health survey in each of the communities to establish a health profile and should have specifically identified subpopulations that suffer from asthma,

upper respiratory illness, and/or are otherwise susceptible to exposure to PM 2.5. Based on such a health profile, DSNY should have assessed the specific health risks associated with the PM 2.5 impacts from the Transfer Stations. In addition, DSNY should have assessed whether the masking agents used for odors have any public health impact, including triggering of asthma events.

Another major omission is DSNY's failure to assess the health consequences of exposure to air toxins. As noted above, even though DSNY acknowledged that there are 15 air toxins associated with the diesel engines used for Transfer Station operations, including six carcinogenic compounds, DSNY did not analyze the impacts of these compounds in the communities that are in and surround the DSNY Study Areas. Lastly, DSNY failed to examine the public health concerns associated with vermin that are commonly associated with Transfer Stations, particularly putrescible Transfer Stations.

CONCLUSIONS AND RECOMMENDATIONS

As discussed in this Report, DSNY's analysis of the impacts of Transfer Stations is severely flawed and does not support DSNY's conclusions that the clustering of Transfer Stations does not have significant and adverse impacts. Despite the severe limitations in the manner in which DSNY studied the environmental impacts of the clustering of Transfer Stations, DSNY's analysis shows significant and adverse impacts from this clustering.

Given the serious flaws in the CW Study, particularly its numerous conflicts with the CEQR TM, the CW Study cannot be used as a basis for the SWMP, the Environmental Impact Statement of the SWMP, or the Transfer Station Siting Regulations. If the CW Study is to serve DSNY's stated goal of being a "foundation for the Department's efforts to develop a new comprehensive Solid Waste Management Plan (SWMP) for the next 20 years," as proclaimed by Commissioner Doherty in his April 12, 2004 transmittal letter for the DSNY Study, a more comprehensive analysis must be performed.

In order to comprehensively identify the deficiencies, it is recommended that, based on the deficiencies identified in this report, the following additional analyses must be done:

(1) Review Underlying Basis of DSNY's Review of Clustering

Perform an analysis of the "geographic proximity" or clustering of Transfer Stations that assesses the full range of "aggregate impacts" and is consistent with

the requirements of a full Environmental Impact Assessment as detailed in the CEQR Technical Manual including:

- Develop alternative Study Areas for each impact issue analyzed in the CW Study

- Identify impact issues not analyzed in the CW Study and develop Study Areas and methodologies for such analyses based on the requirements of the CEQR Technical Manual

- Identify all sensitive receptors – examining receptors included and excluded (excluded receptors would include community facilities, parks, etc.)

- Evaluate "prototypical" waste stations to determine whether they accurately represent actual land based facilities in operation in New York City

  - Review field surveys of Transfer Stations

  - Evaluate design and operational assumptions

  - Evaluate permits for each of the Transfer Stations

- Check data on input used in analysis to verify that emissions/impacts estimates are correct, e.g., emission estimates of number of vehicles on-site

- Assess "replacement scenario" to determine whether replacement use assumptions are based on existing and proposed land use plans (as opposed to presuming replacement with similarly impactful industrial uses). Also examine the extent to which areas were rezoned for the purpose of Transfer Station sitings.

(2) Review operational improvements analysis

- Identify deficiencies

- Prepare recommendations for best design and operation practices based on regulatory and industry standards; and on authority of DSNY.

(3) Review Proposed Transfer Station Siting Regulations

- Determine whether current proposed regulations adequately protect all sensitive receptors (not only those listed in the regulations) from adverse impacts of individual and clustered Transfer Stations.

- Develop model siting regulations based on:

  - Regulations in place nationally and internationally

- Existing literature and understanding of the potential harms of Transfer Station systems and of potential mechanisms for minimizing harms and ensuring equitable distribution of impacts.

- Analysis of DSNY authority over the siting of Transfer Stations

(4) **Evaluate Volume II: Commercial Waste Generation and Projections, and compare projected waste to current capacity and projected capacity under the Marine Transfer Stations plan.**

(5) **Evaluate Volume V: Manhattan Transfer Station Siting Report and determine whether the conclusions regarding the feasibility of additional Transfer Stations in Manhattan are valid.**

- Evaluate whether potential Marine Transfer Station sites exist in Manhattan, in addition to the existing Marine Transfer Station sites at West 59th Street, East 91st Street, and West 135th Street, for the processing of DSNY-managed and commercial waste.

- Evaluate whether the Volume V assessments of barriers to creating four additional Marine Transfer Stations, and the conclusions drawn from these assessments, are valid.

(6) **Evaluate Volume III to determine whether the analysis and conclusions regarding the conversion of existing Marine Transfer Stations are accurate.**

ATTACHMENT 1 – DSNY's Four Study Areas (Maps CD)

Hunts Point, Bronx CD - #2 and 9 Study Area - The area is comprised of 11 census tracts in the Hunts Point Neighborhood and covers most of Bronx CD #2 -- it includes the Hunts Point peninsula with portions of the East River and Bronx waterfronts, and extends inland several blocs north of the Bruckner Expressway. The census tracts are: 011900, 008900, 0111502, 08500, 009100, 08300, 011501, 00900, 008100, 009700, 010500.

Port Morris, Bronx CD - #1 Study Area - The area studied is comprised of 13 census tracts in the Port Morris area and covers the southwestern portion of Bronx CD -- #1, which is roughly about 1/3 of the districts overall area -- extends along the Harlem River and East River waterfronts from near the 145th Street Bridge at the northwest to about East 149th Street at the southeast, and inland several blocks east of the Major Deegan Expressway and north of the Bruckner. The census tracts are: 004900, 004700, 005301, 002300, 001700, 002500, 02702, 02701, 001500, 001100, 08100, 03100, 008300.

Brooklyn Study Area - 17 census tracts in the northeastern portion of Brooklyn Community District #1 - census tracts 050300, 049500, 048100, 051300, 048300, 045300, 057900, 058900, 059300, 047300, 051500, 047700, 046500, 049700, 050100.

Jamaica Study Area - 12 census tracts the over the northern portion of Queens CD - #12 and a portion of CD - #8 to the north. It straddles the LIRR corridor north of John F. Kennedy International Airport and west of the Jamaica Station. The census tracts are: 045800; 045400; 044602; 046000; 044601; 044200; 024400; 041000; 044000; 024600; 024800, 041400.

40.3.4.2 DSNY Response to Organization of Waterfront Neighborhoods (OWN) Comments on Commercial Waste Study

40.3.4.2.1 Introduction

This document responds to the comment document in the preceding section prepared for the Organization of Waterfront Neighborhoods and the New York Lawyers for Public Interest by ARC Engineering et al and EA Engineering (undated), that addressed Volume I of the six volume, March 2004, Commercial Waste Management Study (CWMS) prepared by Henningson Durham & Richardson Architecture & Engineering P.C. (HDR) and its subconsultants (the HDR Team) for the New York City (City) Department of Sanitation (DSNY). The subject document will be referred to herein as the "OWN comments" and the commenting organizations will be collectively referred to as "OWN."

The CWMS was prepared under DSNY's direction in response to Local Law 74 of 2000 (LL74), which required a study of the environmental and public health effects of the relatively high numbers of commercial waste transfer stations in some areas of the City. Many of the specific comment responses below necessarily address certain of the mischaracterizations of the CWMS purpose, and are not intended to constitute a complete response to all of OWN's comments. The responses below focus on the OWN comments as they relate the CWMS analysis and its findings.

40.3.4.2.2 General Responses to OWN Comments

The vast majority the OWN comments reflect significant misconceptions and/or mischaracterizations by the commenters about the purpose of the CWMS. The following are summary statements of an OWN comment, followed by the response:

1. **Comment:** The OWN document extensively (approximately 100 times) cites City Environmental Quality Review (CEQR) requirements as if they apply to the CWMS, and critiques the study for being in "violation" of these requirements.

Response: The OWN document improperly evaluates the CWMS as if it were a permitting exercise or an environmental review for a proposed "project" or action. The OWN comments use the word "project" in quotes several times, implying that the commenters understand that the CWMS is not, in fact, a proposed project. The OWN comments inappropriately critique the CWMS for not applying methods and criteria that are applicable to single-facility or "project" actions, thus concluding that the CWMS was a seriously flawed study.

CEQR requirements do not apply to the CWMS since the CWMS does not evaluate an action subject to CEQR such as the siting of a new project in the City or a programmatic action – rather, it evaluates existing privately owned and operated transfer stations. Since this was a unique study, when feasible CEQR methodologies were used as a means to analyze the potential effects of these existing transfer stations (for example, a 3 dBA increase for noise was used as a threshold for perceived impacts when the study area analyses modeled existing facilities, and then the contribution of multiple facilities on a sensitive receptor in relation to the background monitored levels at that receptor since that is a recognizable threshold), but to cite any inconsistencies with CEQR as "violations" is inappropriate.

Once the CWMS is placed in its proper context, as a study rather than an environmental review of a new project or action, most of the OWN comments are not applicable. The analytical approach used for the CWMS was a reasonable attempt to quantify the cumulative, overlapping impacts on neighborhoods and sensitive receptors from the effects of multiple transfer stations in a geographic area. The CWMS Scope, issued for public comment, described this approach and the comments received on the Scope were favorable.

2. **Comment:** The OWN comments state that DSNY claimed credit for future modifications at Transfer Stations in the analysis and that DSNY believes it has the authority to implement "some" of the changes recommended in the CWMS.

Response: Credit for future facility modifications were not claimed for the analysis. The methodologies for noise analysis indicated that, if significant effects were identified at a receptor as a result of the detailed stationary noise modeling, attenuation measures would be modeled. Since no significant effects were identified, these mitigation measures were not applied. If areas of overlap were identified for potential effects from odors under the conservative assumption that none of the facilities had odor control measures, the study applied reductions due to the known presence of odor control systems at certain facilities. If facility modifications were approved and underway at the time of the study, the modifications were included in the analysis, as appropriate, as in one instance, where an extensive environmental review with extensive community involvement had been conducted. It should be noted that DSNY has proposed changes to its transfer station rules that contain operational and design changes that, when implemented, will improve conditions at and around the transfer stations.

3. **Comment:** The OWN comments indicate that no analysis was presented for potential land use, community facilities and socioeconomic effects and that the neighborhood character analysis excluded the majority of residential areas and community facilities.

Response: As noted, the CWMS was undertaken to comply with Local Law 74 and to assist in the development of the new comprehensive SWMP. The study scope was expanded during the publicly-reviewed scoping process and the topics considered in the final study reflect this. The environmental studies conducted, however are not required under CEQR, and consequently do not specifically represent every topic considered in a CEQR environmental review. For example, the neighborhood character component of the CWMS was performed according to the accepted final scope of work for the CWMS, based on general land use, population characteristics, urban design/visual quality, parks and other community facilities prevalent in the study areas. The neighborhood character evaluation served two purposes: it informed the technical studies (air, odor, traffic, and noise), and it provided the opportunity to characterize any adverse effects which the air, odor, noise and traffic analyses demonstrated were due to the Transfer Stations' cumulative presence and operations. Because these technical analyses found no adverse effects that could be attributed to the combined effects of Transfer Stations, no adverse effects to neighborhood character were identified as well.

40.3.4.2.2 Specific Comments and Responses

4. **OWN Comment:** On pages 17-18, in a critique of the replacement trip generation (RTG) component of the CWMS, OWN makes the comment that the CWMS "simply makes the assumption - - without justification - - that the areas are zones manufacturing and that, therefore, future uses will be manufacturing ones."

Response: The assumption that, absent transfer stations, the future land use of the Study Area sites would be manufacturing is reasonable. The analysis cannot assume a non-industrial land use different from what the City has mandated for a manufacturing zoned parcel, especially since many other adjacent businesses depend on that zoning.

5. **OWN Comment:** On the bottom of page 18, OWN says that the DSNY did not analyze the impacts of each individual transfer station especially at "receptors" immediately adjacent to individual stations.

Response: DSNY agrees with this statement. LL74 directs that the CWMS evaluate the effects of multiple transfer stations concentrated in a geographic area . Putting receptors on or near fence lines and reporting these results would do nothing to inform the public and city officials regarding the "aggregate" effects of the facility groupings, and how these groupings affect the neighborhood. Rather, such receptors would reflect effects that are either totally or almost entirely caused by the one facility on whose fence line the receptor is placed. Such analysis is appropriate for individual facility permitting actions and individual facility environmental analyses, and for enforcement of permitting and zoning standards, but is not helpful in evaluating aggregate effects of facilities in geographic proximity on a neighborhood scale.

6. **OWN Comment*:*** On page 22-23, in critiquing the size of the Study Areas defined for the CWMS, OWN says that the "analysis of environmental impacts should be based on the projected distance of the impacts from the project."

Response: The Study Areas are, in fact, large enough so that the areas encompassed the locations of highest combined effects due to multiple facilities for on and off site noise, air quality, odor and traffic so that the predicted parameters (noise levels, pollutant concentrations) were clearly decreasing to well below the peak predicted levels at the edges of the Study Areas.

7. **OWN Comment:** The paragraph beginning on page 27 and continuing on page 28 of OWN's comments critiques the use of a 100-meter setback (the setback is responded to under Comment #5 above) for the air quality analysis of aggregate effects of the transfer station groupings. This paragraph then refers to Table 1, which is a listing of residential areas and community facilities supposedly excluded from the air quality analysis.

Response: This OWN comment implies that the listed facilities in "Table 1" are within the 100-meter setback and were thus excluded from the air quality modeling analysis. This is misleading because while the listed residential areas and community facilities are not within the air quality modeling domains selected for analysis, the vast majority of these are in fact well beyond 100 meters from the facilities studied, and are in fact outside the Study Areas modeled.

For example, Thomas A. Edison Vocational and Technical High School is listed by OWN as a community facility excluded from the Jamaica Study Area air quality analysis. A review of City maps confirms that this school is in fact outside the Jamaica Study Area, is over two (2) miles northwest of the nearest commercial waste transfer station in this study area, and is across a major freeway (Van Wyck Expressway) from the Jamaica Study Area. Such potential receptor locations are rightly excluded from analysis, especially because they are well outside the modeled area, which was large enough to easily encompass areas of maximum aggregate effect from the subject Study Area facilities.

8. **OWN Comment:** On page 31 of OWN's comments, a critique is made of the size of the air quality modeling domain (Study Area) for the CWMS, with a comparison to the modeling domain sizes used in the MTS EIS analyses. OWN says that that MTS analyses were completed in accordance with CEQR criteria, which are acceptable to OWN. OWN cites the MTS analyses as using a grid that extended at least 500 meters in all directions beyond facility fence lines.

Response: The air quality modeling grids used for the CWMS extend approximately 500 meters beyond (North, South, East and West) the transfer station facility locations that bounded the group of transfer stations in each Study Area. Therefore, OWN's critique is unfounded.

9. **OWN Comment:** On the bottom of page 34 of OWN's comments, they state that CEQR requires a "worst-case" analysis of the "project's operations," which DSNY's CWMS did not accomplish.

Response: The CWMS did include a reasonable worst-case analysis of air quality impacts for annual averages even though a worst-case analysis is more appropriate for permitting and environmental reviews for proposed projects, while the CWMS is not a "project" (i.e., it does not deal with a single facility or a proposed action), it is not a permitting action, and it is not subject to CEQR review.

The goal of the CWMS was to estimate potential effects of the relative concentration of existing commercial waste transfer stations in the Study Areas, rather than to permit new ones. Based on information obtained from the private transfer station operators and DSNY, average and peak facility operations were estimated for each type (putrescible, non-putrescible and fill material) of facility. Average operations were assumed over 16 hours for putrescible transfer stations, 12 hours for non-putrescible transfer stations and 10 hours for fill material transfer stations. Peak hour operations were assumed to be 24 hours per day for putrescible waste and non-putrescible waste transfer stations and were assumed to be 12 hours per day for fill material transfer stations since operations do not occur 24 hours per day at this type of transfer station. Therefore, a worst-case analysis was used to evaluate existing conditions for air quality analyses, particularly on a short-term basis.

10. **OWN Comment:** Beginning on page 42, OWN contends that "air quality impacts of the NAAQS pollutants are severe and should have been judged significant and adverse." They state on page 43 that "A more appropriate standard for assessing whether air quality impacts are significant and adverse is the Significant Impact Levels (SILs) established

pursuant to the Clean Air Act to assess the significance of impacts of a facility's proposed air permit."

Response: The statement that air quality impacts exceeding federal SILs are "significant and adverse" is an incorrect interpretation of the meaning of the SILs. The federal SILs are used to determine when impacts are insignificant, not adverse. Impacts above the SILs do not necessarily represent adverse impacts, but rather, indicate that such impacts above the SILs should be added to background (existing) concentrations to determine total pollutant concentrations. The total concentrations are then compared to the NAAQS to determine whether a proposed individual source could contribute to exceedance of the NAAQS. As noted in the preceding sentence, the federal SILs are also not applied to groups of facilities, but rather, to one facility at a time.

The dispersion modeling analysis shows, for pollutants other than $PM_{2.5}$, that background concentrations plus modeled impacts are below NAAQS. For 24-hour $PM_{2.5}$, the analysis shows that background plus modeled concentration do not exceed the NAAQS. For annual $PM_{2.5}$, some existing monitored concentrations already exceed the NAAQS, and EPA recently designated the New York City area as "nonattainment" with respect to $PM_{2.5}$ as a result. The analysis accurately presents the estimated (modeled) portion of existing $PM_{2.5}$ levels that are due to operation of each group of commercial waste transfer stations.

For areas where monitors indicate that NAAQS are being exceeded, it is appropriate to consider which emissions sources should be further regulated to bring the area into compliance. The analysis shows that commercial waste transfer stations collectively are a relatively small (< 10%) contribution to the total monitored concentrations in each Study Area, and that even complete elimination of such emissions would not bring about attainment of the annual $PM_{2.5}$ NAAQS in these areas. Also, as noted in the CWMS, EPA's national programs to apply more stringent emission limits to existing and new power plants, new on-road and non-road engines, and its mandated reductions in sulfur content used in the transportation sector, will continue to bring about further reductions in $PM_{2.5}$ levels in the future, beyond the reductions in the City's $PM_{2.5}$ levels that have occurred in the past two decades.

11. **OWN Comment:** On page 45, OWN critiques the CWMS for not evaluating effects of "air toxic" pollutants, which are being evaluated in the MTS EIS.

Response: The evaluation of air toxics in New York is generally performed in accordance with NYSDEC policy; it is not mandated by rule or law. The NYSDEC policy defining procedures for air toxics review stipulates that these procedures are applicable to a facility seeking a Permit to Construct or a Certificate to Operate. These procedures do not apply to groups of facilities or their aggregate effects, which was the subject of the CWMS.

Also, it is important to understand that air toxics, by necessity, are evaluated on an incremental risk basis. This is the case in New York and in many other states that have air toxics policies or air toxics rules. In other words, no attempt is made in the NYSDEC policy to evaluate "background" risk from emission sources other than the one seeking the permit, or from other "risk" factors that might constitute a portion of an exposed individual's risk of, for example, lung cancer. The "background" cancer risk, that attributable to other sources, and especially to indoor air pollutants, cigarette smoke, etc, is likely to be many orders of magnitude higher than the "one-in-a million" target risk limit for an individual source seeking a permit under the NYSDEC policy.

12. **OWN Comments:** On pages 48 and following, OWN critiques the CWMS for its approach to odor impact analysis, complaining about the "overlapping" effects approach, the basis for odor emission factors, which was sampling conducted at four putrescible waste facilities, and the "novel" type of emission factor, on a mass per tons stored basis.

Response: The evaluation of odor effects from the groups of facilities analyzed was consistent with LL74, which mandated that the study consider the aggregate, overlapping effects of the groups of facilities, rather than individual facility effects.

The basis for the emission factors, including multiple samples at each of four facilities, is considered to be quite sound, and also fairly conservative, in that the highest emission factor obtained for any sample was used for estimating emission rates for model input. Using the highest emission factor likely caused overestimation of the number of times per

year when a particular receptor would perceive a given level of odor. In addition, it was conservatively assumed that no odor control system was in operation, when in fact odor control is mandated.

With respect to the "novel" type of emission factor, expressed on a mass per tons stored basis, there is no industry standard or acceptable regulatory approach in establishing units for odor emission factors for solid waste processing operations. The HDR Team evaluated the sampling data with two potential sets of units for emission factors, those being a mass per ton processed, and a mass per ton stored basis. Because the waste movements (unloading, transfer) at the commercial waste facilities tend to be more in a batch than a continuous mode, the mass per waste stored basis seemed more reasonable for these facilities. However, in terms of modeling results, either type of emission factor basis would provide similar results.

13. **OWN Comments:** On page 51, OWN says that the CWMS failed to truly evaluate health impacts, and simply made reference to the air quality and odor analyses. OWN makes the statement that the study should have documented the asthma and respiratory illness rates in the Study Area communities and should have assessed the respiratory health risks due to $PM_{2.5}$ emissions from the transfer stations.

Response: Since risks to health are a function of amounts of exposure, health risk assessments properly compare amounts of exposure from a specific source to health-based standards or guidelines: when such amounts of exposure range from very small to insignificant, risks to health are expected to be proportionately small or insignificant. This was found to be the case for airborne impacts due to the $PM_{2.5}$ emissions from the transfer stations analyzed.

In general, fine particulate matter concentrations of $PM_{2.5}$ in ambient air are somewhat smaller now than they were when systematic monitoring began (in 1999), and perhaps 30% lower than estimates from the 1970's and 1980's (see, for example, http://www.epa.gov/airtrends/pm.html). Thus, although PM concentrations have decreased over the past several decades (in the City and in the U.S. as a whole), reported

asthma rates have increased during this same time period. National regulations are continuing to further reduce airborne concentrations of diesel particulate matter (DPM), due to reductions in the sulfur content of diesel fuel, engine redesigns, and pollution control devices, such as catalytic converters. More generally, DPM levels in New York are smaller than DPM levels in comparable European cities, given the heavy reliance on diesel-powered cars in Europe. The weight of scientific and clinical evidence on asthma and other respiratory illnesses fails to support the hypothesis that $PM_{2.5}$ emissions from the transfer stations at issue would aggravate or otherwise exacerbate these illnesses.

40.3.4.3 Other Comments and Responses on Commercial Waste

1. **Comment:** One commenter had numerous questions concerning the Commercial Waste Management Study (CWMS), which was referred to in some of the analyses in the DEIS. Specifically, they wanted to know why the 7 AM to 6 PM time period was the most appropriate time for evaluating local traffic impacts. They believed that the impacts of the private waste transfer stations should have been based on their permitted capacity. They questioned how the "worst-case" intersections were chosen, since one intersection did not have a single waste truck pass through it. Additionally, the off-site noise impacts utilized a "noise impact spread sheet" which was developed for the FEIS for the 2000 plan. This spreadsheet should be included in the DEIS. The CWMS lacked information to determine if the intersections evaluated were the most conservative choices.

Response: Chapter 3 of the DEIS and this FEIS presents the methodologies used for evaluating potential impacts. For traffic, a.m., facility and p.m. peak traffic was analyzed to represent the reasonable worst case time periods – when either background traffic or project-generated traffic volumes are highest. These time periods varied depending on a particular site, but generally, the facility peak hour occurred after the a.m. peak hour when background traffic volumes were higher.

A CEQR-level analysis of potentially significant adverse impacts related to processing Commercial Waste at the Converted MTSs is included in the Commercial Waste Management Study (CWMS)– Volume III, which was prepared in response to the

mandates in LL74, is included as Appendix I to this FEIS, and was also included in the Draft New SWMP. The analysis of potential noise impacts in that analysis is updated and refined in this FEIS.

CEQR requirements did not apply to the evaluation of existing commercial waste transfer stations located in geographic proximity (Volume I of the CWMS). The CWMS did not evaluate an action subject to CEQR such as the siting of a new project in the City or a programmatic action – rather, it evaluated existing privately owned and operated transfer stations. Where appropriate, CEQR methodologies were used as a means to analyze the potential effects of these existing transfer stations, for example, a 3 dBA increase for noise was used as a threshold for evaluating perceived noise impacts in the study area analyses of the contribution of multiple facilities at a sensitive receptor in relation to the background monitored levels at that receptor, because a 3 dBA increase is a recognizable threshold.

2. **Comment:** The substandard conditions at commercial transfer stations and their concentration in certain communities is not adequately addressed, and there are no concrete plans for reducing capacity in communities overburdened by them. The new Siting Regulations may prevent further degradation in specific areas of the Bronx and Brooklyn, but will not ameliorate existing burdens. The City needs to develop a strategy to strengthen operational and siting rules that would result in the closure of or a diminished number of land based facilities, including a timeline for achieving this goal. How will the City enforce its regulations, including the usage of designated truck routes by private haulers?

Response: Following recommendations in the Commercial Waste Management Study, DSNY has promulgated new operating rules for private transfer stations that include stricter requirements for odor and dust control and facility maintenance. DSNY is committed to reducing permitted putrescible capacity in the communities with the greatest number of transfer stations once the Converted MTSs open. DSNY will work with the industry, the Council and community groups to achieve this reduction in capacity. If DSNY is unable to obtain the cooperation of the industry, DSNY will work

with the Council on legislation that will clarify DSNY's authority to reduce permitted capacity at transfer stations. DSNY has proposed revisions in its Siting Rules that impose more stringent requirements on the siting of new transfer stations. DSNY's Permit and Inspection Unit and the Police Department are responsible for enforcing tuck limits on designated truck routes. If a truck route does not provide direct access to a destination, trucks are permitted to use local streets to reach their destination.

3. **Comment:** The Converted MTSs are designed to process commercial waste without an adequate study of the resultant impacts. Referring to the CWMS is not sufficient to analyze the impacts. Commercial haulers will not be subject to DSNY regulations for emissions, odors, or noise, therefore impacts will be greater. The City needs to develop a better system to handle commercial waste that won't place such heavy burdens on residential neighborhoods, and needs to be more specific about the use of the MTSs for commercial waste.

Response: A CEQR-level analysis of potentially significant adverse impacts related to processing Commercial Waste at the Converted MTSs is included in the Commercial Waste Management Study (CWMS)– Volume III, which was prepared in response to the mandates in LL74, is included as Appendix I to this FEIS, and was also included in the Draft New SWMP. The analysis of potential noise impacts in that analysis is updated and refined in this FEIS.

Each Chapter in the DEIS and this FEIS that reviews a Converted MTS has a section summarizing that more detailed CEQR level analysis in the CWMS – Volume III (see Section X.18 of each Converted MTS chapter). On-site operations were analyzed assuming 24-hour operation. For example, for the noise analysis, it is assumed that the facility is operating all of its equipment during the quietest background hour, which, given the amount of commercial waste that might actually be processed during this period, is conservative. Neighborhood character is assessed based upon, among other things, a compilation of all of the on and off-site analyses in the DEIS and this FEIS, which analyze the acceptance of commercial waste at certain levels between 8:00 p.m. and 8:00 a.m. As discussed in the DEIS and this FEIS, a restriction on the number of

Commercial Waste vehicles delivering waste to the Southwest Brooklyn, Hamilton Avenue, East 91st Street and North Shore Converted MTSs during certain hours will mitigate estimated off-site noise impacts at receptors along the routes to these facilities between 8:00 p.m. and 8:00 a.m.

The DEIS and this FEIS analysis assumed a City metro area-specific mix of ages for diesel powered waste collection vehicles, which would include commercial waste hauling vehicles. Because DSNY's fleet of waste collection vehicles is newer than the average for the City area, the DEIS and this FEIS air quality analysis is already quite conservative, because newer diesel engines are subject to lower emissions standards than the existing fleet average. Additionally, the on-site and off-site air quality analyses were revised for this FEIS using the most current approved New York State Department of Transportation (NYSDOT) Mobile 6.2 emission factors, which accounts for the even lower emissions produced by DSNY's newer fleet. Also, it should be emphasized that new diesel powered vehicles purchased today are subject to emissions standards far lower than engines manufactured 20 years ago, and that starting in 2007, new diesel engine emission standards for particulate matter and nitrogen oxides will drop by at least an order of magnitude from today's emissions standards. Thus, fleet-wide diesel engine emissions are dropping and will continue to drop even more dramatically with time.

Also see the response to Comment #1.

4. **Comment:** (J5) The clean fill transfer stations are not really addressed in the SWMP, but they are some of the worst run transfer stations in the City. They are very dusty, and residents in the vicinity of these facilities cannot open their windows. Additionally there is no mention of waste prevention in the Construction and Demolition waste stream. C&D could be recycled, reused and/or re-sold.

Response: Volume II of the CWMS, Commercial Waste Generation and Projections, evaluated the quantities of non-putrescible waste processed at the 47 facilities permitted to process non-putrescible waste, 22 of which are clean fill facilities. (See Appendix I of this FEIS for the Volume II of the CWMS.) Over the period of 2000 to 2003, the volume

of clean fill material processed at these facilities ranged between 20,000 tpd to 27,000 tpd. The bulk of non-putrescible waste was clean fill, ranging from approximately 54% to 69% of the total. Clean fill is projected to increase by approximately 39% over the period of the New SWMP, 2004-2024. These facilities provide an essential service the City's construction industry. Most of the material processed at these facilities is recycled as aggregate or fill used on new construction projects. DSNY has proposed measures as modifications to its transfer station Rules that address control of dust at fill material transfer stations. Specifically, all fill material transfer stations will be required to have paved entrance and exit areas, and to have a method of cleaning dirt from vehicle tires before exiting a facility.

5. **Comment:** A number of speakers thought that commercial waste should be processed at all the MTSs in order to have one comprehensive waste management system, under the City's control. The commercial carters should be coaxed by franchise, financial incentives, or other means to use the Converted MTSs as well as the West 59th Street facility. There must be a meaningful discussion in the SWMP of economic flow control, how it would operate, what the tip fees might be, and what incentives and disincentives DSNY would use to ensure the redistribution of commercial waste, including milestones to achieve closure. Franchising, in particular, would have the added benefit of reducing truck miles, by not having multiple trucks from multiple firms traveling down the same block. It should also discuss the lack of incentive for integrated waste management companies to forego favorable disposal costs at their own facilities.

Response: The issue of what incentives or mandates may be required to attract commercial carters to use the MTSs will be addressed during City Council adoption of the New SWMP.

6. **Comment:** Will every single commercial waste vehicle be checked to make sure that there is no asbestos, lead, or other contaminated material in the truck, prior to taking the waste to a transfer site?

Response: Given the resources required, it is not practical to check every single commercial waste vehicle. However, DSNY's PIU does conduct periodic inspections

and transfer stations are at risk of serious permit violations if they accept hazardous materials.

7. **Comment:** The FEIS must incorporate an analysis of the impacts of the current network of commercial waste transfer stations included in the draft SWMP. This must include the impacts of the massive volume of truck traffic impacting on the South Bronx and Brooklyn CD1. More information is needed on the methodology and analyses used to evaluate commercial waste impacts. The EIS needs to include a timetable to close existing inadequate facilities or to bring them into conformance with regulatory requirements. The existing commercial waste system as well as the proposed changes to the system should be fully analyzed. In addition, an analysis of the new commercial waste initiatives must be incorporated into the FEIS, as well as the siting regulations and the operational regulations included in the SWMP.

Response: This analysis was reported in the Commercial Waste Management Study, Volume I, which is included as Appendix I to this FEIS.

8. **Comment:** There are so many uncertainties surrounding the issue of commercial waste processing at the MTSs that it seems reasonable to assume that more commercial waste could end up at the Converted MTSs than predicted. Other parts of the plan may fail or "Upset conditions" might occur more than expected, resulting in more commercial waste being sent to the MTSs. Due to all these uncertainties, the environmental assessment should assume worst case scenario in terms of the amount of commercial waste processed.

Response: The arrangements that DSNY would enter into with private carters for delivering waste to a Converted MTS would include contractual recourse against the carter for failure to follow the agreed upon procedure. For example, the contract could stipulate that a carter who arrives before or after his appointed hour on a given night would forfeit his dumping privileges and fee for that evening. Clearly, in time, such a stipulation could cause carters to adhere to schedules set.

9. **Comment:** Although the DEIS provides the maximum tonnage of commercial waste that could be processed at each MTS without significant adverse noise impacts, there is no explanation of how these maximum tonnages were determined. Additionally, how can DSNY ensure that these caps will not be exceeded? The DEIS figure for the maximum allowable number of commercial waste vehicles is for a 12-hour period. Some hours are more vulnerable to adverse noise impacts, and this was not taken into consideration.

Response: See response to Comment #1, #3 and #7 above.

10. **Comment:** The New SWMP should encourage commercial waste haulers to consider exploring CNG-fueled or other alternative-fueled vehicles. The SWMP should include specifics on how that might be achieved. Most private waste haulers are reluctant to implement new fuel and emission reduction programs in the absence of requirements to do so. DSNY's CNG refuse truck initiatives can help show commercial haulers which technologies may work best on New York City's streets. The New SWMP should outline specific incentives for commercial carters to adopt CNG vehicle programs and ensure infrastructure that supports the implementation of CNG vehicles in order to achieve emission reduction goals. DSNY should review the regulatory powers of BIC to assess mechanisms that would improve emissions performance of the commercial fleets. The New SWMP should also consider methods of supporting the development of CNG infrastructure, in addition to a purchase commitment.

Response: The CWMS included as Appendix I to this FEIS, includes in Section 2.2 of Volume VI, Waste Vehicle Technology Assessment a discussion of the advantages and disadvantages of CNG as a fuel source for waste collection vehicles. Cost and the fueling infrastructure requirements are significant barriers to the use of this technology. Furthermore new regulations requiring use of low sulfur fuel diesel trucks and the production of substantially cleaner engines by 2007 will significantly reduce particulate emissions from these vehicles. See also Response to Comment #61 in Section 40.3.1.8.

40.3.5 Transfer, Transport and Disposal Plan

This interim report was prepared as a supplement to the New York State Department of Conservation (NYSDEC) Part 360 Solid Waste Permit. Its purpose is to show that the available capacity at intermodal terminals in the New York Harbor region and the capacity of rail and/or ocean barge transport that serve these facilities are sufficient to transfer and transport containerized waste from the City's Converted MTSs as proposed in the City's Draft New Solid Waste Management Plan (Draft New SWMP). This report includes conservative estimates of the equipment requirements for the transfer, transport and disposal system. Finally, it describes the available disposal capacities in various states based on proposals received by the New York City Department of Sanitation (DSNY) in response to its Request for Proposals to Transport and Dispose of Containerized Waste from One or More Marine Transfer Stations (MTS Containerization RFP) issued in December 2003.

The City's Draft New SWMP proposes to develop four Converted MTSs— two in Brooklyn, one in Manhattan and one in Queens—that on a daily[11] average basis would containerize a total of approximately 5,770 tons per day (tpd) of DSNY-managed Waste. Depending upon the arrangements that may be decided upon between DSNY and the City Council during the Draft New SWMP adoption process, the Converted MTSs could also containerize a total of up to 3,880 tpd of Commercial Waste delivered by private carters operating in the City.

In response to the MTS Containerization RFP, DSNY received proposals from proposers in February of 2004 and has since short-listed four of these proposers for contract negotiations. These proposers are:

- TransRiver (American Ref-Fuel);
- Onyx Waste Services;
- IESI Corporation; and
- Waste Management, Inc.

[11] Calculated on a 302-day per year basis (six operating days per week excluding holidays).

The proposals offered a variety of transfer, transport and disposal scenarios, and identified the MTSs that would be served, the intermodal facilities that would be used, the mode of transport (rail or coastal barge), and the disposal facilities that would dispose of the waste. DSNY is currently in negotiations with the short-listed proposers with the objective of entering into 20-year Transport and Disposal Contracts with one or more of them. Accordingly, the specific elements of the waste transport and disposal system have not yet been finalized. The final arrangements could involve various combinations of the facilities described herein. When contracts are finalized, a final Transfer, Transport and Disposal Plan (TTDP) will be developed.

This report is based on the responses to the MTS Containerization RFP, information gathered during the ongoing negotiation process and independent investigations.

40.3.5.1 System Requirements

Table 40.3-5[12] shows the assumed average daily system throughput of the four Converted MTSs, inclusive of both DSNY-managed and Commercial Waste. The DSNY-managed Waste is estimated to average a total of approximately 5,770 tpd for the four Converted MTSs. There is also a total of approximately 3,900 tpd of capacity potentially available at these four Converted MTSs for use by commercial carters. All system requirement estimates provided within this report are based on average daily throughputs. Factors, such as contingencies or spare factors have been included in the analyses to account for peak throughput events. To establish system requirements for the number of railcars, barges and containers, this TTDP assumes that the Commercial Waste would be integrated into the MTS waste system over a four year period, as shown below in Tables 40.3-6 and 40.3-7. This four-year period is referred to as Phases 1 through 4, corresponding to the years 2007 through 2010.

[12] Adapted from the 2004 Draft Solid Waste Management Plan (Draft New SWMP), Table 3.4-1, Converted MTS Average Throughputs.

Table 40.3-5
Converted MTS Average Throughputs[(1)]

Converted MTS Location	(1) DSNY Average (tpd)	(2) Commercial Waste (tpd)	(3) Total (Sum of Columns 1 and 2) (tpd)
Hamilton Avenue	1,900	1,274	3,174
Southwest Brooklyn	950	828	1,778
East 91st Street	720	780	1,500
North Shore	2,200	1,000	3,200
Totals	5,770	3,882	9,652

Note:

(1) Column 1 is the average tons per day (tpd) derived from historical data for DSNY-managed Waste generated in the specific MTS wastesheds that DSNY has designated in the Draft New SWMP for each of the four Converted MTSs. Column 2 is the quantity of Commercial Waste that could be processed during the 8:00 p.m. to 8:00 a.m. time period, based on the analysis presented in the Draft New SWMP FEIS. Column 3 presents the total capacity that can be used at each facility between 8:00 a.m. and 8:00 p.m. for processing DSNY-managed Waste and between 8:00 p.m. and 8:00 a.m. for processing DSNY-managed Waste and Commercial Waste.

Table 40.3-6

Phasing of Commercial Waste into Converted MTS System Waste Stream

Average Daily Tonnage

Waste Type	Phase 1	Phase 2	Phase 3	Phase 4
	tpd	tpd	tpd	tpd
DSNY-Managed Waste Tonnage (Average)	5,770	5,770	5,770	5,770
Commercial Waste Tonnage (Average)	0	1,294	2,588	3,882
Total	**5,770**	**7,064**	**8,358**	**9,652**

Table 40.3-7

Phasing of Commercial Waste into the Converted MTS System

Daily Containers Requirements

Waste Type	Phase 1	Phase 2	Phase 3	Phase 4
	Cont/day	Cont/day	Cont/day	Cont/day
DSNY-Managed Waste Containers (Average)	263	263	263	263
Commercial Waste Containers (Average)	0	59	118	177
Total	**263**	**322**	**381**	**440**

Note:

(1) Container requirements are calculated assuming the net payload of waste per container is 22 tons.

40.3.5.2 Harbor Barge and Container Requirements for In-City Harbor Container Transfer

Containers of waste would be moved by barge from the four Converted MTSs to waterfront intermodal facilities located in the region of New York Harbor. To calculate the number of barges and containers required for in-City harbor barge transport during the first four years of operations, the following assumptions were used.

- Containers from each of the four Converted MTSs would be towed to the intermodal terminal in the New York Harbor region that is the greatest distance by barge from that Converted MTS (to conservatively estimate barge requirements);
- Each harbor barge would transport 48 containers, with a net payload of 1,056 tons[13];
- The round-trip cycle time[14], inclusive of barge handling at both the departing and receiving locations would be a maximum of 10 hours[15];
- Except during barge-switching operations, there would be two barges moored at each Converted MTS at all times; and
- The spare factor for barges would be 20 percent.

Tables 40.3-8 through 40.3-11 provide estimates of the number of barges required for in-City harbor barge transport from the four Converted MTSs to the intermodal terminal(s) during each of the four phases of the program. Over this period, the number of barges required would grow from 16 to 25, including spares.

Assuming 48 containers per barge, between 768 and 1,200 containers, inclusive of spares, would be required, taking into account the cycle time between the intermodal facility and the disposal facility(ies). Note that these containers are a subset of the system-wide containers that would be required.

---

[13] According to the MTS Containerization RFP, harbor barge dimensions would be 150 feet in length and 46 feet wide.

[14] Cycle time includes an allowance for the time required to load/unload full/empty containers at the end-of-route terminals

[15] Only intermodal facilities in New York Harbor were considered for this analysis.

Table 40.3-8
In-City Harbor Barge Requirements Phase 1

MTS	Tonnage (tpd)	(Full) Barges[(1)]	(Empty) Barges	(Full & Empty) Barges	Spares	Total Barges (Rounded)
Hamilton Avenue	1,900	1.8	1.8	3.6	0.7	5
Southwest Brooklyn	950	0.9	0.9	1.8	0.4	3
East 91st Street	720	0.7	0.7	1.4	0.3	3
North Shore	2,200	2.1	2.1	4.2	0.8	5
Totals	**5,770**					**16**

Table Note:

(1) Because the barge requirement calculations are shown on an average ton per day basis, fractional units of barges are shown in these tables. This is done only to explain the calculation, as all barges moved within the harbor would carry 48 containers.

Table 40.3-9
In-City Harbor Barge Requirements Phase 2

MTS	Tonnage (tpd)	(Full) Barges[1]	(Empty) Barges	(Full & Empty) Barges	Spares	Total Barges (Rounded)
Hamilton Avenue	2,325	2.2	2.2	4.4	0.9	6
Southwest Brooklyn	1,226	1.2	1.2	2.3	0.5	3
East 91st Street	980	0.9	0.9	1.9	0.4	3
North Shore	2,533	2.4	2.4	4.8	1.0	6
Totals	**7,064**					**18**

Table Note:

(1) Because the barge requirement calculations are shown on an average ton per day basis, fractional units of barges are shown in these tables. This is done only to explain the calculation, as all barges moved within the harbor would carry 48 containers.

Table 40.3-10
In-City Harbor Barge Requirements Phase 3

MTS	Tonnage (tpd)	(Full) Barges[1]	(Empty) Barges	(Full & Empty) Barges	Spares	Total Barges (Rounded)
Hamilton Avenue	2,749	2.6	2.6	5.2	1.0	7
Southwest Brooklyn	1,502	1.4	1.4	2.8	0.6	4
East 91st Street	1,240	1.2	1.2	2.3	0.5	3
North Shore	2,867	2.7	2.7	5.4	1.1	7
Totals	**8,358**					**21**

Table Note:

(1) Because the barge requirement calculations are shown on an average ton per day basis, fractional units of barges are shown in these tables. This is done only to explain the calculation, as all barges moved within the harbor would carry 48 containers.

Table 40.3-11
In-City Harbor Barge Requirements Phase 4

MTS	Tonnage (tpd)	(Full) Barges[1]	(Empty) Barges	(Full & Empty) Barges	Spares	Total Barges (Rounded)
Hamilton Avenue	3,174	3.0	3.0	6.0	1.2	8
Southwest Brooklyn	1,778	1.7	1.7	3.4	0.7	5
East 91st Street	1,500	1.4	1.4	2.8	0.6	4
North Shore	3,200	3.0	3.0	6.1	1.2	8
Totals	**9,652**					**25**

Table Note:

(1) Because the barge requirement calculations are shown on an average ton per day basis, fractional units of barges are shown in these tables. This is done only to explain the calculation, as all barges moved within the harbor would carry 48 containers.

40.3.5.3 System Railcar and Container Requirements for Long-Haul Transport

The estimate of the maximum system railcar and container requirements for long-haul transport to out-of-City disposal facilities during the first four years of operations is based on the following assumptions:

Containerized waste from the four Converted MTSs would be transloaded onto railcars at intermodal terminals and transported to the proposed disposal location that is the greatest distance by rail from the City.

- Containers on rail cars would be moved in merchandise trains departing the City daily[16;]
- Each railcar would hold four containers;
- The net payload of waste per container is 22 tons;
- The round-trip cycle time from the City to the disposal location would be 18 days[17];
- The spare factor for railcars would be 20 percent;
- The number of spare containers would be the number of spare railcars multiplied by four; and
- The four Converted MTSs would operate 302 days per year.

Table 40.3-12 presents the estimated maximum number of railcars and containers required for long-haul rail transport to the furthest proposed disposal location for the first four years of operations.

Table 40.3-12
Maximum Amount of Railcars and Containers Required for System

Phase	Tons Per Day	Total Railcars Required (Including Spares)	Total Containers Required (Including Spares)
Phase 1	5,770	1,426	5,704
Phase 2	7,064	1,750	7,000
Phase 3	8,358	2,052	8,208
Phase 4	9,652	2,376	9,504

[16] Given the high volumes of containers, it is possible that the railroad companies may decide to handle this operation in a manner that is more efficient than sending a separate merchandise train each day; however, for this study it was assumed that the containers would join three merchandise trains per day in order to calculate a conservative estimate of the number of railcars and containers required.
[17] This round-trip cycle time assumes that the disposal facilities will be able to offload the arriving containers on a continuous basis, thereby avoiding queuing of railcars. Cycle time includes both transit and loading and unloading of containers. This cycle time is an average cycle time based on proposed origins and destinations and assumes merchandise, not unit trains.

40.3.5.4 Ocean-going Barge and Container Requirements for Long-Haul Coastal Transport

Based on the proposals received from the MTS Containerization RFP, as well as an investigation into potential barge-to-ocean-going barge facilities in the New York harbor region, the maximum throughput of waste from the four Converted MTSs that would be transported by ocean-going barge is 263 one-way containers, or all the DSNY-managed Waste. The estimate of maximum system ocean-going barges and container requirements for this long-haul transport during the first four years of operations is based on the following assumptions:

- Waste would be transloaded onto ocean-going barge at intermodal terminals and transported to the proposed disposal location that is the greatest distance by ocean-going barge from the City.
- Containers would be transported by ocean-going barges departing the City six days per week;
- Each ocean-going barge would hold 320 containers;
- The dimensions of the ocean-going barge would be approximately 86 feet wide by 350 feet long;
- The round-trip cycle time from the City to the disposal location would be 4 days[18];
- One ocean-going barge would be required as a spare;
- 320 containers, i.e., sufficient to fill one ocean barge, would be required as spares;
- Barge operations at the intermodal facility would occur on three shifts; and
- The four Converted MTSs would operate 302 days per year.

Table 40.3-13 presents the estimated maximum number of ocean-going barges and containers required for long-haul coastal transport to the furthest proposed disposal location.

[18] This round-trip cycle time includes the transit time and container loading/unloading time.

Table 40.3-13
Maximum Amount of Ocean-going Barges and Containers Required for System

Phase	Tonnage (tpd)	Number of containers per day	Ocean-going Barges Required (Including Spares)	Number of Containers Required
Phase 1	5,770	263	5	1,369
Phase 2	7,064	322	6	1,604
Phase 3	8,358	380	6	1,840
Phase 4	9,652	434	7	2,075

40.3.5.5 Rail Capacity in Northern New Jersey

The majority[19] of the barge-to-rail solutions being described within this report would involve rail transport from locations in northern New Jersey. As can be seen in Attachment A, the northern New Jersey rail network is a very complex collection of lines and terminals. Adding to the complexity is the multiplicity of rail operators working within the territory. There are four major (Class 1) freight railroads operating in the territory. Additionally there are passenger operators and regional and short-line freight railroads.

The four Class 1 freight railroads operating in northern New Jersey are CPR (Canadian Pacific Railway), CSX Transportation, CR (Conrail) and NS (Norfolk Southern Railroad). CPR has a relatively limited role in the area, consisting of operating into and out of a CPR facility at Oak Island Yard. The relationship between CSX, CR and NS is more complicated and deserves some explanation. In 1999 CSX and NS purchased and split up Conrail. While in most markets the two acquiring railroads simply divided the assets, in three specific markets the rail infrastructure was so complex that a different solution set was reached. Northern New Jersey is one of those complex areas. The resultant territory is now referred to as the North Jersey Shared Assets.
Within the shared asset area in northern New Jersey, CSX and NS maintain separate routes into the terminal areas, as well as retaining certain yard facilities (NS routes and terminals are shown

[19] Steel Style Shipyard would not involve rail transport through northern New Jersey, as it is located on the Hudson River Line.

in green on the map in Attachment A, CSX routes and terminals are shown in red). Other routes and facilities (shown in blue on the map in Attachment A) are maintained and operated by the residual Conrail for the benefit of both of its parents (CSX and NS).

The rail network in northern New Jersey supports three major traffic flows. To understand how the DSNY containerized waste from Converted MTS facilities will flow within the network, it is prudent to describe the current traffic flows. Section 3.1 below describes how the different traffic flows impact various components of the network, and more importantly how the combined traffic and flows helps to identify potential capacity constraints.

It should be noted that the Class 1 railroads and PANYNJ have identified a series of infrastructure improvements that, when complete, will mitigate the majority of these capacity constrain locations. The combination of these infrastructure improvements and close coordination with the Class 1 railroads will ensure that there is adequate capacity to move the proposed containerized waste from the Converted MTSs.

40.3.5.5.1 Potential Congestion Due to High Traffic Volumes

Factors that affect the rail system's capacity to transport the containerized waste from the four Converted MTSs are the several other rail traffic flows in northern New Jersey, with their differing service and physical plant requirements. Each of these individual traffic flows is further complicated by the fact that some are more tightly scheduled than others. These rail traffic flows are discussed below.

40.3.5.5.2 Intermodal Traffic (Domestic and International)

There is a concentration of intermodal facilities in northern New Jersey, as shown in Attachment A. These include:

- CSX at North Bergen;
- NYSW (New York Susquehanna and Western) at North Bergen;
- NS at Croxton;
- NS at E-Port Yard;

- CSX at Kearney; and
- Facilities along the Chemical Coast Secondary in Newark and Elizabeth, including Port Newark Yard, Portside Yard, Port Newark Container Terminal (PNCT) and Express Rail.

The outbound intermodal rail traffic tends to move away from New Jersey in the evening and over night, and inbound intermodal traffic arrives from mid morning through early evening. Of particular interest in regards to the movement of containerized waste from the four Converted MTSs from barge to rail, is the fact that the Port Authority of New York and New Jersey (PANYNJ)-supported facilities in Newark and Elizabeth (i.e., Maher, APM/Maersk and PNCT) as well as the New York Container Terminal on Staten Island all utilize the Chemical Coast Secondary and Oak Island Yard to access and egress the region.

40.3.5.5.3 Automotive Traffic

Automotive traffic into North Jersey has historically included transporting finished automotive vehicles to Doremus Avenue Auto Unloading Facilities, auto parts to the Metuchen Auto Plant, and used automotive vehicles from NYSW. The Metuchen Auto Plant is scheduled to close. With its closure, all major automotive traffic will be confined to yards and support facilities at Oak Island Yard, which serves Doremus Avenue, and North Bergen. Inbound automotive traffic tends to move into the region in the evening so cars can be placed for morning unloading while the used automotives from NYSW move in the afternoon.

40.3.5.5.4 Merchandise Traffic

Merchandise traffic is the designation given to all general freight. This traffic moves in slightly different patterns than do intermodal traffic and automotive traffic. Schedules for inbound and outbound long-haul merchandise trains as well as local freight trains are designed around operating "windows" and customer needs, so these trains tend to operate throughout the day and night as opposed to the more restrictive intermodal and automotive networks.

The merchandise traffic must be brought into yards, such as Oak Island, and re-classified for movement by various local trains to either serving yards or directly to the consignee. Therefore, while intermodal and automotive traffic have extreme impact on specific locations, merchandise

traffic tends to impact major yard structures such as Oak Island Yard because of the need to classify these railcars and then build them into local delivery trains. The return of the empty containers on local trains has similar impacts on yards and facilities. Merchandise traffic generally affects the entire rail system evenly. Unlike intermodal and automotive, which are time sensitive and operate during certain windows, merchandise traffic tends to occupy the available additional line capacity. Because of the high volume of merchandise traffic and the numerous "windows" required to move this traffic, merchandise traffic generally affects the entire rail system evenly.

40.3.5.5.6 Chemical Traffic

There is significant chemical traffic (i.e. acids, gas, petroleum products, etc.) throughout the northern New Jersey area, with a strong concentration in Newark and Bayonne and additional heavy use all along the aptly named Chemical Coast Secondary.

40.3.5.5.7 Warehouse Traffic

Northern New Jersey enjoys a strong base of rail-served warehouses. This traffic is delivered to and picked up from consignee locations by a number of scheduled local trains. These local trains add additional layers of congestion on the already busy northern New Jersey rail system.

40.3.5.5.8 Other Traffic

Various other rail-served customers for commodities such as foodstuffs, paper, lumber and other manufactured goods exist along many of the rail lines in the region. These traffic flows overlap and utilize many of the same facilities and, therefore, place multiple stresses on the system. The rail movement of the containerized waste from the Converted MTS, whether it moves in merchandise traffic or dedicated unit trains, would be considered part of the merchandise network.

40.3.5.5.9 Critical Components of the Rail System

Some of the most critical pieces of the general rail system that may impact the movement of intermodal and/or merchandise trains with waste from the four Converted MTSs are:

- The Chemical Coast Secondary between Oak Island Yard and Bayway Yard;
- The Oak Island Yard Complex; and
- The CSX River Line.

As described below in Section 4, proposed infrastructure improvements carried in the current PANYNJ capital plan will help to relieve the congestion at the locations described herein. While primarily designed to support the port intermodal traffic, these improvements will favorably impact the movement of waste from the four Converted MTSs as well.

In recognition of the congested areas cited above, inclusion of the proposed tonnages of waste from the four Converted MTSs on these lines and yards will require close coordination with the four Class 1 railroads (i.e., CP, CSX, NS and Conrail). As mentioned above, with this close coordination, the rail infrastructure will be adequate to support the proposed tonnages.

40.3.5.6 Intermodal Terminal and Disposal Facility Components

This section defines the total potential operational and storage capacities of the intermodal terminals investigated, and reviews those facilities and disposal facility locations that are potentially available to the City.

40.3.5.6.1 Potential Intermodal Terminal Total Operational Capacity

Phone interviews with intermodal terminal operators and site visits to the intermodal terminals referenced in this section identified the capacity potentially available to serve the four Converted MTSs. The facilities investigated include:

- All PANYNJ-owned marine container terminals;

- Intermodal facilities that were offered by proposers in their response to the MTS Containerization RFP,
- Intermodal facilities that have been identified during the MTS Containerization RFP negotiation process; and
- Marine terminals or railyard facilities, identified by New York and New Jersey rail and/or port experts that could potentially serve the needs of DSNY.

Two potential transport modes are possible for shipping waste from the four Converted MTSs from an intermodal terminal to the disposal location: rail and ocean-going barge. The harbor barge-to-ocean-going barge operation would occur at a single intermodal terminal. The harbor barge-to-rail operations would occur at either a single intermodal terminal with on-dock rail or at two different terminals in reasonable proximity to each other, one providing harbor barge loading and unloading service and the other providing railcar loading and unloading service with a short dray in between.

The intermodal facilities listed below are grouped into the three following categories:

- Marine terminals: facilities that have the capability to service harbor barges and/or ocean-going barges;
- Port-Serving On-Dock Rail facilities: railyard facilities that are adjacent to and dedicated to marine intermodal terminals and have the capability to load and unload railcars;
- Near-Port Rail facilities: railyard facilities that have the capability to load and unload railcars, are within one mile of the New York Harbor region, but are not necessarily dedicated to a marine terminal.

The evaluation of potential intermodal capacity assumed that in Phase 1 DSNY would allocate all of the DSNY-managed Waste containers from the four Converted MTS to one terminal, or allocate containers from two of the four Converted MTSs to each of two terminals. Based on this assumption and the system requirements presented above in Section 2.0, it is assumed that either 263 containers (5,770 tons) per day would be transported to one intermodal terminal, or 132 containers (2,885 tons) per day would be transported to each of two intermodal terminals. These assumptions do not purport to predict the result of the DSNY negotiations. DSNY could contract separately for each of the four Converted MTSs or award a single contract for all. These

assumptions are simply being used as a screening tool to focus the analysis on intermodal terminals with large capacity. As described below, there is sufficient intermodal capacity available to handle all Phases of tonnages as shown in Table 40.3-6.

40.3.5.6.2 Survey Methodology

The phone interview format included the questions listed in Attachment B. To assess the amount of intermodal capacity available, facility operators were asked if their facilities would have the capacity to handle either 2,885 tpd (approximately 132 one-way containers) or 5,770 tpd (approximately 263 one-way containers) for a period of twenty years starting in late 2007. Information that was compiled from facilities that would not have this available capacity was recorded and filed, but is not presented in this TTDP.

40.3.5.6.3 Intermodal Capacity

The intermodal terminal investigation determined that there is a sufficient intermodal capacity to handle approximately 1,582 containers per day by rail and approximately 1,185 containers per day by barge, as shown in Table 40.3-14 below. This potential intermodal capacity exceeds DSNY's Phase 4 requirements (440 containers per day) by approximately a factor of three.

Table 40.3-14
Intermodal Facility Capacity Potentially Available to DSNY

Marine Terminals	Port-Serving On-Dock Railyards	Near-Port Railyards	Location	Status	Estimated Available Capacity (Barge to Rail) Daily One-way Container Throughput[1][2]	Estimated Available Capacity (Barge to Ocean-Going Barge) Daily One-way Container Throughput[1][2]
Maher Terminals[3]	Express Rail	------	Elizabeth, NJ	Planned improvements include expanding Express Rail and Corbin Street to support increasing intermodal traffic	132	132
Port Newark Container Terminal[3]	Port Newark Container Terminal Intermodal Yard	------	Port Newark, NJ	Improvements planned include construction of an additional two tracks at the PNCT intermodal facility	132	
ASI at Port Newark	N/A	------	Port Newark, NJ	Currently, this facility is a landside receiving and delivering satellite terminal for Red Hook		263
New York Container Terminal (Formerly Howland Hook)[3]	New York Container Terminal (Formerly Port Ivory)	------	Staten Island, NY	Improvements planned include the construction of an intermodal yard at Port Ivory which will provide direct access to the Chemical Coast Secondary.	263	263
APM/Maersk Terminal[3]	Express Rail	------	Elizabeth, NJ	Planned improvements include expanding Express Rail and Corbin Street to support increasing intermodal traffic	132	132
Newark Rail Terminal	Newark Rail Terminal	------	Newark, NJ	Potential new facility on former oil terminal site.	263	263
Duraport	Duraport	------	Port Newark, NJ	Currently active marine and rail facility. Both marine and rail require modifications for proposed operation	132	132
New Jersey Rail Carriers	New Jersey Rail Carriers	------	South Kearney, NJ	Currently active railyard with remnants of former marine facilities. Planned improvements include increasing number of tracks and potentially marine facilities	132	

Table 40.3-14
Intermodal Facility Capacity Potentially Available to DSNY
(Continued)

Marine Terminals	Port-Serving On-Dock Railyards	Near-Port Railyards	Location	Status	Estimated Available Capacity (Barge to Rail) Daily One-way Container Throughput[(1)(2)]	Estimated Available Capacity (Barge to Ocean-Going Barge) Daily One-way Container Throughput[(1)(2)]
Steel Style Shipyard	Steel Style Shipyard	------	Newburgh, NY	Piers need repair, dredging and rail improvements necessary. Site would be subject to environmental review	132	
------	------	EPIC Industries - at Brill's Yard	Newark, NJ	Two tracks in single-ended railyard. Planned improvements include making railyard double-ended and leasing additional track space to expand capacity	132	
------	------	Greenville Yard	Jersey City, NJ	Ten track railyard currently capable of serving DSNY needs. Have had negotiations with marine terminals, but no final deal has been made	132	
Total Daily One-way Container Throughput					**1,582**	**1,185**
Total Throughput (Tons per day)					**34,804**	**26,070**

Table Notes

(1) The analysis assumes that DSNY would either send all of its DSNY-managed Waste to one facility or divide the waste to be barged to two facilities. Therefore, assuming 22 tons per container, the two potential throughputs are 132 daily one-way containers, which is equivalent to approximately 2,885 tpd and 263 daily one-way containers, which is equivalent to approximately 5,770 tpd.

(2) If a facility is shown to have both barge-to-rail and barge-to ocean-going barge available capacity, this should be interpreted to mean that the facility could do either barge-to-rail OR barge-to ocean-going barge, (i.e., these are mutually exclusive).

(3) PNCT, Maher, APM/Maesrk and NYCT Terminal are heavily dependent on the build-out of Corbin Street to relieve the pressure of building trains on the Chemical Coast Secondary.

40.3.5.6.4 Intermodal Terminal Storage Capacity

The MTS Containerization RFP requires proposers to provide a sufficient number of containers to handle the volume of waste in the system offered in its proposal, taking into account cycle time, maintenance, peak event and transport contingencies. The investigation of potential container storage capacity at intermodal terminals indicated that all facilities listed in Table 40.3-15 have sufficient capacity to store the empty containers for a two-day buffer-period in the event of disruptions in transport service. The facility operators that were contacted for this assessment indicated that DSNY's operation would require storage of approximately one or two days of empty containers. This amounts to storage of between approximately 132 and 263 containers for half the DSNY-managed waste (approximately 2,885 tons per day) and between 263 and 526 containers for the entire DSNY-managed waste stream from the four Converted MTS (approximately 5,770 tons per day).

40.3.5.6.5 Marine Terminal Capacity

The information presented below appears by marine terminal facility. In addition to being based on interviews with marine terminal operators and site visits, it is based also on reviewed PANYNJ reports, including the Comprehensive Port Improvement Plans. Attachment C to this report provides a map that locates these facilities, as well as the Port-Serving On-Dock Rail facilities and Near-Port rail facilities discussed below.

40.3.5.6.5.1 Maher Terminal

The Maher Terminal is a 445-acre site located in Port Newark/Elizabeth in northern New Jersey. The berth length at Maher Terminal is approximately 8,900 feet with more than nine effective berths. The berth depths average between 35 to 50 feet. This facility has more than 20 container cranes that operate the barge and container-ship loading and unloading process. The terminal facilities at Maher Terminal have undergone a $200 million upgrade program recently with the objective of increasing its current capacity from 300,000 lifts per year to 750,000 lifts per year by 2010. The upgrade consolidated Maher's Fleet Street and Tripoli Street Terminals into one

contiguous facility with on-dock rail provided by Express Rail. Maher operators indicated that approximately 1,000 feet of berth space would be available for DSNY harbor barges, and that the marine facilities at this site could handle a daily throughput of 132 containers from two of the four Converted MTSs for either barge-to-ocean-going barge transport or barge-to-rail transport, which is discussed below in Section 4.1.5.1.

40.3.5.6.5.2 Port Newark Container Terminal (PNCT)

The PNCT is a 176-acre site located in the Port Newark/Elizabeth area of northern New Jersey with a total wharf length of 4,400 feet. The PNCT operator indicated that two adjacent underutilized berth spaces (Berths 51 and 53) with a total length of 600 feet and a 33 foot draft would be available to handle the barges from DSNY. These berth spaces are underutilized because they are of insufficient length to berth large container ships, but would be sufficient for berthing the harbor barges that were specified in the MTS Containerization RFP.

PANYNJ has planned site improvements for the marine facilities at PNCT. According to the terminal operator, PANYNJ funding is in place for these improvements, but the schedule has not yet been finalized by PANYNJ. The terminal operator expects these improvements to occur within the next one to two years (2005 - 2006). Currently, PNCT handles approximately 440,000 container moves per year. The PANYNJ site improvements would increase this capacity by more than 25%, to approximately 550,000 to 560,000 container moves per year. The terminal operators at PNCT indicated that the marine facilities at this site would have the available capacity to handle the container throughput from two of the four Converted MTSs, i.e., 132 containers per day for barge-to-rail transport.

40.3.5.6.5.3 ASI at Port Newark

The ASI Newark Terminal is a 20-acre container/barge handling facility located in Port Newark/Elizabeth in northern New Jersey. The ASI Newark Terminal[20] has approximately 1,200 feet of berth space with two available berths for handling containers. ASI uses two mobile

[20] ASI's Red Hook terminal in Brooklyn has only a three-year lease with PANYNJ, so was not considered in this analysis.

harbor cranes to handle containers off the barges. The berth depth at ASI Port Newark is approximately 27 feet. The terminal operators at ASI Port Newark indicated that this facility could handle the daily throughput of 263 containers from all four Converted MTSs for barge-to-ocean-going barge transport.

*40.3.5.6.5.*4 New York Container Terminal (NYCT)

NYCT is a 187-acre site located on the northwest corner of Staten Island bordering Kill van Kull and Arthur Kill. NYCT, formerly Howland Hook, has approximately 3,000 feet of berth, and it would be able to dedicate approximately 300 to 400 feet of existing berth space to handling the barges of containerized waste from the four Converted MTSs. NYCT's operator indicated that barge-to-barge container transfer would occur with a container moved between a harbor barge and ocean-going barge moored in parallel. NYCT would be capable of operating at a sustained rate of 30 container moves per hour (accounting for breaks and barge moves) over a 20-hour workday. Therefore, NYCT would be capable of handling the 263 one-way containers per day from all four Converted MTSs for either harbor barge-to-ocean-going barge transport or barge-to-rail transport, which is discussed below in Section 4.1.5.3.

40.3.5.6.5.5 APM/Maersk Terminal

The APM/Maersk Terminal is a 266-acre site located in Port Newark/Elizabeth in northern New Jersey. The berth length at APM/Maersk is approximately 6,000 feet with just under six effective berths. The berth depth averages between 35 and 50 feet. This facility has nine container cranes that operate the barge and container ship loading and unloading process. The terminal operators at APM/Maersk Terminal indicated that this facility could handle a daily throughput of 132 containers from two of the four Converted MTSs for either barge-to-ocean-going barge transport or barge-to-rail transport, which is discussed below in Section 4.1.5.1.

40.3.5.6.5.6 Newark Rail Terminal

Newark Rail Terminal is a 40-acre site located in Newark, New Jersey. The potential developers of this site indicated that there are plans to develop this site into a barge-to-rail or barge-to-ocean-going barge intermodal facility. The proposed barge dock would provide moorings for six 150-foot long harbor barges. The barge dock would be a high-level concrete platform structure measuring 635 feet by 120 feet. The off-loading and loading of containers would be accomplished through the use of two straddle-type container cranes. These two cranes would be able to off-load six barges, or approximately 6,300 tons, in about five hours.

Additionally, the facility would be capable of mooring two additional barges tied-up to mooring dolphins outboard of the proposed barge dock and bulkhead. In addition to the pier and bulkhead modifications, this site would require dredging to handle barges. The proposed water depth is 15 feet, which would require the dredging of approximately 80,000 cubic yards.

Based on the information from interviews with the potential site developers, this site could handle a daily throughput of 263 containers from all four Converted MTSs for either barge-to-ocean-going barge transport or barge-to-rail transport, as discussed below in Section 4.1.5.4.

40.3.5.6.5.7 Duraport

The Duraport Terminal is a 50-acre site located on the Kill van Kull in the southeastern Bayonne area. The terminal facilities at Duraport are currently used for barge-to-barge operations. The wharf would require rehabilitation in order to serve the needs of DSNY. The terminal operators at Duraport indicated that this facility could handle a daily throughput of 132 containers from two of the four Converted MTSs for either barge-to-ocean-going barge transport or barge-to rail transport, as discussed below in Section 4.1.5.5.

40.3.5.6.5.8 New Jersey Rail Carriers

New Jersey Rail Carriers are located on a 15-acre site on the Kearney Peninsula on Newark Bay. This site was formerly Columbia Coastal, which was a marine terminal with some rail capabilities. The current marine facility would not be adequate to handle the unloading and

loading of barges as it was designed to unload petroleum products from barge and/or ship. The marine facilities would require significant repair and modification to handle barges. If these repairs were made, it is feasible that the marine terminal at New Jersey Rail Carriers could handle approximately 132 containers per day of DSNY-managed waste from two of the four Converted MTS for barge-to rail transport.

40.3.5.6.5.9 Steel Style Shipyard

Steel Style Shipyard is a 35-acre site located on the west side of the Hudson River in Newburgh, New York, approximately 25 miles north of New York Harbor. This site was formerly known as New York Trap Rock and PC Freight. The potential selection of this site by DSNY would be subject to environmental review for the necessary permit applications.

Currently, there are two piers at the site approximately 700 feet long and 70 feet wide. Some repairs to these piers would be required in order to operate a barge handling facility. The depth at the piers is approximately eight feet, so dredging would be required in order to berth harbor barges. The terminal operator at Steel Style Shipyard indicated that this facility would have the capability to handle approximately 132 containers per day of DSNY-managed waste from two of the Converted MTSs for barge-to-rail transport.

40.3.5.6.6 Port-Serving On-Dock Railyard Capacity

40.3.5.6.6.1 Express Rail (Serving Maher Terminal and APM/Maersk Terminal)

Express Rail is a 33-acre site in Elizabeth, New Jersey that is used jointly by Maher Terminal and APM/Maersk Terminal. All containers lifted off a barge would move directly into the Express Rail facility onto railcars via straddle carriers.

Both domestic and international containers move through Express Rail for distribution to the North American rail network. Railcars move from Express Rail to the Corbin Street and/or Oak Island Yard to be assembled into outbound trains to final destination and disposal. Rail

movement to and from Express Rail currently uses one of the two Chemical Coast Secondary tracks parallel to Corbin Street for train assembly. This affects through train operations on the Chemical Coast Secondary.

The long term plan is to increase terminal throughput from Maher and APM/Maersk by building a railyard with six 7,200-foot tracks along Corbin Street Yard to assemble complete trains. According to the terminal operators at Maher Terminal and APM/Maersk Terminal, the planned improvements at Express Rail would make it feasible for this facility to support the rail movement of the 263 containers per day from the four Converted MTSs.

40.3.5.6.6.2 Port Newark Container Terminal Intermodal Yard

The Port Newark Container Terminal Intermodal Yard is a three-acre site located adjacent to Corbin Street in Port Newark, New Jersey. The site currently consists of two tracks that have the ability to handle up to 53 cars. Current operations are designed for one train per day on site. At this time the site is fully subscribed; however, it is planned that two additional tracks will be built on site. According to the operators of Port Newark Container Terminal, these two tracks could potentially support the movement of approximately 132 containers of DSNY-managed Waste from two of the four Converted MTSs.

The marine facilities and the rail facilities are not adjacent to each other. A short dray is required to move containers between the Port Newark Container Terminal and the Port Newark Container Terminal Intermodal Yard, however, a truck flyover is planned that will connect PNCT with the PNCT Intermodal Yard.

40.3.5.6.6.3 NYCT (formerly Port Ivory*)*

The railyard at NYCT, formerly Port Ivory, is a 39-acre railyard integrated with the adjacent NYCT port terminal. Phase I of this railyard is in construction and is designed to potentially handle both international containers and DSNY containers with a five track layout, each approximately 1,500 feet long. Three of these tracks could be dedicated to DSNY. Later phases of construction would increase the track layout to eleven.

Containers delivered by harbor barge to NYCT would be loaded by rubber-tired gantry cranes (RBTGs) into drop frame platform cars on the dock, three to a car, and towed by tractor to the adjacent railyard for loading onto railcars. Reach stackers would be available as back up to the cranes. The port terminal, in combination with the three tracks in the railyard, has the capability to handle 300 one-way DSNY-container moves a day. Construction of six additional tracks would provide the capacity to move the additional DSNY containers indicated in Phase 4 of the combined DSNY and Commercial Waste program.

The NYCT railyard is adjacent to and integrated with Arlington Yard, part of the Staten Island Railroad (SIRR), owned by the New York City Economic Development Corporation. With the completion in late 2005 of the Chemical Coast Connector, SIRR will interconnect with the Chemical Coast Secondary in New Jersey on which CSX and NS, Class 1 railroads, operate. Arlington Yard is undergoing a major upgrade and expansion that will provide the capacity to support unit train movements from SIRR onto the Chemical Coast Secondary.

40.3.5.6.6.4 Newark Rail Terminal

As described above in the Marine Terminals section, DSNY has received a proposal to develop this 40-acre site in Newark, New Jersey into a barge-to-rail or barge-to-ocean-going-barge intermodal facility. Potential site developers have identified a multiple use site design that would have at least two 2,000-foot-long loading tracks on site and 8,000 feet of storage tracks. In addition, the proposed site may include a 5,000-foot-long lead track that would extend to Oak Point Yard. This potential extension track to Oak Point could dramatically improve the transit times, flexibility and reliability when moving cars to and from Oak Point because Brills Yard, which is very congested, currently lies between the Newark Rail Terminal and Oak Point. The extension track would eliminate the need to move through Brills Yard.

The proposed area for loading the containers on to the railcars would be comprised of two parallel railroad sidings, each with a capacity of 25 railcars. Containers would be loaded on to the railcars through the use of rail-guided, straddle-type container cranes. Each siding would be equipped with two cranes. According to the potential developers of this site, if built, the facility would be capable of handling all 263 one-way containers per day of DSNY-managed waste from the four Converted MTSs.

40.3.5.6.6.5 Duraport Railyard

As described above, Duraport Railyard is a 50 acre site located on the Kill van Kull in the southeastern Bayonne area. It is served and supported by Bayonne Yard. Currently, there are limited rail facilities on the Duraport site; however, there is a long storage track between East 5th and 2nd Streets that reaches the site. It appears that one or perhaps two more rail storage and/or staging tracks could be built to handle increased volumes of railcars out of Duraport. Additional rail intermodal tracks would also have to be built on the Duraport site. Railcars could then be loaded on site and cuts of cars assembled between East 2nd and 5th streets before moving the cars to Bayonne Yard. From Bayonne Yard, the cars would probably move to Oak Island and then to final destination for unloading and disposal. The operator at Duraport Railyard indicated that this facility would have the capability to handle approximately 132 containers per day of DSNY-managed waste from two of the Converted MTSs for barge-to-rail transport.

40.3.5.6.6.6 New Jersey Rail Carriers

New Jersey Rail Carriers is a 15-acre site located in South Kearney on Newark Bay. This site was formerly a marine/rail oil terminal. Currently, the site has a warehouse, a small two-track single-ended railyard, and the remnants of a marine barge facility. Each of the two tracks is about 1,300 feet long. The operators of this site have plans to build up to five additional tracks as rail traffic increases.

This site is currently being used for the movement of outbound loaded containers on railcars. The site is served by Norfolk Southern directly via Croxton Yard, though it could potentially be served by CSX via Kearney Yard. With upgrades to the rail facilities, this site could potentially handle the 132 one-way containers per day from two of the four Converted MTSs.

40.3.5.6.6.7 Steel Style Shipyard

Steel Style Shipyard is a 35-acre site located on the west side of the Hudson River in Newburgh, New York, approximately 25 miles north of New York Harbor. The potential selection of this site by DSNY would be subject to environmental review for the necessary permit applications.

The existing Steel Style facility has two short rail spurs that are located on the northern portion of the property. The CSX River Line is a single track railroad (on a double track right-of-way) as it passes the site. Just south of Steel Style, there is a double-ended passing siding on the location of the second main track. The industrial lead to Steel Style comes off the north end of the passing siding and runs north by the main gate of Steel Style to the small two-track facility on the north end of Steel Style.

At this time, it is assumed that containers would not be able to be unloaded directly from barge to railcar and that there would be a short dray to move containers between the two modes. However, to accommodate the loading and unloading of railcars by either a sideloader or gantry crane, it would be necessary to configure at least two long tracks in the facility.

According to the terminal operator, if both rail and marine improvements were made, there would be sufficient capacity to move about 132 one-way containers per day of DSNY-managed Waste by rail to and from Steel Style Shipyard to the CSX River Line for movement to the final destination.

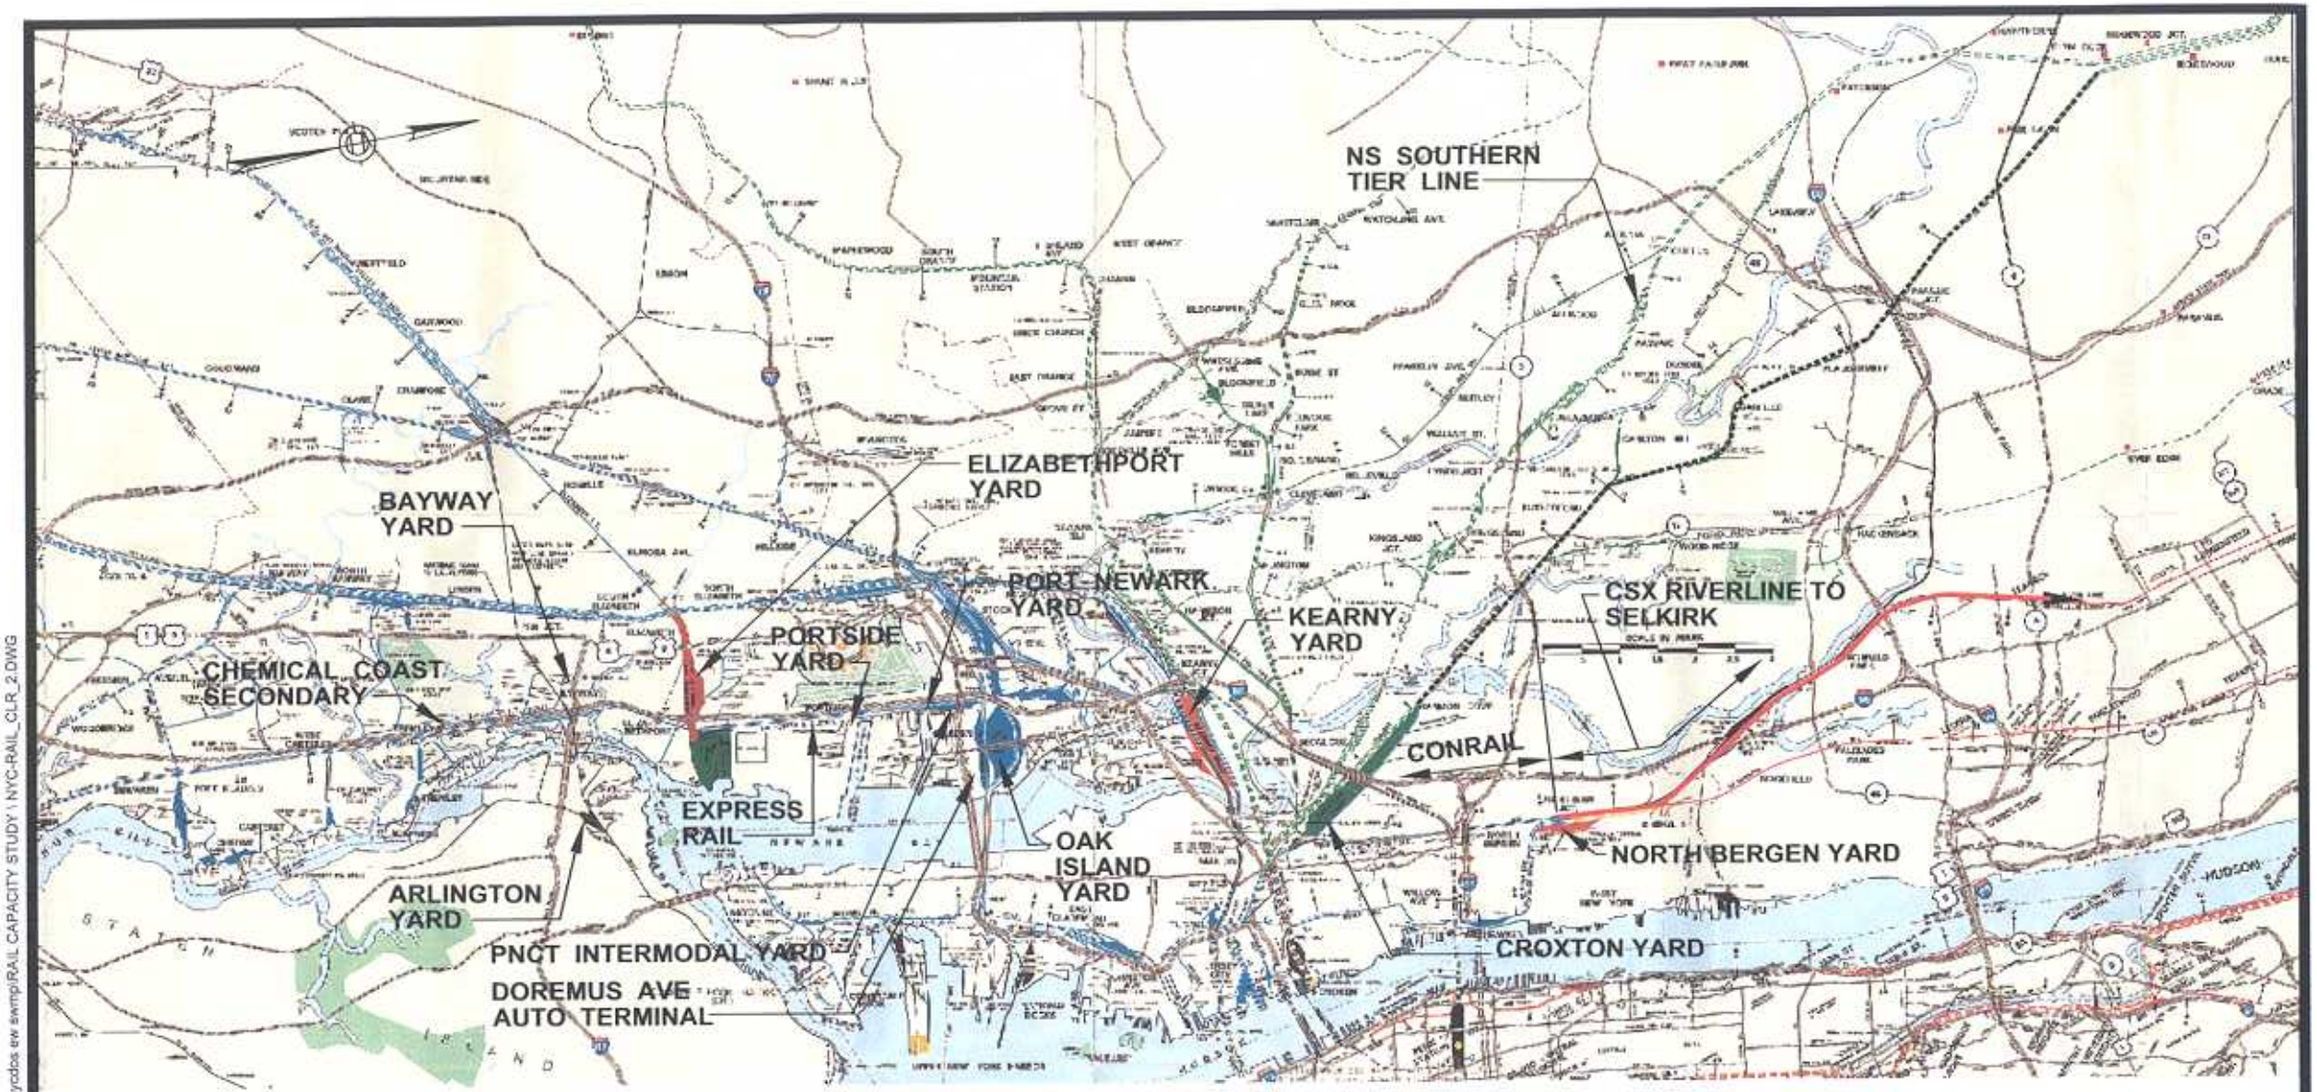
40.3.5.6.7 Near-Port Rail Facilities

40.3.5.6.7.1 Epic Industries at Brills Yard

Epic Industries leases a 6-acre site from Conrail that is located between Brills Yard and the New Jersey Turnpike in Newark, New Jersey. This site, which has two tracks in a small single-ended railyard, is currently used to move outbound loaded containers on railcars. The operators of this site indicated that they have recently been expanding their railyard and have plans to make it

double ended, which would improve their ability to increase the amount of cars that are loaded daily. In addition, the operators of Epic Industries are considering leasing additional space for additional track.

While this site does not have any waterfront access, it is within close proximity to Newark Bay. Therefore, with upgrades to the on site rail facility, it is feasible that containers could be drayed to this site from one of the near-by marine facilities mentioned above. The operators indicated that there would be sufficient capacity to move about 132 one-way containers per day of DSNY-managed Waste by rail.



40.3.5.6.7.2 Greenville Yard

Greenville Yard is a 27-acre site located in Jersey City, New Jersey. The New York Cross Harbor Railroad (NYCHRR) in Jersey City operates Greenville Yard, which was formerly the yard and car float facility for the Pennsylvania Railroad. Currently, NYCHRR performs both car float business from 51st Street in Brooklyn and loading and unloading of railcars at Greenville Yard in Jersey City.

According to terminal operators, this ten-track railyard would be capable of transporting approximately 132 containers per day of DSNY-managed waste from two of the four Converted MTSs. Merchandise and/or unit trains would depart from Greenville to Oak Island Yard (CSX) and then to the general railroad system of North America.

40.3.5.7 Potential Disposal Capacity

The City's disposal capacity requirements were set forth in Section 9.5.6 of the MTS Containerization RFP that required proposers to make disposal capacity guarantees to DSNY in their proposals. In effect, proposers are required to maintain five years of capacity going forward for the term of the contract. Based on the information provided by respondents and DSNY's own surveys, there is approximately 37,700 tpd of barge or rail accessible disposal capacity potentially available to the City in New York State, Georgia, North Carolina, Ohio, Pennsylvania and Virginia.

Attachment B: Interview Questions for Terminal Operators

Questions for Terminal Operators:

1. Given that DSNY intends to send containerized waste by barge to be transloaded onto either ocean-going barge or rail, is there any scenario under which the facility you operate could envision serving the needs of DSNY?
2. What, if any constraints, affect the ability of the facility you operate to service container barges? How many container barges could be docked at one time?
3. What is a reasonable assumption to use regarding the turnaround cycle time for unloading full and loading empty containers onto the barges described above?
4. What would be the operating procedure for moving containers from dockside to the railhead? What types of railcars and container handling equipment would the facility you operate anticipate using?
5. What is the maximum number of DSNY containers per day that the facility could envision handling in the time frame of 2007 (for Barge-to-Rail and/or Barge-to-Ocean-Going Barge? How much track capacity could be dedicated for DSNY containers? Would this increase, and if so by how much, in subsequent years?
6. What are reasonable operating assumptions relative to the dispatch and receipt of railcars with containerized waste from your facility?
7. What are reasonable assumptions relative to the dispatch and receipt of ocean-going barges with containerized waste from your facility?
8. How could your facility increase the number of railcars handled daily?
9. If improvements are planned at your facility, how will these improvements impact the throughput at your facility?
10. How much storage capacity for containers would be available at your facility?

40.3.6 Enhanced Environmental Justice Public Participation Plan and Interim Implementation Report

The New York State Department of Environmental Conservation (NYSDEC) issued policy guidance on Environmental Justice and Permitting in March 2003 (EJ Policy). The EJ Policy applies to certain NYSDEC permitting actions and environmental reviews for which NYSDEC is the lead agency. The Draft and Final Scoping Documents issued in May and October 2004, respectively, described DSNY's proposed plan for implementing an Enhanced Public Participation program, consistent with NYSDEC's EJ Policy. DSNY implemented the Enhanced Public Participation program during the public processes for the environmental review of the Draft New SWMP, including both the public scoping meetings for the supporting DEIS, the public hearings on the DEIS and the preparation of this FEIS. Public hearings held in connection with the City's Uniform Land Use Review Procedures (ULURP) were also used as opportunities to convey information on the NYSDEC permit process.

Among other things, the Draft New SWMP proposes and the DEIS and this FEIS evaluates, as elements of the Proposed Action for Long Term Export, the construction and operation of the four Converted Marine Transfer Stations, the barge and/or rail export of DSNY-managed Waste from private transfer stations that would serve wasteshed in the Bronx, Brooklyn and Queens that were formerly served by the existing South Bronx and Greenpoint MTSs. The Converted MTSs require Solid Waste Management Facility Permits under 6NYCRR Part 360, Article 15/25 permits and State Facility Air Permits. Draft applications for these permits have been filed with NYSDEC. Consequently, the Enhanced Public Participation program will continue to be conducted in connection with the permit review process, including any public hearings that NYSDEC holds in connection with the permit applications, once these are deemed complete by NYSDEC.

This Plan describes DSNY's implementation activities to date, including:

- The completion of the public Scoping process;
- The publication and distribution of the Final Scoping Document;
- The public hearings on the DEIS and ULURP applications; and
- The publication of the FEIS.

The Enhanced Public Participation program was implemented in the communities identified in the project area maps, published in the Draft and Final Scoping Documents. The project area maps were prepared using the USEPA database (prescribed in the EJ Policy), to identify the census block groups with populations that meet the EJ Policy criteria (EJ community). The project area maps also identified facilities in the project area that would likely be included in an environmental burden analysis, if such an analysis were required based on a finding that the Proposed Action would cause potentially significant unmitigatable adverse impacts[21]. The maps provided information about the environmental review analyses that would be performed and were published in the Draft and Final Scoping Document. The project areas, in which an Enhanced Public Participation program was conducted, included all the communities that would host one of the four Converted MTSs or the private transfer stations that were elements of the Proposed Action for Long Term Export, whether or not they met the EJ Policy criteria for an EJ community.

40.3.6.1 Enhanced Public Participation Program

DSNY, as lead agency for the environmental review of the Draft New SWMP, is implementing this Enhanced Public Participation program to provide meaningful opportunities for citizens to be informed about and involved in the environmental review and the facility permitting elements of the Proposed Action (including Alternatives to the Proposed Action). The program includes enhanced outreach, document and information dissemination and community meetings accessible to each EJ project area. The proposed Enhanced Public Participation program was drafted using a combination of best practices, identified by the DSNY team, and the suggested activities detailed in the NYSDEC publication, "Tips for Preparing a Public Participation Plan." This Enhanced Public Participation program describes activities completed through the publication of the FEIS. A final report will be submitted to NYSDEC on completion of the permit public hearing phase. This will include a written certification by DSNY that it has complied with the Enhanced Public Participation program, as proposed in the Final Scoping Document and as updated in the DEIS and thereafter.

[21] The FEIS does not report any such findings.

40.3.6.1.1 Advance Planning

During the Public Scoping process and prior to the publication of the Draft New SWMP, DSNY identified nine of ten potential project areas, eight Converted MTS sites and alternative facility locations that met EJ criteria. The Draft Scoping Document included a description of the Enhanced Public Participation program. DSNY elected to implement the Enhanced Public Participation program in all ten project areas, beginning with Public Scoping Meetings in locations in each of the EJ project areas. In the initial stage of implementing the Enhanced Public Participation program, DSNY identified stakeholders, met with community district managers, coordinated logistics and support for each meeting, and prepared reader-friendly outreach materials. All activities were conducted in accordance with the CEQR schedule.

.40.3.6.1.2 Identification of Stakeholders

Stakeholder lists were developed through online review and consultation with the District Managers of each of the ten Community Districts in which potential export facilities were located. The lists included, but were not limited to, community-based organizations, civic groups, religious groups, neighborhood housing agencies, and schools. The stakeholder lists were continuously updated through phone requests, attendee lists from public information meetings/hearings, and other sources.

40.3.6.1.3 Meetings with Community District Managers

The DSNY team requested one-on-one meetings with the District Manager of each Community Board in a potential project area. These meetings introduced the potential project; described the Enhanced Public Participation program; and verified previously gathered information about the neighborhood, including area demographics, stakeholder contact information, special needs, and preferred meeting locations. Eight of 10 district managers or their representatives were able to meet with the DSNY team (refer to attached Thank You letters in Appendix H). Two Community Board contacts were unable to meet with DSNY. As a result, web searches were conducted to gather stakeholder and demographic information for those Community Districts.

The DSNY team also met with representatives of the Hunt's Point Economic Development Corporation and held a joint meeting with the district managers of Manhattan Community Boards #4 and #7.

40.3.6.1.4 Outreach Materials Prepared

Public information materials consisted of trifold flyers mailed to stakeholders in advance of the Public Scoping Meetings, a Welcome handout and fact sheets, Comment sheets and large display boards. Materials were tailored to each EJ community and project. The flyers, handouts and displays encouraged public participation, described the facility permitting activities, the design and operation of the proposed facilities, including the Converted MTSs; answered frequently asked questions (FAQs); and presented other pertinent information on the permitting process, including the location of the Public Document Repositories in each EJ project area. The Public Scoping trifold mailers are provided in Appendix H. Samples of Scoping outreach materials for the North Shore Converted MTS are also provided in Appendix H .

A Welcome handout and fact sheets provided at each of the Public Scoping Meetings, summarized information presented on the display boards. Comment sheets were available for completion at the meeting, or for submission to DSNY by mail or fax on or before July 11, 2004. Copies of the Draft Scoping Document were also available for review at the meeting and online, as well as in the two Public Document Repositories located in each EJ project area.

40.3.6.1.5 Meeting Logistics and Support

Meeting venues were selected based on various criteria including familiarity and access, proximity to the proposed site, and availability. The following meeting logistics and support were provided for each location:

- Necessary permits and/or authorizations for meeting venues;
- A public-friendly layout for sign-in, display units, and a brief power-point presentation;
- Audio/visual equipment, including amplifiers, speakers, microphones, projector, screen and laptop computer;

- Speaker registration cards, attendee sign-in sheets, and comment sheets;
- A stenographer to record public comments;
- Simultaneous or consecutive interpreters where requested by the community or local representatives (it should be noted that a Spanish interpreter was available at 8 of 10 meeting venues, although not always utilized).
- Public outreach staff stationed at display boards, provided handouts, and answered questions on outreach materials or the outreach process.

40.3.6.1.6 Information Dissemination Program

40.3.6.1.6.1 Notices of Public Scoping

Notices of Public Scoping were published in the Environmental Notice Bulletin and the City Record on May 17, 2004, 30 days prior to the first Scoping Meeting which was scheduled on June 16, 2004. Subsequent notices were also published in these publications. A sample of the Notices of Public Scoping is provided in Appendix H .

40.3.6.1.6.2 Newspaper Display Advertisements

Based upon the formal Notice of Public Scoping, similar versions of Public Display advertisements were prepared for publication in local newspapers. Two newspapers per site initially were selected through consultation with each Community District Manager, with revisions made to avoid duplication. Two weeks prior to the scoping meetings, easy-to-read, site-specific or borough-specific display ads were placed in twelve community-based newspapers; and full display ads were placed in Spanish, Korean and Chinese Newspapers. Samples of newspaper notices, including those that appeared in Korean, Mandarin and Spanish, are included in Appendix H .

40.3.6.1.6.3 Document Repositories

Two accessible document repositories were established in each of the ten EJ project areas. The repositories were selected through consultation with the Community Boards, as well as review of project area maps. All project-related material, including draft and final permit applications for the MTSs, Scoping Documents, the DEIS, Public Notices or permit–related Notices, is available

for review by the public at these sites. Locations for documents include one public library; and the Community Board office for each community district in which a Proposed Action project is located. In addition, documents are available upon request from DSNY and for review at community liaison offices within pertinent state and federal agencies; borough halls; and legislative offices. A list of the public document repositories is included in Appendix H .

40.3.6.1.6.4 Public-Friendly Mailings and Flyers

Written information on potential projects and related permit review processes was prepared in an easy-to-read format, and translated, as appropriate, in advance of the Scoping Meeting. A site-specific tri-fold mailing was sent to approximately 2,200 stakeholders, and extra copies mailed to repositories and Community Board offices. The flyers were mailed two weeks in advance of each meeting to maximize attendance. See Appendix H for a sample of the flyers.

40.3.6.1.6.5 Toll Free Hotline

A toll-free hotline was established in May 2004 (1-888-NYC-SWMP), to receive comments and answer questions related to the project. The hotline phone number is available on the DSNY web site and was provided on all DSNY outreach and meeting/hearing materials and in public notices/display ads. Messages received via hotline are documented, substantive comments considered by DSNY, and Frequently Asked Questions (FAQs) answered. The hotline also receives requests for translation/interpretation services; special needs of residents within a particular project area; and additions to the stakeholder lists. The hotline voice message and operator offer information in English and Spanish.

40.3.6.1.7 Scoping meetings

40.3.6.1.7.1 Meeting Schedule

Public Scoping meetings were held between Wednesday, June 16th and Thursday, July 1st, 2004. Preferred venues identified by the Community District Managers were contacted, and where a site was unavailable on the dates requested, other nearby and easily accessible locations were selected. The Scoping Meeting schedule is provided below:

Table 40.3-16
Public Scoping Meeting Locations

Project Area	Date	Location
West 135th Street MTS	June 16, 2004	I.S.195 (Roberto Clemente School) 625 W.133rd Street, New York NY
Southwest Brooklyn MTS	June 17, 2004	I.S. 227 (Edward B. Shallow School) 6500 16th Avenue, Brooklyn, NY
West 59th Street MTS	June 21, 2004	West Side Y.M.C.A. 5 West 63rd Street, New York, NY
South Bronx MTS	June 22, 2004	P.S. 48 (Joseph Drake School) 1290 Spofford Avenue, Bronx, NY
South Bronx MTS Alternatives	June 23, 2004	Alfred E. Smith High School 333 East 151st Street, Bronx, NY
Hamilton Avenue MTS	June 24, 2004	Brooklyn 7 Community District Office 4201 4th Avenue, Brooklyn, NY
East 91st Street MTS	June 28, 2004	New York Blood Center (Auditorium) 310 E. 67th Street, New York, NY
North Shore MTS	June 29, 2004	Union Plaza Health Care Facility 33-23 Union Street, Flushing, NY
Greenpoint MTS Alternative	June 30, 2004	Sunnyside Senior Center 43-31 39th Street, Sunnyside, NY
Greenpoint MTS	July 1, 2004	Swinging Sixties Senior Center 211 Ainslie Street, Brooklyn, NY

40.3.6.1.7.2 Meeting Format

Each meeting began with an informal "open session" with display stations at the perimeter of each room or in an adjacent hallway, depending on the facility. The open sessions included an area for attendee sign-in and speaker registration for those attendees who wished to give testimony; a comment area; and a series of displays on the Proposed Action, EIS Topics, and Public Involvement Process. The displays remained available for review during the formal portion of the public meeting; and take-home summary handouts were also provided.

The formal portion of the public meeting took place in an auditorium style-set up. The meetings commenced with an opening statement and brief Power Point presentation made by Assistant Commissioner Szarpanski. The presentation described the Proposed Action for each site and included information about the wastesheds to be handled by the proposed facilities, renderings of the proposed Converted MTS buildings and access ramps and diagrams that depicted how waste would be containerized and loaded onto barges. A stenographer recorded the opening statement and Power Point presentation, as well as all of the comments made by meeting participants following the presentation. Copies of Assistant Commissioner Szarpanski's opening statements and presentations were made available at the end of each meeting, and a sample is provided in Appendix H .

40.3.6.1.7.3 Follow up Information Dissemination and Translation Services

DSNY representatives and outreach staff were available to respond to questions at the close of each public scoping meeting. Several attendees requested specific information, including hard copies of the Draft Scoping Document; meeting transcripts, attendee sheets, and outreach activities, among other information. DSNY representatives followed up on each request to provide further information by phone or email.

In response to requests for interpretation in Spanish, these services were provided at eight out of ten meetings. After experimenting with alternating Spanish and English translation, simultaneous Spanish translation services (with United Nations style headsets) were subsequently provided at the Scoping Meetings, but were very sparsely used. To ensure that translation services are available where they are needed and that the attending public is aware of their availability in advance of the public hearings, the public outreach flyers that were distributed prior to the DEIS public hearing phase, emphasized the availability of such services upon prior request.

40.3.6.1.7.4 Final Scoping Document Publication

The Final Scoping Document was published in October 2004. The Final Scoping Document contained a more than 30-page summary of Comments & Responses that addressed all of the substantive comments received during the public Scoping process. Appendix B of the Final

Scoping Document contained transcripts of the 10 Scoping Meetings and a compendium of written comments received that was also published and made available on request. The Final Scoping Document and Appendix B were placed in the public document repositories and appear on the DSNY web site at www.nyc.gov/sanitation.

40.3.6.1.8 DEIS Publication Phase

40.3.6.1.8.1 Public Notices, Newspaper Display Advertisements, and Trifold Mailings

As with Scoping, a Public Notice announcing the issuance and availability of the DEIS was published in the Environmental Notice Bulletin and the City Record. During the Scoping period, Scoping Meeting attendees routinely indicated that they had not seen the multiple newspaper display advertisements placed in the EJ project area newspapers. Because of feedback that newspaper adds were an ineffective way of reaching the EJ Communities than anticipated, , display advertisements for the DEIS and Part 360 permit hearings were published in two mainstream newspapers in the EJ project areas, the New York Post and El Diario (Spanish publication), and in the Staten Island Advance, two weeks prior to those Public Hearings.

Stakeholder lists were updated with the addresses of individuals who attended the Public Scoping meetings or submitted comments; trifold mailings were sent to over 3,000 stakeholders. To keep all EJ Communities informed, Public Notice flyers that provide a schedule of all of the eight DEIS Public Hearings were mailed to all stakeholders of MTS and alternatives sites that are not proposed in the New SWMP (West 59th Street, West 135th Street, and South Bronx). In addition, the Public Notice flyer was translated into Spanish and sent to Spanish-speaking stakeholders identified by active community liaisons or groups.

40.3.6.1.8.2 Public Hearing Schedule

Outreach documents continued to be distributed widely through various mailings and at the DEIS Public Hearings held within the EJ project areas for the Proposed Action facilities. Stakeholders were informed of the Hearings at least two weeks in advance.

DEIS Hearings were scheduled between Wednesday, December 1st and Monday, December 20th, 2004. Preferred venues identified by the Community District Managers were contacted, taking into account sites utilized during the Scoping process. Note that while not an EJ project area, a DEIS Public Hearing was held in Staten Island to take comments from all Staten Island communities on the New SWMP and the DEIS; the Staten Island Transfer Station previously received all required approvals and permits and is under construction. The DEIS Hearing schedule is provided below:

Table 40.3-17
DEIS Hearing Locations

Project Area	Date	Location
Staten Island	December 1, 2004	Staten Island Community Board 2 460 Brielle Avenue, Staten Island, NY
Greenpoint/Williamsburg , Brooklyn (private facilities)	December 2, 2004	Swinging Sixties Senior Center 211 Ainslie Street, Brooklyn, NY
Port Morris area, Bronx (private facilities)	December 6, 2004	Alfred E. Smith High School 333 East 151st Street, Bronx, NY
Queens (Greenpoint MTS area) (private facility)	December 8, 2004	Sunnyside Senior Center 43-31 39th Street, Sunnyside, NY
Hamilton Avenue MTS	December 13, 2004	Brooklyn 7 Community District Office 4201 4th Avenue, Brooklyn, NY
North Shore MTS	December 14, 2004	Union Plaza Health Care Facility 33-23 Union Street, Flushing, NY
Southwest Brooklyn MTS	December 15, 2004	I.S. 281 Joseph B. Cavallaro School 8787 24 Avenue, Brooklyn, NY
East 91st Street MTS	December 20, 2004	New York Blood Center 310 East 67th Street, New York, NY

40.3.6.1.8.3 Meeting Format and Meeting Materials

The DEIS Public Hearing format was similar to the format used for the Scoping Meetings. DSNY provided a short opening statement and Power Point presentation. Display boards, handouts and comment sheets were made available. To inform the public about the NYSDEC permit review process, the Power Point presentations and handouts contained information about the NYSDEC permit applications (solid waste management facility, air and marine resources) for the Converted MTSs. (See Appendix H). The new slides provided specific information about the permit review process and details on how and when, as part of DSNY's DEIS public comment period, to submit comments on the State environmental permit applications. Fact sheet handouts expanded on the information provided during the Power Point presentation and provided specific information about the public document repository, including the location, contact person, and days/hours opened for each potentially affected community. A sample of the fact sheet handouts for the North Shore Converted MTSs is in Appendix H.

A stenographer was present to record all of the proceedings, outreach materials were translated into other languages for comprehension by non-English speaking stakeholders, and simultaneous Spanish interpreter services was provided, when requested. Copies of the DEIS and New SWMP documents were made available to the public at each of the hearing venues for their review.

40.3.6.1.8.4 Follow up Information Dissemination

DSNY representatives and outreach staff were available to respond to questions at the close of each public hearing. Transcripts of the hearings and the responses to comments/questions received during the Hearing process and public comment period have been incorporated into the FEIS. The New SWMP hotline was in operation throughout the extended DEIS comment period and will remain in operation through the end of the NYSDEC permit review process.

40.3.6.1.8.5 Informational Meetings During the Extended DEIS Comment Period

During the four Public Hearings held by Community Boards on the Converted MTSs, DSNY made a presentation on the Uniform Land Use Review Procedure (ULURP) applications. DSNY's presentation included information about the NYSDEC permit review process and the availability and contents of the State environmental permit applications on file for each of the Converted MTSs. Handouts describing the permit review process that were distributed at the DEIS Public Hearings were also made available to the Informational Meeting attendees. The DSNY presentation was followed by a question and answer session. Attendees had an opportunity to ask questions about the NYSDEC permit review process and DSNY's State environmental permit applications for the Converted MTSs.

Public notices and display ads about the informational meetings held in mid-January 2005 listed in the following table were placed in local newspapers during the last week of December 2004. In addition, DSNY mailed out flyers to community stakeholders during the last week of December 2004. The flyers provided information about the DSNY permit applications, the NYSDEC permit review process, the public document repository and included an invitation to the Community Board Informational Meeting/ULURP Hearing. Samples of the invitational/project update flyers, fact sheet handouts, and public notices/display ads are attached in Appendix H.

Table 40.3-18
Informational Meeting/ULURP Hearing Locations

Project Area	Date	Location
Hamilton Avenue MTS	January 13, 2005	Brooklyn 7 Community District Office 4201 4th Avenue, Brooklyn, NY
North Shore MTS	January 10, 2005	Union Plaza Health Care Facility 33-23 Union Street, Flushing, NY
Southwest Brooklyn MTS	January 13, 2005	I.S. 281 Joseph B. Cavallaro School 8787 24 Avenue, Brooklyn, NY
East 91st Street MTS	January 12, 2005	Hunter College School of Social Work 129 East 79th Street, New York, NY

Stakeholder lists continued to be updated throughout the DEIS public comment period (through January 2005) to include those who provided comments or attended the DEIS Public Hearings and the Permit Review Process Informational Meetings/ULURP Hearings (October 22, 2004 through January 24, 2005).

40.3.6.1.9. Permit Hearing Phase

DSNY will continue to implement its public participation plan through the end of NYSDEC's permit review process. Another mass mailing is anticipated to provide project updates and inform community stakeholders about the upcoming NYSDEC permit hearings. These mailings will be sent at least two weeks prior to the scheduled permit hearing dates. Project stakeholders may continue to view the DSNY web page for project updates and use the "New SWMP" toll free hotline to ask any project or permit related questions.
